Abstract Name: **Interrogation of CB1 and CB2 Receptor Signaling in Living Mammalian Cells**

The medicinal properties of cannabinoids, have garnered elevated interest during the last two decades with increased legitimacy and research of Cannabis sativa. Most notably perhapsis the potential role of cannabinoids as anti-cancer agents. There is accumulating evidence suggesting that the anti-cancer properties of cannabinoids are attributed to reduced cell proliferation, increased cell death and dysregulation of the cell cycle. However, it is the process of autophagy that likely lies at the heart of the cannabinoid-induced effects on cancer cells. While it is clear that cannabinoids induce autophagy in cells, the molecular mechanisms that underlie cannabinoid-induced autophagy are not well understood. Cannabinoid receptors1 (CB1) and 2 (CB2) are the primary targets of cannabinoids at the cellular level. Stimulation of the CB1 or CB2 receptor leads to activation of two major cell signaling pathways. One signaling pathway involves the conversion of ATP into cyclic AMP (cAMP). The second signaling pathway involves phosphorylation of a protein kinase known as extracellular signal-regulated kinase 1/2 (ERK). A comparison was performed on CB1 and CB2 receptor-mediated cAMP and ERK signaling in MIN6 cells, which express both receptors. To study ERK phosphorylation, we treated MIN6 cells with the synthetic cannabinoid receptor agonist WIN 55,212-2 and performed immunoblotting. To interrogate the role of the CB1and CB2 receptors, cells were treated with the antagonists AM251 or AM630, respectively. Both receptors play an equivalent role in cannabinoid-induced ERK phosphorylation in MIN6 cells. Using a FRET-based cAMP biosensor, we measured cAMP dynamics in response to WIN 55,212-2 in the presence or absence of the antagonists. We found that activation of cannabinoid receptors elicited a decrease in cAMP levels, and this was dampened by inhibition of either receptor. Thus, both the CB1 and CB2 receptors are required for ERK and cAMP signaling in response to WIN 55,212-2.

Abstract Name: The Relationship Between Mindfulness, Directed Coping and Perceived Stress

With mental health becoming more recognized as a national problem, it is important to study the different aspects of how it affects lives and how it can be improved. Multiple studies have shown the positive effects of mindfulness to improve patients' stress levels through intervention. Studies have shown the preliminary effects of directed coping to also reduce perceived stress levels in people who are in consistently stressful environments. The current study sought to explore the relationship between mindfulness and directed coping skills among college students and their perceived stress levels. It was predicted that there will be a negative relationship between mindfulness scores and perceived stress levels; that there will be a negative relationship between directed coping scores and perceived stress levels, and that there will be a positive relationship between mindfulness and directed coping scores. Through a convenience sample, 183 college students were assessed through a voluntary survey. The survey consisted of the Perceived Stress Scale, the Directed Coping Scale, the Five Facet Mindfulness Questionnaire (Short Form), and a demographics section including age, academic level, and gender items. The results found a significant moderate negative correlation between perceived stress levels and mindfulness scores, a significant low negative correlation between perceived stress and directed coping scores, and a significant low positive correlation between mindfulness scores and directed coping scores. All hypotheses were supported. Recommendations for future research include replicating the research to include a wider range of cultural perspectives and differences in age.

Abstract Name: Retention Pond Recovery Practices and their Effects on Water Quality and Littoral Vegetation

There are more than 8,000 retention ponds in Lee County, which are critical for pollution reduction and flood prevention. Many of these retention ponds, however, do not fulfill their intended purpose of preventing flooding and reducing pollution; rather they suffer from an imbalance in the nutrient levels and vegetation die offs. A variety of littoral and aquatic plant life plays an important role in improving the pond's health by acting as a filter to sequester nutrients which aids in reducing pond pollution. By comparing the water quality and plant biodiversity of differing retention ponds, the effectiveness of various pond management strategies can be evaluated. In this study, three different Lee County retention ponds with various management practices and implementations were compared. The pond labeled FGCU Library Pondserved as the control because it is specifically designed to mimic natural conditions and resembles a wetland with lower nutrient levels and higher plant biodiversity. The ponds labeled Fairwinds and Southland are in different stages of restoration. Since November 2021,Fairwindshas had a "no-mow" zone, eliminated pesticide and copper dye applications, and has removed an invasive plant species. Until May 2022 when the community implemented the same recovery program as Fairwinds, Southland mowed the littoral zone and used pesticides and copper dye which killed all vegetation.Water quality samples and data analysis evaluating the impact of the restoration strategies have shown significant lowering of nutrient levels after the change in management practices. As of May 2022, theFairwindspond showed similar nutrient levels as theFGCU Library Pondwhile thenutrient levels of theSouthlandpond are steadily decreasing. Our next phase of research—the continuation ofplant composition surveys—looks to determine the impact of lower nutrient levels on plant biodiversity.

Abstract Name: **A Teacher Resource Guide to Latinx Composers and Contexts incorporating Comprehensive Musicianship through Performance Unit Plans and Culturally Relevant Pedagogy**

Culturally relevant pedagogy echoes the significance of cultivating a sense of community through student centered strategies, putting cultural identity and diversity at the forefront of their education, and the philosophy that each student is successful in their own right. This research investigates the significance of Culturally Relevant Pedagogy as it pertains to Latinx students and how to justify the academic need for Culturally Relevant music curriculum to education administrators. The purpose of this study is to generate a resource guide focusing on choral pieces within a Latinx context that highlight systems of oppression within the Latinx community. The following pieces were analyzed for this teacher resource guide: “No, Nos Moveran” found in the Social Justice Choir Songbook, “De Colores” arranged by Franscico J. Nuñez, “El Pueblo Unido” by Sergio Ortega and arranged by Gene Glickman, and “Ayudame” by Carlos Cordero. These four pieces have been analyzed through a sociohistorical, musical, and pedagogical lens using the Shaping Sound Musicians (O’Toole) Comprehensive Musicianship Project (CMP) Unit Plans. The pieces were assigned a difficulty level based on the rubric provided by the text, Teaching Music through Performance in Choir: Volume 1 (Buchanan et.al). These pieces were chosen because they serve as a vehicle for culturally relevant pedagogy, provide narrative insight to the inequities experienced in Latin America, culturally validate the Latinx experience, and will create conversations of social justice within the music classroom.This resource guide for educators aims to address and emphasize the Latinx experience through a lens of social justice that will build musicianship through critical thinking of culturally relevant repertoire.

Abstract Name: **Neural and Behavioral Correlates of Sensation Seeking**

We sought to clarify both behavioral and neural characteristics of sensation seeking. In particular, we were interested in two components of event-related brain potentials (ERPs) elicited during a response inhibition task: the P3a, which is elicited by novel, unexpected, stimuli, and the P3b, which is elicited by targets. Participants completed self-report questionnaires to measure their sensation seeking. During the task, participants were presented with three types of visual stimuli in randomized order at a rate of approximately one every 1.25 s. The stimuli were (1) non-targets, to which they should make a response, (2) targets, to which they should withhold a response, and (3) novel stimuli, to which they should withhold a response. The targets and non-targets were relatively benign,but required sustained attention to tell them apart. The novel stimuli were photographs depicting arousing situations (e.g., skydiving).Based on previous research, we predicted that (1) the P3a would be positively correlated with sensation seeking, (2) the P3b would be negatively correlated with sensation seeking, and (3) response accuracy to novel stimuli would be inversely correlated with sensation seeking. P3a and total sensation seeking were positively correlated, but the relationship was small and not statistically significant. In contrast to our prediction, P3b was moderately positively correlated with total sensation seeking. Finally, response accuracy was not correlated with total sensation seeking. Although none of our hypotheses were supported for total sensation seeking scores, we did find relationships between the ERP components and total sensation seeking, boredom susceptibility, and disinhibition.

Abstract Name: **The Symphony of the Cell: Using Data Sonification to Engage Students in Molecular and Cellular Biology**

As technology advances in all aspects of our lives, the demand for careers in science, technology, engineering, and mathematics (STEM) hasincreased exponentially. However, many students find STEM challenging, and further, lack key experiencesto gain a sense of belonging in STEM and consider pursuing it as a career. Thus, providing STEM learning modules that introduce key concepts while engaging students can make an impact in addressing this need. A particularly difficult topic for students to understand is the relationship between cells and how the sequence and structure of proteins ultimately contributes to their function. In order to introduce these basic principles to introductory students, our team has constructed a virtual authentic-learning tool that utilizes data sonification in which each amino acid in a protein sequence is assigned a musical note and rhythmic value based on its hydrophobicity. This allows a harmonious musical piece to be composed based on the sequence of a functional protein. Disease-associated mutations become disharmonious which allows users to auditorily identify disruptions in a protein sequence and understand how it impacts the cellular symphony. We will present our preliminary survey data supporting our hypothesis that this data sonification learning module helps students gain an understanding of the molecular basis of disease while improving students attitudes towards STEM.

Abstract Name: **BIOMARKER EVALUATION OF NAPROXEN TREATED RAT BLADDER CANCER TISSUES**

Introduction: Bladder cancer (BC) is the second most common cancer of the genitourinary tract. 75,000 Americans are diagnosed with this disease, and 16,700 patients die annually. It is a highly recurring disease and the most expensive to treat. Therefore, it is imperative to prevent this cancer. At CCPDD, experiments are being conducted in animal models to study and identify promising drugs that can prevent the development of BC. In the present study, BC was induced in female rats by administering a chemical carcinogen (BBN) and divided into two groups: placebo (vehicle group) and experimental group (drug-treated). After BBN treatment, rats were administered vehicle or Naproxen (a commonly used pain medicine). After 35 weeks of drug treatment, rats were euthanized, and bladders were excised and graded histopathologically for cancer incidence. Molecular change in drug-treated tumor tissue is studied to compare and correlate with tumor response to the drug. Using Immunohistochemistry, we studied changes in the expression of Ki-67 and Cyclin D1 in response to drug treatment.Methods: Tumors were excised following euthanasia and fixed in formalin. These tumors were further processed and embedded into paraffin blocks. Tissue section measuring 4µm thickness were placed onto slides for hematoxylin and eosin (H&E) or IHC staining. Lastly, stained tissue slides were analyzed for their respective biomarkers and tumors were classified into various categories/stages based on factors such as grade, invasion, and metastasis.Results: When compared to the vehicle group, naproxen treatment inhibited bladder adenocarcinoma formation in drug-treated rats suggesting a chemopreventive potential. Biomarker analysis demonstrated significantly reduced in inflammation and tumor cell proliferation in tumors exposed to naproxen. Complementing this finding, a significant reduction in Ki-67 positive staining and Cyclin D1 expression was also observed in treated tumors.Conclusion: Timely intervention with anti-inflammatory drug naproxen, may help prevent BC development and its progression.

Abstract Name: **Tying Object Counts to Location: A Case Study Using GPS Video Data and the R Project for Statistical Computing**

Object detection methods have improved rapidly over the past several decades, and these methods have the potential to be valuable tools in the study of land use and the built environment. Leveraging these methods, this project demonstrates how counts of objects – such as people, bicycles, automobiles, and street signs – can be extracted and tied to location using GPS video data and the R Project for Statistical Computing. This project is unique in that it makes use of a more flexible and "mobile" sensor deviating from the traditional approach of using a stationary camera. GPS video data was collected with several GoPro HERO 8 cameras mounted to bicycles and captured at locations with various land uses in Eau Claire, Wisconsin. Scripts were created using R packages Platypus, av, exfitoolR, gopro2gpx, and other various packages in the Tidyverse. The scripts (1) ingest GPS video data, (2) extract objects present in individual frames using OpenCV, (3) summarize results in a table, (4) and create maps of object counts. Such an approach can be utilized by other practitioners in land use analysis. Extensions of this project in the future will lead to the development of an installable R package, with user-friendly functions that streamline analytical processes.

Abstract Name: **Isolation, Characterization, and Host Range of Novel Microbacterium foliorum Bacteriophages**

Abstract Bacteriophages are viruses that thrive by infecting bacteria, using the host to replicate, and ultimately killing the host. Bacteriophages are essential viruses, and they can be found in different ecosystems and living organisms. Studies on bacteriophages have shown that these organisms have the potential to treat antibiotic-resistant bacteria, given their ability to infect and disrupt a variety of bacterial cells.3 Phage therapy has been a subject of interest in the medical field since the end of WW2, and clinical trials are being conducted to further understand the phage's antibacterial properties. This research focused on bacteriophage isolation, identification, and a host-range test. DNA extraction and sequencing were performed on three out of five phages, and transmission electron microscopy was also performed to identify the family type to which all five phages belonged. Since the phages were collected from different places, upon their successful isolation and purification, their lysates were diluted to the same titers for the host range test to reveal each phage's potential to infect different Microbacterium species, Staphylococcus epidermidis, and Escherichia coli. We found that the five phages have differing host ranges; some also infect S. epidermidis. Genome annotation of the phages Cedar Bank, Extercus, and Guetzie will reveal further information on why each phage has its unique host behavior toward different Microbacterium. Furthermore, genome annotation will also be used to analyze the spike protein, which allows the phages to adsorb to their host species. The genomes of the Microbacterium species will also be compared to elucidate what makes some species more susceptible to different phages, in this case, the Cedar Bank, Extercus, and Guetzie. Further testing is still needed to determine the isolated phages' potential uses.

Abstract Name: **Vicon sensed Post-stroke rehabilitation exercise assessment using Attention-based CNN**

Cardiovascular diseases are one of the concerning problems in the United States. According to CDC, approximately 805,000 people suffer heart-related problems every year, out of which 605,000 are the first time. Physicians suggest rehabilitation exercises to the surviving patients as these exercises will help the patients in bringing back their physical function and mobility before the injury. Due to recent technology amelioration, many are using Motion Capture Systems to perform the suggested movements. To improve the performance of these sensors, we develop a model that concentrates only on dominant parameters skipping the rest. With the help of optimization techniques and algorithms, built models will identify the critical parameters from the inputted data. We introduce an Attention-based CNN model on 117-dimensional Vicon sensor angle data to enhance the sensor's performance in identifying the performed exercise. Convolutional layers in the network will help extract the input data's in-depth features, and LSTM layers mine the long-time series features. We have used the UI-PRMD - Vicon ten movements data for building the proposed model. Our attention model has outperformed many complex architectures with an overall average of 0.007881 MAD and 0.012343 RMSE for ten movements.

Abstract Name: **Analysis of Laser Machined Nitinol Flow Diverters for Aneurysms**

Flow diverters have become one of the most efficient endovascular procedures to treat brain aneurysms, which are also known as cerebral aneurysms. Presently, flow diverters (FDs) are mainly braided from microwires such as nickel titanium (nitinol) and chromium-cobalt alloys. The controlling design parameters of the braided FDs are limited. The purpose of this research is to explore the possibility of making fine meshed non-braided nitinol FDs using precision laser machining and studies the effect of the laser parameters on the quality of laser fabricated nitinol FDs. Fine pores were designed and then fabricated using a precision fiber laser machine with varying laser powers, focal distances, laser translation speeds/passes and cooling media (air and underwater). The fabricated FDs were polished using an in-house custom polishing tumbler. The surface quality of the fabricated FDs were evaluated using scanning electron microscope (SEM) and high-resolution images. The degree of surface burning was quantified with a scale from 1 – 10 using high resolution images. The results showed that the laser power and focal distance have a pronounced impact on avoiding excessive burning of the surface and bulge formation. Water as a cooling media provides more flexibility in selecting laser power and passes. However, the frequent refilling of water was inconvenient since the water was evaporating too quickly. Fine tuning of laser power and passes with air cooling provided burn free and high surface quality FDs. The findings of this study will contribute to the development of non-braided FDs for the treatment of brain aneurysms with more controllable parameters.

Abstract Name: **Effects of Narrative Case Studies in Science**

In information-dense introductory science courses, students are required to define, describe, and explain complex mechanisms, and then expected to retain, recall, and apply that information in upper level courses. However, many introductory course curricula do not provide the proper context for how these concepts apply to real life scenarios. Case-based learning is an active learning method that uses short narrative case studies to demonstrate to students the real-world applications of course content and encourage them think critically about what they are learning in lecture. Previous studies have shown that introducing case-based learning in a variety of science courses has correlated with improvements in student comprehension and knowledge retention and increased student satisfaction and interest in science. In this study, we aim to develop a series of narratively connected case studies for a 200-level Human Anatomy and Physiology course and determine the impact of these cases studies on student learning outcomes and course satisfaction. We hypothesize that replacing traditional assessment with these case studies will improve higher-order cognitive thinking skills, increase knowledge retention, and make our course more enjoyable for students. In this presentation, we will explain our process and rationale for developing five narratively connected case studies focused on concepts from the endocrine, cardiovascular, respiratory, digestive, and urinary systems. In addition, we will compare preliminary results from two class sections. One section will be assigned traditional quizzes on these body systems and the other will have those quizzes replaced with our case studies. Findings from this study will provide educators with resources for developing and implementing case-based learning assignments in their courses, and add to the growing body of literature aimed at assessing the impact of case based learning on student outcomes.

Abstract Name: **Fabrication of UV-Protectant Cellulose-Nanoparticle Composites through a Mesoporous Fiber-Welded Intermediate Structure**

The Natural Fiber Welding (NFW) process produces mesoporous, cellulosic materials through partial dissolution of the biopolymer surface with ionic liquid and subsequent rinsing with a non-polar solvent gradient. In this study, nanoparticles of titanium dioxide (TiO2) and zinc oxide (ZnO), two common mineral sunscreen ingredients, were incorporated into cotton from a colloidal suspension using a fiber-welded, mesoporous intermediate structure. Scanning electron microscopy, energy dispersive X-ray spectroscopy, atomic absorption spectroscopy, and diffuse transmittance UV/Vis spectroscopy were used to characterize the composites. The data reveal how this approach can deliver composites with high nanoparticle loadings and enhanced ultraviolet protection that is sustained through multiple washing cycles.

Abstract Name: **Quality Control In 16s-Based Microbiota Compositional Analysis**

Introduction: A microbiome is a collection of microorganisms in a specific ecological niche, e.g., the human gut, and their associated metagenome. Human microbiota has been widely recognized as a key mediator in both health homeostasis and many pathologies. High-throughput sequencing of the 16S rRNA gene, the bacterial marker gene, has led to the generation of massive metagenomic data, creating a pressing need for efficient bioinformatic protocols to process the raw sequence reads. Significant ambiguity exists as to how to best perform 16S-based microbiota compositional analysis, as many programs exist for this purpose. This study evaluated three of the most used algorithms for taxonomic inference (DADA2, QIIME2, and mothur). Additionally, parameters for quality control of sequence reads were examined and optimized because there is a growing recognition to move away from “off-the-shelf” data processing.Method: Two key parameters, based on Illumina-assigned quality scores, were isolated across our pipelines: (1) limits on allowed base-pair errors per short-read fragment and (2) truncation of erroneous read ends based on a quality score threshold. First, impact of parameter value on retention of input sequence reads was assessed. Then, output compositions were compared to a known mock community via weighted UniFrac distance.Results: How parameters are set significantly affects read retention. Optimal value for allowed error limit was pipeline-specific while there was unanimous agreement on best quality score threshold for read truncation. Sensitivity and specificity of mock community approximation varied by pipeline.Conclusion: To improve inference of microbiota compositions, 16S-based analysis must be performed with consideration for unique user dataset. Results generated based on this marker gene should be interpreted with caution.

Abstract Name: **Label-free, point-of-care urine biosensor for the diagnosis and management of Chronic Kidney Disease**

Chronic Kidney Disease (CKD) is a serious health problem that affects nearly 8-16% of the global population. If left undiagnosed, it can lead to end-stage renal disease (ESRD) where treatment options become limited and increasingly expensive, and dialysis or a kidney transplant may be required to maintain life. Early detection of CKD is crucial for treatment success and improved patient outcomes. Creatinine (UCr) and chloride (Cl-) are two key urinary biomarkers that are used to assess kidney health and renal function. In this work, we have developed a label-free, point-of-care electrochemical biosensor that can reliably detect Creatinine and Chloride levels in urine samples of <100 µL in under 5 minutes.An affinity-based, planar gold three-electrode system was used to detect these biomarkers in their physiologically relevant ranges in human urine. A highly specific ssDNA aptamer was used to capture creatinine molecules while a highly selective, synthetic chloride ionophore was used to capture the chloride ions. The binding of thebiomarkers to their respective capture probes resulted in a modulation of electrical properties at the electrode-urine buffer interface. At its core, the biosensor relies on Electrochemical Impedance Spectroscopy to transduce subtle changes at the input Creatinine and Chloride levels in neat, unprocessed urine and can operate over a wide dynamic range of 0.15-5 mg/mL for Creatinine and 15-105 mM for Chloride. Using a combination of these biomarkers, it was demonstrated that our sensor is capable of disease state classification for timely triage and precision therapy.The developed sensor can act as a companion diagnostic tool that can help physicians by improving patient outcomes through early diagnosis, timely management, and successful treatment of CKD. Further, it can be used for routine self-monitoring of renal health at home, which can reduce the financial and psychological burden on patients and their families.

Abstract Name: **The Assessment of Aging Self-Efficacy: A Comparison of Persons in Rural and Urban Environments**

Extant research shows that age-related physical and mental health outcomes often differ between persons based on the degree of urbanization of their living environment. These health outcomes differ in relation to factors such as socioeconomic status, health care access, nutritional intake, socialization opportunities, etc. However, the potential role of aging self-efficacy has not been explored. Self-efficacy itself has been studied in various adult populations, but only in the sense of their current life situations. A sample question related to memory performance might be “How able are you to remember life events from the past week?” The current study, however, will investigate prospective aging self-efficacy, which is a person’s sense of how able they will be to age healthily. A sample question (directed at a younger adult) might be “How able will you be to remember life events from the past week when you are 80 years of age?” Additionally, this mixed-methods study will investigate the reasons adults hold the beliefs they do. For example, a person answering the previous question might say that they believe they will not be able to remember the events of the past week when they are 80 years of age because their older relatives were unable to do so; or they may hold generally negative stereotypes about aging (e.g., all older adults have a bad memory). We hypothesize that aging self-efficacy will differ between undergraduate participants based on the degree of urbanization of their childhood hometowns such that those from more rural environments will feel less able to age healthily compared to those from more urban environments.Additionally, we expect that those who expect more negative aging outcomes will report feeling less in control of their aging process and hold more negative stereotypes about aging than those who expect more positive aging outcomes.

Abstract Name: **Understanding the Molecular Mechanism of Opioid Action in the Human Body Through a Course Embedded Computational Research Project**

Chemistry has and will continue to play an essential role in the development of new drugs. Specifically, chemical synthesis has resulted in several synthetic opioids, for example, morphine, oxycodone, and codeine. In this research, the goal is to gain an improved understanding of the interaction between an opioid and the opioid receptors present in the human nervous system and determine which pain relievers are the most effective. In general, the two chemical properties that regulate the reactivity of a molecule are its electronegativity, or the ability of an atom in a molecule to attract electrons, and chemical hardness, which is the ease with which the atom’s valence electron clouds can be distorted. The chemical properties of twelve prescription pain medications are investigated computationally. The drug molecules are constructed using a web-based tool WebMO, and their electronegativity and hardness are determined using a quantum chemistry program called Q-Chem. Also, the interactions between prescribed opioids and opioid receptors are analyzed using the online resource SWISSDOCK. Additionally, SwissADME is used to investigate the pharmacokinetics of each drug molecule. Our findings will offer insight into how different opioids interact with opioid receptors and how that information could be used in developing better pain medications. The preliminary results of the research will be presented.

Abstract Name: **Valuable Time Saved: Designing and 3D Printing a Prototype to Reduce Bladder Irrigation Procedure Time**

Bladder irrigation is a medical procedure that repeatedly flushes the bladder with a saline solution after an operation to reduce blood clots. The existing procedure for bladder irrigation involves repeatedly disconnecting and reconnecting syringes to different catheters which creates an inefficient process. The objective of the research project was to create a prototype device that would simplify the bladder irrigation process and reduce the procedure time. The prototype device has three outlets and a handle that allows the user to change the directional flow without moving the syringe. 10 different iterations of the prototype were designed and 3D printed. An iterative design process was applied to make improvements between each iteration after they were tested for functionality and watertightness. An experiment tested the time to flush the bladder for the existing procedure and the novel procedure using the prototype device. The procedures contained common steps of filling and emptying the syringe and the distinct step of changing the connection by either disconnecting and reconnecting the catheter or twisting the prototype device. An average time for each step was found across 30 trials, and the average aggregate time for the existing procedure was 44.2 seconds while the time was 39.6 seconds for the procedure using the new prototype. A statistically significant 10.5% time reduction was accomplished using the prototype. The time to complete one cycle of flushing the bladder was used in the experiment, but the bladder is flushed multiple times during bladder irrigation leading to a larger overall time difference. Future work would include utilizing different manufacturing techniques to improve watertightness and conducting additional experiments to determine differences in leakage and patient comfort between the existing and novel procedure.

Abstract Name: **Fabrication and Characterization of Photovoltaic Devices in Air**

Photovoltaic cells are devices that convert light energy into usable electrical energy. Perovskite solar cells are a widely studied type of photovoltaic cell produced by depositing thin films of compounds with perovskite structure. While perovskite devices have progressed to high efficiencies, manufacturability of the devices must be addressed for them to become commercially viable. Most current fabrication methods are conducted inside a glove box, which makes large-scale manufacture complex and expensive. The goal of this research is to develop a procedure to fabricate perovskite solar cells in ambient conditions to simplify and improve manufacturability. Fluorine-doped tin oxide (FTO) coated glass substrates were etched using zinc powder and hydrochloric acid. Once etched, the glass was cleaned sequentially using acetone, isopropyl alcohol, and deionized water in an ultrasonic bath. A solution of titanium dioxide and acetic acid was then spin coated onto the substrates to form a mesoporous layer. After heating the samples, a solution of lead iodide and methylammonium iodide (MAPbI3) was spin coated to form a thin film. The device was then quickly heated to dry the perovskite layer before a thin layer of gold electrode was sputtered over the film. The entire procedure was completed outside of a glove box under ambient conditions.Once the devices were fabricated, the samples were immediately tested. When exposed to light, the devices demonstrated photovoltaic activity and behaved as photodiodes. Future research includes exploring alternatives to lead, such as tin, as well as refining the procedure to improve the efficiency of the devices.

Abstract Name: **Sex Differences in the Relationship Between Psychopathy and Cerebral Lateralization During an Empathic Challenge.**

Hemispherical dominance or cerebral lateralization is characterized as activity in the brain being elevated in one hemisphere more than the other, typically during presentations of affectively laden stimuli. The right hemisphere is associated with feelings of negative affect, while the left hemisphere is associated with positive emotions (Robinson and Price, 1982). Empathetic responses in relation to hemispheric dominance and the degree of psychopathy has not been examined in non-clinical populations, and sex of participant even less so. Social/emotional processing in females may differ from males; the human brain is sexually dimorphic, with various structures being different between the sexes (Nopoulos et al., 2000).Using the ratio of alpha power between the left and right frontal cortices (F3 vs. F4) as an index of relative cerebral activity, we found a non-significant linear (R^2 = 0.005, F = 0.096; p = 0.760) but a near significant quadratic (R^2 = 0.248, F = 2.803, p = 0.089) negative relationships between right hemisphere lateralization and psychopathy when viewing a highly empathic video of someone in distress. Females had a strong relationship between psychopathy scores (LSRP, Levenson, et al, 1995) and lateralization (R^2 = 0.003, linear; R^2 =0.319, quadratic). Females low in psychopathy demonstrated stronger right hemisphere activation when viewing the empathetic stimulus. Females high in psychopathy had less cerebral lateralization. Males showed a weaker relationship between lateralization and psychopathy scores (R^2 = 0.039, linear; R^2 = 0.272, quadratic). Group size (12 females, 8 males) may have resulted in insufficient statistical power to demonstrate a significant overall effect or a much stronger relationship in females.

Abstract Name: **Developing Computer Vision Tools for Automatic Animal Behavioral Classification**

Automating the classification of animal behavior is a major challenge in neuroscience. In recent years, machine learning and computer vision techniques have become part of the neuroscience toolkit for the high-throughput study of animal behavior. While progress has been made, existing strategies for behavior classification require the preprocessing step of keypoint prediction. Keypoints, which are 2D coordinates that describe locations of body landmarks (e.g., snout, hind limb, tail base, etc.), are a useful abstraction scientists often go through because tools for keypoint estimation are accessible, and keypoints are a high signal to noise abstraction for describing an animal's position and locomotion - and are easy to represent. While keypoints carry a lot of relevant signals for reasoning about complex locomotion sequences, we hypothesize that the raw RGB video data itself (from which key points are predicted) could be invaluable for reasoning about behaviors since many behaviors of interest are visually indicated. We will compare behavior classification strategies that directly predict behaviors from RGB video (without the abstraction of keypoints), to existing methods that utilize keypoints. To do so, we will construct a dataset of animal behaviors, along with thorough validation of the various classification strategies on our behavior classification dataset. We anticipate that RGB video behavior classification models will perform competitively with models that go through the abstraction of keypoints when classifying behaviors.

Abstract Name: **Decadal Variations of Six Criteria Air Pollutants Over Texas**

The Clean Air Act requires the US Environmental Protection Agency (EPA) to set National Ambient Air Quality Standards (NAAQS) for six common air pollutants (also known as “criteria air pollutants”). These six pollutants are carbon monoxide, lead, nitrogen oxides, ground-level ozone, particulate matter, and sulfur oxides. These pollutants are found all over the U.S. They can harm health and the environment and cause property damage. The EPA must designate areas as meeting (attainment) or not meeting (nonattainment) the standard in accordance to the Clean Air Act. States must develop a general plan to attain and maintain the NAAQS in all areas of the country and a specific plan to achieve the criteria for each area designated nonattainment for a NAAQS. This study presents in-situ surface measurements from the Air Quality System (AQS) EPA for six air pollutants from 2005 to 2022, as well as the weekly, monthly, and yearly trends for these pollutants over Texas’ major population centers. This study will analyze these trends for any correlation with petrochemical industry, vehicle usage, technological advancement, and natural events. Although the overall trend is that of a decrease in the concentration of these pollutants over time, it is worthwhile to explore more granular trends in an effort to identify their underlying causes.

Abstract Name: **Photocatalytic synthesis of Atropisomeric Indoles with an N-C Chiral Axis using CsPbBr3 Chiral Perovskite Nanocrystals**

Our objective is to propose an efficient methodology for therapeutic agent synthesis providing a novel approach toward axially chiral N-C bonds of heterocycle targets. With the use of our catalyst chiral perovskites, we should be able to efficiently synthesize pharmaceutical motifs using photocatalytic reactions. We propose that if we use a chiral ligand in our perovskite, then it will give us the atropisomer chiral indole compound. With the use of our first synthesized chiral perovskite (CP1), we obtained a yield of 50% but no enantiomeric excesswas detected. Therefore, we determined that if we use a more suitable chiral perovskite then we will get a higher enantiomeric excessand a higher yield. With the use of our second chiral perovskite (CP2), we received a yield of 37% and 30% enantiomeric excess, which concludes our hypothesis that if we use a suitable chiral perovskite, we will get the chiral product with enantiomeric excess. Funding Acknowledgement:This project was supported by NIH MIRA to Y.Yan.This project was additionally supported by the National Cancer Institute of NIH under award numbers U54CA132384; U54CA132379.

Abstract Name: **Effect of short-term hormone treatment on the behavioral anxiety response in adult zebrafish when exposed to acute stress**

Chronic hormonal treatment may have significant effects on anxiety levels and, as a result, observable behavioral stress responses. Previous literature has suggested hormone treatment may affect psychological structures, shoaling behavior, and development, but no previous literature has focused on the relationship between hormone treatment and anxiety like behaviors. Adult zebrafish were treated with a 25ηM concentration of either 17-βestradiol or 11-ketotestosterone for 14 days, then exposed to an acute stressor before fish were placed in the novel tank test for observation. The zebrafish were randomly assigned among ten three-liter tanks that housed individual small groups. These small groups consisted of no more than five and no less than three fish. Each fish had the possibility of being assigned to one of three groups: control, 17-βestradiol hormone treatment, and 11-ketotestosterone hormone treatment. To ensure proper hormone concentration was maintained during constant exposure, water was changed out every second day. Temperature (25°C±1) and pH (7.0-7.2) were monitored daily to make sure the environment was consistent. Upon completion of the 14 day treatment period, all zebrafish groups were exposed to an acute stress, net chasing, for a total of two minutes, then were immediately placed in a novel tank to measure behavioral responses. Responses were recorded based on the amount of time it took the fish to transition into the upper portion of the tank (latency period), total transitions to the upper tank, total time spent in upper portion of the tank, and number of freezing bouts. No significant results were found based on anaylsis of treatment or gender differences in relation to modified behavioral stress responses.

Abstract Name: **How can ponderosa pine seedlings be propagated to improve drought resistance in the field?**

Ponderosa pine, a widespread species in the western US, is a valuable species economically and environmentally. The preservation of this species is important for the ecological health of many forests due to increased temperatures, drought, and frequency of forest fires. Reforestation efforts following fire and timber removal often fail because seedlings propagated in greenhouses are not resilient to stressful field conditions. To increase seedling field survivorship, drought resistance, and to decrease mortality rates, we implemented a number of treatments in the greenhouse during the initial propagation. The treatments were a manipulation of water supply and different types of fertilizer, tested with seeds collected from varied elevations. After three months of growth in the greenhouse under these treatments, we measured height and both shoot and root biomass of the seedlings. We also measured days to mortality on a subset of the seedlings. Seedlings subjected to drought treatment and amino fertilizer grew shorter but survived longer. These seedlings allocated more biomass below ground, which likely contributed to their longer survivorship in the days to mortality test. However, despite the potential benefits these treatments conferred to seedlings in the greenhouse, all seedlings experienced nearly 99% mortality after they were outplanted to a nearby field site. We suspect that most of this mortality was due to frost-heaving, a process whereby seedlings can be pushed out of the ground during frost-thaw cycles that occur in soils in the winter, and is exacerbated by the creation of bare patches of soil around the seedling during planting.

Abstract Name: Promoting and Retaining bilingualism in multicultural houses in South Korea: Experiences of bilingual coaches

The dominant assimilation practice and policies in South Korea have translated into monolingual, Korean-only practices in all aspects of the society. Nevertheless, it is worth noting that the major recent government policies reflect an assets-based perspective on immigrant mothers' heritage languages (HLs) and their children's potential bilingualism. Since 2015, bilingual coaching services have been provided for multicultural families under the initiative called Bilingual Education Environment Fostering Plan. Bilingual coaches with immigration backgrounds educate the families about bilingual education, teach parents strategies about interacting with preschool children in their first language, foster a community for the families, and provide further guidance to families about bilingual. Given most children continue to be deprived of the right to acquire mother tongue in the South Korean context, initiatives like the bilingual coaching program hold promise. Examining the ways, it is actually implemented from the perspective of the practitioners could help sustain a well-intended program, which contributes to the children's bilingual and bicultural development. The current study aims to explore perspectives and experiences of bilingual coaches who work at local Health Family Support Centers across South Korea. Data primarily collected from individual interviews with seven bilingual coaches, who were originally from China, Japan, and Vietnam. Thematic coding method yielded that all coaches emphasized the immigrant mothers' dedication to bilingual education as the most important factor in promoting bilingualism in the family. They also drew on their own experiences as immigrants in South Korea when coaching other families. While they found the work rewarding, they also pointed out challenges, such as heavy caseloads, not having expertise in early childhood education, and having to coach families in whose language they do not have proficiency. The ongoing research has implications for policies, programs, and practices for multicultural families and children beyond the South Korean context.

Abstract Name: **Effect of Steric Hindrance on the Kinetics of a Silver Nanoparticle Surface Substitution Reaction**

Biosensors are devices that detect a wide variety of biological molecules. During the design of many biosensors, a receptor needs to be immobilized onto a transducer surface. A frequently used reaction to complete this attachment is through a nucleophilic substitution reaction between a surface-tethered NHS ester and the desired macromolecule. However, the research into the kinetics and mechanism of this reaction is lacking, and these insights would aid future rational design of biosensors depending on the steric bulk of the receptor. This study investigated the rate and mechanism of a substitution reaction with imidazole and sterically-hindered derivatives with tethered NHS esters on a silver nanoparticle surface using SERS Raman spectroscopy. A slower rate of reaction with increasingly sterically hindered imidazole compounds suggests a possible mechanistic change from an SN2 to SN1 mechanism for very bulky proteins.

Abstract Name: **Using Limulus Amebocyte Lysate (LAL) to Discover the Presence of Endotoxins in the Tanks at the Pritzker Marine Biology Research Center**

Endotoxins are harmful for many organisms, including those that live in the water. Therefore, it is important to identify effective ways in identifying if they are present in water environments. Research has been conducted to show that Limulus amebocyte lysate (LAL) is an effective way to determine if endotoxins are present. In this study, LAL was used as the main reagent to detect if endotoxins were present in the tanks at the Pritzker Marine Biology Research Center. It is believed that LAL will be able to detect the presence of any endotoxins in the tanks at Pritzker. The first part of the procedure to do this was to collect 5mL of water from each tank at Pritzker. After the LAL reagent was dissolved in LAL Reagent Water, the gel-clot assay was then produced. 0.1mL of the reagent was added to each assay tube. 0.1mL of each product sample or control was transferred into each assay tube, beginning with the negative control and ending with the highest endotoxin concentration. The contents of the tubes were mixed and incubated undisturbed in a 37 C heating block for 60 minutes. After incubation, each tube was examined for gelation. A positive test is defined as the formation of a firm gel capable of maintaining its integrity when the assay tube is inverted 180 degrees. A negative test is characterized by the absence of gel or by the formation of a viscous mass which does not hold when the assay tube is inverted. Endotoxins were detected in an average of 13 tanks at Pritzker. To expand upon these findings, quantifying how many endotoxins are present in the tanks and what types of endotoxins are present in the tanks will be tested.

Abstract Name: **Insect Net Worth: comparing traditional entomological surveys and citizen-science data to monitor insect diversity**

Globally, entomologists seek to determine if insect diversity is declining in response to human activities,like habitat loss, pesticide use, and climate change. With a need to establish baseline counts of insect species richness to monitor these levels, this study aimed to catalog historic diversity housed in the University of Minnesota-Duluth insect collection, and use it to assess two methods for monitoring insect diversity: a traditional insect collecting survey and crowd-sourced photographs from iNaturalist, a citizen-science platform used for organism identification. To assess which method optimizes diversity and time, specimens collected during asystematic entomology classsurvey around UMD between July and September 2020 were compared to iNaturalist occurrences with more than two agreeing identifications in Saint Louis County observed during 2020, using Saint Louis County specimens in the UMD insect collection to highlight total species diversity within the county. By quantifying several factors influencing data use for seven families of insects, such as collection effort, richness, and identification rate, I was able to identify strengths and weaknesses of each collection method for long-term diversity monitoring projects and identify points of focus for improving the diversity captured in the UMD insect collection. iNaturalist yields many specimens with little time input, with a greater ability to capture short-season groups or highly active groups that are easily identifiable. Traditional sampling methods, while requiring much more time, are vital for groups with minute differences between species, and provide a wealth of information that is not provided by photographs alone. These trends are critical to take into account when designing long-term sampling surveys to monitor insect diversity to yield scientifically useful specimens while optimizing collecting efforts.

Abstract Name: **Does Chronic Illness Diagnosis Alter Sense of Purpose in Older Adults?**

Maintenance of a sense of purpose serves as a psychological resource for late-life health. A strong sense of purpose in older adulthood is associated with a reduction in health incidents (Kim et al., 2013) and mortality, and lower psychological distress (Musich et al., 2018). Limited research has examined whether one's purpose is threatened by chronic illness diagnoses. This study leverages data from the National Health and Aging Trends Study (NHATs; N = 831) to establish trajectories of purpose across three such diagnoses (i.e., dementia, heart disease, no diagnosis) using three-year (pre-diagnosis, year of diagnosis, post-diagnosis) timespans. Results demonstrate a decrease in purpose following a dementia diagnosis ($F=9.18$, $p=.001$, $n2=.05$) which deviates from trajectories of those who received a heart disease diagnosis ($F=3.04$, $p=.05$, $n2=.006$) or no diagnosis ($F=1.29$, $p=.24$, $n2=.001$), where purpose did not change over time. Findings suggest that older adults who receive a dementia diagnosis are vulnerable to a threatened sense of purpose. Interventions that support health priorities navigation and pursuit of purpose despite diagnosis appear to be a priority for dementia care.

Abstract Name: **Equilibrium Quartet presents Keen by Roshanne Etezady**

Equilibrium is a saxophone quartet at the University of Wisconsin-Eau Claire. The quartet was formed in Sepember of 2021 and is composed of undergraduates students, all with different majors: music education, applied instrumental music, integrated strategic communication-advertising, and biology. In our time as a quartet, we have performed in master classses, auditioned for competitions, and prepared multiple recitals.As an ensemble, we are interested in exploring timbre, balance, and color within the constraints of saxophone quartet. The saxophone is an incredibly flecible instrument capable of producing a wider range of wounds and colors. Roshanne Etezady's piece,Keenutilizes the saxophone quartet's unique ability to blend into one homogenous sound by leaning on droning characteristics to drive the piece. Etezady also highlights the individual instrument's timbral qualities in solo passages. We chose this piece because it explores a wide range of colors and challenges musicians to maintain consistent blend and balance in the extreme registers and dynamics of the saxophone. We are excited to share the music of Roshanne Etezady, a contemporary classical composer who uses timbre and balance to capture intense emotions in the pieceKeen. To keen means to express grief with a loud and sustained cry of sorrow. Etezady uses the concept of keening to stucture the piece and model the emotional affect of the title. However she goes beyond imitating this human response to grief. The unison drones are contrasted by shifting melodic lines andintense dissonances that further evoke a distressing affect. In our performance, we hope to convey this intense feeling of sorrow and highlight the work of composer, Roshanne Etezady.

Abstract Name: **Improving diagnosis of kidney cancer using Infrared Spectroscopic Imaging**

Infrared Spectroscopic Imaging has been shown to be a powerful approach to rapidly image human tissue biopsies to identify biochemical signatures associated with disease outcome. In this study we have applied two types of IR imaging to distinguish between two types of kidney cancer, chromophobe and oncocytoma. These two cancers represent a very difficult problem for the medical community to diagnose as the clinical symptoms are similar and they look almost identical to the experience pathologist. Definitive diagnosis between the two types is critical as the treatment options and prognosis for these two kidney cancers are very different. In this study we demonstrated that tradition IR imaging using a Fourier Transform based approach could allow for excellent objective diagnosis of these cancers. A newer faster laser-based approach which has potentially better applicability for clinical practice also demonstrated classification between the two groups. A comparison of the results between the two imaging tools will be compared and contrasted. Furthermore, we will present some new results about how kidney cancer can be effected by the diabetic status of the patient.

Abstract Name: **Examining the Experiences of STEM Students in Linked-Learning Communities**

Women, students of color, and students of low socioeconomic status are historically underrepresented in science, technology, engineering, and mathematics (STEM) programs. While women are half of the population, they only make up 34% of STEM workers in the United States. African Americans, Latinx individuals, and Alaska Natives make up 23% of the STEM workforce, despite being 30% of the population (National Science Foundation, 2021). Disparities in representation for minority groups perpetuate stereotypes about who belongs in STEM (Brockman, 2021; McGee et al., 2017), while also limiting the voices and contributions of a broader population. Interventions, such as linked-learning communities (Goldman, 2012), diversity programs (Burt et al., 2020), and mentoring programs (Apriceno, 2020) have been introduced in STEM programs to combat underrepresentation; however, the research thus far is predominantly quantitative. While providing useful insight, quantitative data does not reflect unique individual experiences, so qualitative research would better allow for understanding of student experiences. The College of Math and Science at Bridgewater State University is conducting a randomized control trial on linked-learning communities of first- year STEM students. In these linked-learning communities, students take three classes together to build community and sense of belonging. As part of the larger study, this research will examine the role of linked-learning communities among STEM students with varying social identities and backgrounds. Students will answer open-ended questions regarding their experiences in the college, in their major, with peers and faculty, and their personal identities during semi-structured interviews. Data will be analyzed using thematic analysis to identify patterns (Braun; Clark, 2020). We anticipate that students will highlight connections with peers that were supported through the linked- learning communities. This examination of student experiences will increase our understanding of student success and belonging in STEM, particularly for traditionally underrepresented students.

Abstract Name: **A Potential Picasso: A Syncretistic Signature Analysis between Pablo Picasso and a Thrift Shop Find**

Since the summer of 2019, Museum Studies and Chemistry students at the University of Tampa have collaborated on the “Potential Picasso Project,” an interdisciplinary investigation of a “thrift shop” painting signed “Picasso 1905” in the lower left corner. This project installment utilizes art historical and forensic graphological resources to conduct a syncretistic analysis of the signature evidence to determine if attribution of the subject artwork can be made to Pablo Picasso according to his signature conventions from 1904 to 1906. The year 1905 is significant when conducting art historical research regarding Picasso, as it marks a shift from his stylistic “blue period” to the “rose”. Therefore, signed, authentic oil paintings created by Picasso across both stylistic periods (during the years 1904, 1905, and 1906) have been selected to establish a set of qualitative signature conventions to compare the subject artwork against. Concurrently, an analysis of a large sample of Picasso’s main body of work from this period, pulled from a catalog raisonné, determined how often and where Picasso signed his work and how often he dated it. This quantitative analysis establishes a statistical foundation for determining the probability that Picasso made the subject artwork during the period in question. Preliminary evidence collected during the Fall term shows that Picasso often signed his work; however, observed signatures seldom match the one found on the subject artwork. This suggests several possibilities: the subject artwork was not painted by Picasso and is a forgery, the subject artwork was painted by someone close to Picasso who believed they could replicate his painting style, or the artwork may be an authentic Picasso but does not belong to the year 1905.

Abstract Name: Walleye Size Structure in Mississippi River Pools 11 and 13 Relative to Harvest Regulations

Size structures of a fish population provides managers with valuable information to set regulations. Biologists create these regulations to improve size structures for anglers' preferences and prevent any future stunting of a population. The objectives were to determine if walleye size structure increased in a pool after a regulation change was in place. Plus, to see if the regulation change made a positive impact on the size structure on one pool compared to another that had no regulation change. Walleye from pools 11 and 13 on the Mississippi River were sampled in during the fall months from 1993 to 2014; with having a regulation change occur in pool 13 during 2004. The walleyes were sampled using electrofishing from a boat. Wings dams were targeted and shocked on the upstream side. Walleyes that were caught were measured to the nearest millimeter. Fin clips were used to distinguish if a walleye was already captured or not. Pool 13 had an improvement to the size structure after the new regulation took place. Pool 11 had shown no drastic change before nor after pool 13 had a change in regulations. Although, there was no significant difference between pools 11 and 13 average lengths before and after the regulation change. This study can conclude that a change in harvest regulations could positively increase the size structure and value the larger portion of a population.

Abstract Name: Evaluation of Star Rating and Text Reviews

A popular field of study in research is opinion mining in subjective text, such as reviews, tweets, and other forms of data. This study aims to analyze the similarities and differences in the sentiment between text reviews (qualitative) and numeric star ratings (quantitative) on Yelp using sentiment analysis tools. To conduct this study, the Yelp dataset is retrieved from the Yelp Open Dataset, which contains 7 million reviews and 150K businesses. This dataset consists of five large JSON files, including a business, checkin, review, tip, and user file. To process these files and make them easier to read, they are converted to CSV files. The CSV file that contains the Yelp reviews is plugged into a Python program that includes four sentiment analysis tools: TextBlob, Vader, an NRC Lexicon, and Stanza. Because the sentiment analysis tools and Yelp's star rating have different ranges, the values and 5-star ratings are normalized to a 0 to 1 scale. A subset of the data (3,500 reviews) and their normalized sentiment scores are taken and plotted on scatter plots to visualize similar trends and differences between the 5-star rating with TextBlob, Vader, NRC Lexicon, and Stanza. The subset of data is then put through a Python program that returns the Pearson correlation coefficient between the star rating and sentiment analysis tools to measure how well they are related. The chi-square test is also performed on the subset of data to compare the observed and expected results. To further this project, we use machine learning techniques to make the sentiment of the reviews to predict the 5-star ratings so that it can be used for products or businesses on different platforms that do not have a star rating.

Abstract Name: Active Learning Pedagogy in Organic Chemistry: Analysis of Final Exam Data

Organic Chemistry is a notoriously challenging course, required for pre-Health majors, with drop and failure rates commonly in excess of 30-40%. This project examined the effect of active learning on reaction mechanism pedagogy to increase engagement and decrease student failure rates. We studied two semesters with no active learning pedagogy, two semesters with half active learning pedagogy, and two semesters with full active learning pedagogy. Preliminary results suggested that student achievement greatly improved and drop/failure rates were halved when active learning was used, as shown by analysis of formative (ungraded) assessments. Upon review of final exam data of the studied semesters, we found that our analysis strongly supports the preliminary findings from formative assessments and drop/D/F rates. Taken into combination, the aggregate data provide strong support for the effectiveness of active learning in this “hardest college course”. In order to analyze the data in question, we developed rubrics that applied to 6 semesters worth of final exams. Students had better mechanistic understanding and knew how to portray a mechanism better when they were exposed to more active learning in their organic chemistry semester. In these rubrics, students were not given a grade, but rather scored based on individual steps in the mechanisms in question. These scores were based on logic and mechanistic reasoning rather than simple correctness, as our study seeks to analyze the effect of active learning on student understanding rather than memorization of mechanism steps.

Abstract Name: Wearable Carbon Dioxide, Oxygen, Carbon Monoxide, and Methane Sensor within OSHA limits

According to the Center for Disease Control and Prevention, accidental gas poisoning affects approximately 50,000 people every year in North America alone across a wide variety of locations. A wearable, lightweight device that detects toxic forms of gas is ideal when prioritizing safety for individuals who need this information displayed while on the move. The purpose of this experiment is to design one device that measures exposure to common toxic compounds found in nature: Carbon Dioxide (CO2), Oxygen (O2), Carbon Monoxide (CO), and Methane (CH4). The current design uses gas sensors from Adafruit, Arduino, and Grove to detect dangerous concentration levels. The Occupational Safety and Health Administration (OSHA) defines maximum exposure in parts per million (ppm). A microcontroller and electronics have been designed to display concentrations in ppm on an LCD screen and provide a 1 second audio alert and danger signal if over OSHA standards. The system can measure CO2 within 5.7%, O2 within 4.6%, and CO within 1% of a commercial sensor. This project is 6 in x 3 in with plans to reduce to 1in x 1in.

Abstract Name: **Competition Demands of NCAA Division III Women?s Collegiate Lacrosse**

In an effort to assess the demands of NCAA DIVISION III woman's collegiate lacrosse, Global Positioning Systems (GPS) were used to quantify positional demands during the 2022 College Conference of Illinois and Wisconsin season (NCAA Division III) for the Carthage College Women's Lacrosse team. GPS data was collected from twelve female athletes using a sampling rate of 10 Hz (Titan 2, Integrated Bionics Inc. Austin, Texas). When comparing total distance by position, a statistically significant difference was found between the midfielders and attackers (0.01; ES = 1.75, large) and between the midfielders and defenders (0.01; ES = 1.95, large). No differences were observed between attackers and defenders (p = 0.15; d = 0.34, small). The main finding was that midfielders covered significantly more total distance than both attackers and defenders. Calder et al. (2021) observed similar distances among female defenders (7517 ± 786 m), midfielders (6972 ± 770 m), and attackers (6806 ± 586 m) at the NCAA Division I level. Calder's findings were that defenders covered the most distance during competition; conversely, the midfielders covered the most distance in this study. These differences are likely due to the teams' style of play and talent level. Furthermore, all positions experienced a decline in total distance covered as the game progressed, consistent with other studies (Calder et al., 2021; Varley et al., 2014). These effects are likely due to fatigue, and by developing positional profiles of volumes throughout match-play, coaches can ensure their athletes are prepared for competition demands. It is suggested that coaches and practitioners ensure lacrosse players can handle distances of 6130-8110 m during match play; it is best achieved if players are trained by positional needs. This specific training may help reduce the progressive loss in total distance covered with each quarter played.

Abstract Name: **Dubai's Journey to Become the Fashion Mecca of the World: Arab Fashion Week and Saudi Arabia's Modesty Standards**

In an effort to establish Dubai as a fashion capital of the world alongside other haute couture powerhouses such as New York, Paris, and Milan, the Dubai Design District (D3) chose to host an annual Arab Fashion Week (AFW) beginning in 2015. This research will exploreif and how AFW designers reconcile with Saudi Arabia's enforcement of modesty standards for women's clothing before and after the codification of the Saudi Public Decency Regulations in 2019. I will conduct an exploration of designers' balance between preserving the artistic value of couture clothing design and respect for the Saudi Public Decency Regulationsto build upon existing scholarship on the impacts of Saudi Arabian politics on Saudi women's wardrobe freedoms. Through textual and observational analysis, I will assess the evolution of the AFW women's runway collections' in relation to theSaudi PDR. Textual analysis will be conducted with respect to the Public Decency Regulations and news articles, while observational analysis is conducted on images of women's spring and summer collections presented at AFW. The results are hypothesized to indicate designers' indifference to modesty standards implemented by the Saudi government. Amidst the backdrop of abundant scholarship on the relationship between gulf governments and women's rights, Saudi Arabia's Arab Fashion Week provides a peculiar case in which political beliefs and the desire to hold international attention engage on the battlefield of women's couture attire.

Abstract Name: **Gender as a Moderator for Creativity and Risk-taking among Preschoolers**

Creativity involves producing unconventional ideas and exploring uncertain situations, suggesting a potential connection with risk-taking behavior. Creative personality and ideation strongly predict adult risk-taking, especially in social and recreational domains, but little is known about whether the relationships extend to preschoolers. Boys tend to engage in more risk-taking than girls. However, the relationship between gender and creativity is less straightforward. For example, girls demonstrate more creative thinking and detailed verbal responses, but no gender differences for other forms of creativity. The current study investigated relations between imagination, risk-taking, and gender in preschool-aged children. As part of a larger study, 105 children ages 4-5 completed the Ability Test, a risk-taking task evaluating overestimation of personal abilities at two levels of difficulty: just beyond (8% above maximum ability; JB) and well beyond (13% above maximum ability; WB). Then, they completed the Thinking Creatively in Action and Movement (TCAM) to assess imagination. Parents also reported their child's risk-taking behavior using the Injury Behavior Checklist (IBC). Three regression analyses predicting performance on the two ability test levels and the IBC were conducted, with imagination as a predictor, gender as a moderator, and age as a covariate. Gender only significantly moderated the effect of imagination on the ability test tasks for the IBC. Simple slope analyses revealed that at high levels of imagination, boys were riskier than girls. Thus, high levels of creativity influence decision-making among preschoolers. Boys with higher levels of creativity may be more explorative and thus riskier. Comparatively, girls with higher levels of creativity may implement more creative thinking and problem-solving, which leads to less risk-taking. Previous research about socialization reveals that parents usually discipline sons for their reckless behavior and educate daughters for not thinking safely. The findings offer potential gender-appropriate interventions for dangerous risk-taking behavior.

Abstract Name: **Synthesis of mesalamine and curcumin capped silver nanoparticles for the treatment of Irritable Bowel Disease (IBD)**

Silver nanoparticles are innovative materials which have found uses in the field of antiseptics and drug delivery systems as of late. The term IBD (Inflammatory Bowel Disease) is used to describe the series of chronic illnesses that are characterized by inflammation of the intestinal track lining. The two main diseases are Ulcerative Colitis (UC) and Crohns' disease (CD). One (UC) affects mainly the entirety of the colon while the other (CD) affects the entirety of the digestive system (from mouth to anus). To aid in the remission of an inflamed bowel, 5-ASAs (Mesalamine, balzalaside etc.) and curcumin are beneficial, alongside corticosteroids (prednisone) and biologics (Adalimumab and Infliximab). 5-ASAs (Mesalamine) are used to halt and avert flare-ups within the digestive tract while steroids and natural supplements such as curcumin, assist in the management of inflammatory and oxidative conditions. An effective synthesis of silver nanoparticles involves the use of silver nitrate, a capping agent (such as mercaptosuccinic acid) and a strong reducer (such as sodium borohydride). The two experiments were conducted while studying pH changes at each step. Then, UV-Vis was applied to verify the appearance of the nanoparticles. Signals around the 350-400 nm area confirmed the presence of silver nanoparticles in the two experiments. This work explores conditions that are used to synthesize these nanoparticles, that could be beneficial someday, in the delivery of therapeutic agents straight to intestinal lesions in the colon or digestive track.

Abstract Name: **Herman Goldstein's Wisconsin Idea: How Public Universities Contributed to Mass Incarceration**

In the late 20th century, digital technologies contributed to the United States' expanding carceral state. Police departments embraced computer programs to guide predictive policing, and digital databases published collated criminal data for all to see. These programs resulted in racial profiling, the criminalization of the poor, and creation of the planet's largest prison system. These systems also "outsourced" carceral activity to the civilian community as employers, schools, and the public used readily available records to discriminate—and thus to perpetuate the delinquent class. While scholars have written about these technologies in terms of privacy versus surveillance, asymmetrical power relations, and race-class intersections, few have explored the ways in which social scientists enabled their rapid growth. This project examines scholars who aided the policing process and ensuing technologies. Key among them was Herman Goldstein, UW-Madison legal scholar. He believed police could more efficiently control crime by proactively accumulating, sorting, and extracting criminal incident data for later analysis and public dissemination. While Goldstein and the scholars he influenced claimed they were "democratizing" policework and promoting "community policing," I show that the ways in which they encouraged the outsourcing of policing to the public and the vertical integration of ordinary people into the digital carceral system. Through the interplay of intellectuals at public institutions who lent legitimacy to carceral efforts which burdened the very society they were supposed to serve, I illuminate inconsistent aims which strove to implement academic ideas beyond the boundaries of the Wisconsin classroom.

Abstract Name: **On the Effectiveness of Augmented Data Generation of Brain Tumors Using GAN based Techniques**

Deep learning models have shown promising results in the computer-assisted diagnosis of brain tumors from images. The training data should be sufficient with high quality and generalized characteristics to train the deep learning models accurately. However, in the medical domain, the training data is limited, as it is difficult to collect sufficient patient data because of the problem of patient recruitment, the burden of annotation of lesions by experts, and the invasion of patients' privacy.Researchers have developed different automated Data Augmentation (DA) techniques, such as scaling, cropping, flipping, and Affine transformation, to overcome the problem of limited data for training. Recently, Generative Adversarial Network (GAN) based DA techniques, such as TumorGAN, PCCGANs, and CPGGANs, have shown improved results in generating augmented data. However, the evaluations of the existing GAN-based DA techniques can be questioned as the experiments were conducted either on small-sized datasets or included only some of the available datasets. In this study, we conduct a rigorous investigation to determine the effectiveness of the GAN-based DA techniques by applying those in all the available Magnetic resonance imaging (MRI) datasets.

Abstract Name: Waveform Play Space

One major purpose of this group is to form a collaboration between Music and Visual Arts at UWEC. A group of 4 students from Music, Photography, Graphic Communications, Illustration, Painting and Drawing will work with faculty mentors over the summer to translate sounds from nature that create interesting visual patterns in real time. The vibratons from those sounds will be the basis for developing an interactive installation envirment between Visual Arts and Music; Theater Arts. The resulting installation will be displayed publicly in the Haas Fine Arts Center Lobby in October 2022. This student/faculty team will work for approximately 10 hours per week during the summer and early fall to complete the project. Faculty includes Professor Jyl Kelley from Art; Design, Professor Gary Don from Music Theory, and Assistant Professor Mykola Haleta

Abstract Name: Quantifying Benefits of Bridge Maintenance, Research Project for Minnesota Department of Transportation

The objectives of this research are to quantify the benefits of preventive maintenance on Minnesota pavements and to develop decision trees that will guide the maintenance decisions for Minnesota roads. A literature review was conducted to observe trends of preventive maintenance effectiveness and challenges that are reported by other State Departments of Transportation. From this review, the findings were broken up into two data sets, one for roughness and one for distresses. Quantitative values of improved condition or decelerated deterioration for Minnesota roads in relation to actual project history will be analyzed along with the project costs for both data sets. The relationship between actual projects and the resulting performance will provide an understanding of the effectiveness of current decision guidelines and in what ways the process can be improved by increasing the timeliness of preventive maintenance measures to manage pavement service lives more cost effectively. Quantifying preventive maintenance will guide the development of a set of decision trees to advise project selection based on life cycle cost. These decision trees will help to enhance the selection of projects to lengthen the lifespan of the pavement. With limited budgets for transportation infrastructure, it is essential to improve asset management practices for our roadways.

Abstract Name: **Autism Abroad: Barriers to Collegiate International Education for Students with Disabilities and Implementation of Universal Design for Learning**

This project aims to address barriers to studying abroad in higher education for students with disabilities and explore how “Universal Design for Learning” (UDL) could be implemented to create more equitable experiences for students with ADA accommodations in international education. I draw on my own experience with a short-term immersion program as a case study to highlight issues of inclusion and equity in study abroad and suggest ways that universities, international educators, and future participants can re-envision study abroad and produce more equitable international learning communities. One framework that is often used to foster student growth in a learning environment is UDL, which provides students with equal opportunities to succeed, which can include health services. International travel takes a toll on individuals that can manifest in physical or mental illness and increases the need to supply support, resources, and mentoring to students studying abroad. The unique challenges students with disabilities experience from higher rates of social exclusion, mental illness, and other obstacles emphasize the need for this support. Educators need to think intentionally about ways to address these issues, support all students, and create resources and support systems that allow for more equitable learning communities. The experience I had abroad affirms this belief as shown through developing a psychosomatic illness due to the increased stress that was, in part, due to social exclusion and barriers only I experienced due to my disability status.Universal Design for Learning is used to create equitable learning experiences for all students based on engagement, representation, action, and expression. Reflecting on my experiences abroad, this presentation will analyze obstacles to international education for students with disabilities and apply them to the principles of UDL for educators to use when creating accessible international experiences in higher education.

Abstract Name: **Male Participation in Parent Education**

The student researchers seek to create an environment that motivates fathersto attendparent education courses by exploring the factors involved in the participation of males in parent education. The student researchers targeted a sample size of 78 fathers while utilizing a mixed methodology survey with an emphasis on quantitative. The students distributed this survey through online platforms and local grocery stores. The student researchers collected data during a three-week-long period. The survey contained five demographic questions regarding age, race/ethnicity, marital status, number of female children, and number of male children. The majority of respondents were ages 41 to 50, (28.2%; n=22), 20.5% (n=16) were ages 31 to 40, 16.7% (n=13) were ages 20 to 30, 12.8% (n=10) were ages 51 to 60, 10.3% (n=8) were ages 61 to 70, 7.7% (n=6) were ages 71 to 80, and 2.6% (n=2) were 81 to 90 years of age. Regarding race/ethnicity 85.4% (n=51) of respondents were White/Caucasian, 28.2% (n=22) were Hispanic, 2.6% (n=2) were American Indian/Alaskan Native, 2.6% (n=2) were Black/African American, and 1.3% (n=1) were Asian/Pacific Islander.The student researchers created a code sheet using Google sheets, which consisted of converting the survey questions into a code. The student researchers used the Statistical Package for Social Sciences (SPSS) to analyze data collected. The student researchers utilized the Hahn’s Coding Process to analyze the qualitative data. The themes: Work, Family, Time, and Disability consist of responses that reveal obstacles within the father'slives that would interfere with their attendance toparent education classes. Conducting this research provides information to include programs specifically for males to become more involved in parent education.By gaining insight from fathers in the community, the researchers will brainstorm ideas on how to make it easier for fathers to be able to attend parent education classes.

Abstract Name: Relationships Between Insomnia, Stress, and Perceived Daytime Impairment

The life of a college student is one filled with assignments, tests, work, and a social life squeezed in. During this time, sleep is often neglected as a necessity or even unattainable for some students. Students do not realize how much of an effect sleep can have on their perceived daytime impairment. Stress also seems to have a large correlation with recurring lack of sleep. After completing literary research, a variety of hypotheses concerning insomnia and other sleep issues, stress, and perceived daytime impairment were made. It is hypothesized that insomnia scores will be positively correlated with stress scores; that perceived daytime impairment scores will be positively correlated with stress scores; and that insomnia scores will be positively correlated with perceived daytime impairment scores. One hundred and seven undergraduate students at a small, private university in the southeast participated in a survey to study the correlation between these three variables. The following instruments were administered: Bergen Insomnia Scale, Sleep Related Impairment Measure, and the College Student Stress Scale. It was determined that all three hypotheses were supported with significant moderate, positive correlations. These findings were consistent with existing literature. Recommendations, implications, and limitations will be presented.

Abstract Name: Impact force due to a projectile passing through vibrating liquids

This experiment will analyze the effect vibrations have on an impact force of a spherical projectile passing through a liquid. The spherical projectile was dropped through water, olive oil, and linseed oil twice: once while the medium was vibrating, and once while it was not. The impact force is experimentally collected by a force sensor. The two impact forces with and without vibrations were analyzed to determine the effect of the vibrations on the projectile and the medium. The average force as the projectile passes through air was experimentally collected as 40.0±1N as the projectile passes through air and 13.8±1N as the projectile passes through water. The equations used to predict the impact force analyze the momentum at the time of impact, which relies on the viscosity of the liquid, the mass, and the radius of the projectile.

Abstract Name: **Why are Restaurant Firms are Going Private? Going Private Transactions and Stock Returns of Restaurant Firms**

Access to capital markets is one of the key benefits of becoming a publicly traded company. However, previous research has shown that companies in more recent years have returned to the private sector rather than staying public after the initial public offering. While existing research found numerous reasons for going private, there is a limited number of studies that identify factors that influence the shareholder returns of the decision to go private. This study attempts to uncover external and internal factors that affect shareholder returns. Our study includes U.S. restaurant companies listed under Standard Industry Codes 5810 and 5812 between 1995 and 2021. Our initial sample consisted of 80 firms that had a delisting code 231. Because some of these delistings were for firms that went bankrupt, the final working sample includes 74 firms. Data on going private transactions will be obtained from media outlets and SEC annual filings (10-Ks). Data for the dependent variable (shareholder stock returns) is available in The Center for Research in Security Prices (CRSP). Potential independent variables in our study are firm size, level of undervaluation, governance issues, executive team structure, board composition, etc. Regression analysis will be used to explain the variance in shareholder returns. This study expects that board composition and the executive management structure, will emerge as important factors beyond traditional variables such as firm size as determinants of shareholder stock returns. The findings of this research study can provide important implications for firm executives who are considering going private and private equity investors who are trying to identify the best target firms that can be taken private.

Abstract Name: **DJS Honors in the Major: DEI Throughout 1980s to 2000s**

Due to their experience with DEI (diversity, equity, and inclusivity) practices at the University of Wisconsin-Green Bay, the author wanted to lead a critical discussion on civil rights and liberties, as well as historical movements, for the LGBTQIA2S+, POC, and disabled/differently abled communities. The research presented in this presentation relates to the 1980s to 2000s era cultural shift, a shift from Stonewall and the Disability March to EDI involvement in multiple fields and industries.This project will showcase the voices and stories of those within these communities, highlighting the significance of Wisconsin in EDI history. Using archives from UWGB's Native American history and other archives, the author hopes to inspire further discussions and debates surrounding the LGBTQIA+, Indigenous, Black, People-of-Color, and disabled/differently-abled communities, as well as the work that the Diversity, Equity, and Inclusivity field has done to protect these communities' rights. Historical context is crucial to today's modern society and how every individual views these communities today.This poster will highlight an overview of several crucial events that led to the 1980s movements in Wisconsin leading up to the move for implementing EDI practices in Wisconsin. Including the overturning of Indigenous Boarding Schools, responses to the Vietnam War, the responses to Stonewall, and the implementation of drag and gay bar culture in our wonderful home state! Special thanks to the Archives, the Democracy and Justice Studies department, and all EDI offices at the University for their support in this rigorous study.

Abstract Name: **Reimagining College Support: A Critical Exploration of the Impact of Grief and Loss on the Experiences of First-Year College Students**

Student attrition is a rising concern in higher education given the various challenges that have arisen over the past couple of years. The offset of the COVID-19 pandemic, the racial justice movements, and the current social-political climate have significantly impacted our college students like never before. Of growing concern is the rising mental health crisis that is sweeping through higher education which warrants an immediate and intentional response. Further, students are currently facing dire financial constraints, food and housing insecurities, and many other challenges that complicate their college experiences. As freshman students are now experiencing college for the first time, their experiences may vary drastically from their predecessors. Specifically, current first-year students' college transitions are muddied from their various high school experiences that may have been a remote, hybrid, or in-person with some variation of security measures. Further, the grief, loss, and trauma first-year college students have experienced during the pandemic warrant special attention as we are contending with the types of resources and support, they need to matriculate and complete their degrees. The remnants of grief and trauma from the pandemic still linger and are impacting the college experiences of first-year students and their abilities to navigate their academic and professional goals. Hence, through a qualitative research design, our research explores the lived experiences of first-year college students. Specifically, the research question explored in our study is: How or to what extent has grief and trauma from COVID impacted the educational journeys of first-year students? The aim of this research is to provide an important opportunity to investigate how to better support college students as they move through collegiate experiences.

Abstract Name: **The effect of block length on polybutadiene-b-poly(ethylene oxide) micelle fragmentation kinetics in ionic liquid**

Recently, the equilibration of micelles formed by diblock copolymers has been highlighted due to their applications in various fields; yet, their fragmentation processes are poorly understood. Previous work on the fragmentation kinetics of 1,2-polybutadiene-b-poly(ethylene oxide) (BO), demonstrated that the fragmentation time varies with the total degree of polymerization (Ntotal) as tfrag ~ Ntotal9/5, which is consistent with the theoretical prediction of Dormidontova, even though that was couched in terms of Ncorona. To clearly resolve the contributions of Ncorona and Ncore to the N dependence, each block length needs to be modified separately. In this study, a series of BO diblocks with fixed NPB (9, 14 kDa) and various NPEO from 6 kDa to 20 kDa, was prepared to examine the corona length effect, and another with nearly constant NPEO (9, 13 kDa) and various NPB from 9 kDa to 14 kDa was prepared to study the core length effect. Micelles are formed by direct dissolution of the BO diblocks in 1-ethyl-3-methylimidazolium bis-(trifluoromethylsulfonyl) imide ([C2MIM][TFSI]). The sizes decrease when annealed subsequently at a high temperature (170 ℃). Comparing the fragmentation rates of the series of micelles will establish the individual effects of N-corona and Ncore. The hydrodynamic radius (Rh) of the micelles will be measured utilizing dynamic light scattering. The Rcore changes will be determined by small-angle X-ray scattering and transmission electron microscopy. We hope to establish the significant determining factors for both Ncore and Ncorona regarding micelle fragmentation kinetics.

Abstract Name: Illusions of Space and Motion: The Impact of M?ller-Lyer Lines on Perceived Speed

Motion illusions illustrate the separation between physical reality and perception: physically, motion is the change in location over time; perceptually, however, it is possible for objects to appear to move, but remain in the same physical location (Flynn; Shapiro, 2018). Our perception of motion, therefore, corresponds to the brain's interpretation of the external world rather than directly reflecting reality (though, in most occasions, the brain's constructions correspond to the physical world). Here we are concerned with the properties of the cognitive system that signal motion. In particular, we investigate how perceptions of speed are affected by changes in the perceived distance that an object travels. In physics, speed is a change in distance divided by a change in time; but many illusions can change the perceived length of a line (for instance, the Oppel-Müller-Lyer illusion). Hence an object traveling along the line would travel the same physical distance but a different perceived distance. In a version of the Oppel-Müller-Lyer developed by Todorovic (2017), segments of a circle equal in length appear unequal due to the addition of outward and inward-facing auxiliary lines. We coded a dot that travels around the Todorovic circle and measured changes in perceived speed as a function of the angle of the auxiliary lines. Participants will be asked to adjust the speed of the dot in the "shorter" segments to match the speed of the dot in the "longer" segments. We hypothesize that if perceived distance affects perceived motion, participants will see the dot moving faster when it passes through the "shorter" segments of the circle than when it passes through the "longer" segments. Experiments are ongoing, but interaction with a demonstration program (an illusion) that shares the experiment's configuration suggests strong individual differences as to whether the auxiliary lines affect perceived speed.

Abstract Name: In House Development of the Foot Platform for Body Scale Haptic Interface, ForceBot

The work presents a design, analysis, and build of an ergonomic foot platform for a body-scale haptic interface called ForceBot. The ForceBot is a robotic haptic interface that embodies human-pilot into virtual reality (VR), which enables physical interaction between the user and the simulated world. The human pilot is connected to the robotic platform with the feet mounted on a gait simulator that consists of two planar gantries and two foot platforms. To render realistic sensational feedback, the physical human-robot interface (pHRI) in the system, such as the foot platform, must provide adequate range of motion and degree-of-freedom that corresponds to the human input motions. pHRI must be carefully analyzed ensuring user safety while inherent ergonomic design that suits the operator. The design of the platform has considered application of load and stress concentration and was validated through performing Finite Element Analysis (FEA) and Destructive Tensile Test. The rotation control of the platform was initially an interrupt-based electromagnet control which is being developed into an actuated version to ensure precise control of the angle. Foot platform, as an end effector, enables application of position and force feedback to the user through pHRI according to the interaction in VR. This body-scale haptic interface elevates the fidelity of VR sensational feedback, which aims to be a dynamic scenario generator to assist a broad group of society. ForceBot aims to be a versatile experimental platform for industries as well as for the researchers to conduct study and experiment before the technology is deployed into the real world.

Abstract Name: **The effects of arbuscular mycorrhizal fungi on plant defense in Nicotiana rustica in response to simulated herbivory**

Plants have evolved various techniques by which they protect themselves from herbivore damage. In developing these defense mechanisms, plants allocate resources away from growth to increase chances of survival. In effort to compensate for this distribution of resources, studies have shown that plants can enlist the help of arbuscular mycorrhizal fungi (AMF), a mutualist that penetrates roots and exchanges in organic nutrients for sugars. Prior research has indicated that under certain conditions both growth and defense increase inAMF-inoculated plants.Nicotiana rustica is one species that is associated with AMF. This tobacco species possesses both physical and chemical defenses, primarily in the form of trichomes and the alkaloid, nicotine. Through inoculation of this tobacco with AMF, we can investigate the mutualists effect on growth and defense mechanisms. In this greenhouse experiment, we will be looking at the effects of inoculation timing coupled with simulated physical herbivory. Plant mass measurements will betaken72 hours post herbivory. Nicotine levels and trichome density will be analyzed on select leaves of each treatment group. Based on previous research, we expect to see increased defense in all herbivore damaged plants as well as heightened growth in all AMF inoculated plants. Higher levels of defense will be shown in all damaged inoculated plants, with the greatest levels seen in plants inoculated post germination.

Abstract Name: **RU a Twin? Correlations between the Big 5 Personality dimensions and Altruism Levels in Twins**

Altruism is typically a desirable and virtuous trait because it is considered favorable to care for the welfare and suffering of others (Kaufman, 2020). Studies have been conducted investigating the environmental and genetic structure of altruism, and most of these studies use a self-report altruism scale (Ando, 2021). Ando found that 51% of altruism is explained through genetic effects without shared environmental effects (Ando, 2021). They found personality profiles such as neuroticism, extraversion, openness to experience, and conscientiousness create different types of altruistic personalities (Ando, 2021). Other studies looked at pathological altruism (PA) and healthy selfishness (HS) (Kaufman, 2020). Results showed a relation between HS and psychological well-being (Kaufman, 2020). Pathological altruism was associated with vulnerable narcissism, maladaptive psychological outcomes, and the Big 5 personality traits (Kaufman, 2020). This current study aims to investigate the correlations between the Big 5 personality dimensions and altruism levels. Specifically in this study data collection is ongoing but we have collected data from 129 participants thus far. Each participant answers 20 questions about the five personality dimensions (Benet-Martinez; John, 1998; John et al., 2008; John et al., 2011), and 12 questions about altruism (Friedland el al 2020).We would like to collect enough data about altruism traits and personality constructs in twins so that we can analyze them in a behavioral genetics format. More interestingly we will be able to look at the possible overlap in genetic influence across these different factors. This can inform us about possible common cognitive and brain processing underlying the different factors.This part would be our next steps after this study is executed smoothly.

Abstract Name: **Effects of Phenolics and Antioxidants Four Types of Legumes on Callosobruchus maculatus**

Callosobruchus maculatus are infamous grain store pests that choose specific beans for oviposition (egg laying) and have different outcomes on different bean types. It is also known that black-eyed peas with higher metabolites, such as phenols, are more resistant to C. maculatus. There is a gap in knowledge regarding how the antioxidant and phenolic compounds relate to life history factors across bean species. To test these biological outcomes, four bean types: black-eyed pea, yard-long bean, chickpea, and mung bean, were evaluated separately on the initial fecundity and offspring outcomes. Two male and two female adults were put in four cups with 7 g of separate bean type and the offspring resulting from these cups were counted, sexed, and removed 2 days after eclosion to allow for mating times. Oviposition was monitored on one gram of the same bean type for females and lifespan was monitored for both sexes. Using the DPPH free radical scavenging assay, the antioxidant content is calculated in L-ascorbic acid equivalence. Total phenolic compound concentration is determined through the Folin–Ciocâlteu reagent and absorbances are relatively compared.

There is a significant difference in offspring amounts between black-eyed pea hosts and mung bean hosts (p=0.0002) which is not clearly explained by the antioxidant results which indicated yard-long beans have the highest concentration. Yard-long bean offspring amount and outcome did not have any significant differences from that of black-eyed peas. The total phenolics in chickpeas were much lower than that of the other 3 bean types and which explained the high amount of oviposition on the chickpeas compared to black-eyed peas (p=0.0002). It can be concluded that phenols may act as a defense mechanism in many beans because when there are fewer phenols present, C. maculatus have a higher incidence of oviposition.

Abstract Name: **Mechanism of Conductivity of AlGaN Semiconductors Determined from EPR Spectra**

AlxGa1-xN is an ultrawide band gap (5-6 eV) semiconductor with applications in deep UV LEDs and high-power electronics. In order to enable function and improve performance, UV LEDs need a highly conducting layer which can be achieved with heavily Si-doped AlxGa1-xN. The purpose of this research is to develop an understanding of the mechanism for conductivity in AlxGa1-xN, x > 0.6, by using Electron Paramagnetic Resonance (EPR) spectroscopy. To achieve this, the line width of the EPR spectra and the electron spin densities were measured in doped AlxGa1-xN, with Si concentrations between 1018-1020 cm-3.

In AlxGa1-xN:Si, Si acts as a shallow, neutral donor with an EPR g value of about 1.98. The temperature dependence of the donor EPR line width and concentration indicate band formation at lower temperatures (< 40 K) as well as the existence of the structurally relaxed, EPR silent, negative charge state of the donor at higher Al concentrations. In the talk, the analysis of the temperature dependence leading to impurity band formation, as well as the role of EPR in the measurements made will be discussed. This work was supported by ULTRA, an EFRC funded by DOE-BES, Award No. DE-SC0021230.

Abstract Name: **Conflict-Affected Women's Socioeconomic Roles in Post-War Sri Lanka**

Women's post-conflict experiences are under recognized in mainstream discussion of post-conflict reconciliation and socioeconomic policy. This research project will examine how conflict-affected women's socioeconomic roles have changed in post-conflict Sri Lanka. While existing literature has investigated how women's domestic and public roles shift in response to socioeconomic changes in post-conflict settings, this research will examine this issue at a micro level by analyzing women's accounts of how their lives have changed in post-war Sri Lanka. As scholars have utilized a feminist perspective in research to demonstrate the gendered impact of conflict on opportunities for women, this research will apply feminist theory in analysis. I will use interview data from the book We Are Present, an archival project on the Sri Lankan Civil War and affected women's post-conflict experiences. This research project will employ content analysis to thematically code the narratives and identify recurrent themes and patterns arising from the women's perspectives. The results will likely demonstrate post-conflict socioeconomic opportunities changing women's domestic and public roles in Sri Lanka. Post-conflict reconciliation and policy should consider women's gendered experiences to adequately target the intended population.

Abstract Name: **That's like the inherent sexism that we all deal with: Women's experiences running for office**

This research examines the differences women and men face when they enter the political field. Special emphasis was placed on women's experiences with sexism as they decide to run for office and throughout the election cycle. Previous studies indicate that women in politics perceive their qualifications to be less than those of their male counterparts, and men were more likely to say they were very qualified (Fox; Lawless, 2004). Previous research also showed that women were more likely to experience imposter syndrome than their male counterparts (Weir, 2013), and indicate that women feel less comfortable than men when doing political activities like door-knocking and fundraising (Fox; Lawless, 2012). This mixed-method study adds to previous research by analyzing how political communication affects cultural perceptions and how these perceptions affect the experiences of women who run for office. We collected data through surveys of both men and women who held office in Iowa, interviews with women with past or current political experience in Iowa, and conducted a content analysis of political advertisements. Our results offer updated insights that show an improvement in women's self-perception of their qualifications and give insights about how the imposter syndrome in the political pipeline shifts as women are encouraged to run by those who are already in political office. We also share new insights on how the sexism women experience regularly prepares them to overcome this barrier on the campaign trail.

Abstract Name: Using Mathematical Modeling to Increase Crop per Drop

Chippewa Valley Bean (CVB), located in Menomonie, Wisconsin is the world's largest producer of dark red kidney beans. There is limited research available on dark red kidney beans as they account for less than 1 % of the nation's agricultural land use. CVB agronomists asked, "How much water is required to grow one hundred pounds of dark red kidney beans?" There are many factors that impact the answer to this question. This project focuses on soil characteristics while holding temperature and nutrients fixed. Plant disease and weather-related damage is also neglected. A mathematical model consisting of a system of three coupled differential equations was developed to simulate water use through the soil, plant canopy, and reproductive biomass. The model predicts a kidney bean plant's reproductive biomass at the end of the growing season. Numerical experiments show how much water is needed via daily irrigation to achieve maximum yield for given soil characteristics. The intended use of this model is to help agronomists advise growers on the efficient use of water resources to obtain maximum kidney bean yields.

Abstract Name: Using Deep Learning for Analysis of Methylation Markers Associated with Pancreatic Cancer

DNA methylation is a key epigenetic modification that can modulate gene expression to influence cell differentiation. This process could impact the role of a tumor suppressor gene which possibly lead to cancer. DNA methylation can be measured at single-cell resolution by high-throughput sequencing technology. However, these technologies cannot determine complete CpG coverage and hence prediction of missing methylation states are critical for complete genome-wide analysis. The main challenge for prediction is the high dimensionality and complexity of the methylation data. To address this dimensionality, we propose a two-step method of feature selection and cancer prediction using state-of-the-art machine learning algorithms. In the first stage, Principal Component Analysis, Random Forest, and ANOVA F-test are applied to select the top CpG markers that could be the most important features in this research. The degree of similarity between selected CpG markers would also be analyzed using Correlated Feature Elimination and some of the highly correlated features would be documented and removed prior to classification. Selected features can then be combined with RNA-sequencing data to provide a comprehensive dataset that serves as the basis of prediction. A Convolutional Neural Network would be implemented to develop a diagnostic prediction model for cancer detection from the selected CpG markers and associated RNA sequencing data. Experiments will be conducted on pancreatic cancer-specific CpGs using the publicly available Cancer Genome Atlas Program (TCGA) datasets. Our proposed approach consisting of a Feature Selection stage would make this model scalable and faster while Deep Learning would develop an accurate prediction model capable of expressing non-linear relationships.

Abstract Name: **A look into the mind: How the type of mindset affects self-esteem**

The mind is a powerful thing that can influence one's self-perception. Many times, it can affect how we feel about ourselves. Because of this, one might conclude that manipulating one's mindset would influence feelings of self-esteem. Understanding the process of social comparison through mindset can give researchers a better understanding of how these two interact and affect self-esteem.Mindset includes the mental attitudes or beliefs one holds. Research shows that there are two different types of mindsets: a fixed mindset and a growth mindset. Having a fixed mindset would cause one to think that a certain ability or trait can not be changed, whereas a growth mindset would cause one to believe that improvement is possible. One might expect that the harder a task or ability becomes, the lower their self-esteem may beif the task seems "impossible." The purpose of the current study was to investigate whether the manipulation of mindset affects one's self-esteem. Unfortunately, not many studies have been done to investigate this association. A total of 32 Alverno students were recruited to participate in a Qualtrics study. The State Self-Esteem Scale was used and modified for the purpose of this study. The results showed that there is no significance between mindset and self-esteem, which was inconsistent with the hypothesis. This may be because a fixed mindset leads participants to feel more confident and have higher self-esteem about their abilities when they must overcome a difficult obstacle.

Abstract Name: **The Effect of an IPE Simulation on the Self-Efficacy and Knowledge of PT, OT, and SLP Students**

The implementation of interprofessional education (IPE) for students is an important learning opportunity where they can gain skills that will help facilitate successful collaborations with various professionals in their future careers. Measurement and documentation of student learning is critical to justify ongoing implementation of these IPE experiences. Most tools that are used to assess student learning about IPEand interprofessional practices (IPP) are self-efficacy scales that measure students' own perceptions. Measurement of change in student knowledge associated with IPE is rarely reported in the literature but would lend more support to the value of IPE. The purpose of this study is to determine how students' self-efficacy compares to their actual knowledge before and after participating in an IPE simulation. Speech language pathology (SLP), occupational therapy (OT), and physical therapy (PT) students willwork in interdisciplinary groups to complete a co-evaluation of a simulated stroke patient, with opportunities for discussion and feedback during the process. The students will complete the Interprofessional Collaborative Competency Attainment Scale (ICCAS) and answer knowledge-based questions before and after the simulation in a Qualtrics survey. Student self-efficacy and knowledge-based scores will be reported as quantitative data. Students will also complete a reflection on the event, providing qualitative data about their learning and growth. The results of this study will help determine whether this type of IPE simulation is effective in increasing students' knowledge about working in interprofessional teams.

Abstract Name: Borodin String Quartet No. 2

Borodin's Second String Quartet in D Major is a piece that requires advanced ensemble techniques, fine intonation work, and balanced melodies. It is an essential quartet piece within the string repertoire, and one which our group has grown from immensely while preparing.
The passing of melodies from cello to first violin and viola to second violin requires eye contact, breathing, and togetherness as a group. Borodin includes immediate tempo changes marked at the two animatos, as well as poco a poco dim. e rit at the end of the piece.
Beginning in the deceptively easy key of D Major, intonation inaccuracies are not easily hidden in this piece. Several moments require the performers to play in unison or octaves, and every chord must be carefully tuned. Compounding this, the piece changes keys several times during its development. The F#s in these keys are naturally dissonant and difficult to tune, especially in a group setting. Our quartet has spent hours together refining our intonation.
Throughout the piece, the first violin and cello converse with each other by trading the main melody. Later in the development section, the melody is passed around to the rest of the quartet. At the recapitulation, the cello hands the melody to the viola, requiring a strong sense of balance among the group. Because of this, our quartet has been working on balancing the melody and the accompaniment. The passing melodies require each member to use the same bow techniques and distribution, keeping everything uniform and beautifully phrased.
An influential work for any group, Borodin's second string quartet blends beautiful melodies and textures with flawless technique to create a timeless masterpiece.

Abstract Name: The Cardiorespiratory Response while Nordic Walking vs. Regular Walking Among Middle-Aged to Older Adults

Background/Purpose: Around 60-80% of waking hours for adults are spent in sedentary behavior while physical inactivity accounts for 9% of all deaths worldwide. Furthermore, there is a strong dose-response relationship between physical inactivity and all-cause mortality, cardiovascular health, and metabolic health. Recently, Nordic walking (NW) has been introduced as a superior mode of exercise where one can increase energy expenditure due to increased engagement of upper body musculature while walking at a moderate intensity pace. NW is like regular walking except for using walking poles. Within established findings, most work has been done in a laboratory which can interrupt natural NW mechanics. Therefore, the purpose of this study was to measure the cardiorespiratory and energy expenditure differences in Nordic walking and regular walking in a field setting. Methods: Twenty middle-aged and older adults participated in this study. Each participant's initial session included Nordic walking familiarization, 10-m gait speed test, and a peak oxygen uptake (VO2peak) test. The two exercise sessions consisted of either NW or regular walking on an indoor track for 30 minutes. All metabolic variables were measured via the COSMED K5. Results: A paired-sample t-test revealed a significant difference between NW and regular walking for %VO2peak values ($p = .008$), kcal·min-1 ($p = .005$), and total kcal expenditure ($p = .001$). No significant difference was found for preferred gait speed ($p = .485$) between NW and regular walking. Conclusion: NW is superior to regular walking in eliciting a higher %VO2peak despite similar walking speeds, a higher kcal·min-1, and greater total kcal expenditure. In turn, these data agree with previous research and supports the use of NW to increase energy expenditure to potentially prevent the risk of one's metabolic and cardiovascular risk.

Abstract Name: Economic Impacts of Russia-Ukraine War

The Russian-Ukrainian war began in February 2022. The war not only resulted in thousands of deaths, but also brought an agricultural crisis to the world. Wheat is Ukraine's second major agricultural product and accounts for approximately 28% of Ukraine's food supply. Based on data collected from various sources, including the U.S. Department of Agriculture, this study examined trends in Ukraine's production and exports and found that both production and exports were declining in 2022 due to the ongoing war. Compared to 2021, wheat production is down about 30% and exports are down about 48%. The study also found that the war is having a negative impact on the global economy by affecting energy and food prices, causing significant inflation. And its impact on developing countries is greater than its impact on developed countries. This is because developing countries are at a disadvantage in terms of trade compared to developed countries. This study reports on modern warfare and its impact on food supplies and economies, starting with the impact of the Russo-Ukrainian war on the world economy. Not only this war, but also other conflicts are taking place around the world, both within and between countries. The effects are not confined to a single country but affect many countries. Focusing on developing countries, the report examines the impact from major grain producing and importing countries. The study will also examine the likelihood of conflict in those countries and how war is a threat to the world based on the country's food supply.

Abstract Name: Visualizations

Visual art and dance created by emerging artists, is something that is not really explored. A lot of choreographers use famous paintings to create a piece of work. However, by allowing visual artists that are emerging to create work and then create something from that work, is allowing for an exploration into the unknown. There is so much potential that could be done with collaborating with emerging artists and dancers, but there is never really any known knowledge to create that bridge with the two. This piece of work is created to show that art does not have to be created in a vacuum. That instead it can be created by many different artists that are starting to make their way or finding their way. There is a sense that if visual art is going to be portrayed through dance, then it needs to be a famous painting. However, this piece was created to show that dance can still portray visual art through artists that are up and coming. By creating a piece of work that is inspired by emerging visual artists, my end goal is to show that even if you don’t have a prominent name in the art world, you can still create something that is beautiful by collaborating with other emerging artists. This piece was created to inspire people to collaborate more and to go into the unknown, no matter how scary it may be. There is beauty in everything and creating something that can combine two art disciplines, can create something that is exceptional.

Abstract Name: Enhancing Healthcare with Real-Time Body Gesture Recognition: The DroneX Solution

Due to the increasing popularity of drones in mainstream entertainment and business sectors and the limitation of controllers, we realized the need for hands-free control and expansion of user-defined commands that hardwired controllers cannot support for drones. This project uses the DJI Tello drone to recognize different commands through body gestures. The DroneX should distinguish between a series of body gestures and return the desired commands to the Drone. We have implemented the MediaPipe tool by using its APIs to currently recognize eight gestures; stop, take/up, land, forward, backward, left, right, and flip. We also used OpenCV and its APIs to display the image on a separate device. The DJI Tello drone is used as the environment for deploying the DroneX software. The Tello is connected to a separate device via Wi-Fi limited to 100 meters. It has a camera that is 5 megapixels (2592 x 1936), has an 82.6-degree field of view, and is HD 720 p. We are aware that DJI RyzeTM has a drone called the DJI Spark that uses hand gestures to issue commands. We are using body gestures to have a better range than hand recognition. Social media platform Snapchat also had a drone called Pixy that would take a selfie of the user, but Snapchat discontinued the efforts to develop it in August 2022. Pixy would just take a picture and return it to the user's hand. Currently, the DroneX project has some limitations, such as working in low-light flight conditions, harsh environment flight, and in an area of multiple detected objects. In future work, we plan to overcome the mentioned limitations, detect gestures at big distances, and include larger body gestures in our dataset.

Abstract Name: Discrimination through Inadequate Healthcare for the Roma: Democratic Backsliding in the Czech Republic and Slovakia

The decline of liberal democratic institutions and norms is an increasingly prevalent phenomenon in Eastern Europe. In the Czech Republic and Slovakia, the inequality in access to healthcare between the Roma and non-Roma suggests democratic backsliding is taking place.Upon accession to European Union membership in 2004, the European Commission critiqued both states for the mistreatment of the Roma, incentivizing the governments to establish plans to improve their conditions. Yet these extensive, comprehensive programs have either stagnated or never taken effect. Despite democratic transition processes, discrimination towards Roma people endures, which is puzzling. How does the lack of healthcare protections for the Roma reveal a deeper-rooted problem of backsliding in democracies?The Roma are the largest ethnic minority group in both states. They constitute about 10% of the population and have been settled there since the mid-fourteenth century. Seven centuries later, they face severe racism and discrimination, especially with respect to obtaining adequate and consistent healthcare, which negatively affects their socioeconomic wellbeing. Adequate and consistent healthcare is perhaps a "high" expectation for anywhere – but the Roma are at a disadvantage in accessing healthcare when compared to non-Roma people in both countries. The unequal access sheds light on a lack of adequate social provisions for a minority group as a symptom of democratic backsliding.This study will analyze several key policies and outcomes from the time of EU accession and onward that focus on improving maternal healthcare, and thus socioeconomic welfare protections, for the Roma; policies will include the "Decade for Roma Inclusion," policies set forth by the OECD, and policies proposed by both the Czech and Slovak governments, among others. Statistical data from surveys and studies concerning discrimination will also contribute to this particular study.

Abstract Name: **Parental Involvement in Education B**

How relative is parental involvement in a child's education to the overall success of the child? Can parents be too involved in their child's education? In society today we are seeing an increased debate over the different types of parents and how good or bad they are to the overall growth and development of their children. Are helicopter parents harming their children's future? Are free range parents raising children with no rules or boundaries providing a need for society to deal with the evenual negative outcomes? The goal of this research is to study the different parental involvement levels in the education of their children and determine what positive and negative outcomes are present under each type of parental behavior. Some criteria that will be important in this study are the level of parental invovlement, to what age of the child does the involvement continue, academic performance and self-efficacy of the children. Other areas of interest in this study include whether gender and race/ethnicity are impacted differently under differing parenting styles. Correlational analysis will be completed through data collection in the spring semester of 2023.

Abstract Name: **Analysis of Social Control Mechanisms in Colonial Tanganyika**

In colonial Tanzania, British occupiers operated in a resource-limited environment. Colonizers largely maintained control through social methods rather than blatant coercion. Following independence, many social control systems failed. Systems of control were reinstated through economic means. Seemingly altruistic aid often made countries dependent on their former colonizers. Newly independent countries frequently became dependent on technology they could not maintain. Western countries frequently apply tariffs to African finished goods, keeping the country poor and labor cheap. Through the lens of Social Science, I explore the reinstatement and legacies of colonial systems of control in an independent study research paper. I will draw literature from political science, history, and sociology, as well as archival material. Any increase in personal liberty comes at the expense of the powerful; understanding the methodology of those who resist social justice allows leaders to create change more effectively. Modern social justice movements frequently oppose the legacies of colonial power. Understanding how systems of control are maintained is crucial to effectively changing society.

Abstract Name: **Systemic Racism Domino Effects Amongst the Black Community: Housing, Education, and Mental Health**

Systemic racism continues to place Black people in a position of disadvantage. It involves multiple systems that establish complex and penalizing institutional laws to perpetuate discrimination and oppression amongst minoritized groups. Deriving from slavery, systemic racism originated when President Abraham Lincoln abolished slavery by ratifying the 13th amendment in 1865. Under President Andrew Johnson's leadership after the assassination of President Lincoln, states were allowed to continue to create their own local laws under the Reconstruction Act of 1867. States soon started to enact what was known as The Black Codes, which were laws that restricted Black people from their freedom and further exploited them as a cheap labor force. As time went by, these laws led to the full development of Jim Crow Laws in the 20th century. Similar to the Black Codes, the Jim Crow Laws continued to legalize racial segregation and limit opportunities for Black people. Despite the abolishment of slavery, segregation and discrimination against Black people still put limitations on true freedom. President Lyndon B. Johnson enacted the Civil Rights Acts of 1964 and 1968 that protected minorities from discriminatory acts in the workforce, education, housing, and other systems. In turn, White people in power developed underlying institutional policies to continue to limit progress for Blacks, which came to be known as systemic racism. This was prominent in housing, with discriminatory policies such as zoning and redlining. Research suggests that Black people's struggle to attain homeownership has had a domino effect on difficulties in other areas of daily life including education and mental health. The current comprehensive literature review sought to spread awareness of the long legacy of systemic racism and explore the ways in which this has impacted the housing, education, and mental health status of Black people living in America.

Abstract Name: **Dietary preferences of invasive red swamp crayfish (Procambarus clarkia) from the Patuxent Research Refuge, Maryland**

Invasive species are a leading cause of environmental degradation in freshwater ecosystems. Invasive crayfish, for example, can displace native crayfish and consume large quantities of both aquatic macrophytes and native animals. While Maryland is home to three invasive species of crayfish, relatively little is known about their impacts to local food webs. Here, we collected invasive red swamp crayfish (Procambarus clarkia) from the Patuxent Research Refuge in Laurel, Maryland and performed a feeding experiment to understand their dietary preferences and likely influence on refuge food webs. Crayfish were housed in 20 x 12 x 10-inch glass tanks equipped with air stones and polyvinyl chloride pipes for refuge. They were offered native plants and animal matter in three separate week-long trials, and their diet preferences were quantified based on the percent of food mass remaining at the end of a trial. We also used the stable carbon and nitrogen isotopic composition of wild red swamp crayfish to understand how their dietary niche compares with that of a common, native omnivore, the eastern painted turtle (Chrysemmys picta picta). Our feeding experiment showed that on average, red swamp crayfish preferred smartweed (Persicaria sp.) over other species of aquatic plants and animal matter over native plants. We also documented substantial variation among individual crayfish – a finding echoed in wild crayfish's variable nitrogen isotope values. Finally, we observed considerable overlap between the red swamp crayfish's isotopic niche and that of the eastern painted turtle. These results provide insight into the impact of an invasive species within one of the largest green spaces in the Washington, D.C.-Baltimore corridor.

Abstract Name: **Free Lunch For Whom? Racialization of School Meal Policy Attitudes**

There has been quite a bit of research regarding the racialization of welfare and other economic distribution policies in the United States. However, this research has not yet addressed the question of how racial factors impact economic policy surrounding free and reduced lunch in the K-12 education system. Our ongoing research studies the impact of both racial resentment and racial threat on the likelihood of supporting legislation to provide universal free meals to K-12 public schools among White survey respondents. These data were collected in the summer of 2022 using Amazon's Mechanical Turk system (n= 575). Based on the existing literature, our first study plans to evaluate whether those higher in racial resentment and those situated in geographies with a higher proportion of people of color will express increased opposition to a universal school meal policy. In study two, we will turn our attention to a novel measure of racial affect: White Solidarity; an expression of in-group salience among White people. In this second study, we seek to assess whether a novel racial priming experiment will increase opposition in White respondents with higher levels of racial resentment and white solidarity. With white solidarity specifically, we expect that effects will be mediated by the percentage of students of color in the district, since their approval may be impacted based on their perception of which groups might benefit. Data analyses are in progress and results will be provided along with an in-depth discussion of the project's relevance and impact.

Abstract Name: **Inhibition of Acid Ceramidase Augments Herpes Oncolytic Virus-Based Therapy in Recurrent Glioblastoma**

Glioblastoma (GBM) is the most common malignant brain tumor in adults, is highly aggressive, and evades standard of care surgical resection, radiation, and chemotherapy, leading to near-universal recurrence. One mechanism through which GBM cells may avoid cell death is through a dysregulated sphingolipid metabolism, specifically, an increased abundance of sphingosine-1-phosphate (S1P) and decreased abundance of ceramides. Ceramide hydrolyzation by ceramidases produces sphingosine, which can then be phosphorylated to S1P by sphingosine kinases. Decreasing the production of S1P and increasing ceramides via inhibition of ceramidases constitutes a potential strategy for anti-cancer therapy.We recently demonstrated that inhibition of the acid ceramidase ASAH1, via genetic targeting with shRNAs or with the blood-brain barrier permeable drug carmofur, decreased glioma growth and migration. Interestingly, ASAH1 expression in macrophages was recently found to facilitate encapsulation of herpes simplex virus-1 (HSV) in multivesicular bodies, thereby mitigating disease. These data suggest that ASAH1 inhibition in GBM could also improve the efficacy of oncolytic HSV therapy. Therefore, we explored the effect of pharmacologic and genetic inhibition of ASAH1 on cancer cell killing of oHSV G207 in patient-derived xenografts. Our preliminary data has demonstrated a significant decrease in GBM cell growth upon treatment of cells with the combination of carmofur and G207. Our data also suggest that recurrent GBM xenolines with shRNA knockdown of ASAH1 are significantly more sensitive to G207 compared to non-targeting controls. Considering G207 is safe in both adult and pediatric glioma patients and carmofur is used internationally for the treatment of colon cancer, we believe that our findings are highly translational.

Abstract Name: The Effects of Pressure on the Electrochemical Behavior of Fast Charging Lithium-Ion Batteries

Current battery technologies provide a barrier to more widespread adoption of electric vehicles. Batteries are needed that enable long range transportation with a charge that resembles a gas station like stop, known as fast charging. There are two main degradation mechanisms that cause battery capacity fade. Loss of lithium inventory (LLI) leads to less active lithium available to cycle through the battery as it charges and discharges due to lithium plating on the graphite anode. Volume changes during the cycling process cause electrode damage that leads to a loss of active material (LAM). This project focuses on the effect of pressure on the electrochemical behavior of lithium-ion batteries. The batteries are cycled with a uniform pressure application at 10 psi, 50 psi, and 125 psi. Batteries are also cycled between rigid plates, which provides a non-uniform pressure. A uniform pressure application leads to a more homogeneous reaction environment and reduces electrode volume changes. Batteries are constructed using graphite anodes and NMC-532 cathodes from two different electrode series with different capacities. A higher capacity leads to more room for lithium intercalation during the charging process. The batteries are cycled up to 140 cycles at 3 different charge rates: 1C, 6C, and 9C, where 1C is the time it takes to fully charge the battery in 1 hour. Once the batteries finish cycling, we look at trends in the electrochemical data, namely capacity fade, and dQ/dV (change in charge over change in voltage). This experiment is currently in progress, but the initial results are showing less variability for batteries cycled under higher pressures and using the higher capacity electrodes.

Abstract Name: Evaluation of Aggression throughout the Estrous Cycle

While aggressive behaviors have commonly been explored in males, females are just as likely to express aggressive behaviors. Enhanced estrogen levels are correlated with increased aggressive-like behaviors. It is unclear if the changes in estrogen levels during the estrous cycle will modulate aggressive-like behaviors, such as dominance. There is still a lot to be discoveredabout the underlying molecular mechanisms involved in estrogen's regulation of these behaviors. Neuropeptide Y (NPY) could serve as a mediator between estrogen and aggression. NPY is highly expressed in brain regions associated with aggressive-like behaviors, such as hippocampus and prefrontal cortex. Pharmacological and genetic manipulation of the NPYergic system inversely modulates aggressive behaviors. For example, loss of NPY Y1 receptors enhanced biting behaviors. In addition, estrogen regulates NPY levels and has been shown to have a sexual dimorphism. In the arcuate nucleus, NPY mRNA levels are variable based on the stage of the estrous cycle. Thereby, indicating the importance of estrogen and NPY to aggression. This study will determine whether NPY levels modulated by the estrous cycle are involved in aggressive-like behaviors. In this study, aggressive-like behaviors will be assessed using the social dominance tube test. The high estrogen (proestrus, estrus) stages were paired against low estrogen stages (diestrus, metestrus) as determined by vaginal lavages. The preliminary data suggests that in young adolescent mice (5-9 weeks), the non-sexually receptive group is more dominant compared to the sexually receptive group. Using tissue harvested the same day as tube tests, ELISAs will be conducted to determine NPY levels. We hypothesize that NPY levels will be lower during low estrogen phases of the estrous cycle, and correlate with aggressive behaviors. Overall, this study will help fill the gap in understanding the underlying mechanism involved in female aggressive behaviors.

Abstract Name: Microscale Synthesis of Fusible Alloys and Low-Melting-Point Metallic Nanoparticles

Fusible alloys melt at a low temperature and typically consist of metals such as indium, gallium, bismuth tin, and zinc. These alloys can be used in applications such as electrical solder, thermal fuses, liquid metal coolants, die casting, and rapid prototyping. Additional metals such as mercury, lead, cadmium, and even thallium could also be used but are more restricted in their potential applications due to high toxicity. Some of these metals, such as indium and gallium, are relatively expensive making it advantageous to conduct microscale research of new fusible alloy compositions on a small scale. Such syntheses are challenging due to the comparatively high surface area to volume ratio of microscale samples leading to significant oxide formation when being mixed in the melt phase. A method has been developed to prepare alloy samples of various compositions at a 500 mg scale using a rosin-based flux to protect the molten surface and promote mixing without the need for a vacuum furnace or inert atmosphere. The resulting alloy samples were characterized by dynamic scanning calorimetry (DSC) and optical microscopy and were found to have the expected melting points and microstructure when compared with known phase diagrams found in the literature. Fusible alloy samples were then converted to low-melt-point metallic nanoparticles using an ultrasonic nanoemulsion method. Samples of the selected alloy were pre-heated and sonicated in mineral oil using a probe sonicator. The resulting high shear converted droplets of molten metal into particles ranging in size from tens of nanometers to a few microns depending on the intensity and duration of the applied sonication. Particle size and distribution were characterized by optical and scanning electron microscopy. The methods used to prepare and characterize fusible alloy samples and nanoparticles will be discussed.

Abstract Name: Computational Analysis of Pop Music Across Cultures

Songs are heavily influenced by culture. This project focuses on finding similarities and differences in both the lyrics and chords of popular songs in Spanish, English, Japanese, and Chinese. First, we collect a database containing the songs' title, lyrics, and artists by scraping several online websites. We then analyze the lyrics of the songs, performing sentiment analysis and analyzing other psycholinguistic categories on the songs as a whole and also as a word usage time series. Using clustering and topic models, we identify commonalities in songs across languages. This project also includes a chordal analysis to determine whether there are common chord structures and key signatures that are inherent to a specific culture's music. The result of this analysis provides an exact cultural interpretation of the lyrics for non-native speakers.

Abstract Name: **Does General Education achieve its goals for post-secondary education? How one US university General Education course meets the assigned student learning objectives (SLOs)**

The academic literature emphasizes the importance, framework, expectations, and design of General Education (GE) curricula in higher education. However, actual assessment and accountability for the achievement of student learning objectives (SLOs) remain inconsistent in higher education. In the USA, the term General Education refers to university requirements which ensure an interdisciplinary education for a quarter or more of an undergraduate degree, The curriculum often is aimed to nurture competency in communication and mathematics, critical thinking and self-initiated learning, and moral education as a member of the global and diverse society. This investigation was conducted at an American Midwest public university in southern Minnesota. The GE curriculum fosters skills in communication, interdisciplinary knowledge and perspective within a diverse society with an ethical mindset and lifelong learning approach. This project will assess how one course, Human Relations in a Multicultural Society (HRMS), meets the assigned SLOs. HRMS provides education in self-awareness and skills that are essential for living and working socially in a democratic society. Since this is a GE course, the instructor wished to investigate its achievement of the many SLOs embedded in this course. In Fall 2022, the course instructor began using the 'Competencies' function of D2L Brightspace. She identified assignments and assessments related to each SLO. The research will report the course's effectiveness in meeting GE SLOs with data from each assessment (assignment). The results may be valuable for: course redesign, assessment practices, accountability to stakeholders, and institutional assessment.

Abstract Name: **Designing a 2D Traversing System to assist a DBD Plasma Wound Healing Probe**

A Dielectric Barrier Discharge (DBD) plasma probe was designed (Patent-US9433071-B2) to enhance rapid wound healing/sterilization. Investigation shows that process of wound healing is accelerated as the wound's surfaces are exposed to DBD plasma jets [Singh et. al. NCUR2022]. For this application, the DBD plasma probe needs to be held on a robotic arm to scan the targeted wound surface. In this work we are developing a 2D traversing mechanism that will hold the plasma probe to scan the surface (12x12 in2) at a desired speed. For the current design SolidWorks is used to build the 3D model for the entire system of the robotic arm. The designed 2D stages include two ball screws, aluminum rails, pillow blocks, and rail carriages that are fabricated to provide the required 2D movement to the arm. Raspberry Piis selected for activating the system. Two Nima 23 Standard hybrid stepper motors are selected for this project. A Qunqi L298N Motor Drive Controller Board is employed to control the stepper motor. Experiments show that the stepper motors reach to high temperatures after a continuous run of about 30 minutes. For an effective thermal management, two heat sinks (12V/55mm Heat Sink- VGA-CPU 8) are being attached to the motors and active cooling methods (fans) are used to convectively cool down the motors. This automated robotic arm is controlled through a microprocessor Arduino. The DBD plasma torch holder is machined from an insulated material to avoid any electrical sparking between the traversing rail and the torch that is powered by an ac voltage (5-10kV/15-30kHz) and uses helium as a working gas to generate plasma jet. The poster presentation will present the details on the design, calculations and the prototype system development and its testing with a DBD active plasma torch on a solid target surface.

Abstract Name: Mechanistic Analysis of Ball Milled Chemical Syntheses

Ball milling is a mechanochemical strategy of growing value in green chemistry due to its simplicity, efficiency, and success in product conversion under liquid assisted grinding conditions. Moreover, its applicability to syntheses relevant to natural and pharmaceutical product development make an understanding of its mechanism one of high priority in both academia and industry. Despite its simplicity, however, the nature of ball milling prevents real time analysis of the chemical environment within reaction vessels, and byproducts within these vessels have been shown to produce unanticipated outcomes that are likely unique to their mechanochemical environment. Here we address these limitations through an investigative study of ball milling via byproduct analysis from ball milled cross electrophile coupling (XEC)reactions using a series of characterization methods meant to shed light into the elusive environment of ball milled reactions. Beginning with a thorough investigation of the seemingly unpredictable darkening of centrifuge tubes containing byproducts of ball milled XEC reactions, we analyze these byproducts via spectroscopic methods to show that this darkening of vessels is due to a gradual sublimation of molecular iodine associated with low XEC selectivity. Metallic behavior is also explored through isolation of catalytic and reductive metals in replicated XEC reactions to demonstrate the breadth of their contribution to product conversion in ball milled chemistry. Lastly, broader characterization techniques are employed to provide even more insight to the nature of chemical interactions within a ball milled environment.

Abstract Name: Time Series Classification for Real-Time Feedback in Brain Computer Interfacing Video Game

Brain-Computer Interfaces (BCI) provides a direct communication link between brain and computer. Through the Functional near-infrared spectroscopy (fNIRS) technique, BCI measures brain activity. Research in BCI has been mostly focused on medical applications. However, BCI machines can also be utilized for recreational and meditative purposes, enhancing user engagement by utilizing brain signals as an additional form of input to interactive devices. Accurate classification of brain signals is one of the main challenges of BCI machines, preventing them from expanding their application and usage in everyday tasks. Our research focuses on the exploration of SK-time python library time-series classifiers for robust classification of mental workload to be integrated into an interactive BCI video game. NAML, a system that automates the running of time series machine learning algorithms on neural data, was used to access and analyze classifiers. Using NAML, two independent case studies were replicated to cross-validate classifiers with highest consistent accuracy on disjointed datasets. Four classifiers were chosen for further experimentation on The Tufts fNIRS Mental Workload Dataset, the largest open-access fNIRS dataset comprising of 68 participants. Samples chosen from the dataset included diverse subjects from different sexes and ethnicities given that we were aware models trained on homogeneous fNIRS training sets may not generalize as well to other racial groups. As a result of our investigation, we present the configuration of parameters for our best choices of NAML classifiers with the highest accuracy in classifying mental workload from fNIRS datasets. Future research is required to explore additional parameters and combined classifiers' experiments to develop classification models to be used in BCI video games.

Abstract Name: **Yoga As An Approach to Mental Recovery 48 Hours After an Intense Workout**

Background: Along with physiological changes, knowledge about yoga and meditation strategies for post workout mental recovery has been investigated. Results show that it improves mental clarity and reduces stress and anxiety levels. Purpose: The purpose of this study is to examine the effects of a 30 min yoga session on mental recovery 48 hours after a high intensity workout. Hypothesis: We hypothesize that if a yoga session is done immediately after an intense workout, it will produce greater mental recovery compared to those who do not participate in the yoga session. Methods: Twenty undergraduate students will complete a 30 minute intense workout. Following the workout, the intervention group will complete a thirty minute yoga/meditation session. The control group will not do anything outside of their usual routine. Conclusion: If our results align with our hypothesis, individuals can incorporate yoga into their exercise routine to benefit overall mental health and recovery.

Abstract Name: **Systematic Review and Meta-Analysis of how Heat and Antipyretics Affect the Course of Viral Upper Respiratory Infections in Adults**

Viral upper respiratory infections (URIs) are common (i.e. the common cold) and have caused pandemics in 1918 and 2020. URIs are frequently treated with fever-blocking medications (antipyretics, like acetaminophen or ibuprofen), because they reduce symptoms. However, feveris an evolutionarily-conserved response to infection that mechanistically enhances various immune processes and experimentally improves survival in animals.Human studies exploring the effects of antipyretics on the course or outcome of viral URIs are inconsistent. We performed a systematic review to see how body temperature modulation affects the course of viral URIs in adults. Our primary outcome was time to symptom resolution. We used predefined search criteria of peer-reviewed articles on Embase, CINAHL, PubMed, and Cochrane databases. Inclusion criteria included observational studies and randomized controlled trials of viral URIs (e.g. no antibiotics) in adults that compared antipyretics or heat-based therapies (e.g. sauna or exercise) to a control group. Each article was reviewed by two independent reviewers with discrepancies resolved by a third party. We reviewed the abstract and title of 8886 articles and 140 full texts. Thirty-one studies met inclusion criteria for data extraction, of which 27 studies tested antipyretics and 3 tested heat-based therapies. There was significant heterogeneity among studies and only five studies reported the primary outcome. Meta-analysis of randomized controlled trials found no significant effect of antipyretic use on the average number of days it took to resolve an URI: -0.2 days (95% CI: -1.3 to 1.0) comparing antipyretic group versus control. In conclusion, we did not find evidence that antipyretics significantly prolong URIs overall. However, there may be other costs of blocking fever in URIs (e.g. complications like pneumonia) or antipyretics may prolong illness in specific types of infections or patients. Our inconclusive findings underscore the importance of further research into this common clinical scenario.

Abstract Name: **Improving Patient Outcomes for Cancerous Tumor Removal**

Advancements in tumor ablation through use of biocompatible foam will allow for an optimized procedure, leading to decreased postoperative pain. Ablation involves using medical imaging, such as ultrasound and CT-tomography, to remove cancerous tumors in the liver, kidney, and lung. Targeted microwave energy is used to kill and remove cancerous cells. There is risk of thermal damage to neighboring healthy tissues, which can lead to potential complications to nearby organs and blood vessels, as well as unnecessary postoperative distress. There are current techniques to displace tissues and provide a buffer between the target tissue and its surroundings. Saline or CO2 can be used to separate the tissues, but are not always effective due to gravity. Saline tends to pool at the bottom of the cavity and CO2 rises, making both inadequate displacement agents. Creation of a biocompatible foam was completed, through a collaboration with Mayo Clinic Health Systems-Eau Claire and UW-Eau Claire, to replace current methods. The stiffness and stability of the foam displaces tissues for the duration of the procedure, and eventually dissipates. The foam provides thermal insulation during the procedure and prevents thermal damage from the ablative process. Such properties of the foam were quantified using agar hydrogel tissue mimics with a series of ablation trials. The hydrogels were embedded with thermochromic dyes that change color at a given temperature, and each temperature change represented the extent of tissue damage. Photos captured during the ablation allowed analysis of the color change in individual pixels to map to temperature to determine the insulative foam properties during the duration of the procedure. Through manipulation of biocompatible materials, an enhanced foam properly separates and insulates tissues. This will prevent extensive discomfort during and after the ablation procedure to remove the cancerous tissue and protect the healthy tissue, thus improving patient outcomes.

Abstract Name: **Aging Lung Tissue Regeneration: A Novel Way of Reopening the Plasticity Window of Postnatal Alveolar Type II Cells**

Prevalence of chronic lung diseases, such as pulmonary fibrosis and chronic obstructive pulmonary disease, have been found to increase with age. Pulmonary disease can occur from failure to maintain alveolar type 1 (AT1) and alveolar type 2 (AT2) cells located in the epithelium of the lung. It is currently known that AT2 cells are the facultative stem cells of the lung, and can transform into AT1 cells which make up the structure of the alveoli. This process happens throughout embryonic development, but AT2 cells can also replenish AT1 cell populations post lung injury. This research investigates whether this process that normally occurs during development can also occur in mature AT2 cells, and studies this question using genetically engineered mouse models at a postnatal stage. Using a double inhibition mechanism, we attempted to increase cellular proliferation by administering an agonist and conducted cellular lineage tracing with an SpcCreER lox system via tamoxifen-induced GFP expression. Through lineage labeling, we saw 7.5% (n=272) of GFP+ cells that were AT1 cells arising from AT2 cells that became plastic, mirroring the plasticity observed in development. Further research is needed to determine if this agonist can be used to epigenetically unlock mature AT2 cells. This result would provide a mechanism to temporarily induce plasticity in a patient's own AT2 cells in an attempt to regenerate their lungs in disease.

Abstract Name: **The Monstrous Woman: Tracking Dissociative Feminism From Frankenstein to Fleabag**

Since the early 2010s, a trend has been emerging in women-led and feminist media— one that has found itself as well in the individual and larger cultural psyches of the Global North's feminine people. In her article, "The Smartest Women I Know Are All Dissociating," Emmeline Clein identifies and calls this trend dissociation feminism.What Clein's article reveals is a mindset deeply resonant among women— a subjection to struggle, a resignation to the notion of painful womanhood. At its very core, dissociative feminism takes external patriarchal forces and turns them inward; no longer is a patriarchal society mentally, physically, or politically oppressive, intrinsically unsustainable for women's survival and well-being. Instead, dissociative feminism decides that women are inherently familiar with hardship, for femininity itself is pain. When this abuse is presented to come from within, women are therefore equipped with a dissociative instinct in the face of their trauma— feminine struggles become absurd and darkly comical, while detachment and self-destruction become tools of survival. Using historical feminist theory to examine Mary Shelley's 1818 novel Frankensteinand Pheobe Waller-Bridge's screenplay Fleabag (2016-2019), this paper illustrates how lost, ignored, and disregarded sexual autonomy causes a nihilistic dissociative affect to emerge as the dominant cultural response to patriarchy in separate moments of sociopolitical crisis. Despite its pervasiveness in the feminine psyche, this dissociative affect hides itself in women's literature as an under-critiqued mode of self-voyeurism and manifestation of patriarchal trauma. Such inquiry is relevant in order to detect and examine harmful expressions of feminist theory in a new digital age, as well as consider the future of the movement as it moves into fifth-wave feminism.

Abstract Name: **Measuring bioaccumulation of selenium and its role in synthesis of proteins in False Map Turtles (Graptemys pseudogeographica)**

Metals and metalloids are becoming more prevalent in lakes and reservoirs of South Dakota which are toxic and hazardous in high concentrations or when biomagnified through trophic levels. Selenium is of particular concern as it can bind into the structures of proteins in place of other elements, changing protein structure and function within affected organisms. Zebra mussels (Dreissena polymorpha) are an invasive filter-feeding metal-bioaccumulating species that are rapidly spreading upstream through the Missouri River. False Map Turtles (Graptemys pseudogeographica) are a common predator of Zebra Mussels. Detectable selenium content in the proteins of False Map Turtles may confirm that high concentrations of selenium contribute to uptake into the proteins themselves. It was predicted that there would be a difference in selenoprotein content between turtles downstream vs upstream. To test this hypothesis, False Map Turtles were randomly sampled from Lake Francis Case (upstream) and the 59 Mile Stretch of the Missouri River (downstream). Blood samples were randomly selected from both sites and centrifuged down for plasma samples which were were tested for selenoprotein concentration using an ELISA protein assay. Based on a Bayesian statistical model, there is a 96.3% probability that Lake Francis Case absorbance values are higher than the 59 Mile Stretch of the Missouri River absorbance values. Higher absorbance values are indicative of higher concentrations of selenoprotein. This suggests that the turtles of the 59 Mile Stretch are exposed to lower levels of selenium than those of Lake Francis Case despite its predicted higher concentration due to the consumption of invasive Zebra mussels downstream. This work demonstrates the critical need to monitor the impacts of this invasive species on threatened turtle species.

Hayes, David

Abstract Name: **The Power of Party over Purchasing Plans**

In recent years, home prices have risen by a shocking 43.7%. The median home price grew from $268,606 in January 2020 to $385,959 in July 2022. Americans looking for a home are faced with a difficult question: as prices continue to increase, is it better to buy or rent? According to my survey, 66.8% of Americans believe that it's better to buy. With this in mind, I wanted to find out how one's political affiliation influences purchasing decisions. I believed that if someone was a Republican, then they were more likely to purchase a house in the next year than a Democrat.To test my hypothesis, I wrote a survey using Survey Monkey and gathered 200 responses from Americans over 18 using Amazon M-Turk. While the results showed that about 67% of Republicans and Democrats think it's better to buy a home than rent one in the current market, their actual likelihood of buying tells a different story. Surprisingly, 50.8% of Republicans were very likely to buy a home within the year compared to only 37.2% of Democrats, which is statistically significant at the 1% level. This stark difference between parties' short-run purchasing plans is surprising, and public officials can use this contrast to garner support for housing-related policy in the future.

Abstract Name: **Growing Together: Children's Expectations and Reactions to an Urban School Garden Experience**

Children from low-income families are at high risk for food insecurity, unhealthy diets, and low intake of fruits and vegetables (Nury 2017). In general, community gardens have been suggested as a possible method to address food insecurity. Community gardens have been shown to increase intake of fresh vegetables (Algert, Diekmann, Rendellda,; Gray, 2016). These gardens can provide food insecure communities with more access to fresh vegetables and fruits that they might not have access to on a regular basis. School gardens have the potential to teach children a variety of educational concepts. Additionally, school gardens may help children increase their intake of fruits and vegetables and have been recommended as a unique way to address food insecurity by providing children with more access to more fruits and vegetables. School children play a large role in the success of school gardens. Thus, the purpose of this project is to examine children's expectations, motivations, and reactions to a school garden experience. Additionally, the project seeks to examine the impact of school gardens located within urban, food insecure communities. The project will be implemented with a partnership between Winston-Salem State University's Growing Together Program and a local Title I Elementary School in the county. Using surveys, data will be collected from elementary school children (ages 10-11) who participate in an after-school gardening club program. Data analysis will include examining children's expectations, motivations, and experiences.

Abstract Name: **Using Museum Specimens for Taxonomic and Molecular Research: A Study of the Marine Annelid Terebellides stroemii**

Natural history museums are valuable repositories of biodiversity that can provide insight into the evolutionary diversification of organisms living and extinct. Yet, genetic data often remains locked away in formalin-fixed museum specimens, as this fixation process preserves tissues but crosslinks proteins and DNA, resulting in fragmented sequences. This leaves unanswered questions about phylogenetic relationships as well as the presence of cryptic species within previously described species. Cryptic species occur when genetically distinct individuals are found to be erroneously grouped together due to their morphological similarities. One species in particular, the marine annelid worm Terebellides stroemii, has been the subject of recent morphological and molecular studies, in which the presence of multiple cryptic species has been indicated. However, older museum deposits of T. stroemii have not been re-evaluated since their initial collection and identification. Thus, it is possible that these samples may have been misidentified and could represent other members of the genus Terebellides. To comprehensively investigate and revise the taxonomy of a species such as T. stroemii, it is necessary to use both morphological and molecular techniques, so that morphological findings can be corroborated and compared to underlying genetic information. Here we investigate the taxonomy of preserved museum specimens of T. stroemii by conducting a morphological analysis, designating morphotypes, and developing a protocol for extracting DNA from formalin-fixed tissues. The contributions made by this project will help build a more thorough genetic record of Terebellides, and will build on previously established methods for unlocking genetic data in museum specimens. This knowledge is essential for creating more informed conservation efforts and ensuring that the collections deposited in museums are credible and comprehensive sources for future research.

Abstract Name: **Mozart Basset Horn Trio**

The UWEC Clarinet Trio has prepared a performance of Divertimento No. 3, K. 229 (439b)by Wolfgang Amadeus Mozart. Although this work was originally composed for basset horns (a member of the clarinet family with a lower, rounder tone),we will beperforming this piece on the modern standard: B-flatclarinets.This five-movement work opens and closes withfastmovements (the Allegro and Rondo). The middle movements are two medium-fast Menuettos, and one slower movement (Adagio). Overall, the work is light-hearted with the Adagio providing a more thoughtful character and tone.Throughout our time rehearsing as an ensemble, we have learned many things about the history of this music and the Classical style. Mozart was considered to play a big part in forming a new musical era known as the Classical Era. His groundbreaking style of composing was uniquebecause itused a newer homophonic sound rather than polyphonic texture. Divertimento No. 3 is homophonic, meaning it has a melody and an accompaniment. In this work, each movement illustrates a different moodvia varying harmonies that are supplemental to the melody, which is usually played by the first clarinetist. The articulations and dynamics assist in portraying the emotions of the piece. We have chosen to switch parts toallow each member of the ensemble to lead and also play the supporting parts. This is important for each member to show their take on the piece.

Abstract Name: **Effects of Ketamine on SK-n-SH Cell Line and Opioid Receptor Presence: A Feasible Study**

It is estimated that roughly 30% of people in the US have some form of treatment resistant depression, and ketamine has been shown to alleviate symptoms of depression in treatment resistant populations. Evidence suggests ketamine's antidepressant effects are the result of increases in brain-derived neurotropic factor (BDNF) potentiation and activation of the mTORC1 pathway, promoting synaptic plasticity and growth in addition to modulating glutamate. In the process of investigating cortical spheroids as a non-animal model of depression, we first wanted to observe the effects of ketamine in the SK-n-SH human neuroblastoma cell line to establish procedure and proof of concept. It was expected that ketamine administration would increase dendritic complexity in the differentiated cell line by promoting BDNF potentiation and mTORC1 pathway activation. SK-n-SH cells were differentiated into neuronal-like structures, exposed to different ketamine concentrations over two weeks, and imaged for Sholl analysis to assess dendritic morphology. Our ANOVA results showed significant differences in branch number and mean complexity index, but not in mean branch length suggesting high concentrations of ketamine resulted in an increased number of smaller dendritic spines. Additionally, the presence of opioid receptor in these cell populations was confirmed and future work will observe if ketamine exposure has an effect on receptor density. Going forward, we plan to repeat this experiment for a greater N value to increase reliability and validity of the results and run similar experiments in human cortical spheriods.

Abstract Name: **A Deep Learning Model for Pancreatic Ductal Adenocarcinoma Chemotherapy Outcome Prediction**

Pancreatic Ductal Adenocarcinoma (PDAC) is an aggressive abdominal malignancy, with an overall 8.5% 5-year survival rate. PDAC is often detected too late for surgical resection and is associated with resistance to chemotherapy and radiation. To minimize ineffective chemotherapy treatment, the ability to identify tumor characteristics and predict chemotherapy response is essential. Morphological characteristics of PDAC tumors can be extracted from CT scans and are associated with tumor characteristics and behavior. In this research, a deep-learning system for predicting chemotherapy outcomes based on CT scans is being explored. To establish the foundation for this system, a segmentation model is being developed and optimized. The effects of novel data augmentation techniques, including window-leveling, histogram matching, five-fold cross-validation, and YOLO bounding-box-based cropping on segmentation accuracy are examined. The morphological characteristics of PDAC tumors, upon initial inspection, revealed that over 50% of Radiomic features are statistically different between normal and abnormal patient populations. By establishing techniques for standardizing CT scans from different datasets and using a flexible segmentation model, we aim to create a pipeline for pancreas segmentation followed by tumor extraction using Radiomic texture analysis.

Abstract Name: Racial-Ethnic Identity and Academic Success B

There is immense discussion on what helps orhinders academic success. A person knowing who they are, no matter who, tends to know what they want and how to get it. This is not different in the academic setting. There are many different levels of understanding who we are within the culture from which we come. This study aims to connect several components of identity development with the resulting success in college. The aim is to see how the level of connection with one's racial-ethnic group, awareness of the perceptions by others and how one's racial-ethnic group is seen through the lens of academic achievement will impact the overall success in college. Other areas of interest in this study include college experience and how it impacts the motivation to attend classes and involvement in on campus activities connecting the student to the college leading to academic success. The final area that will be considered in this research is the level of college preparedness of the student and how the family or culture contributed to that preparedness. Correlational analysis will be completed through data collection in the spring semester of 2023.

Abstract Name: Developmental Delays in the Ts65Dn Mouse Model of Down Syndrome

Down syndrome (DS) is caused by the triplication of human chromosome 21 (HSA21) and produces developmental abnormalities including hypotonia, delayed development of age-appropriate motor skills, and delayed development of normal reaction times to stimuli. These developmental delays impact the quality of life of individuals with DS. Ts65Dn mice contain a triplication of approximately 100 protein coding genes that are orthologous to genes on HSA21 and exhibit brain structure abnormalities and sensorimotor developmental delays similar to humans with DS. We hypothesize that trisomic mice will reach strength milestones, righting reflexes, and responses to tactile stimulation later than their euploid counterparts. These three tests are performed on postnatal (P) 3 through P21. Tests are scored by immediate observation and from video recordings, with criterion for achieving the test being set as two days of successful target behavioral responses. This is defined as holding onto a bar with both forepaws for 10 seconds three times in a row for forepaw suspension, flipping over onto all four paws in under three seconds for righting reflex, and removing a sticker from the mouse's nose within 60 seconds for tactile stimulation. Preliminary data shows that, for forepaw suspension, euploid animals achieved the task after trisomic animals. For righting reflex and tactile stimulation, however, euploid animals achieved the task before trisomic animals. The completion of this research will allow us to create a timeline of sensorimotor development for the Ts65Dn mouse model to provide a reference point and timeline for future research and potential interventions.

Abstract Name: **Comparing genotype and phenotype of antibiotic resistance profiles of Staphylococcus aureus isolates from cystic fibrosis patients**

One of the most common bacterial pathogens found infecting the lungs of cystic fibrosis (CF) patients is Staphylococcus aureus. Over time, S. aureus has mutated and evolved to evade antibiotic treatment by acquiring resistance genes. This resistance to treatment has contributed to an increase in chronic infections that decrease patients' quality of life and leads to death. Researchers often know what genes are responsible for these antibiotic resistance traits and sequencing technology has allowed the search for these genes among clinical isolates to be fast, easy, and inexpensive. However, the presence of a gene in an organism does not always correlate to its physical expression, sometimes leaving clinicians in the dark about the true antibiotic resistance of isolates infecting patients. Research is lacking on the comparison between gene presence and observed expression of antibiotic resistance for a wide array of current S. aureus isolates infecting CF patients. Therefore, this work seeks to investigate if genotypic data of antibiotic resistance obtained from different isolates of S. aureus matches with the resistance shown when grown with antibiotics. Clinical isolates of S. aureus obtained from the Cystic Fibrosis Biospecimen Registry at Emory University have been tested with six different antibiotics, each from a different class. To do this, different concentrations of antibiotics are added to media growing each isolate to understand how much antibiotic is needed to kill the bacteria. As expected, the results depict some discrepancy between the genotypic expectation and the physical expression of antibiotic resistance in strains of S. aureus, inviting further investigation into genetic predication of pathogens for antibiotic treatment. Overall, this work will provide valuable information of precise resistance levels of each specific isolate of S. aureus, which could later be used for more accurate predictions when looking only at the bacterial genome.

Abstract Name: **Understanding Hhex deletion impacts on adrenal zonation**

The adrenal cortex is a key component of the endocrine system, which regulates hormone release throughout the body. The cortex contains 3 cell layers, each responsible for the production of steroid hormones. The Zona Glomerulosa, which produces mineralocorticoids, the Zona Fasciculata (zF), releasing glucocorticoids, and the Zona Reticularis, responsible for the androgens precursors synthesis. To adequately respond to hormonal needs, the adrenal cortex, and particularly the zF, is under tight control of the hypothalamic-pituitary-adrenal axis (HPA) via the pituitary hormone ACTH. ACTH drives proliferation through cellular division and increases adrenal cell size. Using single-cell profiling of the adrenal cortex, the laboratory newly identified HHEX, a transcription factor, as a gene enriched in the Zona Fasciculata. Its role in the differentiation process of other organs, such as the liver and pancreas, suggested HHEX implication in zF maintenance and glucocorticoid production. To gain insights into the role of HHEX in adrenal cortex function, we previously generated a mouse model of HHEX deletion in a context of high ACTH and observed that the adrenals were enlarged upon Hhex deletion. In this project, we aim to explore the impact of Hhex deletion on adrenal gland zonation and cell proliferation. We hypothesize that the adrenal hyperplasia observed is due to a dysregulation of cell proliferation and/or cell fate determination. Using Immunohistochemistry, we will assess the expression of known zonation markers of the Zona Fasciculata (AKR1B7, ABCB1B, and CYP2F2) and proliferation markers (KI-67). With this project, we are expecting to gain a better understanding of HHEX's role in adrenal function and maintenance. We will use our findings to provide the next steps toward furthering our understanding of adrenal gland pathophysiology.

Abstract Name: Piperine Reduces the Inflammatory Effect of Cigarette Smoke on Immune Cells: Implications of Multiple Sclerosis Pathology

Multiple sclerosis (MS) is a chronic inflammatory disease that affects the central nervous system, commonly referred to as the brain and spinal cord. Inflammation causes demyelination of the nerves leading to neuronal damage and disability in patients. Inflammation, demyelination, glial activation, and oxidative damage are authenticated markers for MS. Smoking cigarettes is a lifestyle factor with severe health consequences. Smoking increases the susceptibility to developing MS and worsens the disease prognosis with severe health consequences for the general population. Cigarette smoke has over 4,000 chemicals that cause abnormal cell responses and tissue damage in the lungs, which drives pathology in MS. Our lab has shown that MS patients who smoke have elevated levels of S100 proteins in the blood. S100s are damage-associated molecular pattern proteins (DAMP), which drive severe inflammation in the central nervous system of MS patients. Black pepper (Piper nigrum) contains 5%-9% of the bioactive alkaloid, piperine, which may have neuroprotective, anti-inflammatory, and antioxidant properties. The goal of this project was to determine if piperine reverses the inflammatory effects of cigarette smoke. To test this hypothesis, we assessed piperine's in vitro effects on human peripheral blood mononuclear cells (PBMCs) cultured in cigarette smoke extract (CSE). Specifically, we cultured PBMCs with either 0%, 20%, or 40% CSE in the presence or absence of increasing concentrations of piperine. In the absence of piperine, CSE-induced PBMCs secrete the inflammatory DAMP, S100A9. Strikingly, we found a dose-dependent reduction of S100A9 by piperine in PBMCs cultured with either 20% or 40% CSE. This data provides evidence of a novel anti-inflammatory mechanism of piperine that inhibits DAMP release by immune cells induced by CSE. Our study gives cellular experimental evidence that black pepper components can mitigate the detrimental inflammatory effects of smoking.

Abstract Name: The Benefits of Universal Hashing for Message Authentication

In coding theory, Hashing and Hash functions are used to map messages to a short fingerprint that allows users to authenticate the identity of the code's sender.Hashing can be an optimal choice in securing messages against an adversary as long as the probability of two hash functions returning the same result is low (this is called a collision). In my research I investigate Universal Hashing, a method of selecting random Hash functions from a Hash family to guarantee a collision rate of 1/ (size of functions range). By applying Universal Hash algorithms to previous coding strategies that have utilized different Hash algorithms, I will investigate whether Universal Hashing provides fewer collisions and optimizes efficiency by decreasing the complexity in decoding.

Abstract Name: End Correction in Cylindrical Pipes

The goal of this project was to determine the end correction for circular tubes of varying lengths and diameters. Unlike a vibrating string, which has a node at each fixed end, a tube with open ends has a pressure node that extends beyond the physical end of the tube. This extra distance, which depends on the diameter, is the end correction. To determine this end correction, measurements of the tube's harmonics, length, diameter, and speed of sound were made. This presentation will display the frequencies (of the fundamental and first harmonic) and corresponding end corrections for tubes with varying lengths and diameters. Our results were compared to a well-known theoretical model. We found that the model underestimated the size of the end correction for low harmonics.

Abstract Name: Transcription and Translation: Challenges, Methods, and Lessons Learned from Translating Spanish Language Oral History Interviews

Oral history interviews are a method of qualitative research that provide opportunity for stories to be heard that may otherwise be left unnoticed, in order to learn from these stories and enable change based on the perspectives that are shared. Voces del Campo/Rural Voices is a research project that aims to document and preserve the life experiences of people in Wisconsin, specifically in the Latinx community, by conducting oral history interviews. Given that Spanish is the primary language of many of the interviewees, transcription and translation of these interviews are key steps in the documenting and sharing of these experiences with a wide audience. Neither process is as straightforward as it may seem and can have crucial impacts on the integrity of the interviewee and the quality of data provided by the interview. This research first intends to explore methods of translation and transcriptions including naturalized versus denaturalized transcription and semantic versus contextual equivalence in translation. Furthermore, challenges such as accuracy, slang, word equivalency, figures of speech, and translator cultural competence and language familiarity will be examined. This will be accomplished by analyzing previous literature on these processes and offering a student perspective from the Voces del Campo project. Finally, a discussion of the lessons learned from transcribing and translating oral history interviews highlights the significance of the responsibility transcribers and translators have in accurately conveying the stories of the interviewees and the significance of the trust placed in them to do so in a respectful manner and offers practical advice for students performing interviews or oral history research in the future. The lessons additionally emphasize the importance of cultural understanding in these processes and the increased cultural understanding that comes with being a part of them.

Abstract Name: **Law Enforcement and Mental Health**

Law enforcement is a stressful career that can lead to or exacerbate mental health issues in officers. The objective of this project was to identify and analyze stressors and mental health needs of local law enforcement officers in the Chippewa Valley. The study location helps us learn more about unique stressors and mental health needs of officers in small and medium-sized departments. To do so, we surveyed officers from six law enforcement agencies and conducted follow-up interviews with those who wanted to provide more insight. We found that the stress of shift work, strained personal relationships, and negative public perceptions were foremost on officers' minds. Additionally, officers reported that mental health resources were provided through their department in various ways including debriefing, peer support, and professional counseling. However, officers suggest that resources could be improved or expanded. This poster will highlight these findings, and more, in depth and discuss the implications of the results.

Abstract Name: **Comparison of pathways and detection strategies for Pancreatic Ductal Adenocarcinoma (PDAC) using genetically engineered mouse model (GEMM)**

Pancreatic ductal adenocarcinoma (PDAC) is a deadly, invasive pancreatic cancer. Currently, there are five central models used to investigate PDAC, namely, human PDAC cell line, cell line xenograft, patient derived xenograft, genetically engineered mouse models(GEMMs), and organoids. Cell lines don't represent the heterogeneous nature of PDAC nor the pressures of the human immunesystem making them less relevant than other models. Xenografts have a low engraftment rate making the number of models available exceedingly small, and organoids are still in development and analysis phase. In this research, we focus on exploring GEMMs, themost useful in biomarker discovery and specific gene mutations. Using these GEMMs, an in-silico model will be developed for simulating PDAC. Steps would include, developing a model, genetically modifying it, and predicting how often PDAC develops in the model to understand the importance of that gene in PDAC progression. Preliminary research revealed several detection strategies like PanIns, CA 19-9, stromal-related circulating molecules, biomarkers, and mitochondrial DNA. Some gene activity or pathways toexplore may include COX-2, Notch pathways, MMP-7 expression, and MAPK pathway.

Abstract Name: **Determinants of MSA-Level Employment and Wages**

This study examines the determinants of intra-industry wage and employment differentials at the Metropolitan Statistical Area (MSA) level. There are several factors that potentially cause these differentials; the current study examines six relevant factors: corporate tax rate, cost of living, education, governor political party, civilian labor force, and unemployment rates. To answer my research question, I collect data from a variety of US Government and other websites, such as the US Census Bureau. For my analysis, I examine the “Construction and Extraction Occupations” sector, because the count and wages of these workers are less likely to be impacted by omitted factors, such as educational prestige. I construct a panel dataset at the MSA-year level, which includes observations from 2011 to 2019. Using ordinary least squares regression and panel data analysis techniques, I find that wage and employment variation between MSAs is due to a variety of factors. Most important, corporate tax rates significantly affect wage and employment at the MSA level; this impact is consistent with the current literature on the topic. My results also suggest that the state-level cost of living had a large effect on wages, which suggests that wages at the MSA level follow the general costs of that area. Surprisingly, the partisan affiliation of the governor plays an important role on wages and employment. States with a Democrat governor have higher average wages than those with a Republican governor for all years, likely because of the impact of higher wages in more populous states. Finally, I use simulation methods to compare current wage and employment values to those predicted in my model and find that my model predicts these outcomes well. Collectively, my results present important policy implications, as state-level policy can be crafted to improve wage and employment outcomes for workers in the US.

Abstract Name: **Studying the Effects of Aging on the Structure and Properties of Off-Eutectic Pb-Sn Solder Joints for In-Space Applications**

Soldering is a process in which molten metal is used to metallurgically bond two components together without melting the components themselves, predominantly used to create electrical and pressure joints. Metal joining processes such as soldering are currently being considered at NASA as possible techniques for use in in-space joint repairs and Mars rover sample return mission. However, the reliability of these solder joints is compromised when subjected to extreme conditions. Soldering studies during the in-space soldering investigation (ISSI) in 2003-04 aboard the International Space Station (ISS) were designed to gain a better understanding of solder porosity development, surface wetting, and equilibrium shape formation in microgravity. But these investigations have not considered the effect of aging on the solder microstructure and properties. Previous investigations have shown that near-eutectic 40Pb-60Sn soldering alloys exhibit grain coarsening and reduced mechanical properties with age, even at room temperature. Additionally, these investigations have shown that microgravity samples follow a similar aging pattern as terrestrial samples.In our current NASA EPSCoR project, solder samples will be produced in microgravity onboard the ISS and sent back to Earth for testing. The new experiments will include off-eutectic 50wt%Pb-50wt%Sn solder, a composition where the effect of aging is unknown. Understanding the effect of aging on off-eutectic solder is critical to understanding the properties of new samples produced onboard ISS in the coming years, as samples will not be returned to the lab and tested immediately. In this work, we report results from the microstructural characterization using scanning electron microscopy and resultant micro-to-nano mechanical response of 50wt%Pb-50wt%Sn solder produced in terrestrial environments as a function of aging time under room temperature conditions. The understanding gained in this study will enable robust and reliable protocols for solder-based solutions to address repair and fabrication needs in space exploration for years to come.

Abstract Name: **Antenatal Education's Role in the Prevention of PTSD Following Traumatic Childbirth (PTSD-FC)**

Traumatic birth is an experience reported by 45% of new mothers, with 1.5-9% of those who reported traumatic birth developing post-traumatic stress disorder (PTSD) (Beck et al., 2018; PATTCh, 2021). PTSD's debilitating symptoms, including flashbacks and emotional dissociation, seep into every facet of a woman's postpartum and family life (Beck, 2015). Beck also found that intimacy with one's partner and aspects of mother-child relationships were affected, such as breastfeeding; some women even admitted "feeling nothing" for their child. Specific antenatal education strategies were found to reduce PTSD symptoms among Turkish mothers, including cognitive coping techniques and addressing childbirth-related fears (Isbir et al., 2016).This study seeks to understand the ways that antenatal education mitigates the effects of PTSD among United States mothers. Data will be collected from semi-structured interviews with three sample groups: antenatal educators, women who received antenatal education, and medical professionals treating women for PTSD. Researchers will analyze the data and extract emerging themes. Researchers aim to find support for the effectiveness of quality antenatal education. Findings from this study will be used to develop best practices for antenatal educators in the United States, to better the life quality of new mothers with PTSD and their relationships with their partners and infants. This will promote healthier and happier families, as well as improved child development outcomes.

Abstract Name: **Examining Pilots Spatial Abilities While Encountering Common In-Flight Distraction**

Throughout all phases of flight, pilots experience distractions such as a dropped pen, radio communication from air traffic control, or communication from other crew members. These distractions may influence a pilot's ability to determine their own or other aircrafts orientation within their operational airspace, decreasing the pilot's situation awareness. This study examined how pilot's spatial abilities are affected when encountering common in-flight distractions, specifically, audible radio communications. Eighty-five participants consisting of undergraduate students enrolled in a collegiate aviation program completed the Revised Minnesota Paper Form Board Test (RMPFB) that specifically tests the individual's ability to cognitively visualize objects in space. Forty-two participants completed the test with a distraction present (air traffic control audio communications) and forty-three participants completed the test without a distraction present. The participants represent an array of experience levels ranging from student pilots to flight instructors as well as other demographic factors that were recorded with a survey questionnaire. The analysis of variance (ANOVA) statistical analysis process was used to identify the differences between the two groups. Potential applications of this research will assist flight training managers in their development of training scenarios and protocols to further acclimate student pilots for various unexpected audible distractions.

Abstract Name: Graph Partitioning Applied to Congressional Redistricting and Gerrymandering

Every ten years in the United States, congressional districts are drawn in each state by hand by state officials or committees. This can lead to biased drawings since the officials or committees want a certain demographic's voice to be dominant or a certain political party to win most of the elections. This is called gerrymandering and it is often discussed how exactly the U.S. should go about preventing the occurrence of gerrymandering, one such way is to create the districts mathematically rather than drawing them by hand. In this talkwe explore a method of turning a state into a graph using census block group data, then using a graph partitioning algorithm to divide the state into districts based on only population and edge cut. Through this process we found that the inclusion of edge cut came with some unforeseen geographic biases that brought the objectivity of the algorithm into question.

Abstract Name: Panel discussion: Creating a developmental curriculum to build research skills

In this panel discussion, moderated by Abby Hemmerich, four panel members will share examples of undergraduate research embedded across the curriculum and within individual courses. These examples will highlight principles of research woven through progressive courses in chemistry, psychology, kinesiology, and natural sciences, helping students build skills developmentally from their first year to graduation. David Durkin (co-author, Darion Isom) will discuss a series of integrated labs to grow research skills throughout the middle years of the chemistry major, culminating in an independent, problem-based learning project. Details about the final "Special Project" will be presented; this project requires students to utilize all of their skills to independently design the experiment, request materials, perform of the experiment, and write the research report.Nicole Depowski will present a case study of a psychology program with research introduced at the introductory level, integrated practice across the curriculum, and a capstone senior thesis project. Early exposure to scholarship focuses on locating and reading research, while students gain skills in research ethics and design at the next level. The third year requires use of primary sources, with synthesis and analysis, culminating in a senior thesis project in which students produce their own research. Brian Wallace will discuss the process for building evidence-based practice and research principles into the kinesiology curriculum to prepare students for graduate school or health and fitness professions. Changes to student engagement in research and outcomes related to faculty-mentored research will be discussed.Chimdimnma Esimai (co-author,George Ude) will present a series of course-based research experiences that engage a whole class of students in a research question or problem. Although individual projects are restricted to a single course, students experience multiple opportunities for these projects across the curriculum, providing complementary content and developmental progression in skills.

Abstract Name: **Supporting Best Management Practices Through the Purchase of Local Products**

In districts in or around the Wisconsin Red Cedar Watershed, phosphorus and other nutrients pollute the lakes, causing a substantial number of problems within the environment. As a community, it may feel impossible to help solve such a large-scale problem, but economically supporting farms that are utilizing best management practices is one of the biggest ways to help. One group of leaders within the Red Cedar Watershed communities collectively expressed interest in selling grass-fed beef directly to residents and local businesses. The ground beef would go directly to consumers' homes using subscription boxes, becoming easier to access and increasing revenue to the farms following best management practices. One of the questions facing farmers is how to market this new "lakes-approved" ground beef. This study used a 2 (Environmental vs. Economic Message) x 2 (Scarcity Cue vs. No Scarcity Cue) design, which combined to create four different mock advertisements. Survey results found that respondents who received an advertisement containing an environmental benefit message were significantly more willing to purchase this product. These consumers were also willing to pay more when their advertisement contained the environmental message. Neither variable directly changed intention to buy the product. This is important primarily because intentions have been shown to be a stronger predictor of behaviors. Respondents also indicated that personal qualities, like taste, effect on one's own health, and quality of the product, were the most significant deciding factors in purchasing products. These qualities could be used in combination with an environmental message to push consumers towards making a purchase rather than just gathering interest in doing so.

Abstract Name: **The Battle in Europe against Fascist Graffiti by Contemporary Street Artists Irmela Mensah-Schramm and Pier Paolo ?Cibo? Spinazze.**

In the later years of the 2010's, far right and fascists groups across Europe have managed to gain footholds of power in the political offices in their respective countries. This newly found traction has allowed and inspired fascists to spread their ideology to the public on the streets by the means of graffiti. Much of the time, this graffiti is ignored or left alone as by the public due to complacency. How are artists in Germany and Italy combatting the spread of pro fascist graffiti on the streets of their cities? There are two notable artists in particular, Irmela Mensah-Schramm and Pier Paolo Spinazzè, also known as 'Cibo' who use their tenacity and artistic talents to combat the expanding issue with fascist graffiti. The research for this topic is done by using interviews and current news sources from both Germany and Italy. Secondary sources extend out to articles written about each of the artists from various sources such as photographers and political observers. Other sources collected were websites that include far right political organizations and street art education pages. With this data, this paper will show that these artists bravely use their talents in the face of violent threats to put up artwork to express hope, love, and togetherness.

Abstract Name: Spray Integration in the Cooling of High Heat Flux Electronics

Spray cooling is an efficient cooling technique for high heat flux applications like metal forming and electronic cooling. However, without fundamental knowledge of fluid mechanics in these applications, spray cooling can be ineffective due to dry-out at low spray rates, or excessive liquid accumulation at high spray rates. In electronics like computer chips, these errors can cause crucial and expensive failures. The purpose of this research is to further understand the fluid mechanics and heat transfer processes behind spray cooling, enhance the ability of the process, and develop a phase diagram of collected data. The first technique researched was single droplet impingement. To obtain data, a high-speed camera was used to take detailed videos of microdroplets produced from a piezoelectric nozzle. Microdroplets of various liquids, including ethanol, isobutanol, and isopropanol, were dropped onto a heated copper surface, with the surface temperature ranging from 60 to 200 degrees Celsius. Droplet diameter, velocity, and resident time were tracked, as well as the associated behavior of evaporation, boiling, or leidenfrost, and the rate at which this occurred. These results contribute to the understanding of mechanical properties of microdroplets, discovering which combinations of droplet diameter, velocity, and liquid properties will improve their function in spray cooling. Another aspect researched was the ability of multi-droplet sprays to cool a heated surface via impingement and evaporation. An experimental setup was developed and assembled consisting of a pressurized air and water supply connected to an ultrasonic atomizer nozzle, heated plate, and thermocouples that relayed results to a data acquisition system. Preliminary results determined that cycling nozzle operation yielded similar cooling results to continuous spray, while saving up to 70% of fluid consumed. Future variables to explore include recycling atomized vapor, determining optimal timing of cycles, and testing additional liquids.

Abstract Name: Sanar: Honoring Earth's Unwavering Resilience

Sanar is a solo choreographic project created in honor of mother earth and the pursuit of environmental awareness. The movement research consists of embodying the elements of nature and exploring the West African Adowa dance of the Ashanti tribe. This piece invites consideration of what it means to be in coexistence with the earth; what is our impact as humans? And how do we honor its unwavering resilience? The Adowa dance is inspired by the movements of an antelope. This dance was once used to heal the great Ashanti queen from sickness. Sanar's intention is to call forth a sense of healing, like the Adowa dance, for our environment. It invites critical reflection on environmental inequalities for marginalized populations, such as air pollution, food insecurity, contaminated land and water. Sanar is a reminder that environmental and social justice are intrinsically connected, and we have the agency to create change through awareness and respect.

Abstract Name: **An Elastohydrodynamic High-pressure Seal for Super Critical Carbon-Dioxide Power Plants**

Supercritical CO2 (sCO2) power cycles are superior to traditional water-based, air-breathing, direct-fired, open Brayton cycles, or indirect-fired, closed Rankine cycles in terms of efficiency and equipment footprint. They hold great potential in nuclear power production, fossil fuel power plants, concentrated solar power, geothermal power, and ship propulsion. sCO2 power cycles must be demonstrated on the scale of 10–600MWe and at the sCO2 temperatures and pressures of 350–700°C or 20–35MPa for nuclear industries. The lack of suitable shaft seals at sCO2 operating conditions is one of the main challenges at the component level. So far, conventional seals all suffer from the incapability of handling sCO2 pressure and temperature in one way or another. To this end, we propose an elastohydrodynamic (EHD) high-pressure, high-temperature, and scalable shaft seal for sCO2 cycles. The higher the pressures are, the tighter the sealing while sustaining a continuous sCO2 film. For proof-of-concept purposes, a 2” static test rig was designed at Georgia Southern University before the actual dynamic testing at the Sandia National Laboratories. For simplicity, nitrogen gas was chosen, and the tests were conducted at room temperature. The test rig consisted of a 16.5MPa N2 tank; a cylindrical housing enclosing the static shaft and the test seal; steel tubing with compression-type fittings; an OMEGA–PX5500C0-2.5KA10E pressure sensor; and an OMEGA-FMA-1623AI mass flow meter. The static shaft had a diameter of 1.9995" and was made from steel, the test seal was made from PEEK. Data was measured using LabVIEW software and a National Instruments DAQ-Module-NI-9205. The experiments were performed for 50µm initial clearance and inlet pressure increased to 600psi. Initial experiments successfully demonstrated the throttling behavior of the EHD seal. Based on these preliminary results the EHD seal design could potentially be used in sCO2 turbomachinery. US-DOE through STTR Phase I and II grants, no: DE-SC0020851

Abstract Name: **Thiamin Deficiency in Steelhead Trout: A Comparison Between Lake Ontario and Lake Michigan**

Thiamin deficiency complex (TDC) has been documented in salmonine species from the Great Lakes. In this study, we measured thiamin concentrations in steelhead trout eggs collected at the Salmon River Fish Hatchery between 2015 and 2022. Eggs were also fertilized in 2015, 2016, 2017, 2022, and incubated to determine offspring survival and the lethal concentration that causes 50% of offspring mortality (LC50). Egg thiamin concentrations were also assessed in steelhead trout collected from Lake Michigan at three locations: Little Manistee River Michigan, St. Joseph’s River Indiana, and Kewaunee River Wisconsin. A new LC50 was determined at 5.4 nmol/g, lower than the previously estimated concentration. In Lake Ontario, egg thiamin concentrations in varied significantly among years (0.05), with the highest concentrations reported in 2016 (4.97 ± 1.50 nmol/g) and the lowest in 2020 (2.07 ± 0.75 nmol/g). A substantial number of fish (84.5 ± 17.92%) produced eggs below the LC50 across all years. Average egg thiamin concentrations of steelhead from all Lake Michigan sites were significantly higher than the ones reported in Lake Ontario and were above the LC50. To assess the cause of TDC, we investigated yearly changes in and fatty acid composition. We found that yearly fatty acid signatures in eggs significantly differed among years (0.05) and the fatty acids most responsible were 22:6n-3, 18:1n-9, 20:5n-3, and 16:0. Although these results suggest a potential shift in steelhead trout diet, average egg thiamin concentrations were below the LC50 across years and further investigation are required to determine how diet affects thiamin concentration.

Abstract Name: **A Culturally Informed Approach to Improving Forest Diversity in Bad River Tribal Lands**

Forest diversification is essential to creating and maintaining healthy, resilient forest ecosystems. Forest diversification buffers the effects of climate change, creates new habitats for plants and animals, and improves biodiversity increasing the speed of succession. Without forest diversification, plant and animal life are at higher risk of localized extinction. More species and populations of plants and animals thrive in an ecosystem that facilitates their habitat needs. In this project we worked with the Mashkiiziibii (Bad River) Natural Resources Department to diversify their forested lands. We acknowledge that the Mashkiiziibii tribal lands are of cultural significance and their cultural values play an important role within their community. For this project, we used LiDAR images and superimposed soil maps to locate sand lenses that have the potential to house new tree species and improve biodiversity. By collecting and analyzing samples from the study areas in the field, we were able to verify our observations from remotely sensed data.

Abstract Name: **Effect of shortenings on the physicochemical, textural and sensory properties of gluten free cupcakes**

The objective of the study was to determine the effect of shortenings (butter, margarine, and vegetable shortening) for optimizing the cupcake formulations on the physicochemical, textural, and sensory properties of gluten-free cupcakes. The demand for gluten-free baked products is increasing gradually because a large number of populations are affected by gluten intolerance. Also, the right butter replaces and different gluten-free flour ingredients in cupcakes open a healthier cupcake option for the consumers. In this study, three cupcake doughs with oat milk and gluten-free flour were prepared using three dairy-free shortenings (butter, margarine, and vegetable shortening). The cupcake doughs were baked at 350°F for 20 min to develop the gluten-free cupcakes. The physicochemical, textural, and sensory properties of the cupcakes were determined. The statistical analysis ANOVA indicated that those three shortenings affected the physicochemical and textural properties significantly (0.05). However, the sensory panelists were not able to determine the difference among the cupcake samples (p>0.05). The sensory analysis for the overall acceptability results indicated that the vegetable shortening cupcake was the most preferred cupcake formulation having a score of 6.39 and the butter cupcake formulation was the least preferred one having a score of 6.11. The variation of water activity (0.72-0.76), L-value (57.28-65.09), and total color difference (34.12-78.61) wasfound among the cupcake samples. Relatively moderate textural properties such as hardness (15.70 N), cohesiveness (2.00), springiness (0.16), gumminess (26.14), and chewiness (26.57) were achieved by the vegetable shortening cupcakes. The findings of this study will be beneficial for the commercial development of gluten-free cupcakes with healthier ingredients.

Abstract Name: **Mozart Basset Horn Trio**

The UWEC Clarinet Trio has prepared a performance of Divertimento No. 3, K. 229 (439b)by Wolfgang Amadeus Mozart. Although this work was originally composed for basset horns (a member of the clarinet family with a lower, rounder tone),we will be performing this piece on the modern standard: B-flat clarinets.This five-movement work opens and closes withfastmovements (the Allegro and Rondo). The middle movements are two medium-fast Menuettos, and one slower movement (Adagio). Overall, the work is light-hearted with the Adagio providing a more thoughtful character and tone. Throughout our time rehearsing as an ensemble, we have learned many things about the history of this music and the Classical style. Mozart was considered to play a big part in forming a new musical era known as the Classical Era. His groundbreaking style of composing was uniquebecause itused a newer homophonic sound rather than polyphonic texture. Divertimento No. 3 is homophonic, meaning it has a melody and an accompaniment. In this work, each movement illustrates a different moodvia varying harmonies that are supplemental to the melody, which is usually played by the first clarinetist. The articulations and dynamics assist in portraying the emotions of the piece. We have chosen to switch parts toallow each member of the ensemble to lead and also play the supporting parts. This is important for each member to show their take on the piece.

Abstract Name: **Expressions of Cultural Identities**

How might expressions of cultural identities take shape through language, stories, and other learning experiences in an elementary classroom? If preservice educators listen intentionally to the expressions of elementary students, will those studentsshare about their diverse backgrounds and cultural identities? Can these conversations support the classroom in an effort to be more culturally responsive? We will partner with a local elementary school and spendtime on site conferring withstudents about theirperceptions and contributions, connecting students' cultural knowledge to themselves and others through multimodal learning experiences, and gatherdata that will influencefuture teaching practices. Multimodal instruction is instruction that uses social and cultural resources such as drawings, technology resources, picture books, and storytelling. Student voice is listening attentively to students' perceptions and contributions.Cultural identity is the perception of self and others, and how children see themselves as a member of a group.

Abstract Name: **Valve control for the improvement of the main network of an aqueduct for human supply**

In Panama, there are problems with the hydraulic network for the supply of drinking water. In different provinces and towns, there is the problem that, for the distribution of the vital liquid, there is no automatic valve control system to control the pressures according to the demand of each section of the hydraulic network. This causes overpressure in the network and, consequently, an inefficient supply. These overpressures in the pipelines bring about different unfavorable situations such as shortening their useful life, increasing maintenance costs and, in the worst case, a rupture, thus causing the community to constantly remain without water for several days. Using a PLC and the outputs of voltage variables, and being able to close or open the valve depending on differences in pressure and flow and, at the same time, performing a remote monitoring of these variables through telemetry. The objective is to distribute water more efficiently, avoiding waste and extending the useful life of the hydraulic network and, more importantly, guaranteeing the availability of the vital liquid. Currently in the country there is the necessary equipment for the automatic control of the mains installed in multiple points of the country, but they are currently underutilized since they are activated manually by an operator on site. Without the knowledge of how to do it, so the idea was born to make a project that automatically avoids overpressure in the lines, thus avoiding waste of vital liquid, increasing the life of the matrix network, and lowering operating costs, since it avoids having to send an operator to the site for the activation of the valves.

Abstract Name: **The Effects of Voluntary Exercise on Memory and Anxiety in Young Adult Female C57BL/6 Mice**

Exercise increases spatial memory and decreases anxiety. Physiological mechanisms are unknown, but a larger hippocampus can be associated with both of these outcomes. Nonspatial memory is not necessarily associated with the hippocampus, and thus may not similarly be increased by exercise. This study investigated the effect of three weeks of exercise on nonspatial memory and anxiety levels in young adult female C57BL/6 mice using the open field test (anxiety) and object recognition test (nonspatial memory). We hypothesized that mice in the exercise group would exhibit less anxiety-like behavior and would perform better on the nonspatial memory task compared to the sedentary group. Results showed that exercise did not change nonspatial memory and may have increased anxiety, contrary to the hypothesis. These findings may have been due to the tests used, so future studies could investigate other nonspatial memory and anxiety tests.

Abstract Name: **Development of silicon tracking detectors for particle tracking experiments**

Silicon pixel detectors are an important element in particle physics experiments operating at the Large Hadron Collider (LHC) whose purpose is discovery of new physics and improved understanding of the Standard Model of particle physics. The Large Hadron Collider and its detectors will undergo upgrades in coming years that will enable them to observe increasingly rare processes which could be the key to discoveries. The upgrades entail development of new tracking detectors with excellent position resolution, excellent timing, and high tolerance to radiation damage. I will present my measurements of the qualities of state-of-the-art silicon tracking detectors under development for LHC experiments. I will also describe my work developing a test stand at the University of New Mexico to characterize the timing resolution of 3D silicon detectors as a function of hadronic and gamma dose. These results may have implications for the design of experiments throughout the first half of the 21st century.

Abstract Name: **"Don't Upset Your Grandmother": Disclosure Patterns of Latina Childhood Sexual Abuse Victims**

Despite being the fastest-growing community in the United States, few psychological theories have been developed concerning Latine mental health. Particularly, the origin of trauma-based coping mechanisms has yet to be examined from a culturally competent point of view. The development of a proper psychopathological theory is important because reports have shown disproportionately high rates of domestic and sexual abuse within the Hispanic community. This is accompanied by low percentages of police reporting and avoidance of subsequent treatments, like therapy. This study focuses on the help-seeking behavior of Hispanic women who have been sexually abused as children, with an emphasis on cultural factors that may influence non-disclosure. This will aim to address the lack of information about sexual abuse in Hispanic households and help develop a proper theory about cultural motivators that prevent help-seeking. Specifically, this study seeks to examine the relationship between the perpetrator and the victim (e.g. blood-related family vs. other) and how this affects disclosure and outreach behaviors. I hypothesize that a tendency for non-disclosure becomes the default response to traumatic events when children are raised according to passive values. I also hypothesize that I will find an association between non-disclosure and higher rates of machismo-oriented values in those who were sexually abused by family members, rather than non-family members. We use a semi-structured interview format that consists of two main parts. The first half of the interview focuses on open-ended qualitative questions that inquire about their family's response to the abuse. The second half includes surveys that measure cultural perceptions of gender norms (machismo and marianismo scales), self-concept, and severity of abuse. We will run a correlation test to see the relationship between machismo and marianismo as well as use narrative analysis to find themes within the interviews.

Abstract Name: Voices of Gun Violence

Voices of Gun Violence (VGV) is a an interdisciplinary, community-based project that provides a space for residents of southeastern Wisconsin to share their stories on gun violence. VGV uses qualitative research by conducting phenomenological interviews that are recorded and transcribed. The stories are analyzed revealing a wide variety of gun violence experiences. VGV has archived stories of gun violence that have impacted the community through homicide, domestic violence, neighborhood shots, robbery, suicide, bar/club shooting, domestic terrorism, and police brutality. Stories are shared on the project's website, which offers a living archive that allows the community to understand the multidimensional experience of gun violence. Thus far we have almost 50 stories on the website and working on 25 more. In response to their experiences, some VGV storytellers have become advocates in the community, while others have created educational opportunities, explored preventative tactics, or offered grief counseling to residents of the Greater Milwaukee area. VGV has provided a trusted platform for community members to have their voices heard, while attempting to bring into view the micro- and macro-level issues related to gun violence.

Abstract Name: The Tools to Change: A Guide to Developing Healthy and Intersectional Relationships with Masculinity in the Time of Radicalization

"The Tools to Change: A Guide to Developing Healthy and Intersectional Relationships with Masculinity in the Time of Radicalization," is an ongoing research project that explores the ways in which boys and young men are becoming more susceptible to incel and anti-women rhetoric as a way of maintaining oppressive forms of patriarchy and gender roles, both violent and not. Based on All About Love andThe Will to Change by bell hooks, this project seeks to inform audiences, regardless of gender, the importance of recognizing the steps of incel/incel-adjacentindoctrination as well as understanding ways in which we can combat toxic masculinity through empathy and willful learning. The project thus utilizes feminist theory to examine the ways in which gender roles create stringent social codes that inhibit a mutuality between the sexes. By acknowledging the importance of the male experience within feminism, one can contextualize the reasons formale violence, male loneliness, andmale rage through a feminist contextin order to offerlove, self-reflection, andcommunity as a transformative tool for men everywhere.

Abstract Name: Hands-On Learning: Assessing the Effectiveness of Model Kits in the Organic Chemistry Classroom

One of the most important skills for students to learn in organic chemistry courses is being able to recognize and convert molecules to varying representations such as skeletal structures, Newman projections, and chair conformations. Past strategies for developing this skill include computer based molecular visualization, commercially available model kits, and 3-D printed molecules. Since this ability is foundational in undergraduate organic chemistry learning, we want to investigate if using Molymod student model kits in the classroom translates to improved student understanding of different molecular representations. Gaps in student understanding that come from the nature of abstract concepts can be bridged through mechanical learning. Molymod student model kits are used throughout the (bio)chemistry University of Minnesota Rochester curriculum to promote multi-sensory learning and provide a medium that allows students to physically manipulate abstract molecules. This study illustrates examples of how the organic chemistry curriculum requires students to use the model kit to translate between wedge and dash drawings, perform conformational analysis, and determine the stereoisomeric relationship between molecules. Students also used models to identify octet violations in resonance structures, observe resonance patterns, and predict the stereochemistry of E2 eliminations. Quantifying student outcomes associated with model kit usage was performed through in-class multiple choice “clicker” questions, quizzes and exam questions. Methods of successfully implementing model kit usage solicited and unsolicited will be discussed.

Abstract Name: Kinetic Modeling of Dopamine Transport Protein Inhibition by Indole Based Modafinil Analogs Using Rotating Disk Voltammetry

Dopamine neurons, which synthesize and release the neurotransmitter dopamine, create the reward circuit in our brains which allows us to feel pleasure and motivates us to repeat pleasurable behaviors. For example, eating a piece of chocolate causes the release of dopamine and reinforces the pleasure associated with chocolate consumption. Other functions of dopamine are regulation of sleep and motor movement.Presynaptic dopaminergic neurons release dopamine which diffuses across the synaptic cleft and binds to receptors on the receiving (postsynaptic) neuron. The signal is terminated when dopamine is transported back into the pre-synaptic cell that released it by a protein called the dopamine transporter. The dopamine transporter is the target of the therapeutics modafinil (a narcolepsy medication) and Ritalin (an ADHD medication) and the drugs of abuse cocaine and amphetamines. By inhibiting the dopamine transporter, these drugs slow down the reuptake of dopamine, increasing the dopamine signal. Modafinil specifically does this to promote wakefulness in people with sleep disorders. The goal of our project is to use small molecules with structures similar to modafinil (called structural analogs) to see how they affect the rate of reuptake of dopamine. The collected data is analyzed using kinetic models to learn about the dopamine transporter protein.

Abstract Name: **Partners4Literacy: A Comparative Classroom Discourse Analysis During Delivery of Readtopia Instruction**

Summary Problem: Beginning communicators and preliterate learners in special education classrooms may not have access to the vocabulary necessary for developing dialogic behaviors essential for participation in their learning environment. Purpose: To examine teacher discourse with middle and high school students with complex communication needs during language literacy instruction within the first year of Readtopia (BuildingWings, 2022), an evidence-based and comprehensive literacy curriculum. Research Question: What are the number and type of dialogic behaviors that educators use during Readtopia? What are the barriers and supports toward the development of a transactional model of communication in three self-contained, special education middle and high school classrooms? Background: It is essential that beginning communicators and preliterate learners have access and the opportunity to participate in learning by asking questions and communicating with peers. When students with complex communication needs have question words accessible and educators available to teach them how to use them, there are increased learning opportunities.Methods: Research Design. Non-experimental mixed methods approach to analyzing teacher discourse during video recorded language literacy lessons. The unit of analysis is at the classroom level. Participants: Three teachers, serving 72 students in special-day, self-contained middle and high school special education classrooms. Procedure: Quantitative and qualitative approaches were used to analyze teacher-student discourse from eleven video recordings during 30-45-minute Readtopia lessons. Question types and prompt types were coded, categorized, and conceptualized.Results:Preliminary results of the discourse analysis revealed six primary barriers to, and potential supports of, the development of a transactional model of communication critical for the joint construction of knowledge.

Abstract Name: **Isolation of Compost Bacteria with Antimicrobial Activity Against Human, Fish, and Plant Pathogens**

Due to many pathogenic bacteria developing antibiotic resistance, there is an urgent need to search for microbes that produce novel antimicrobials. These organisms can be used to produce antibiotics for human use and/or as biocontrol agents in aquaponics systems to protect fish and plants from pathogenic organisms. Plants and fish are highly important because they are essential resources to humans and the environment. Alverno College has an aquaponics system inside its greenhouse that could potentially benefit from these antimicrobial-producing microbes. Using these antimicrobial-producing microbes on plants and fish may help with their growth and cultivation. Previous studies have reported isolation of antibiotic-producing bacteria from compost, soil, water, and other environments. In this study, bacteria were isolated from two different compost samples. One gram of compost soil was emulsified in 9ml of sterile dH20. Each compost sample underwent serial dilutions and was plated on Brain Heart Infusion (BHI) agar. Plates were incubated at 30° C and colonies were transferred to Luria Broth (LB) agar plates. The isolates were tested for antimicrobial activity against Gram-negative Escherichia coli and Gram-positive Staphylococcus epidermidis, because drug-resistant pathogens are found in both groups of microbes. However, Gram-negative microbes are generally more resistant to antimicrobials. Strains that inhibited the growth of both organisms were chosen for further study and tested against additional pathogens: Pseudomonas aeruginosa (human pathogen), Pseudomonas fluorescens (fish pathogen), and Erwinia carotovora (plant pathogen). The results of the test showed that four strains from compost sample #1 inhibited the growth of all three pathogens. Future research will consist of the characterization of the compost isolates, DNA sequencing, and testing against other pathogenic organisms.

Abstract Name: **Efficacy of Social and Physical Support for Cancer Patients**

Cancer is the second leading cause of death in the United States. In addition, cancer treatments provoke harsh side effects that demand extra strength from the patient. Cancer causes lifestyle modifications that can be detrimental on the patients' health; however, healthy habits can potentially increase the chances of a positive prognosis. Additionally, physical, and social support has proven to help patients in their fight against cancer. Since the lack of physical and social activity in patients with cancer has been shown to correlate with mental and cognitive decline, ultimately reducing quality of life, the purpose of this study is to examine the relationship between physical activity and quality of life in patients with cancer And increase their overall quality of life.This project included eight female participants that are currently struggling with cancer, or the cancer is in remission. The program consisted of group discussions, fine motor movements, and various physical activities twice a week for three weeks. Using pre/post intervention questionnaires and a dependent t-test, the significance of social and physical activities amongst the participants were analyzed. The dependent t-test showed a significant difference (t=-3.729, p=0.007) in the overall quality of life between pre and post program. These preliminary results imply that implementing a support group such as Healthy Habits that includes the use of physical and social activity, improves the overall quality of life of patients with cancer. In conclusion, the program created an additional outlet for individuals with cancer to find a relatable support group that can aid with daily struggles. Further analyses in a larger sample and with longer duration will provide stronger evidence about the relationship between physical activity and quality of life in patients with cancer.

Abstract Name: **Design, Development, and Evaluation of Landfill Model for Education and Outreach Programs**

Landfills are currently a crucial infrastructure in modern civilization. In order to progress towards a circular economy, we must reduce our waste production and lessen the need for landfills. Despite this need for reducing waste production, little attention is given to how our trash is disposed of, once it is out of sight. Current educational efforts on waste disposal and management are centered around youth in elementary and middle school. However, little research has studied the design and assessment of physical artifacts for waste disposal and management education. The focus of this research is to determine the effectiveness of one method of educating people of various age groups on the modern engineered landfill and, in turn, encouraging them to reduce their waste production. We plan to build a physical landfill model based on WM's general landfill design. It will be small enough to be easily transported, while effectively presenting the necessary details about the operation of the landfill. We want to evaluate the effectiveness of this model in educating various age groups on modern landfills. The age groups will vary from elementary school kids up to elderly citizens. We will conduct a pre and post tests survey to assess change in knowledge of landfills and their perception of waste disposal. We will be working with the Internal Review Board to get approval for this study. We expect that after interaction with the model, the participants will improve their knowledge about landfills, and their perception of waste disposal will change positively. The results of this study can be used to improve educational strategies on landfills and waste reduction.

Abstract Name: **Differentiated Spelling and Word Study Instruction: Using Qualitative Spelling Assessment Data to Drive Instruction**

According to Tomlinson (2000), “Teachers are as different as their learners” (p.4). Vast differences among learners are the best argument for why differentiated instruction is crucial in classrooms today. If we know every individual is different, then why are so many teachers content to use one-size-fits-all teaching strategies instead of differentiating? According to researchers, many novice teachers do not feel confident to implement instructional strategies different from the status-quo, even if they believe those methodologies are more effective for students. As a result, teachers often conform to the methods already in place when they get hired. Many teachers get frustrated and change teaching positions or leave the profession completely (Allington, 2002; Darling-Hammond, 2006; Maloch et al, 2003). One of the most important teaching strategies teachers should be prepared to employ in their classrooms is differentiating for the needs of their learners.The presenter will briefly explain ways to differentiate in the classroom in general, followed by specific, research-based, differentiation methods for spelling (Cunningham, 2017; Devries, 2019; Palmer; Invernizzi, 2015). Specifically, the presenter will demonstrate how to use a qualitative spelling assessment appropriate for grades K-12to differentiate instruction in spelling, word study and phonics. The presenter will also share actual student data which has been analyzed to identify each child’s spelling stage of development. Furthermore, the presenter will share how to use the information gathered from the data analysis to provide the students with appropriate learning activities utilizing effective teaching methods.This presentation will be of interest to education majors, especially those teaching English Language Arts or working with English Language Learners. It may also interest higher ed professionals working with pre-service teachers. Attendees will learn practical strategies they can implement immediately. The session will conclude with time for questions from the attendees.

Abstract Name: **Variations in System Parameters at Low Energy Input on Thermosiphon Collector Efficiency**

A thermosiphon is a system of components that passively generates a closed cycle of flowing water wherein solar energy is stored as useful thermal energy. Systems used in real-world applications contain no mechanical or electrical components, making it useful in areas lacking capable infrastructure. Flow starts in the collector by heating the water, decreasing its density, and creating a buoyant force, which drives the fluid through a hot leg pipe into a raised tank. This heat contained in the tank could be extracted for domestic hot water heating or building supplemental heating applications. The water cools, increasing its density, and sinks down the cold leg pipe and re-enters the collector where the process continues cyclically. Thermistors, located at the collector inlet and outlet pipes, measure system temperatures and an open-bore flowmeter measures flow through the system. During steady-state, a period where flowrate, inlet and outlet temperatures remain relatively constant, collected data is used to calculate the instantaneous efficiency of the system. The discreet efficiency values are then used to calculate overall efficiency. Components of the system allow the ambient temperature around the device to be controlled, a parameter overlooked by most thermosiphon research projects. These components include insulated, removable walls enclosing the device, a fan to circulate the air inside the enclosure, and a space heater and AC unit to control the temperature. Previous research has used high-power input to the collector simulating sunny-days, but current research conducted low-power tests simulating cloudy-days to compare trends across both conditions. The base parameters that are varied and researched are collector angle, hot leg height, cold leg height, hydraulic resistance, and input power. By conducting a range of diverse test series, each investigating the effect of altering a single parameter, the team explored the effects of each system parameter on overall efficiency trends.

Abstract Name: **Investigating the use of crayfish as environmental water quality sentinels for metal pollution in Indiana creeks**

Ephemeral creeks and streams can be difficult to monitor and assess for water quality. Unfortunately, these same water systems can play a significant role in the input of metals and other pollutants into major waterways. Metals are often the result of nonpoint source or historic point source pollution that is no longer active, making assessment and exposure prevention difficult. An economical and reliable approach to determine water quality in these areas would be the use of reliable sentinel species that are endemic, easily identified, and respond in a quantifiably way to metals in the environment. Macroinvertebrate assemblages have been historically used to create comprehensive biotic indexes, but these indices can be complicated, seasonal, and difficult to assess without identification bias. For this project, crayfish samples, water samples, and sediment samples were collected in several creeks in Indiana representing a variety of environmental exposures. We hypothesized that because are omnivores and biotic engineers, their environmental interactions place them in a unique niche making them a reliable sentinel species. By testing and comparing the bioaccumulation of metals in crayfish tissue, water, and sediments to dominant species, average crayfish size, and population density, we can reliably predict creek health for metals. Our results determined thatFaxonius rusticus(rusty crayfish) were found in creeks with higher environmental metals. Also, crayfish cephalothorax measurements were smaller in higher metal environments. This data, along with metal bioaccumulation and biomagnification make crayfish an excellent sentinel for water quality in creeks.

Abstract Name: **Korean American Adoptees: A Transnational, Transracial Asian American Experience (1950-present)**

In the United States today, there are over 150,000 citizens who were born in South Korea and internationally adopted into American families, the vast majority of these families being white. While Korean American adoptees (KAAs) constitute a small fraction of the total American population, they make up about ten percent of the Korean American community. Despite their substantial numbers, KAAs are incredibly underrepresented in media and academia. This research attempts to counteract adoptees'underrepresentation by centering KAA voices and experiences in the historical narrative of the post-war relationship between South Korea and the United States and beyond. The institution of Korean-American international adoption as it is known today began with Harry and Bertha Holt in 1995 when the evangelical couple adopted eight Korean "G.I. orphans," the mixed-racechildren of Korean mothers and American fathers—abandoned by their biological parents and ostracized by their birth country. These first adoptions were heavily publicized and glorified by American and Korean media, pushing Korean-American international adoption as the humanitarian solution to the post-war influx of orphaned, abandoned, or unwanted children in South Korea. In reality, corrupt systems of bureaucracy, damaged Korean infrastructure and economy, and entitled feelings of American exceptionalism perpetuated this altruistic image of transnational adoption. In addition to the traumas of international adoption, many KAAs struggle with racial and ethnic identity formation from childhood to adulthood, commonly attributed to their white or non-Korean adoptive households intentionally or unintentionally separating them from Korean culture. Considering the significant population of KAAs in the Korean American community, this lifelong disconnect from Korean traditionsand heritage has massive implications on broader Korean American culture. Separated from their birth families, removed from their home country, and raised in racial isolation, KAAsshare a unique, distinct Asian American experience unlike any other Asian community in the United States.

Abstract Name: **Using a Filter and Arduino to Increase a Pump's Functionality**

The overall research project was to use mechanical and electrical engineering to create an irrigated planter box. The goal of this portion of the project was to develop a pumping sub-system that includes 3D printing a passive pump filter and programming an Arduino to prevent the pump from running dry. A replica of the pump and filter cover were created using CAD software (Onshape, PTC, Boston Massachusetts). The filter cover was designed to be slightly larger to accommodate shrinkage during printing and a layer of filter material. The cover was sliced and printed on a PRUSA Mini+. Design for Manufacturing (DFM) was also applied, which included: rotating the part 180 degrees on the roll axis and using arches to prevent the need for supporting material and post-print touchups. An Arduino UNO, ultrasonic sensor, and relay were used to control the power to the pump.The efficiency of the pump was tested with and without the filter and relay to compare efficiency. The water used in the experiment was previously filtered, so the effectiveness of the filter in removing contaminants was not tested. However, the filter did not prevent the pump from raising the water above 6 feet. The Arduino successfully prevented the pump from running dry by using an ultrasonic sensor to read the height of the water and turning off the pump when the water level dropped to a minimally acceptable value. When the pump was not connected to the Arduino it would run dry.This research demonstrates the increased reliability of a pump that is controlled by a distance sensor. A pump that is connected to a sensor can be left “ON” at all times, without the need for monitoring.

Abstract Name: **The Impact of Interactive Care With patients at End-of-Life on Healthcare Personnel's Perceptions of Life and Death and Psychological Well-Being**

Literature regarding workplace burnout and compassion fatigue among healthcare personnel and hospice workers working in end-of-life care is greatly documented in previous literature (Keidel, 2002; Potter et al., 2010; Yoder, 2010). However, an understanding of the psychological well being of hospice care and healthcare workers is underdeveloped; experiencing suffering with psychological problems is only interpreted as part of a professional requirement demanded of workers (Moreno-Milan et al., 2019). As medicine and technology advances, healthcare personnel find themselves spending more time with patients as they're actively terminally ill, yet are still able to build relationships and socialize (Viola, Leven,; LePere, 2009; Wasserman, 2008).The understanding of the development of compassion is fundamental for the quality of end-of-life care. Harper (1994), in her model of the coping mechanisms of the health professional working in hospice and palliative care, noted that feelings of experienced health professionals involve feelings of self-realization (e.g., attitudes about life and death, revaluation of interpersonal relationships) accompanied by compassion. Previous research has not examined the relationship between the development of compassion, interaction with patients, and other aspects of personal growth for healthcare personnel and hospice. The purpose of this study is to address the gap in previous literature in defining the experiences of hospice care workers, and healthcare personnel working in end-of-life care. In particular, this study sought to better understand how interactions with patients at end-of-life impact healthcare personnel’s perceptions of life and death, psychological well being, and experiences of interacting with death and bonding with the dying.

Abstract Name: Monitoring Antibiotic Resistant Populations as a Correlative to Water Quality

Agricultural land use can have adverse effects on the surrounding waterways, which may cause environmental and economical disturbances including but not limited to species assemblage disruption, loss of habitat and wildlife and human health impacts. There is a need to monitor in vivo aquatic systems, specifically those in agricultural areas, to not only provide a more holistic view into the correlation between agriculture land use and aquatic environmental disruption but also to develop more succinct and effective monitoring and management guidelines. The Blanchard River serves as an excellent model system suitable for monitoring antimicrobial resistant microbe sustainability within a highly agricultural area that serves as a contributor to the Lake Erie basin. Several indicators suggest that the Blanchard River watershed may provide a suitable habitat for the antibiotic resistant microbes including MRSA (methicillin resistant S. aureus). Outside nosocomial infections, minimal research has been completed to determine the reservoirs of MRSA and other resistant microbes. One hundred and twenty-six sites within the Blanchard River and its tributaries were monitored for antibiotic resistant microbes including MRSA. All sites had antibiotic resistant populations while twenty-six of the sites harbored MRSA. Sixteen Areas of Concern (AOCs) were chosen in conjunction with the Blanchard River Watershed Partnership to determine if traditional water quality measures of E. coli concentrations,nutrient levels and macroinvertebrate populations correlate with antibiotic concentrations and resistant populations. Additionally, microcystin concentrations were measured as they are known to enhance horizontal transfer of antibiotic resistance genes. There is no correlation between land usage or antibiotic concentrations and the presence of antibiotic resistant microbes. There were weak correlations between antibiotic concentrations and pollution resistant macroinvertebrates and a weak negative correlation between E. coli levels and pollution sensitive macroinvertebrates.

Abstract Name: Randomly Generating the Unknot

The definition of a knot in knot theory is an embedding of a circle in 3-dimensional space. Two knots are called isotopic if they can be deformed to each other without cutting or passing a strand through another. Knot theory was first introduced in the 1960s by chemists Frish-Wasserman, and biologists Delbruck-Fuller. We study a new perspective on the theory of random knots based on the universal knot diagrams introduced in a recent paper by Even-Zohar--Hass--Linial--Nowik. We ask what the probability of a randomly generated potholder knot is unknotted. A potholder knot consists of a family of knots starting with an n-by-n square grid. As the parameter n goes to infinity every knot admits such a diagram. By studying small potholder diagrams, we present some numerical evidence toward the conclusion that the probability of a randomly generated potholder knot being unknotted should be zero. We present explicit computations of the expansion of these potholder diagrams in one direction. By studying the process of randomly generating a potholder knot in terms of a Markov chain, we present forward progress towards proving this result. These preliminary results represent a work in progress.

Abstract Name: **The World Happiness Report and Public Health**

The United Nations Sustainable Development Network has released an annual report on the statistical happiness of nation-states since 2012. Four years in a row, Finland has held first place in the UN's ranking four years in a row. Democracies hold the highest ranking each year but consistently the top five have been Scandinavian countries. This research looks to find the key differences between a top ranked and lower ranked democracies, looking at what gives these Scandinavian countries the lead. Finland, Iceland, and Switzerland are the top three democracies of 2021's report, making them the leaders in world happiness for multiple years. The following literature analyzes the political institutions in Scandinavia, America, and the United Kingdom. Key influencers are healthcare policy and reform, public health, political history, voter patterns, and occupational healthcare. Further research includes the top 46 countries on the ranking and comparing their rankings from the World Health Organization and the Commonwealth Fund's health profiles on major countries.

Abstract Name: **Isolation and characterization Halotolerant endophytes of Ceanothus velutinus and their Potential as Biostimulants**

Part of a plant's biosphere are endophytes, microbes found between the cells of a plant. Plant-microbe relations are integral to plant survival and crop productivity. Endophytes can be beneficial to help a plant cope with abiotic stressors such as salinity. Climate change has increased soil salinity worldwide, and water availability is becoming scarcer, leading agriculture to use more saline sources to irrigate. Thus, salt is a concern for farmers.We aim to identify halotolerant endophytes which can benefit plant health. Microbes were isolated from Ceanothus velutinus, known as snowbrush, native to the Intermountain West region of the United States that thrives in dry and semi-arid conditions. Roots were surface sterilized and crushed, and resuspended in the sterilized water. The suspension was serially diluted, spread-plated on nutrient agar media with varying salt concentrations, and incubated at 28oC for 3-5 days.Visually unique colonies were isolated andpurified by the streak plate method and identified by 16S rRNA sequencing. They were also tested for a few plant growth-promoting traits such as; nitrogen fixation, phosphate solubilization, and production of siderophore andIAA. The literature review found that many of our bacteria are knownPlant-Growth Promoting Bacteria (PGPB), including members from the genus Streptomycetes, Pseudomonas, Anthrobacter, and Bacillus. The identified endophytes were tested on crops Medicago sativa (alfalfa) andZea mays (maize) in the greenhouse under control and saline conditions for plant growth and development. Growth characteristics such as biomass, stomatal conductance, net photosynthetic rate, relative water content, and electrolyte leakage were measured and compared. We are testing these microbes on model plantArabidopsis thaliana. Identification of plant growth-promoting halotolerant endophytes can lead to the development of biofertilizers for saline soils and be utilized as a tool in sustainable and productive crop production for these harsh environments.

Abstract Name: **Multi-Omics Immune Interaction Networks in Lung Cancer Tumorigenesis, Proliferation, and Survival**

There are currently no effective biomarkers for prognosis and optimal treatment selection to improve non-small cell lung cancer (NSCLC) survival outcomes. This study further validated a seven-gene panel for diagnosis and prognosis of NSCLC using RNA sequencing and proteomic profiles of patient tumors. Within the seven-gene panel, ZNF71 expression combined with dendritic cell activities defined NSCLC patient subgroups (n = 966) with distinct survival outcomes (p = 0.04, Kaplan–Meier analysis). ZNF71 expression was significantly associated with the activities of natural killer cells (p = 0.014) and natural killer T cells (p = 0.003) in NSCLC patient tumors (n = 1016) using Chi-squared tests. Overexpression of ZNF71 resulted in decreased expression of multiple components of the intracellular intrinsic and innate immune systems, including dsRNA and dsDNA sensors. Multi-omics networks of ZNF71 and the intracellular intrinsic and innate immune systems were computed as relevant to NSCLC tumorigenesis, proliferation, and survival using patient clinical information and in-vitro CRISPR-Cas9/RNAi screening data. From these networks, pan-sensitive and pan-resistant genes to 21 NCCN-recommended drugs for treating NSCLC were selected. Based on the gene associations with patient survival and in-vitro CRISPR-Cas9, RNAi, and drug screening data, MEK1/2 inhibitors PD-198306 and U-0126, VEGFR inhibitor ZM-306416, and IGF-1R inhibitor PQ-401 were discovered as potential targeted therapy that may also induce an immune response for treating NSCLC.

Abstract Name: **The Study of a Bacteriophage on the Wartburg College Campus**

Bacteriophages are viruses that only infect bacteria and are also known as “phages” for short. Soil samples were collected on Wartburg College campus in hopes of findingphages in the soil samples. The goal is to get an image of the phage, analyze its genome, and DNA it contains to further understand how it works. Phages were isolated near a pipe located next to the science center. The coordinates were 42°43'37''N 92°28'59''W. After retrieving the soil sample, the phage particles had to be isolated from the soil sample. Novel bacteriophages were isolated via direct and enriched isolation at 30oC on PYCa medium. Once plaques were found, picking a plaque, plaque assays, serial dilutions, webbed plates to form lysate, and spot test could be performed. A plaque is what a phage forms after being transferred to a plate that contains bacteria. They appear as blank spots on the plate that can range from a few to many, and small to large. Plaque assays dilute a plaque picked from serial dilutions to purify it. Serial dilutions help manipulate concentration of phages in a sample. After making a plate that had many plaques, the next step was to generate a concentrated phage solution or lysate. The lysate that was extracted helped obtain the phages’ DNA and store it for a longer period of time to help with later parts of the experiment which includes sequencing. Next, phage samples were mounted for TEM by negative staining them. The purpose of this is to prepare a phage sample for viewing with a TEM. As stated in the beginning of this abstract the goal is to identify and characterize a novel phage.

Abstract Name: **Are Gender and Social Disparities Associated with STEM Persistence in Kentucky Colleges?**

Background: Even though children in the U.S. have the right to receive a quality education, concerns about disparities in school funding, facilities, and resources between different counties within a state have emerged. This "zip code effect" causes some students to be "predestined" to receive a poor foundational education depending on their home address. Because high school science and mathematics (STEM) classes require lab space, materials, equipment, and specialized teachers, disparities in school funding can impact students who want STEM careers. To make matters worse, once in college, female students are less likely to declare a STEM major and persist in it until graduation, especially in quantitative fields. Methods: The researcher analyzed data from the Kentucky Department of Education and Morehead State University. Chi-square and ANOVA tests were performed to determine factors affecting STEM degree attainment depending on whether students declared and graduated from the same STEM major (Major Persisters, n = 358), declared but switched to a different STEM major (STEM Persisters, n = 353), or switched from the original STEM major and graduated in a nonSTEM major (STEM Departers, n = 290). Results: The researcher found that low-income students are significantly less likely to be Major Persisters or STEM Persisters, and significantly more likely to be STEM Departers (X2 = 13.81, p = 0.001). Male and female students were Major Persisters, STEM Persisters, and STEM Departers at similar rates (X2 = 0.88, p = 0.64), which suggests a welcoming college environment for women in STEM. Average school size and funding per pupil were also similar for the three groups of interest (F = 0.38, p = 0.68; F = 0.35, p = 0.70). The fact that STEM-interested Pell Grant receivers are more likely to be STEM Departers calls for increased support through targeted financial aid and academic assistance.

Abstract Name: **Expression profile of selected DNA damage repair genes in Saccharomyces cerevisiae exposed to arsenic (III) oxide.**

DNA damage response is composed of multiple intercellular mechanisms capable of repairing impaired DNA sequences in order to prevent mutation spread. Various genes and pathways may be activated depending on the specific type of damage induced by a genotoxic agent. Among other factors, arsenic present in the form bioavailable compounds can act as an environmental pollutant and hazard to human health due to its mutagenic potential. This study utilizes aSaccharomyces cerevisiaemodel to investigate which DNA repair genes are activated in response to arsenic (III) oxide exposure. We herein apply previously optimized conditions of an arsenic (III) oxide treatment which results in moderate cellular toxicity (IC45-70, approximately 10.0% mortality). Expression of 20 different genes with a known role in either base excision repair, nucleotide excision repair, mismatch repair, homologous recombination or non-homologous end joining is examined using Real Time-quantitative Polymerase Chain Reaction (RT-qPCR). We anticipate that comparative analysis of arsenic-treated vs. untreated cells will demonstrate a distinct expression profile for genes involved in different DNA repair mechanisms.

Abstract Name: **The Evolution of Prominent Female Figures in Fashion of the 1900s**

Fashion is evolving and ever-changing. While fashion includes everyone, it is a practice that predominantly highlights and affects women. Despite this, there is a gap in literature on the representation of women who have influenced fashion. Our research aims to trace the development of styles, forms of dress, and appearance in relation to changing social, cultural, economic, technological, environmental, and political factors in the Western world while highlighting prominent female figures who helped make these changes in the 20th century.To explore this topic further, we first conducted a content analysis using scholarly publications and books to identify prominent female figures of the 20th century. We researched the historical climate of each of these decades, then selected female figures who represented these decades and their respectful fashions. After analyzing each decade, we focused on four decades, the 1920s, 1940s, 1960s, and the 1980s. The women identified include Greta Garbo, Marlene Dietrich, Jacqueline Kennedy, Twiggy, and Madonna. Greta Garbo and Marlene Dietrich were actresses of the 1920s and 1940s who influenced women to move away from cultural norms of dress; Twiggy and Jacqueline Kennedy. were prominent figures of the 1960s who showcased the polarized climate of the time, and Madonna was a singer who was known for her rebellious image in the 1980's. We then conducted an artifact analysis of styles and silhouettes of clothing from the 20th century using the historic dress collection at St. Catherine University in St. Paul, Minnesota. This collection contains over 2,000 garments and accessories dating back to the 1850, which provides evidence of silhouettes of the past. The findings of this research fill a gap in the literature and highlight women's accomplishments and fashion influence throughout the decades. These Findings will be presented in a visual window exhibition at Saint Catherine University.

Abstract Name: **Effects of Residual Arousal on Cognitive Appraisal and Psychophysiological Reactivity to Stress**

Effects of Residual Arousal on Cognitive Appraisal and Psychophysiological Reactivity to Stress When faced with a performance task, individuals may experience a cardiovascular reaction characterized by increased heart rate, sweating, and shaking. There is continued investigation of emotional, physiological, and psychological responses to performance tasks. While past research has found generalized energy expenditure to amplify emotional responses to a target stimuli, the question remains whether predispositions also modify emotional responses. This study investigated how residual arousal after exercise affects psychological and physiological reactions to a performance task, when individual appraisals of the task differ. Participants reported a positive or negative attitude toward job interviews in a pre-study questionnaire and underwent either a highly or minimally arousing exercise task, followed by a mock job interview, to which self-reported and cardiovascular responses were assessed. Using the Biopsychosocial Model of Challenge and Threat (BPSM–CT) as a framework, results showed that during the interview, participants with positive and negative prior attitudes exhibited cardiovascular response patterns consistent with the (BPSM-CT), while residual arousal from exercise led to more positive self-reports of the interview in both groups. In regard to cardiovascular reactivity, it was hypothesized that participants in the positive attitude group would exhibit more challenge-like cardiovascular reactivity to the task, defined as increased HR, increased CO and decreased TPR from baseline, while those in the negative attitude group would exhibit more threat-like reactivity, defined as increased HR, unchanged CO, and unchanged TPR. The findings demonstrate that residual arousal can improve subjective evaluations of a performance task, while pre-existing attitudes can influence task-related physiological reactions. This study is continuing to collect and analyze data in order to determine whether results differ with more participants. Further, this study contributes to a field of research exploring physiological, psychological, and emotional responses and reactions to stress and performance tasks.

Abstract Name: Beyond The Church: Religious Expression and Parallels in Popular Film

This paper seeks to examine religious themes, expressions, and parallels in popular American films, in order to examine not only what narrative elements resonate with Americans, but how religion embodies these elements. While much has been written in recent years about film and religion, many of the studies have centered around explicitly religious films or the spiritual experience that one may have while watching a film. This project, on the other hand, examines how the most popular American films of the last 60 years engage religious themes as the percentage of Americans who identify as religious continues to decline. Scholars have recognized that as fewer Americans identify as religious, more and more Americans are turning to alternative sources for forms of spiritual fulfillment. To better understand these new spiritual mediums, such as film, it is necessary to consider what themes are present in popular films. All the films analyzed in this project are from top 15 films from IMDb.com, omitting franchise repeats. While it will not be the focus of the paper, overtly religious films were also watched and compared to the IMDb top 15 to examine how these genres vary in their treatment of religious themes. Through these analyses, I find that these films have at least three key themes with religious dimensions;the destruction of corruption, the inspiration of hope, and empowerment of the individual. As people begin to desert organized religion, film is increasingly filling the gap left by the perceived failings of religious institutions.

Abstract Name: Mathematical Modeling of Immune Response to SARS-CoV-2

In response to the profound impact the COVID-19 pandemic has had on society, the mathematics and broader scientific community has focused considerable research efforts to understand the spread of the virus. Despite a tremendous volume of research in this area, how the human immune system responds to SARS-CoV-2 has not been yet fully understood due to limited analysis of the experimental or clinical information to date. Mathematical models that account for the interaction between SARS-CoV-2 and the human immune system will improve the scientific community's ability to analyze the vast amount of data available. The model we developed helps in understanding the role of various molecular pathways in successful viral clearance and the key mechanisms responsible for disease severity exhibited by some patients. Specifically, our in-host model explicitly represents the virus, innate immune cells, selected cytokines, and their interactions. These interactions are formulated in a system of coupled ordinary and delay differential equations. We conduct parameter estimation based on experimental data and literature review and investigate qualitative and quantitative behaviors of the model via numerical simulations. Using this model, we then determine the implications of variation of parameters by sensitivity analysis. Our model demonstrates key aspects of immune response to SARS-CoV-2, specifically its sensitive pathways, which might be responsible for differences in disease severity exhibited by COVID-19 patients. Our preliminary results of the mechanisms involved in COVID-19 pathology could identify several therapeutic targets that would provide hypotheses to be tested clinically, thus, serving as a foundation for the development of evidence-based therapeutic strategies.

Abstract Name: **Serotonin N-acetyltransferase Inhibitors for Treating Circadian Rhythm Disorders**

Circadian rhythm (CR) dysregulation contributes to mental health disorders, including major depressive disorder (MDD), bipolar disorder (BD), and seasonal affective disorder (SAD). Melatonin has been strongly associated with CR, but despite years of research, many questions remain regarding its role and how it influences mood. The rate-limiting step in melatonin synthesis involves the enzyme serotonin-N-acetyltransferase (SNAT, AANAT). Inhibition of SNAT would be a valuable approach for studying the physiology of melatonin and could be used to treat disorders such as SAD that involve abnormally high melatonin. Published inhibitors have problems with cell permeability, selectivity, and/or potency, which have prevented advancement to testing in humans. We have applied X-ray crystal-based models to modify a previously described indolinone scaffold with polar substituents as well as aromatic rings for conformational restriction to improve interactions with the Coenzyme A (CoA) binding site of SNAT. The synthesis and structure-activity relationship (SAR) from an enzymatic assay of these new indolinone-containing inhibitors will be presented. Our results could lead to a better understanding of SNAT's function and provide an approach to regulating melatonin.

Abstract Name: **Limited Access to Rural Community Schools**

Sensitive topic agencies have limited access into the education system and are unable to inform school aged children on sensitive topics. Due to the limited ability agencies who facilitate sensitive topic programs contain in the rural community school systems, student researchers introduced a question pertaining to the issue. How do educators in rural communities perceive agencies who facilitate sensitive topic programs? This study aims to understand factors related to sensitive topic agencies. Through a survey, the student researchers collected mixed-methodological data with a concentration on quantitative data. The overall targeted sample size was 75 educators who have worked in rural community school systems. After speaking with individuals, researchers can reach out to schools as a whole. They can practice at a mezzo level by contacting the school about what individuals inside their facility believe is appropriate to be taught to the students. Reaching out to the school can allow researchers to obtain an approved number of topics that are allowed to be presented to the age group indicated. This will then allow agencies to provide some information regarding sensitive topics to schools. In terms of the macro level, agencies often branch out into counties. The student researchers found that a majority of female participants did report a positive perception of sensitive topic agencies, and male participants reported limited knowledge. They also found that age did not matter when looking at the perceptions the educators have on sensitive topic agencies.

Abstract Name: Cracking The Code of Jane Austen's Masculine Femininity

Jane Austen is a feminist writer who questioned women's motivations for marriage in her lifetime. Austen's personification of reasoning applied by female characters in her novels challenges the societal expectations of women through her justifying that women can be more than emotional paperweights.Her characters such as Elinor Dashwood in Sense and Sensibility and Elizabeth Bennett in Pride and Prejudice fight against the stereotype of women in their time by presenting "masculine" actions and thoughts and by confronting the institution of marriage during that time. The author of this paper argues that Austen has created Elinor and Elizabeth to bring traditional gender roles into question while renewing awareness about marriage standards that many women held in her time. And the author maintains that the themes reflected in Jane Austen's novels are also significant for today in thatcontemporary women are still facing both similar and different challenges from society as the women in Austen's time.

Abstract Name: The Acceptability of Mindfulness-Based Approaches Among African American Young Adults

The present study examines mindfulness, preferred coping methods, and the perceptions of mindfulness-based interventions (MBIs) on mental health conditions. Furthermore, this research explores gender differences and how the role of religion impacts the perceptions and acceptability of mindfulness. Additionally, the study provides suggestions from previous studies on ways to enhance mindfulness-based interventions tailored for African American communities, which could potentially increase the acceptability of mindfulness practices. African American students ages 18-25 from the University of Wisconsin-Whitewater are included to fill gaps in the research on mindfulness and African Americans.

Abstract Name: **A Generation of Revenge: An Analysis of Far-Right Youth Radicalization and Holocaust Education in the US Education System**

This study is a comprehensive look at dissident right (far-right political ideologues, including white nationalists, fascists, and National Socialists) attitudes regarding the United States' education system. From the testimonials, literature, and words of members of the dissident right, this study finds that how problems in civic and Holocaust education are taught in schools may contribute to far-right political radicalization. Utilizing qualitative research methods, this study offers an analysis of far-right attitudes regarding the US education and Holocaust education from the words and works of dissent right political actors themselves. The methods of this comprehensive analysis include observation of online dissident right communities and reviews of dissent right media and literature (including books, articles, blogs, social media posts, memes, and podcasts). This survey of dissident right attitudes has found that these political actors commonly identify the role of the United States' education system as contributing to helping them develop their extremist ideology. Specifically, with subjects frequently identifying their experiences and dissatisfaction with Holocaust education as being part of their ideological radicalization. This study hopes to identify intersections between the US education system, civic and historical education, trends within American political culture, and the dissident right in order to better understand far-right youth radicalization.

Abstract Name: **WRAPping Our Heads Around the Impact of Advertisements Near Schools**

The aim of this research project is to generate evidence surrounding the type and amount of advertisements displayed by alcohol/tobacco retailerswithin a one-mile radius of nine high schools in Eau Claire County. This project specifically centers on surveyingthe advertisements of alcohol, nicotine-containing products, and processed foods on the property exteriors(including gas pumps, bollards, entry doors, exterior facing windows, etc.). Studies showthat adolescents are exposed to alcohol advertisements on a daily basis which impacts consumption and drinking habits, as well as the vulnerable developing brain. The U.S. Surgeon General reported that the use of e-cigarettes is on the rise among adolescents and continues to be a public health concern. For this population, close proximity between schools and retailers who sell and advertise junk foods is largely associated with higher consumption rates of these same foods. Based on concerns from Eau Claire County high school students and administrators, amodified survey from the Wisconsin Retail Assessment Project (WRAP) will be utilized to identify the content and quantity of advertisements near local schools. The project outcome involves the creation and dissemination of an original, interactive, and evidence-informed presentation created to inform public health and city officials who then have the opportunity to use the data to affect signage. The results have yet to be determined, but it is predicted that a majority of retailers near Eau Claire County high schools advertise alcohol,processed foods, and nicotine-containing products. This in turn increases accessibility, affordability, and acceptance of further product usage in adolescents.

Abstract Name: **Examining the Role of Acculturation Pressure on Affirmation and Belonging in Minority Populations**

Substantive research has indicated that Hispanic/Latinx youth are at greater risk for internalization symptoms, such as depression (Substance Abuse and Mental Health Services Administration, 2019). Prior research has tied social acculturative stress to increased depression and suicidal ideation among Latino youth (Gomez; Miranda, 2011), yet limited studies have examined how these pressures impact cultural identity development. Given that the effects of acculturative stress on psychopathology likely operate through its negative impact on normative developmental processes (Oshri et al., 2014), establishing the mechanisms of acculturative pressures would provide insights regarding the detrimental impact.Addressing the gaps in the current literature, the proposed study sought to explore how acculturative stress, specifically, pressure for and against acculturation, contributes to ethnic/racial (ERI) and U.S. identity (USI) in a large sample of young adults. The current sample consists of 1340 students (75.5% = Female; Mage = 19.92 years, SD = 2.09) drawn from a multisite university study on identity and culture. We estimated a linear regression model to examine the effect of pressure for and against acculturation on ERI [F(4, 1335) = 68.430, .001] and USI [F(4, 1332) = 23.261, .001]. As indicated in Table 1, pressure to acculturate was positively associated with ERI (β= .45, .001), whereas pressure against acculturation was negatively associated with ERI (β= -.43, .001). Additionally, pressure to acculturate was negatively associated with USI (β= -.27, .001). USI was also positively associated with pressure against acculturation; however, this association was not significant.Interestingly, the decrease in USI paired with higher acculturation pressures suggests a negative, reactionary response. This converse outcome implicates the need for further exploration and understanding on cultural identity development.

Abstract Name: **Water Treatment by Cold Atmosphere Plasma**

The purpose of this project was to quantify and investigate the mechanisms used to degrade perfluorooctanoic acid (PFOA), an emerging contaminant, through exposure to an electrically charged tungsten electrode to water discharge cold-atmospheric pressure (CAP) plasma jet. PFOA was commonly used in man-made products for commercial, industrial, and firefighting purposes, which had led to widespread contamination of groundwater and drinking water. CAP is an emerging technology undergoing intense research to understand what reactive species are produced during experimentation and how it can be used as an effective system for water treatment. A 20 micromolar solution of PFOA was exposed to plasma ignited in both air and argon gasses at a wattage of 10 ± 1 W. Under these conditions,a substantial amount of PFOA degradation occurred with argon and air plasma treatments in positive polarity. PFOA was seen to degrade an average of 54.6% when using an argon gas feed, and 50.0% when using an air gas feed after 40 minutes of treatment. These results indicate that argon plasma is a better conductor for the removal of PFOA from contaminated water. Additionally, CAP does not require expensive or wasteful resources, and does not generate harmful by-products. This project demonstrates that CAP is a promising green alternative to current water treatment processes in use.

Abstract Name: Taxiway Optimization for Runway Duplication at Fukuoka Airport

1. Purpose of the Study. Aviation demand, which declined during the COVID-19 pandemic, is expected to fully recover to pre-pandemic levels by 2023 and continue to further increase. Therefore, there is a need to improve the efficiency of air traffic control in addition to airport capacity. Particularly, congestion among aircraft is an important problem. In recent years, NASA and the FAA have initiated research on this topic to improve the efficiency of ground transfers and departures at airports. Fukuoka Airport has one of the highest congestion levels per runway in Japan, and the resulting delays in takeoffs and landings constitute a major issue. Therefore, we aim to reduce emissions by optimizing routes, operating taxiways at regular intervals, and reducing stop zones. 2. Methods and Results. Using Dijkstra's method and Queueing theory, we identified the shortest taxiway routes, constructed a program to head to an open runway while maintaining constant intervals, calculated the optimal time for aircraft departing the boarding gate and the associated delay time, and constructed a new takeoff and landing timetable. 3. Discussion and Conclusions. Airports judge on-time departure or arrival of a flight to have failed in case of delays exceeding 15 min. In 2021, Fukuoka Airport exhibited an on-time departure rate of 95.74% and an on-time arrival rate of 96.05%. This study accomplished 100% on-time departure and arrival rates, assuming that all passengers arrive on time. Furthermore, the program completely prevents traffic congestion on the taxiway, allaying anxiety in passengers over delays in take-off, as it is designed to maintain a constant interval between different runways. In addition, aircrafts are not required to halt on the taxiway in the proposed system; this considerably reduces exhaust emissions by diminishing energy expenditure.

Abstract Name: Generalized Additive Models for Modeling the Mountain Glacier Terminus Variations in Response to the Climate Factors

Populations residing in arid regions, typically near mountains often depend on run off from melting glaciers for their water during the drier and warmer parts of the year. River systems meandering through portions of Asia are sustained from ice and snowmelt located in the Himalayas and the glaciers within the mountain range, this is particularly true in late summer when a predominant factor contributing to river flow comes from melting glaciers. Much the same is true in the Andes in South America. The socio-political impacts due to the loss of mountain glaciers have the potential to be significant on both the ecological and global political level. The recognition of these contingencies has spurred increased interest into the study of the mountain glacier response to the measurable evidence of fluctuating climate factors such as temperature, precipitation, and CO2.The remote nature of glaciers renders direct measurement impractical on anything other than a local scale. This project uses satellite imagery, taken by Landsat at regular intervals. The goal of this project is to quantify changes in the terminal point of Franz Josef and Gorner glaciers in response to climate factors. Generalized additive models (GAM) are employed to identify significant climate factors that can explain and predict variations in the terminal point of these glaciers. Local temperature, CO2, and precipitation are identified as significant factors for predicting changes in the movements in the terminal point of Franz Josef and Gorner glaciers.

Abstract Name: **Donald Trump, Right-wing Populist Rhetoric, and the Antagonization of Left-wing Parties in Political Discourse: The Relationship Between Trump's Speeches and Tweets and Political Demonstrations in the United States**

With the recent emergence of political discourse, politicians and their rhetoric, especially former U.S. President Donald Trump, has been labeled as populist in explanation for the mobilization of their supporter base. Opponents have characterized Trump's populist rhetoric as aggressive, antagonistic, and insulting. By examining Trump's right-wing populist rhetoric through a textual analysis of Trump's rally speeches and tweets from 2016 to 2021, the study investigates the relationship between Trump's populist rhetoric and political demonstrations and violence in favor and against Trump. The study determines the degree of Trump's populist rhetoric according to a criteria adopted from scholars—with an emphasis on dispositional blame attribution and anti-elitism—and a textual comparison to other right-wing populist politicians, such as President Jair Bolsonaro and Prime Minister Thaksin Shinawatra. Since the aim of populism is based on stripping the elite of power and returning it to the common people, populist rhetoric may utilize personal pronouns such as "we" and "our" and inclusive language such as "the people" in order for a politician to relate to their supporters. The study parallels Trump's rhetoric in tweets—which includes personal pronouns and inclusive language—to a timeline of protests that transpired from late January to early February 2017. Although the study found that there is a need for additional research to determine a causal relationship between Trump's right-wing populist rhetoric and demonstrations in favor and against Trump, studies have found that political demonstrations are correlationally related to populist rhetoric.

Abstract Name: **Cumulative Risk Assessment of Well Water Contaminants in Gallatin and Madison Watersheds, Montana and Formulation of Risk Communication Plan**

Access to safe drinking water is an issue most Americans associate solely with developing counties, however, many rural Americans rely on private drinking water sources that may not be tested or treated for contaminants that pose a risk to human health. Unlike public water supplies, private drinking water (PDW) is not regulated by the Environmental Protection Agency. Instead, the testing and treatment of well water is left up to well owners who may not be aware of potential contaminants present in their water or the health effects associated with these contaminants. Educating well owners is an important step in protecting the health of rural Montanans. This project seeks to communicate the cumulative risk posed by the consumption of home well water, and a high-level idea of what contaminants are likely to be present in well water in the Gallatin watershed (home to Montana State University) and neighboring Madison watershed. The objectives of this research project included: (1) calculating the cumulative risk posed by lifetime consumption of home well water for residents living within the Gallatin and Madison watersheds in Montana using available data from the Ground Water Information Center, and (2) conducting a literature review of existing risk communication best practices and formatting a guide for other researchers at Montana State University communicating well water research. This information will be used to create a 1-page flyer and other educational materials for public health officials and residents of Gallatin and Madison counties. These materials will communicate a high-level idea of what contaminants are likely to be present in residents' well water based on their watershed of residence, and will emphasize the importance of well water testing. They will be shared with local health departments and will be made available on the Montana State University extension program Well Educated website.

Abstract Name: **The Effect of Cold Temperatures on a Common Cover Crop Rhizobia Used in Organic Agriculture**

Nitrogen is an essential nutrient for plant growth, but it can be limiting in agricultural systems. Legumes meet this nitrogen demand by partnering with rhizobia soil bacteria to fix atmospheric N2 into a plant-available from. This study focuses on Rhizobium leguminosarum biovar viciae (Rlv), the rhizobia associated with the winter annual cover crop, Vicia villosa Roth (hairy vetch). This crop can be planted after cash crop harvest in the fall, grown through the winter, and contribute fixed nitrogen to a subsequent cash crop. This contribution of nitrogen is done through both the decomposition following termination of cover crop as biomass decomposes and biological nitrogen fixation (BNF) by rhizobia. Due to its late planting dates of the upper Midwest and other cold regions, hairy vetch must fix nitrogen under cold stress conditions. This study analyzes the growth rate of five strains of Rlv, to determine whether in vitro growth at low temperatures reflect improved BNF rates with hairy vetch grown at low temperatures. Strains were grown at 8, 12, 16, 20, and 28 degrees ℃, with optical density of the rhizobia measured at set time points. We hypothesized that the rhizobia strains with previously documented low BNF in trials with vetch would also have low growth rates at low temperatures. Indeed, the strains that performed the worst in vitro were also the strains that performed the worst in planta at low temperatures. These results suggest that testing rhizobia strain growth in vitro at low temperatures is an inexpensive alternative to testing strains' BNF capacity with hairy vetch grown at low temperatures.

Abstract Name: **The Relationship Between Racial Discrimination and Mental and Physical Health Among College Students**

Racial discrimination is associated with poorer mental and physical health outcomes. Even in spaces meant to improve health, minorities can experience the opposite. For example, situational discrimination, such as in the healthcare setting, has been reported more frequently among racial minorities and is associated with unmet healthcare needs and a greater likelihood of delaying healthcare until condition severity meaning poorer health outcomes. This study's purpose is to examine if experiences of racial and healthcare discrimination are linked to negative mental and physical health outcomes among college students. Students enrolled at UNC Charlotte (n=279) were recruited to complete an online study about being treated unfairly and health. Lifetime experiences of perceived racial discrimination were measured through the Schedule of Racist Events (SRE) scale. Mental and physical health outcomes were assessed through validated and reliable self-report questionnaires including the Cohen-Hoberman Inventory of Physical Symptoms (CHIPS), Center for Epidemiologic Studies-Depression (CES-D), and Perceived Stress (PSS) scales. Experiences of healthcare discrimination will be estimated by averaging two health-setting specific items from the Experiences of Discrimination and SRE scales. Self-reported racial discrimination was positively correlated with healthcare discrimination, depression, negative physical health, and perceived stress. Healthcare discrimination was positively correlated with depression, negative physical health, and perceived stress. Racial minorities reporting higher rates of racial discrimination and healthcare discrimination are more likely to report greater stress, depression, and poorer physical health.

Abstract Name: **Effects of Class Size on Undergraduate Research Thesis Writing Success**

Writing Studies experts generally agree that small class size leads to the most efficacious writing pedagogy. While this practice has been widely studied with regard to first-year writing classes, very little work has been done to consider whether upper-level writing classes are similarly affected. Determining an answer to this question presented an opportunity for study with a growing need for seats in the 2-part writing course series (Undergraduate Research Proposal Writing and Undergraduate Research Thesis Writing) that is a requirement of Georgia Tech's Undergraduate Research Option, a need that could be remedied with by offering class sections with a larger seat cap. The larger class was piloted, allowing students to enroll in either a small class with a cap of 15 students or a large class with a cap of 40 students for both the proposal and the thesis writing classes. Student writing samples were assessed in order to test the generally accepted understanding of class size and writing pedagogy. Experts in writing instruction evaluated randomly selected and anonymized proposals and theses, focusing on measures such as defining the problem, solution, and benefits of the research; clarity; organization; and citational practice. Average scores of the students in the smaller classes were compared to those in the larger classes. No significant difference in student writing efficacy was found. This presentation discusses the assessment project, course design, and the research option more broaadly, with the hope that similar models might be of use at other institutions.

Abstract Name: **Investigation on Acoustic Holographic Lenses for Low Intensity Transcranial Neuromodulation**

Chronic pain is a debilitating condition that is an enigma for both doctors and their patients. The CDC estimated that 20.4% of US adults experience chronic pain which imposes tremendous burdens on the healthcare system and can severely affect a patient's quality of life. The most common form of treatment is medication, though it often comes with undesired side effects. Neuromodulation is an emerging tool for the treatment of chronic neuropathic pain by altering the nerve activity through the targeted delivery of a stimulus. This presentation will discuss the alternative therapy known as tFUS, or transcranial focused ultrasound. tFUS is a new and promising non-invasive technique for safely inducing transient plasticity deep within the brain by sending ultrasound pulses with high spatial precision and depth. In this work, a 3D printed holographic lens is designed using time-reversal and phase conjugation techniques to compensate for skull aberrations as well as target the ventral posterolateral nucleus (VPL). We verify our work using numerical simulations and submerged experiments using a 3D printed skull phantom. Firstly, computed tomography (CT) and magnetic resonance (MR) images are used to obtain the geometry and the acoustic properties of the skull. Simple thresholding is used to infer the skull geometry from the CT images. On top of the previously established skull domain, additional segmentation is done on MR images to derive the geometry of the skin, cerebrospinal fluid, and brain tissue. Secondly, by utilizing the acoustic simulations toolbox “k-wave” the lens is designed using time-reversal techniques that account for the inhomogeneities in the propagation medium and the skull. Developing accurate physical models is essential for providing patients with fast and personalized therapeutic procedures without the need for any invasive interventions. Finally, experiments in a water tank are performed to verify our numerical and computational findings.

Abstract Name: Discrepancies Between Cleaning Procedures in Medical Settings Regarding Clostridioides difficile Prevention

Clostridioides difficile (C.diff), a common healthcare-associated infection (HAI), is a gram positive bacteria that causes life-threatening diarrhea (12,800 deaths in the US in 2017) especially in immunocompromised individuals. Patients who receive extensive broad-spectrum antibiotic treatment develop this infection and it is highly contagious in clinical environments. Despite it being primarily spread through exposure in medical settings, there are no standardized procedures between facilites on sanitizing surfaces after coming into contact with a patient who is positive for C.diff. The goal of this research is to compare cleaning procedures and determine which is most effective at killing C.diff on surfaces as it survives common disinfection due to sporulation. Surveys will be sent to various medical facilities nationwide inquiring about patient history, cleaning techniques, and follow up testing to see if the C.diff spores were eradicated. Following their responses, each procedure will be evaluated on its efficacy to eliminate spores based on CDC guidelines. After the research is performed, it will be evident by the variation of C.diff isolates between regimens that some policies are superior to others and there should be standardization between healthcare facilitesto better prevent the spread of severe HAIs.

Abstract Name: Examining Perceived Interpersonal Relationship Influences on Physical Activity Across the Life Course

The United States has a growing aging population. By 2034, it is predicted that there will be more older adults than children. Physical activity and interpersonal relationships across the lifespan contribute to quality of life. Less is known about how interpersonal relationships influence physical activity. The current study aimed to understand how older adults perceived interpersonal relationships influenced their early life (under age 18), young adulthood (ages 18-34), middle adulthood (ages 35-59), and older adulthood (ages 60+). Participants included 19 older adults (n= 8 men,n= 11 women) between the ages 60 and 83 (mage= 68.9) who were recruited in one community in the western United States. Each participant completed a 50–60-minute audio-recorded interview. Participants were asked questions about their physical activity and interpersonal relationships at each stage of their lives. Interviews were transcribed verbatim. A qualitative case study analysis approach was utilized. Participants' experiences with physical activity and interpersonal relationships across the lifespan were represented by four themes: (1) Exercise trajectory across the lifespan (e.g., types of physical activity at different life stages, perceived personal health), (2) Relationships with parents, siblings, and extended family (e.g., largely focused on how early interpersonal relationships influenced perceptions and experiences with physical activity), (3) Chosen relationships and physical activity (e.g., romantic partner and friend influences on physical activity), and (4) Children, grandchildren, and physical activity (e.g., difficulty exercising when children were young, children and grandchildren as a motivator for exercise).Results will be discussed in relation to existing literature and theory, and future research directions will be provided.

Abstract Name: Is Nile Red an effective tool in the identification of microplastics?

The extensive use of plastics in both industry and commerce has led to the introduction of plastic debris in natural environment. Some of these plastics are fragmented and in turn generates microplastics (MPs) are then being introduced into lakes and rivers. MPs (< 5mm in size) are produced from microsized fragments on account of disposal and decay of plastics. Extensive research has been conducted in the processes of both quantifying and identifying MPs. However, the methodologies are extremely time-consuming. This study found that fluorescence and Nile Red are not reliable techniques for qualitative methods to identify MPs because synthetic polymers are easily confused with organic matter and natural polymers. A combination of fluorescent lights (royal blue (450-465 nm) and cyan (~500 nm)) help to distinguish microparticles that are not visible on a white background. Fourier Transform Infrared spectroscopy (FTIR) with attenuated total reflectance (ATR) and transmission mode are used to identify the type of synthetic polymer quantitatively. It is not recommended to use fluorescent light (over 4000 particles analyzed) as quantitative identification of MPs; our results using Nile Redshowed that only 67.1% of white and transparent fibers were correctly identified as natural polymers and 9.1% of fibers were correctly identified as synthetic polymers. Nile Red can dye fragments (approximately 0.75mm to 5mm) that are white or transparent in color but its effectiveness decreases when dyeing fibers darker in color, such as dark blue or black.

Abstract Name: Pesticide's Impact on Germination Rates of Invasive Phragmites

Phragmites australis (common reed) is an invasive grass prevalent in wetlands across North America, especially the Great Lakes region of the US. Phragmites is a problem in the Great Lakes region due to its rapid growth rate and its ability to outcompete native species in wetlands, harming biodiversity and reducing native ecosystem services. The most common management technique for Phragmites control is application of two systemic herbicides on invasive populations: glyphosate and imazapyr. While these herbicides are effective in killing above and belowground plant tissues, it is unclear whether or not they impact germination rate of seeds the plants disperse after death.We conducted an experiment testing the impact of herbicide application on germination rate of seeds from three different sites. We compared germination rates of seeds grown in optimal conditions to those subjected to herbicide application of both formulations (1) on whole inflorescences (2) soaked on individual seeds, and (3) mixed in growth medium. Our data will demonstrate whether herbicides being sprayed on the plant kill the seeds as well as the plant. According to the labels, neither product is recommended for killing seeds, so we expect that the seeds will not absorb the pesticides before germination, and will only die after a root forms, meaning that while these herbicides remain useful for killing live plants, they will have no effect on the seed bank or seed dispersal. This experiment could be useful for land managers dealing with the invasive Phragmites and improve understanding of how the herbicides used affect the future generation of plants.

Abstract Name: **Catalytic Variants of O-GlcNAc Transferase and Their Role in X-Linked Intellectual Disability**

The OGT gene encodes for the enzyme O-GlcNAc Transferase that is essential for human life and is responsible for the addition of O-GlcNAc onto target cellular proteins. The O-GlcNAc modification plays a role in numerous processes and diseases including diabetes, cancer, neurodegeneration, and neural development. Previously reported mutations in the N terminal Tetratricopeptide Repeat (TPR) domain of OGT have been found to cause X-Linked Intellectual Disability (XLID). More recently, clinicians have identified 3 mutations in the C terminal catalytic domain of OGT. We hypothesize, based on molecular modeling, that the enzyme will not be able to efficiently bind the sugar nucleotide and transfer O-GlcNAc to proteins. Thus, the variants will alter the O-GlcNAc levels on intracellular proteins. To test this hypothesis, we will express the variants, T570A, Y835C, and A952V, in human cell lines to better understand the effects of the mutations in comparison to our positive control, wildtype, and negative control, catalytically inactive K852M. We have created plasmids via site-directed mutagenesis to express the recombinant OGT enzyme variants. We will use western blots to assess the levels of O-GlcNAc normalized to the amount of recombinant OGT expressed in mammalian cells. This can help us better understand the role that these mutations play in the intellectual disability phenotype. By understanding how the variants alter O-GlcNAc levels and enzyme function, potential therapeutics can be created, and we will better understand the role these mutations play in the phenotype of XLID.

Abstract Name: **Starbucks France Branding**

In a country roughly the size of Texas, French consumers drink two times more coffee a year than the international average. Although France has a strong coffee and café culture, international chains, such as Starbucks, have struggled to find a foothold in the country. Starbucks has relatively few locations in France compared to other European countries, and evidence suggests the French have not embraced the global coffee behemoth. This research examines Starbucks' branding in France as well as French customers' perceptions of Starbucks. The topic is important to the field of public relations (PR) because as the world is becoming increasingly connected and globalized, it is critical for PR practitioners to effectively navigate other cultures. It is important that multinational companies (MNCs) consider their communications and marketing to attract customers in countries different from the host nation. Because consumers worldwide often have preexisting perceptions of large brands, MNCs must be aware of their reputation and that of their country of origin before opening in new locations. To understand French consumers' opinions of Starbucks, participant observation was conducted at Starbucks locations in France, in addition to interviews with French Starbucks customers and non-customers. To analyze how Starbucks France communicates with its publics, a content analysis of its website was conducted. Findings from the three methods are discussed through the lens of the circuit of culture, a theoretical framework created by Stuart Hall and other academicians from Open University in Britain who suggest meaning is a cultural practice woven through five "moments." The circuit of culture provides a robust analytic framework to view Starbucks in a cultural context and inform communications strategies for MNCs in general.

Abstract Name: **Disparities Affecting the Knowledge of Female Pelvic Floor Disorders**

Pelvic floor dysfunctions (PFDs) are the most common problems faced by women post-partum, however, only a few have access to and awareness of physical therapy (PT). Due to its prevalence, PFD is now considered a public health issue, including urinary incontinence, fecal bowel incontinence, pain during intercourse, and pelvic organ prolapse. White women and women of color had no significant difference in experiencing PFDs, and yet women of color had statistically less knowledge of PFD conditions. African Americans and other women of color are also less likely than white women to recognize childbirth as a risk factor for urinary incontinence and pelvic organ prolapse. Research demonstrates that women with a higher level of education have greater proficiency of PFDs compared to those with a lower level of education. Socioeconomic factors play a major role in the knowledge of PFDs because a higher annual income can provide better access to education and medical care. The aim of this study is to assess women's knowledge of PFDs and raise awareness about the importance of pelvic PT and its benefits for women after childbirth in order to prevent PFDs. Given that there is a lack of research in this area, we aim to bridge the existing gaps regarding the roles that age, racial, and socioeconomic disparities play in the need for education about PFDs, as we believe that this knowledge will help lower PFD cases with the help of pelvic physical therapy. The subjects will be 30 females between the ages of 20 and 40, recruited from college campuses, community centers, and healthcare providers. Data will be collected via a survey consisting of open- and close-ended questions to ascertain women's knowledge and awareness of post-partum PFDs and available therapy options. The survey will be developed in consultation with two licensed pelvic physical therapists.

Abstract Name: **The Safety Net Response to the Covid-19 Pandemic Recession and the Older Population**

The response of the safety net to recessions for the older population has been little examined in the literature. Studies of its responsiveness to the Pandemic Recession have also not been conducted. We examine how benefit receipt from different programs changed for individuals 50-74 for different programs and for individuals with different characteristics. Our examination yields several new findings. First, we establish that the Unemployment Insurance Program and the SNAP (Food Stamp) program are important for the older population as they are for prime age groups. In recessions, in general, and in the Pandemic Recession, these programs provided significant support to older men and women. Second, these programs provided support to those 62 and older as well as to those 50-61, especially SNAP. Low-income individuals after retirement are, even with programs like Social Security and SSI, eligible for SNAP benefits and they often need to apply for and receive benefits during recessions. Although smaller than for younger individuals, individuals 62 and over often receive UI benefits as well. Third, while we find that less educated individuals in the older population are more likely to increase benefit receipt during recessions than more educated individuals, including during the Pandemic, for the UI program receipt among older men and women increased significantly at all education levels. Fourth, we find some evidence, though not conclusive, of countercyclical effects on SSI and/or DI, with receipt rising during the Pandemic and Great Recession. Fifth, we find that men and women, while showing some evidence of differences in program receipt and uptick during the Pandemic, overall show quite similar patterns of increased receipt.

Abstract Name: **A Lover's Journey: Reconsidering Love in Light of Marion**

In The Erotic Phenomena, Jean-Luc Marion derides the metaphysical explanation of humanity introduced by Descartes. Marion writes that our existence “does not come from metaphysics. When you reduce humanity to its essence, it is erotic” (22). That is, instead of ‘I think, therefore I am,’ Marion suggests ‘I love, therefore I am.’ Marion qualifies this love as ‘Love,’ the quality of giving of oneself because one desires to benefit and care for others, not the romantic desire for another person. This recital is a reflection on this radical reversal, exploring the tension between romantic love and Love. The main theme of this recital is how romantic love, as C.S. Lewis phrased it, can assume the grandeur of a metaphysical pursuit, usurping the place of Love. This recital considers the consequences of when romantic love becomes the guiding principle of life, when a person’s hope and emotional well-being rests on a human beloved.The recital presents a story of a lover who falls in love, makes romantic love their guiding principle, reels from the negative consequences of this ethic, and discovers a different ethic–Love–along with the positive consequences that Love brings for a person’s emotional and spiritual well-being. In considering the repetoire for this recital, Equity, Diversity, and Inclusion was a key consideration. Since love and the role of lover is common to all humanity, it is important to ensure that other voices are heardalongside the traditional Art Song corpus of white, male composers.To this end, alongside the traditional corpus of composers--Schumann, Fauré, Schubert, Tosti, and Saint-Saëns--half of the pieces in this recitalare composed by individualsfrom underrepresented groups,particularlyfemale or blackcomposers--Augusta Holmes, Cécile Chaminade, Francesca Caccini, Ethel Smyth, Eleanor Everest Freer, and Sylvia T. Hollifield.

Abstract Name: **Biodegradable Constructed Floating Wetland**

The goal of this project is to build a bio-based floating wetland. The benefit of constructed wetlands come from their ability to be placed where wetlands are not commonly found. Currently, constructed wetlands have been successful in pollution control by chemical sequestration. In addition, recent discoveries have shown that artificial wetlands are also effective as carbon sinks which is essential for lowering the amount of greenhouse gasses that accumulate in the atmosphere. Artificial wetlands are available on the market; however, they contain polyethylene terephthalate, PET, which is a plastic polymer that has the ability to absorb chemicals. These plastics will eventually breakdown, due to wave action, oxidation and other weathering reactions, and possibly lead to increased toxicity in aquatic environments. The wetland we plan to build will be made from Phyllostachys Henon and Phyllostachys Moso, bamboo grown in Louisiana, hemp twine, coco coir pith and sheets, and Phragmites australis. The testing will proceed in two parts. First, the bamboo skeleton will be built, held together by Japanese square and shear lashings, and tested in LSU lakes for three to four months. For the second part, we will grow the Phragmites australis, or adjacent plant, hydroponically in the coco coir, then proceed to test its durability in LSU lakes. We hope that these constructed wetlands will be a cost-effective and sustainable alternative to those on the market, for lower income communities. Also, it is our intention to use this apparatus as a method of mitigating harmful algal blooms.

Abstract Name: Structure-based design of serotonin 2A receptor agonists as a novel treatment for depression

Depression and anxiety are widespread disorders with a complex relationship to serotonin levels, where increasing the availability of serotonin in the synapse is a potential treatment. Current medications on the market tend to take 4-6 weeks to work and have many side effects that can lead to discontinuation, such as nausea, fatigue, dizziness, and suicidal thoughts. Additionally, many people find themselves with treatment resistant depression that doesn't respond to current therapies. This project focuses on serotonin 2a (5HT2A) receptors, to which serotonin binds to transmit messages from one neuron to the next. Current known agonists of this receptor include various non-hallucinogenic molecules, such as the natural substrate, serotonin, and lisuride, as well as hallucinogenic molecules such as lysergic acid diethylamide (LSD) and psilocybin. The goal of the current study is to design novel serotonin 2a receptor agonists without hallucinogenic effects as a potential treatment for mood disorders. Molecular dynamics simulations are currently in progress with 6 non-hallucinogenic and 8 hallucinogenic molecules bound to the 5HT2A receptor within a membrane. These molecules are being investigated to determine the effects of hallucinogenic versus non-hallucinogenic agonists on the conformation of the receptor protein. Although results are preliminary, simulations have shown unique conformational changes in the receptor when bound to the hallucinogenic molecule, psilocybin. Analyses are in progress to quantify the structural changes that occur so that the information can be used to predict whether novel molecules will be likely to cause hallucinogenic effects. Our preliminary results suggest that computational chemistry methods may be useful in the analysis of conformational changes in the 5HT2A receptor caused by ligand binding. The results from this study will ideally shed light on the effect certain agonists have on the serotonin receptor that can be used in the design of future antidepressants.

Abstract Name: Looking at the Past Through Window Glass: Dating the Construction of Buildings at the Montgomery Site, Kenosha County, Wisconsin

Window glass historically follows a pattern of popular production methods over the past three centuries, beginning with crown glass, followed by cylinder, and eventually leading to plate (or float) glass. Each method produced flat (window) glass with a different range of thicknesses. Window glass shards from historic archaeological sites can be used to determine approximate dates of building construction by measuring the thickness of the glass and using developed glass dating formulas. The purpose of this project is to determine possible dates of construction for four separate residential structures excavated at the Montgomery Site using glass thickness and the dating formulae. An additional goal of the study is to determine which of the glass dating formulas and methods used is most accurate and reliable for this site and this region of North America. I utilize the Moir, Ball, Schoen, and Roenke methods of glass dating to analyze the structures of the Montgomery Site. This historic site in Kenosha County in southeastern Wisconsin dates back as far as the 1830s, when records indicate the first structure was built. Individual glass shards are organized and recorded by excavation location as to differentiate glass from different structures. The thickness of each shard is measured in three separate locations and averaged for the highest accuracy possible to provide data to use with the dating formulae. I anticipate taking the results and comparing them to the recorded dates that exist for any structures and using that information to provide an approximate construction date range for each structure for which we do not have historic records.

Abstract Name: **Pedagogical shift and parental mental health during the COVID-19 pandemic: Evidence from the United States**

The global COVID-19 pandemic has negatively affected the mental health of individuals around the country. As a part of social distancing measures, the pedagogical shift from in-person to online learning and class cancellation for primary and secondary schools has increased the stress and anxiety of parents during the pandemic. In this study, we aim to explore the effect of pedagogical shifts, including in-person to distance learning or class cancellation, on the mental health of parents with school-aged children in the United States. Our study utilizes a national dataset from the Household Pulse Survey collected by the Census Bureau from April 23, 2020, through December 21, 2020. After applying the data to the multivariate regression models, we found that pedagogical shifts significantly increased the severity of anxiety and depression symptoms and worsened parents' mental health. Notably, parents with children who had their classes canceled experienced significantly higher levels of anxiety and depression symptoms than those with children who switched to distance learning. These findings were first verified robustly using an alternative model - the ordered logit regression - by considering the anxiety and depression levels as discrete variables with ranking. We then checked our results by using alternative mental health measures for anxiety and depression disorders and estimated the effects of pedagogical shifts using the linear probability model. We further conducted a heterogeneous analysis by exploringpedagogical shiftingeffects by gender, race, working status, and political affiliation by the 2020 presidential elections. Our results reveal complex variations by different groups of parents affected by the pedagogical shift due to the Pandemic. These findings highlight an urgency for state, federal, and societal policy changes to address the growing mental health issues and disparities among parents with children during these challenging times in the United States.

Abstract Name: **Motivating Factors Behind Following COVID-19 Guidelines Among College Students**

The ongoing COVID-19 pandemic has created vast changes in human behavior. The virus, SARS-CoV-2, was first identified in Wuhan, China in November 2019. While there were early efforts to contain the virus, by March 2020 it became a global pandemic. As of October 2022, there have been over 6.5 million reported deaths. Unlike previous coronaviruses, people can easily contract and spread SARS-CoV-2, due to its high transmissibility and comparatively mild symptoms. However, symptoms can be severe and deadly, especially among immunocompromised and elderly populations.For this reason, organizations such as the World Health Organization (WHO) created comprehensive guidelines to prevent its transmission and spread. These rules include wearing masks in public, staying at home, social distancing, disinfecting hands and surfaces, and later getting vaccinated. These rules were often enforced through mandates and lockdowns, with which most people complied. Yet, there are some people that broke or disregarded these rules.This project seeks to understand the motivating factors behind following COVID-19 guidelines. In addition, I am looking to understand why people continue to follow certain guidelines such as masking and social distancing despite the lifting of these mandates and regulations. These factors include fear, compliance with rules, and safety of self and others. Through my research, I am hoping to find the most relevant motivating factor. Finally, I am also looking to understand what motivates people to not follow or disregard these guidelines.For this research, my subject is Brooklyn College students who were subjected to the CUNY guidelines starting Fall 2021. I aim to analyze previous research done on following COVID-19 guidelines in addition to collecting my own research which will involve surveying students on their motivations behind following these guidelines and analyzing the data using statistical methods. This research will help understand human behavior in following or breaking rules.

Abstract Name: **Community College "CUREs" Engagement Deficits in Biology**

Madison Area Technical College (Madison College) is a public technical and community college serving Madison, WI, and the twelve surrounding counties. Total enrollments exceeded 24,000 students in the 2021-22 academic year, with 42.2% of entering full-time students in Fall of 2020 continuing the following Fall. The Liberal Arts transfer program offers seven tailored pre-majors designed for transfer and satisfaction of the first two years of general studies at some institutions, with the University of Wisconsin-Madison serving as our largest transfer partner. A federally funded initiative to improve transferstudent success through the establishment of Course-Embedded Undergraduate Research Experiences (CUREs) was established in majors' biology courses beginning in Fall 2018. This project has resulted in over 500 students participating in skills-focused CUREs in biology courses, and is expandingbeyond the target courses to include related courses and programs. Prior to our CUREs implementation, only 18% of students completed abiology majors course series within two semesters. After CUREsimplementation, 32% of students complete abiology majors course series within two semesters.Our panel will discuss this, and otheroutcomes of implementing CUREs in our biology courses, as well as the challenges and opportunities associated with implementing CUREs at a community college. Details about two of our collaborative CUREs initiatives, including ourwork implementing Tiny Earth and Sea Phages across three different biology courses will be highlighted.

Abstract Name: **Cumulative Risk Assessment of Exposure to Well Water Contaminants at the Lower Clark Fork Watershed in Montana**

Many Montana residents rely on wells as their source of drinking water. Numerous impurities can insert themselves into the drinking water, many of which are health concerns. The issue is wells are primarily unregulated, and there has yet to be any data showing the cumulative risks of these contaminants in Sanders county, where the Lower Clark Fork watershed is located. This research shows the top five main concerns in the Lower Clark Fork watershed and aims to help citizens educate themselves on what they consume. The groundwater contaminants that are of primary concern include arsenic, manganese, and nitrate. Iron and hardness are also prevalent but only cause cosmetic issues. Nitrate and arsenic are highly harmful to drink and can cause cardiovascular, nervous, and respiratory problems. When living in a rural community such as Sanders county, it is easy to overlook these health concerns as they are not widely discussed. The lack of knowledge about these issues is dangerous. People should have access to safe drinking water at their homes and information regarding what is in their water. With the data from this study, people can take action with proper filters and other devices that can be life-saving.

Abstract Name: **Floriography to Human Relations Portrayed in Etchings**

Understanding the underlying meanings or uses of flowers and other plants has been a long-standing practice since the beginning. Flowers had many social usages in Victorian times; whatever was sent to someone would change the underlying meaning of the gift. Then in many tribal or indigenous cultures, there is a greater purpose to use herbs and other plants for medicinal purposes. Along with that, many human traits are related to flowers and anthropomorphizing them to have a stronger sense of the various meanings of flowers. Working with copper to create prints was also done long ago; this is more commonly known as engravings. The engravings would be cut and carved into the plate to create the grooves in the piece that would print, though, in the more modern world, there is a more straightforward way, etching. Since there is such a short time for this project, etching would be the most convenient way to make all the pieces and still evoke the linework in engravings. This project aims to gain more floriography knowledge and combine that information with a small series of four 4” by 6” copper etchings. When working with the copper etchings, various techniques are displayed, aquatint and mezzotint. These two techniques help to give more depth and texture to work. Aquatint adds a fine mist and smoky tone to an art piece, and mezzotint creates a strong contrast in the composition.

Abstract Name: **The Symphony of the Cell: Using Data Sonification to Engage Students in Molecular and Cellular Biology**

As technology advances in all aspects of our lives, the demand for careers in science, technology, engineering, and mathematics (STEM) hasincreased exponentially. However, many students find STEM challenging, and further, lack key experiencesto gain a sense of belongingin STEM and consider pursuing it as a career. Thus, providing STEM learning modules that introduce key concepts while engaging students can make an impact in addressing this need. A particularly difficult topic for students to understand is the relationship between cells and how the sequence and structure of proteins ultimately contributes to their function. In order to introduce these basic principles to introductory students, our team has constructed a virtual authentic-learning tool that utilizes data sonification in which each amino acid in a protein sequence is assigned a musical note and rhythmic value based on its hydrophobicity. This allows a harmonious musical piece to be composed based on the sequence of a functional protein. Disease-associated mutations become disharmonious which allows users to auditorily identify disruptions in a protein sequence and understand how it impacts the cellular symphony. We will present our preliminary survey data supporting our hypothesis that this data sonification learning module helps students gain an understanding of the molecular basis of disease while improving students attitudes towards STEM.

Abstract Name: Simulation of the Shear Flow Dynamics of Suspended Microscale Particles

Understanding the shear flow dynamics and wall interactions of non-spherical particles suspended in fluid media is important in a number of fields, from large scale phenomena like coastal erosion to mesoscopic and microscale applications such as additive manufacturing with fiber-reinforced composite filaments and shape-based separation of particles and biologicals.In particular,focusing on the geometric orientations of high-aspect ratio fiber-like particles suspended in low- and high-viscosity fluids transported through precision engineered pores with radially asymmetric geometries. This includes usinga combination of analytical methods and numerical simulations with computational fluid dynamics solvers ANSYS Fluent and STAR CCM+ to evaluate the ability of customized microscale pores with tapered sidewalls to orient and align fibers suspended in fluid media. We believe these results to also provide valuable insights into nanoscale applications such as the wafer-scale printing of aligned carbon nanotubes for microelectronic circuits.

Abstract Name: Investigation of Ventilation and Air Quality in Classrooms

The transmission of the coronavirus can be greatly impacted by indoor ventilation and air purifiers according to the U.S. Environmental Protection Agency and other public and private institutions and researchers. The concentration of aerosols in the air that contain the virus can be reduced by proper ventilation systems, which circulate and filter the air for increased quality. Aerosols with a diameter of2.5µm or lessare a possible carrier of SARS-CoV-2. PM 2.5 pollution may also increase the cellular expression of ACE2, associated with greater viral susceptibility. Ventilation to reduce PM 2.5 levels addresses both risks. Tests using incense as an indicator before, during, and after burning were used to see how quickly the ventilation in the rooms was able to remove excess PM 2.5. A calibrated DustTrak II monitor was used to record particulate matter, then Honeywell HEPA air purifiers were emplaced to see if further purification would aid in ventilation compared to only an HVAC system. Room air exchange rates (ACH, hr-1) were calculated using a spreadsheet by Jimenez at UC-Boulder. ACH rates in a small (15 person) meeting room were 5.88 hr-1 with HVAC alone and 16 hr-1 with two added air purifiers. Corresponding rates in an average (35 person) classroom were 9.62 hr-1 and 12.0 hr-1 with a single purifier. In this case, HVAC and air purifier coverage was 1.25–2.72 times as efficient as just HVAC coverage. Results for local weightlifting rooms are currently being investigated and will be included. A limitation of this research was the occasional pooling of incense smoke near the opening of the air monitor leading to a temporary spike in PM 2.5 levels. Use offans can address this issue. HEPA air purifiers reduce PM 2.5 levels and in turn may help lessen transmission risk of SARS-CoV-2 aerosols and airborne viruses

Abstract Name: **The Cardiorespiratory Response while Nordic Walking vs. Regular Walking Among Middle-Aged to Older Adults**

Background/Purpose: Around 60-80% of waking hours for adults are spent in sedentary behavior while physical inactivity accounts for 9% of all deaths worldwide. Furthermore, there is a strong dose-response relationship between physical inactivity and all-cause mortality, cardiovascular health, and metabolic health. Recently, Nordic walking (NW) has been introduced as a superior mode of exercise where one can increase energy expenditure due to increased engagement of upper body musculature while walking at a moderate intensity pace. NW is like regular walking except for using walking poles. Within established findings, most work has been done in a laboratory which can interrupt natural NW mechanics. Therefore, the purpose of this study was to measure the cardiorespiratory and energy expenditure differences in Nordic walking and regular walking in a field setting. Methods: Twenty middle-aged and older adults participated in this study. Each participant's initial session included Nordic walking familiarization, 10-m gait speed test, and a peak oxygen uptake (VO2peak) test. The two exercise sessions consisted of either NW or regular walking on an indoor track for 30 minutes. All metabolic variables were measured via the COSMED K5. Results: A paired-sample t-test revealed a significant difference between NW and regular walking for %VO2peak values (p = .008), kcal·min-1 (p = .005), and total kcal expenditure (p = .001). No significant difference was found for preferred gait speed (p =.485) between NW and regular walking. Conclusion: NW is superior to regular walking in eliciting a higher %VO2peak despite similar walking speeds, a higher kcal·min-1, and greater total kcal expenditure. In turn, these data agree with previous research and supports the use of NW to increase energy expenditure to potentially prevent the risk of one's metabolic and cardiovascular risk.

Abstract Name: **Keeping Shelters in Place: Understanding the Impacts of Residential Landlord Decision-Making on Post-Disaster Housing Stability**

The COVID-19 pandemic illustrated the vulnerability of tenants and the challenge of maintaining rental housing stability in the face of disaster and other shocks to the local housing market. As one piece of a larger, 3-year study investigating rental property owner decision-making across the stages of the disaster management cycle, this research focuses specifically on the narratives of challenge and post-disaster resilience from within the rental housing industry. It asks two research questions: (1) How did the rental housing industry respond to the challenges created by the COVID-19 pandemic? and (2) How has the industry changed as a result of these experiences?" Using interviews with industry representatives from 5 states as well as archival research from industry publications as well as local media, this study identifies key themes in how the rental housing industry frames the problem of rental housing stability and the solutions it puts forward for addressing the challenge.It is our hope that the findings of this study will assist local government officials and other stakeholders in the city and region in developing pragmatic response strategies to allow cities to recover fast and be resilient to future disaster scenarios.

Abstract Name: **A Feminist Defense of Obsession as a Moral Emotion**

One aim of feminist ethics and moral psychology is to morally redeem various emotions traditionally understood to be “detrimental” or otherwise “negative.” Following these pursuits, I attend here to the moral value of “obsession,” which has not yet been given adequate consideration as a morally significant emotion. I focus here on a particular kind of obsession, distinguished from existing understandings of obsession in both psychological and philosophical literature, that is non-clinical and ego-syntonic in nature. To show the moral value of non-clinical, ego-syntonic obsession, I extend four common defenses—found in feminist moral psychology—of other “negative” emotions, such as anger, bitterness, and contempt. In extending these defenses, we see that non-clinical, ego-syntonic obsession can be morally valuable for the same reasons feminists have defended other emotions. I conclude that by not acknowledging the moral value of obsession, feminists deprive themselves of an important line of argument for our existence as valuers.

Abstract Name: **Resiliency of power network under wind event.**

The power grid in the United States faces threats from hurricanes and natural hazards events. Every year, power outages cause millions of dollars to the national economy. Increasingly natural hazards events pose the threat of widespread disruption as demonstrated in 2020, when Iowa was hit by a derecho, causing substantial damages not only to properties but also caused widespread power outages across the state. The Iowa Department of Homeland Security and Emergency Management reported that there were more 480,000 power outages and wind speed as high as 140 mph. The goal of this project therefore is to quantify the resiliency of electric power network during extreme wind events under an evolving climate change. Using a 13-year climate data, our research will model the effect of wind above 20 meters per second andmodel the effect of these winds on the physical infrastructure of the power network.

Abstract Name: **THE EFFECTS OF SCARCITY ON VACCINE UPTAKE: AN EXPERIMENT**

Increased rates of vaccine hesitancy are one of the top ten threats to global health (World Health Organization, 2019). Those who are vaccine hesitant may be more susceptible to communication strategies to encourage vaccination (e.g., Shoots-Reinhard et al., 2022). Vaccine hesitancy may be reduced via changing beliefs about vaccines (e.g., Brewer et al., 2019). Brock's scarcity principle (1968) suggests that the scarcity of an object increases consumers' preference for it, a possibility that has been supported in over 40 studies showing that an item's perceived value can be increased by promoting its scarcity (Lynn, 1991). We suggest that scarcity messaging may help overcome vaccine hesitancy. Pereira et al. (2021) found that when vaccines were scarce, vaccine intentions decreased. However, they tested the COVID vaccine, which is politically contentious, and they were unclear whether at-risk people had already been vaccinated. Moreover, they only tested supply-based scarcity (i.e., vaccine is limited due to low resources) when demand-based scarcity (i.e., popularity of vaccine) has been shown as more effective in consumer behavior research due to the bandwagon effect (van Herpen et al., 2009; Verhallen; Robben, 1994; Worchel et al., 1975). We will use a national sample to test our following two hypotheses using a 2 (scarcity level) x 2 (scarcity type: supply or demand-based) experiment: 1) higher scarcity will increase vaccine intentions, but particularly when scarcity is demand-based versus supply-based and 2) Demand-based (vs. supply-based) messages will mediate the effect of condition on vaccine intentions. We expect to find that scarcity does influence vaccine hesitancy, but that supply-based scarcity is less effective than demand-based scarcity. We further expect to show that risk perceptions, social norms, and attitudes will mediate the effect of scarcity on intentions.

Abstract Name: Examining the abundance, distribution, and behavior of Gray Seals (Halichoerus grypus) in the presence of white sharks (Carcharodon carcharias) off of Scatarie Island, Nova Scotia

Great white shark (Carcharodon carcharias) migratory patterns within the Atlantic Canada waters have been tracked and studied by the OCEARCH research team since 2018. As part of their migration, adult sharks typically spend most of the summer in the coastal waters of the Northern United States and Atlantic Canada. During this span, the gray seal (Halichoerus grypus) serves as an energy-rich food source for these apex predators. Gray seals form dense colonies on rocky outcrops near shore, but must travel to deeper water to forage. While traveling to deeper water, foraging, and returning to the colony, these seals are vulnerable to predation.Gray seals often congregate on “launch pads”, or shallow areas offshore of the colony, which they use as staging and return areas for their foraging expeditions. To examine the abundance of gray seals at a well-established colony in Nova Scotia, as well as the influence of nearby predators on seal behavior, small unmanned aerial vehicles (UAVs) were deployed off of Scatarie Islands. These UAVs were used to assess the abundance of seals, identify shallow water launch pads, and observe seal behavior. Data collection via drone surveillance provided high-resolution imagery of animal locations and behavior within the research area without disturbing the seal colony. The information gained through this study was then provided to OCEARCH to enhance their understanding of this popular white-shark feeding ground and assist with future fishing efforts.

Abstract Name: **Increasing the Accessibility of K-12 Music Education for Minority Students**

Music is a great tool for minority students to express themselves and their cultures. However, traditional music education practices centered only on Western classical music may diminish BIPOC peoples' sense of importance in broader society when they do not see themselves reflected in the curriculum. Limited school budgets and program offerings particularly affect low-income children, a disproportionate number of whom are BIPOC individuals, and further complicate the music education these students receive in public schools. In order to better understand the curricular offerings and opportunities available to students of color, I surveyed K-12 public school music teachers (N = 16) to determine any recurring financial and administrative issues or problems within the community that could adversely impact students' participation in music. The respondents noted less administrative and familial support of music education in schools with high minority populations. Further, teachers had varied opinions about prioritizing non-Western art music in their own classrooms. The findings suggest that implicit bias may be present in public schools and that those in positions of power in schools can negatively affect the learning potential of minority students. Through ethno-pedagogical practices, music education may be able to positively contribute to higher musical achievement by minority students and to further diversify the music field.

Abstract Name: **Examining Low-Income Household Shopping with Supplemental Nutrition Assistance Program Benefits at the Eau Claire Downtown Farmers? Market Using the Market Match Incentive Program From 2018-2022**

Food insecurity is a significant issue facing many American households. The Supplemental Nutrition Assistance Program (SNAP) provides increased access to food for families in need. Additionally, fruit and vegetable (FV) consumption has been shown to improve health and reduce the risk of a variety of chronic diseases. However, poor nutrition among children and adults, including low FV intake have contributed to rising rates of obesity among US children which have been shown to persist into adulthood. It is particularly challenging for low-income households to purchase/eat the recommended amount of FV. Farmers' markets offer a wide variety of fresh, local and healthy foods, especially FV, but data show that low-income households are much less likely to shop at farmers' markets. The Eau Claire Downtown Farmers' Market (ECDFM) sponsors a Market Match Program (MMP) incentivizing SNAP households to shop at the market. In 2020, COVID-19 increased the number of families facing food insecurity while the ECFM also faced challenges regarding how to operate safely. This poster uses administrative data to analyze shopping by SNAP households at the ECDFM using the MMP between 2018-2022. The number of SNAP households shopping at the ECDFM increased in 2020 and 2021 while the associated spending also increased in both years as the SNAP caseload was rising due to the pandemic. As the SNAP caseload declined to about the same level as in 2020, the number of SNAP households shopping at the ECDFM using the MMP and the corresponding spending declined in 2022. The remainder of this study provides more detailed results regarding the patterns in SNAP household shopping at the ECDFM using the MMP over this period. This poster is connected to a another submitted poster analyzing a variety of data from surveys of SNAP households shopping at the ECDFM using the MMP during these years.

Abstract Name: **Polyethylene Upcycling via Hydrogenolysis with an MCM-48 Silica Core-Shell Catalyst**

It is difficult to overstate the importance of synthetic polymers to our industrial society. Plastic is nearly ubiquitous in its presence throughout human activities, and the demand for plastics is projected to rise in the coming decades. However, the stable chemical properties of plastics that give them such high utility are the same properties that make them notorious environmental pollutants. Thus, there is much interest in developing new strategies to eliminate or reuse plastic waste. One such strategy is to develop systems of chemical "upcycling," which is the conversion of plastic waste into other potentially useful chemicals. Upcycling is advantageous because it circumvents the downgrading effects that conventional recycling has on plastic products. Previous research has developed a catalytic system in which a platinum-loaded silica core-plus-shell catalyst converts polyethylene into smaller alkanes. This research demonstrates the changes in catalytic activity in polyethylene hydrogenolysis when the catalyst's core possesses MCM-48 silica morphology instead of the original solid silica morphology. Notable changes include greater selectivity to products with 9 to 57 carbon atoms. Catalytic activity was determined by proper mass balance, and reaction product distributions were analyzed with gas chromatography. The structure of the catalysts was characterized with transmission electron microscopy.

Abstract Name: **Modine Capacitive Liquid Level Sensor**

The purpose of this project is to create a capacitive liquid level sensor that will be equipped in automotives created by the Modine Manufacturing company. The Modine Manufacturing company would like to replace their current liquid level sensor with a new one that is more cost effective and has additional features. The current sensor costs Modine over eighty dollars per piece. The current sensor's only waterproofing is a sticker that must be removed to calibrate, and the sensor has no CAN communication. Modine would like our team to design a drop-in replacement for this sensor that has better waterproofing, CAN J1939 communication, and can be produced in house. The team is utilizing a pre-existing integrated circuit to save space, money, and time in the final design. Since the team will be implementing software calibration, we will be able to forgo openings for physical calibration and end with a far more water-resistant device. Much of our electronic design is complete and being followed closely by development in other areas of our project. The design of our power electronics is complete. Programming of the current IC, design of the sensor's internal PCB, and integration of CAN communication are all well under way. There are prototype devices being worked on and the group will soon be sending out Gerber files for final construction of our printed circuits. This device will be able to accurately measure and relay quantities of coolant inside automotive coolant tanks while remaining robust enough to resist liquid damage. It will be inexpensive to produce and feature up to date vehicle communication protocols.

Abstract Name: **Metal Speciation**

Metals in the natural environment exist in multiple forms or species including soluble organic and inorganic complexes, colloids, and free metal ions. According to the biotic ligand model, free metal ions are more bioavailable than other forms and are therefore considered to be more toxic. We studied the speciation of lead, copper, and mercury in the South Fork New River upstream and downstream of a wastewater treatment plant (WWTP) in northwestern North Carolina. Since WWTPs discharge dissolved organic matter (DOM), we expected metals downstream of the WWTP to be bound by DOM, making them less bioavailable but more likely to be transported throughout the environment. Anodic stripping voltammetry (ASV) with a boron-doped diamond electrode was used to quantify free metal concentrations. Surprisingly, in 2021, we found higher concentrations of free metal ions downstream of the WWTP, even though we expected the WWTP to discharge DOM capable of binding metals. More recent work in 2022, however, suggests similar free metal ion concentrations upstream and downstream of the WWTP. The complexing capacity of the South Fork, or its ability to bind free metal ions, is 5 parts-per-billion both upstream and downstream of the WWTP. We plan to study the seasonal variation in metal speciation and if pH or electrical conductivity impacts free metal ion concentrations and complexing capacity. We will also measure total metal concentrations using acid digestion and inductively coupled plasma-optical emission spectroscopy (ICP-OES).

Abstract Name: **Glyphosate and Dopaminergic Neurotoxicity: Herbicide Impacts on Parkinson?s Disease Development**

Nearly one million individuals in the United States are living with Parkinson's disease (PD). In the past two decades, the death rate from PD rose by about 63 percent in the United States. Major findings have been made in the past five years about the risk of glyphosate (N-(phosphonomethyl) glycine) exposure on the onset of PD symptoms. The purpose of this meta-analysis is to provide a compiled update on the chemical and biological alterations that glyphosate imposes on the human brain. To compile results regarding the association between glyphosate exposure to humans and PD onset, a meta-analysis was conducted to create a quantitative estimate of the connection between PD and glyphosate. Findings suggest that glyphosate exposure causes synaptic terminal alterations which affect the synaptic assembly and neuronal connectivity and glyphosate alters adaptation of gene expression by crossing the blood-brain barrier. Although it is widely accepted that significant alterations in vesicular handling of dopamine occur with exposure to Dichlorodiphenyltrichloroethane (DDT), it was recently found that glyphosate has similar mechanisms, showing a decrease in dendritic complexity and synaptic spine maturation in hippocampal neurons which are closely connected with basal ganglia nerve cells, the cite of dopamine production. Despite DDT being banned 1972, glyphosate still remains readily available for consumer use. The results of this study may be relevant for FDA officials to create safer regulations for this agrochemical.

Abstract Name: **Understanding the Neurophysiological Mechanisms of Anorexia Nervosa**

Anorexia nervosa is a disorder that stems from anxious thoughts and behaviors. Anorexia nervosa has the highest mortality rate of all psychiatric illnesses due to its chronicity and high relapse rate. This highlights a need for a better understanding of the disorder to be able to provide better treatment options. Neurologically, it has been found that periods of starvation lead to reduced anxiety-like behavior in rats. This finding raises the question of what neurobiological mechanisms are behind this reduced anxiety response. Hindbrain neurons, such as the GLP-1 neuron, have been found to have reduced activation during periods of caloric deficit. In addition, the hypothalamus-pituitary-adrenocortical stress response axis shows reduced activation in the hypothalamus during periods of fasting. This reduced activation in the hypothalamus inhibits the stress response and can provide short term stress relief when food intake is decreased. This feeling of a reduction in stress may cause an anxious individual to begin disordered eating in the first place, but as these behaviors continue, maintaining this extremely decreased caloric intake now becomes the source of stress rather than relief. A secondary hypothesis may be that the hypothalamus is involved in glucose regulation through the release of glucocorticoids, and so the hypothalamus may be hyperactivated causing an increase in release of glucocorticoids to compensate for a lack of glucose from food. It is important to understand the level of activation of the hypothalamus and hindbrain GLP-1 neurons to better understand the neurophysiological mechanisms in anorexia nervosa and to gain knowledge in hopes to produce a more effective treatment for anorexia nervosa. Our study aims to investigate how the brain processes stress during periods of caloric deficit by modeling anorexia nervosa using an activity-based anorexia model in rats and highlighting through immunohistochemistry which neurons in the hypothalamus and hindbrain are activated.

Abstract Name: **Synthetic Approaches to Prenylated Coumaric Derived Natural Products Against Type 2 Diabetes**

The natural product Plicatin B is found in the plant Artemisia Scoparia. This chemical compound features a unique structural combination of a p-coumaric acid and prenylated substituents. Plicatin B and it's family members have been reported to ameliorate the effects of type 2 Diabetes Mellitus (T2DM) through in vitro studies. T2DM occurs when the cells in the human body resist the normal effects of insulin, with the purpose of insulin being directing glucose from the blood into somatic cells. Incidences of T2DM have been steadily and significantly increasing in the United States, and for that reason, new therapeutic strategies are needed.
Herein, we present a synthetic strategy using a series of chemical reactions including the Wittig Reaction and Claisen Rearrangement, to develop an efficient synthetic approach to access Plicatin B. The chemical reactions will be conducted under anhydrous conditions in suitable organic solvents, and the products will be monitored by thin-layer chromatography (TLC). The reaction mixtures will then be worked-up with aqueous solutions, and after organic layer separation the solvent will be concentrated via evaporation. Finally, the residue will be purified via normal phase silica gel column chromatography and characterized via NMR spectroscopy.
The desired natural product will be compared to authentic samples available. Plicatin B and its derivatives will be tested via a broad range of in vitro, in vivo, and in silico assays to investigate their mode of action. It is anticipated that an efficient synthesis of Plicatin B and its derivatives will provide the answer to new, potentially therapeutic strategies to alleviate the detrimental effects of T2DM, as well as contribute to lowering the costs of current treatments.

Abstract Name: **Role of rats auditory cortex in processing relevant self-generated sounds during locomotion**

Imagine waking up at night and attempting to get a glass of water in the kitchen. You might need to pay extra attention to your footsteps to determine whether you are walking on the wooden floor of the kitchen or not. The ability to process self-generated sound (e.g., footstep) during locomotion has been debated to provide spatial cues for navigation. From previous research, the sensory-evoked responses of the auditory cortex–a region of the brain that processes acoustic information–are found to be suppressed during locomotion. Yet, this suppression of auditory cortical responses could be explained by the lack of relevance or meaning of the sound to the animals' behaviors. On the other hand, the underlying role of the auditory cortex in processing relevant, self-generated sounds during locomotion remains mostly unclear. With a focus on rats as an animal model, we apply chemogenetic techniques to selectively inactivate rats' auditory cortex and compare their performance with normal rats in a spatial navigation task. We anticipate that the rats with inactivated auditory cortex will perform worse on the navigation task than the normal rats. This reduction in task performance will be consistent with our hypothesis that rats are utilizing their auditory cortex to process relevant, self-generated sounds during locomotion. However, if no such performance difference is observed, we hypothesize that the rats form an internal mapping system during locomoting. Instead of utilizing the relevant self-generated sound as external navigation cues, rats are monitoring their spatial location through internal cues such as vestibular, proprioceptive, and motor efference information, or other sensory cues.

Abstract Name: **"What's That Sound?": A Versatile, Robust, and Lightweight Convolutional Transformer for Environment Sound Recognition**

The conventional hearing aid is both costly and limited in usage, as it is not intended to detect non-speech audio. Our objective is to develop a machine-learning solution to provide a more accurate and affordable mechanism to identify surrounding sounds to improve the safety of the hearing impaired, i.e., if a car is honking behind pedestrians, or a gunshot is fired, and they need to move away from the source. By adding randomized augmentations to audio, concatenating a Mel-Frequency Cepstral Coefficients (MFCCs) diagram and a log-mel Spectrogram, and embedding Convolutional Neural Networks (CNNs) into a Transformer architecture, the Randomized Audiomentational Layered Convolutional Transformers (RALCT) model efficiently extracts features from diversified audio representations. In addition, RALCT is small enough, with only approximately 310,000 parameters, to be deployed into mobile devices. Experimental results on the UrbanSound8K dataset resulted in an accuracy consistently over 93% for all variations of RALCT, with the highest at 94.56%, reaching state-of-the-art levels in the audio processing machine learning research field. To leverage the capabilities of this technology, a mobile app is developed to be integrated with the model to provide real-time safety control. RALCT thus represents a robust, lightweight, affordable, and versatile deep learning tool to aid the navigation and safety of the hearing impaired.

Abstract Name: **A Universal, Efficient Deep Learning Approach to Various Cancer Detections from miRNA Expressions**

According to the National Cancer Institute, approximately 39.5% of individuals globally will be diagnosed with cancer at some point during their lifetimes. Among all cancer types, it is found that breast, kidney, liver, lung, and thyroid are among the most common, with over tens and even hundreds of thousands of new cases annually. As cancer is both a common and life-threatening disease around the world, there poses a question of how best to predict, detect, and diagnose cancers. Recently, microRNAs, or tiny noncoding miRNAs, have been discovered to be critical biomarkers for detecting various forms of cancers, as they result in different expressions in normal and cancerous tissues. Because a certain set of these miRNAs have been linked to specific cancer types, we develop, train, and optimize two different robust deep learning algorithms, Random Forest and XGBoost, to perform miRNA feature selection by first including only significant miRNAs then classifying between tumor and control on miRNA
datasets for quick and convenient identification of cancers. We performed studies on six different cancer types and experimented with both complex and simple versions of machine-learning models. Experimental results demonstrate a 95.536% state-of-the-art average binary classification accuracy across all seven datasets for both models, proving both the miRNA's useful indication of cancer and the promise of deep learning approaches for future research into robust and generalized prediction mechanisms of cancer. Our full process utilizing the R programming language, including datasets, trained models, and results, are available at
https://github.com/TheClassicTechno/miRNACancerClassification.

Abstract Name: **Relative Clause in Tibetan**

The aim of this study is to analyze the formation of Relative Clauses (hereafter RC) in Central Tibetan (Phjuik). Previous studies have suggested that the Tibetan relativization is a type of nominalization with multiple variations (pa, sa, mkhan, yag; DeLancey 1999). We elicited 328 words and sentences from two Central Tibetan speakers. Their ages range from late 20 to early 30, both from India, currently living in the United States. The current study confirms and extends previous findings in two ways: (1) Out of 4, three variants were confirmed, and (2) an additional vowel /i/ was found to follow the three variants, resulting in pronunciation change. As DeLancey (1999)'s data is from a female speaker in her 60's, the variant lost and a vowel addition could be due to a generation difference. An alternative explanation, especially on the /i/ vowel addition was explored in detail. /i/ vowel also appears in other noun phrases (hereafter NP), such as possessive NPs and genitive NPs. As RC is a type of NP in Tibetan, we propose that RC should be analyzed as a type of case, similar to possessive case and genitive case. The advantage of this proposal will be further discussed in terms of grammatical paradigm uniformity.

Abstract Name: **Exploring the Perceptions of Pre-Health Students who Engage in an Interdisciplinary Approach to Learning**

Background/Significance: Interprofessional education involves two or more health professions that collectively create and cultivate a collaborative learning environment with the goal of creating skills and attitudes that result in desired team behaviors (Buring et al., 2009). Minimal opportunities exist for interdisciplinary collaboration between pre-health students at liberal arts institutions, particularly nursing and athletic training. This may potentially hinder creativity and skill development essential for successful patient care. Creative pedagogical strategies that develop interprofessional collaboration abilities are needed at institutions where there is limited opportunity for actual interprofessional collaboration. Purpose: The purpose of this research study was to explore the perception of pre-health students who engaged in an interdisciplinary approach to learning. Methods: This qualitative study utilized Elo and Kängas' (2007) descriptive content analysis approach to complete a secondary analysis of group exam reflections from an unfolding case study. Ninety-three pre-health student responses were analyzed at one rural, liberal arts college in the Midwest. The reflections consisted of two open ended questions about working in groups, focusing on the effectiveness of the group, behaviors, and application to future professional roles. This study was exempt from IRB oversight. Findings: Preliminary findings indicate that open respectful communication, open mindedness, and working with a team with different skills/perspectives were behaviors that positively impacted collaboration. Students indicated the need to integrate these behaviors when working with other health care professionals to maximize learning resulting in comprehensive patient care.

Abstract Name: **Musical Ekphrastic Poetry: Writing for Social and Intellectual Listening**

In his article "What is Ekphrasis For?," Simon Goldhill writes that ekphrasis "is designed to produce a viewing subject. We read to become lookers, and poems are written to educate and direct viewing as a social and intellectual process." While ekphrasis traditionally refers to poetry written in response to a work of visual art, including W.H. Auden's "Musée des Beaux Arts" and William Carlos Williams' "Landscape with the Fall of Icarus" in reference to Pieter Brueghel the Elder's paintingLandscape with the Fall of Icarus, ekphrasis may also refer to poetry written in response to music. Thus, in musical ekphrastic poetry, we read to become listeners, with ekphrastic poems serving to direct this listening as a social and intellectual process. Poems from Langston Hughes' collection The Weary Blues might provide models for this type of ekphrastic poetry based on jazz music. Indeed, Hughes' ekphrastic-type poems direct the listener to engage more fully with the musical genre through the presentation of its social context. Following a similar purpose, I will research the social, historical, musical, and literary contexts of a series of solo classical piano works of contrasting styles, nationalities, and periods (by Bach, Clementi, Liszt, and Prokofiev, for example). Following the example of Hughes, Williams, and Auden, I will write my own ekphrastic poetry based on these musical works, engaging with these contexts as well as the formal structure, musical language, and style of the works in order to guide listeners in social and intellectual listening. Unlike visual art, in which viewers and creators are distinct, those who experience musical works—the listeners—include both the audience and performer. Thus, I intend to explore through these poems how musical ekphrasis might also guide the listener-performer through the practice and presentation of the musical work.

Abstract Name: Low-cost Multispectral Camera for NIR Imaging Analysis

Low-cost multispectral imaging is critical for applications in agriculture, infrastructure, and disaster planning by enabling detection of information beyond human vision or Red-Green-Blue (RGB) cameras. Most of these applications use an Unmanned Aerial Vehicle (UAV) as a platform to carry the sensor payload, and thus require lightweight and inexpensive imaging systems. The current study aims to develop and test a simple, low-cost, yet reliable multispectral camera payload for target detection. By extending the 400 to 700nm range of visible light, we can highlight features that are otherwise unnoticeable by the human eye or digital camera, such as soil moisture levels. Through the development of a low-cost multispectral imaging payload, we will harness near infrared wavelengths for target identification purposes. The camera is developed around a Raspberry Pi (RPi) 4B computer and four different Pi camera modules: two RPi RGB modules and two RPi NoIR V2 camera modules. A python script adapted from existing packages is used to trigger each camera synchronously, simulating flight computer-controller automated data capture. To highlight different wavelengths in the captured spectrum, the NoIR camera modules have been modified by adding either a red or blue gel filter. We will report on ground testing on targets of various sizes, materials, colors, and temperatures to determine detection accuracy. The captured images will be compared against the images taken from a commercial off-the-shelf multispectral camera.

Abstract Name: Embedding social science research in an undergraduate communication course

In this presentation, I will describe and share open educational resources for a semester-long social science research project in an undergraduate communication theory course. This project 1) enables students to understand how theories connect to everyday practices, and 2) gives students practice using ethnographic and discourse analytic methods. More specifically, students are asked to conduct participant observation, write fieldnotes, and analyze media around one communicative context that they are interested and involved in (e.g., sports, friendships, professional communication). Scaffolded activities shared in this presentation invite students to note and analyze how people communicate in these contexts and what people say about communication in these contexts. After gathering data for several weeks, students are then asked to articulate and evaluate practical theories of communication (Craig, 2006)–that is, everyday ideas about what communication is, does, and should be/do–that are evident in the context they studied. Through this project, students become theorists as well as researchers and gain an appreciation for the real-world roots of academic theories.

Abstract Name: **The Effect of Abortion Policies on Maternal Income and Employment Status**

In the United States of America, state-specific restrictive abortion policies could impact maternal employment status and income. The overturn of Roe v. Wade in 2022 has led abortion to become the subject of debate that heavily differs within each state. From, 2015 to 2019, each U.S. state was allowed to enforce its abortion policy providing it adhered to the federal statute of an allowance of abortion before viability (≈ 24 weeks). This statute also deemed that the state could not place regulations on abortion at all within the first trimester (≈12-13 weeks). In the second trimester (post-first trimester, but pre-viability) the state could regulate but not ban abortion. This freedom permitted states to enforce the federal statute with a restrictive gestational week limit, or apply a nonrestrictive statute enforcing their own longer gestational week limit. Using the state-level data on gestational week limits, this paper estimates the impact of restrictive abortion policies on maternal employment status and income within various education and socioeconomic groups. The expected outcome is that restrictive abortion policies lower maternal income and employment status.

Abstract Name: **The Communal Story of Faith and Game: A Defense of Dungeons & Dragons from a Christian Perspective**

Fictional storytelling has often been viewed suspiciously by Christians, and fantasy role-playing games like Dungeons and Dragons (D&D) are often viewed most skeptically, as people claim that these games lead to occultism, satanism, and escapism. This paper will explore the idea that, because D&D is centered around the act of communal storytelling, it contains the potential to be a creative Christian practice. The argument presented in this paper is based on a Christian defense of literature, which will then be expanded upon by exploring the importance of oral storytelling and community in Christianity. Part of the argument will be devoted to arguing against unsavory allegations made about D&D, but it will focus primarily on the positive aspects of D&D, such as the potential to increase empathetic understanding within Christians. One essential aspect of Christian practice is community with other believers, and D&D's primary focus on communal, collaborative storytelling allows one to practice this aspect of their faith in a unique way. To examine the importance of community in storytelling, this paper will also examine the friendship between J. R. R. Tolkien and C. S. Lewis, two Christians whose collaborative relationship was essential to their writing. Achieving a new perspective on D&D is important because it is a game that is still viewed skeptically by Christians today. In particular, this paper will examine the aspects of communal practice in Christian faith, Christian empathetic response, and the imago Dei. The argument presented will show the ways in which D&D can help Christians understand these topics more fully and provide a setting where these qualities can be practiced.

Abstract Name: **Monitoring Antibiotic Resistant Populations as a Correlative to Water Quality**

Agricultural land use can have adverse effects on the surrounding waterways, which may cause environmental and economical disturbances including but not limited to species assemblage disruption, loss of habitat and wildlife and human health impacts. There is a need to monitor in vivo aquatic systems, specifically those in agricultural areas, to not only provide a more holistic view into the correlation between agriculture land use and aquatic environmental disruption but also to develop more succinct and effective monitoring and management guidelines. The Blanchard River serves as an excellent model system suitable for monitoring antimicrobial resistant microbe sustainability within a highly agricultural area that serves as a contributor to the Lake Erie basin. Several indicators suggest that the Blanchard River watershed may provide a suitable habitat for the antibiotic resistant microbes including MRSA (methicillin resistant S. aureus). Outside nosocomial infections, minimal research has been completed to determine the reservoirs of MRSA and other resistant microbes. One hundred and twenty-six sites within the Blanchard River and its tributaries were monitored for antibiotic resistant microbes including MRSA. All sites had antibiotic resistant populations while twenty-six of the sites harbored MRSA. Sixteen Areas of Concern (AOCs) were chosen in conjunction with the Blanchard River Watershed Partnership to determine if traditional water quality measures of E. coli concentrations,nutrient levels and macroinvertebrate populations correlate with antibiotic concentrations and resistant populations. Additionally, microcystin concentrations were measured as they are known to enhance horizontal transfer of antibiotic resistance genes. There is no correlation between land usage or antibiotic concentrations and the presence of antibiotic resistant microbes. There were weak correlations between antibiotic concentrations and pollution resistant macroinvertebrates and a weak negative correlation between E. coli levels and pollution sensitive macroinvertebrates.

Abstract Name: **On the Correlation Between Political Beliefs, Individual Demographics, and Sexual Fetishes**

Although sexual fetishes are relatively common and well-known, there is a vacuum of research surrounding the subject. The majority of the literature that exists focuses on trauma or stigma surrounding fetishes. This research project aims to close this gap of information by studying demographic and political correlations of those who practice fetishistic behavior. While all these factors were considered, identifying if there was a correlation between political identity and fetish interest levels was the original objective of this research. A total of 138 participants responded to a survey, 111 of whom answered all questions, that included questions about age, sexual identity, sexual orientation, political identity, and fetish interest levels. The responses from the 27 participants who did not complete the survey were ignored. The survey was distributed across Reddit and a server on Discord as a means of reaching a variety of subjects. The survey was initially posted on r/SampleSize, but because it had a significant liberal skew in results, it was also posted to r/AskConservatives to obtain an adequate sample of the key demographic.

Abstract Name: **Challenges to the Ability of EMS Systems to Locate an Emergency in Low-Resource Settings: A Qualitative Study**

Introduction: Efficient pre-hospital emergency care can significantly improve healthcare outcomes. Difficulty locating the emergency is a significant challenge that contributes to inefficiency in pre-hospital care. The goal of this study was to describe challenges emergency medical response (EMS) teams face in Rwanda locating emergencies and to explore potential opportunities for improvement. Methods: We conducted 21 in-depth interviews with four stakeholder groups representing the EMS response system in Rwanda: ambulance dispatchers, ambulance field staff, receiving hospital staff, and policymakers. Semi-structured interview guides covered participants' perspectives on the challenges EMS systems face in locating an emergency, how challenges impact quality of pre-hospital care, and what opportunities exist for process and tool development. Audio recorded interviews lasted 30-90 minutes each. Transcripts were coded using NVivo into three domains: the process of locating an emergency, impacts of challenges, and opportunities for processes and tools. Results: The current process of locating an emergency was hampered by the lack of supportive technology, the dependence on individual's local knowledge to describe the location, and inefficient communication channels to share location details between parties (caller, dispatch, ambulance). Three themes emerged related to the impact of challenges in locating an emergency: increased time response, inconsistencies in rapid response based on an individual's knowledge of the area, and inefficient communication between the caller, dispatch, and ambulance. Three more themes emerged related to opportunities to improve efficient location of emergencies: technology to geolocate an emergency accurately and better time response, improvements in communication to allow for ambulance access to real-time interaction between the caller and dispatch, and better location data from the public. Conclusion: Timely EMS response is essential for optimal clinical outcomes, but significant challenges exist in locating emergencies. There is an urgent need to implement locally relevant solutions to improve the efficient location of emergencies in Kigali, Rwanda.

Abstract Name: **Biocides Effective Against Potentially Human-Pathogenic Gym Microbiota**

Potential human pathogens were previously found at the University of West Florida Health, Leisure and Sports Facilities. These microorganisms include bacteria, such as Escherichia coli and Staphylococcus aureus, lipid-dependent human-associated yeasts, such as Malassezia spp., and keratinolytic skin molds, all of which may affect health of gym users, supporting effective sanitization. Malassezia spp. inhabit hair follicles and skin folds of humans and exacerbate acne and cause other skin diseases. Keratinolytic skin molds digest the protein keratin of skin, hair, and nails to cause "tinea" diseases such as athletes' foot, ringworm, and nail infections. Effective sanitization can improve safety of gym facilities. During a previous project, we found that Quat-Stat SCTM, the disinfectant used at the HLS facilities, was effective in controlling growth, and therefore spread, of the microbes listed. Quat-Stat is a proprietary mix of quaternary ammonium salts described on the label as a "disinfectant, virucide, fungicide, and a control against mold and mildew." Results from our previous work supported that Quat-Stat is effective in inhibiting the growth of E. coli and S. aureus but was not effective against M. furfur. Household bleach consistently performed better than Quat-Stat, but was not considered a better product because of its unpleasant odor and potential harm to users' skin. In this study, we broadened prior knowledge by evaluating additional disinfectants being used at the HLSagainst these pathogens, along with exploring other biocides, especially "-azoles" (e.g., clotrimazole, an antifungal medication), found in products targeted to consumers for treating conditions caused by some of them. We tested selected biocides using Kirby-Bauer Disk Diffusion to identify promising agents, and Phenol Coefficients to assess their efficacy. Certain chemical classes of biocides had greater in vitro inhibitory effects on skin yeasts and dermatophytic fungi than others.

Abstract Name: **Knowledge and Awareness of Naloxone Training among Dental Professionals**

Purpose: Due to the significant prevalence of dental anxiety, many people decide to self-medicate in order to cope with their fear of being in a dental chair. As a result of this and a rise in opioid use nationwide, dental professionals are increasingly likely to see the misuse of these substances. They must be equipped to handle any related medical emergencies .Methods: After institutional review board approval, a cross-sectional, web-based, anonymous survey was sent via a closed social media group for dental hygienists across the United States. Descriptive statistics were used to describe the dental hygienists' knowledge and awareness of naloxone and formal naloxone training. The short survey was administered with the data collection tool, Qualtrics with a convenience sample size collected. The data collected through our survey participants will be analyzed on statistical software, SPSS. An evaluation of the knowledge and awareness of naloxone training among dental professionals will be determined using a Chi-square analysis, Mantel-Haenszel test and Mann-Whitney test to interpret our findings. Results: Results are pending statistical analysis. Conclusion: Initial conclusions determine the knowledge and awareness of naloxone training among dental professionals is lacking and needs to be reviewed and improved. Further conclusions are pending additional statistical analysis using the software, SPSS.

Abstract Name: **Phragmites australis Sexual Reproductive Effort: Potential for Hybridization and Recovery Following Die-back in the Lower Mississippi River Delta**

Phragmites australis is a crucial plant for promoting coastal wetland soil stability. In the Mississippi River Delta, it is threatened by a recent case of die-back. Phragmites typically reproduce asexually through underground rhizomes, but recent studies point to the importance of sexual reproduction through pollen and seeds in die-back sites. Sexual reproduction is critical for stressed plants because it increases genetic variability and their capacity to overcome environmental stressors, as recently found in die-back regions in Europe. If similar trends are found in the Mississippi River Delta, then recruitment through seed and hybridization between lineages (Gulf, Delta, and European) could present a promising mechanism forPhragmites regeneration following die-back. We tested for increased sexual reproductive effort in die-back sites and hybridization potential by determining flowering time and collecting and staining pollen from the three lineages.With regards to reproductive effort in recovering dieback sites, we found significantly greater pollen viability in recovering European-type dieback sites as opposed to healthy sites, indicating a relatively high capacity for sexual reproduction in this lineage. Gulf-type Phragmites anthers completely lacked pollen, while Delta-type Phragmites showed very low pollen production. Flowering periods for Gulf-type and Delta-type overlap in the late fall, suggesting hybridization may occur if either haplotype ever produces viable pollen and ovules. However, European-type Phragmites flowered much earlier, producing pollen from June-August. These data, combined with evidence for temporal isolation from different flowering times, suggest that hybridization between Phragmites haplotypes in the lower MRD is unlikely. With regards to broader impacts for Louisiana coastal restoration, our study suggests that finding a cross-lineage Phragmites hybrid will not be a viable method for die-back site restoration, while greater overall pollen production and increased pollen production following die-back suggests that European-type Phragmites patches have potential to recover from dieback through sexual reproduction.

Abstract Name: **Changes in Parental Responsiveness across the Reproductive Cycle in the Biparental California Mouse**

In mammals, maternal behavior is activated by hormonal changes occurring during pregnancy and lactation. Females typically become highly attracted to infants at the end of pregnancy, whereas attraction to infants can wane across the lactational period. In many rodents, however, females gestate and lactate concurrently; it is not clear how maternal responsiveness changes in these species. Moreover, very little is known about fathers' responses to infants across their mates' reproductive cycle. We characterized the parental behavior of mothers and fathers across overlapping gestation and lactation periods in the monogamous, biparental California mouse (Peromyscus californicus), in which females are usually both pregnant and lactating and fathers perform comparable amounts of offspring care as mothers. Each parent was introduced to a young, unrelated pup for 10 minutes at four different time points across pregnancy/lactation, and behavior was compared across time points and between the sexes. Behavioral responses to pups did not change significantly across time points in either sex. At all four time points, however, fathers spent significantly more time than mothers performing parental behavior (i.e., licking, grooming, and huddling) toward the stimulus pup. These findings suggest that concurrent lactation might inhibit the rise in maternal responsiveness that would otherwise occur during late pregnancy, and that parental responsiveness toward infants is higher in breeding males than females in this biparental species.

Abstract Name: **HVAC Design of a Performing Arts Center to be Located in Sidney, Australia**

This work was done as an entry tothe 2022 HVAC Design Calculation Competition being held by the American Society of Heating, Refrigerating and Air-Conditioning Engineers (ASHRAE). The complete HVAC design calculations were performed for a large (over 200,000 ft2, over 500 spaces) higher education performing arts building placed in Sydney, Australia.The calculations required the analysis of heating and cooling loads, and determination of the necessary airflow to each space based on usage and size. The HVAC system was then designed and optimized to maximize the building energy efficiency. The project demonstrated compliance with four standards from ASHRAE: 55, 62.1, 90.1, and 189.1, which are thermal comfort, ventilation for indoor air quality, energy standards, and high efficiency, respectively. As first steps, load calculations were performed by hand to find peak amounts of cooling required, and the necessary airflows were determined to meet the required ventilation levels. Next, the use of Carrier's Hourly Analysis Program (HAP) allowed for a more robust look at each of the five hundred and forty-four rooms. This allowed for structural coordination of placing a roof top unit to serve half of the top floor of the building. Special consideration was given to energy efficiency and sustainability. The energy intensity usage was found to be 27.8 kBtu/ft2 which is compliant with expectations from the New Buildings Institute to be within 30 kBtu/ft2. Overall, the project came together to generate detailed floor plans of the entire building and a detailed model to represent the finalized building layout.

Abstract Name: **Molecule Tilt Angles and Varying Temperature Environments in Self Assembled Monolayers (SAM)**

The sub-nanometer odd-even parity effect on self-assembled monolayers (SAMs) acts oppositely with Ag-based and Au-based substrates. Previous studies investigating this have examined surface roughness characteristics with probing liquids ranging in polarity. These studies failed to consider the effect of surface density on monolayer tilt angle. In this work, we used Ag- and Au-based substrates and varying temperature environments to investigate this odd-even parity further. We report the wetting behavior of SAMs by investigating contact angle of a polar and nonpolar probing liquid on Ag and Au-based substrates in different temperature environments. Polar probing liquids showed a larger disparity between substrates at lower temperatures, and increased temperatures showed converging contact angle measurements. Nonpolar probing liquids showed opposite behavior, diverging as they increased. Based on these observations, we propose that surface roughness is not solely responsible for wetting behavior differences between substrates, and we conclude that there exist temperature-sensitive differences in molecule tilt angles that partially determine SAM behavior.

Abstract Name: **Watermelon Malate Dehydrogenase and Two Mutants**

Malate Dehydrogenase is an enzyme found in the glyoxysomes and mitochondria of plant cells. In glyoxysomes, Malate Dehydrogenase is part of the glyoxylate cycle which converts fatty acids to sugars. In the mitochondria, Malate Dehydrogenase is the last enzyme of the citric acid cycle. The citric acid cycle produces NADH and FADH2, two essential reactants in the electron transport chain for generating cellular energy. Malate Dehydrogenase catalyzes the reversible oxidation-reduction reaction of malate and NAD+ to oxaloacetate and NADH. Malate Dehydrogenase or MDH is an enzyme that converts fatty acids to sugars in glyoxysomes and catalyzes the reversible oxidation-reduction reaction of malate and NAD+ to oxaloacetate and NADH in the mitochondria. This study aims to investigate the effect of two mutations, D132A and R124K, on the activity of glyoxysomal watermelon MDH and determine the role of these two amino acids in the structure of the enzyme. We hypothesize that R124K will decrease activity due to broken intermolecular forces between the enzyme and substrate/ cofactor for R124K. D132A will also decrease in activity because of a disruption of a hydrogen bond in the loop region, which may affect the ability of the loop to close effectively. PYMOL was used to generate the mutated protein structures of 1SMK, and the lowest energy conformations were identified using SPRUCE and SZYBKI. The effects of the mutations were analyzed using computer modeling by superimposing the mutated versions on the crystal structure of the human mitochondrial MDH (4WLU). The activity of the mutants was compared to the wild-type using kinetic assays.In conclusion, the initial rates, specific activity, and turnover numbers calculated for the two mutants were significantly lower than the wild-type confirming that both mutations hindered the wild-type's activity efficiency.

Abstract Name: **Human Scent Analysis in Support of Tracking Dogs**

Tracking dogs can follow the scent of a person for more than a mile after they have left the trail. The current scientific hypothesis about how this is possible involves dogs smelling the volatile organic compounds (VOCs) that emanate from dead skin cells shed as a person moves. However, data from tracking dogs is not admissible in a court case as it is not understood how this scientifically occurs. Our data involves swabs of an individual's left and right arms, using the technique of Gas Chromatography Mass Spectrometry (GCMS) to identify and analyze the amounts of compounds that make up a scent. We have found that the data of an individual's left and right arms is more correlated than two random people in the data set, suggesting that each individual has a unique scent profile. Through the comparison of left and right arms from the same individual we have noticed the same compound is not present in both due to the necessity of the GCMS reaching a threshold amount for a compound to be recognized. Using Principal Component Analysis (PCA) we found that 23.1% of the variation in individuals can be explained through the first two principal components. PCA has also determined that heptanal, acetone, and hexanal, which are commonly found in every individual, are the compounds that explain the most variation between scents. Furthermore, PCA shows that there is a difference in clustering between children (under 18 years old) and adults (18+ years old). Our investigation has shown that the age of an individual contributes to the scent profile, an individual is more correlated to oneself than another, and that there are top VOCs that contribute to the variation in individuals scent profiles.

Abstract Name: **A Smart Door-lock using Facial Recognition**

The vulnerability of traditional door locks against lock picking and minimizing lost key replacement cost, and remote locking or unlocking capabilities have persuaded house owners towards a smart door lock-based system for ensuring security at their home. Primarily these smart locks use fingerprints, keypads, and/or RFID tags to authenticate homeowners and open or close the locks. Due to the nature of the authentication, using fingerprints, keypads, or RFID tags, it is difficult for senior citizens as well as people with disabilities to use these door locks. In this project, a Smart Door Lock is proposed using Face Recognition for security and accessibility purposes. A prototype has been built for the proposed smart door lock using a Raspberry Pi device and a camera module. Motion sensors are used to ensure the camera only starts when it detects a movement to avoid excessive use of energy. An LED display is used for the display of the awaiting command with the user. To enable further communication with the user, a microphone and speaker module are also integrated with the device. Python is used for programming the device. Furthermore, a user-accessible app is built by which homeowners can control the lock remotely through their phones. Through experimentation, it is anticipated to determine the accuracy of the device to identify house owners along with the average response time and the user accessibility of the mobile app and the device.

Abstract Name: **(The complete mitochondrial genome of North American Hirundo rustica, phylogenetic analysis and population studies in central New Mexico)**

The barn swallow (Hirundo rustica) is a cosmopolitan species of bird that build their nests using mud and saliva along with feathers and other fibers. It is one of just 57 species of mud nest building birds in the world (Jung et al., 2021). Over the fall of 2022 and spring of 2023, we will study the population of barn swallows on the grounds of The University of New Mexico – Valencia Campus. DNA was extracted using Qiagen Powersoil Pro DNA extraction kit (Qiagen) from mud taken from nests built on buildings around campus. DNA was amplified and libraries prepared using Nextera DNA flex library prep kit (Illumina). Sequencing done on the Illumina iSeq 100 at the University of New Mexico – Valencia Campus. We will present the assembled and annotated mitochondrial genome. We will compare this genome to publicly available mitochondrial genomes in the genusHirundofrom around the world. We will use phylogenetic analyses to compare this first North American representative genome to the many European, Asian, Mediterranean, and Australian representatives already available. We will discuss brood size and nest usage in comparison to male tail feather length and tail color patterns known to be under sexual selective pressures in the species. We will also describe the incubation behaviors of the species in our sample population. Lastly, we will estimate population change from year to year.

Abstract Name: **Antimicrobial Activity Assessment of a Potential Anti-cancer Peptide**

Cancer is one of the most dangerous diseases in the world, especially with the increasing death rates over the years. Conventional treatment approaches, such as chemotherapy, radiotherapy, and surgery, are still not very effective, in addition to cancer cells acquiring resistance against some of them. A novel approach for treating cancer is anticancer peptides which target cancer cells specifically inhibiting their proliferation and migration. Anticancer peptides have higher efficiency compared to conventional therapies and cancer cells are less likely to develop resistance against them. The objective of this project is the characterization of the antimicrobial activity of a potential anticancer peptide to assess its safety on the microbiological level as a potential cancer drug. The peptide was obtained from metagenomics data retrieved from the Red Sea and was previously found to possess anticancer activity. The antimicrobial analysis was done using two approaches which are computational analysis using bioinformatics tools and wet lab analysis. Viable cell count assay, antimicrobial activity assay, and disk diffusion assay were conducted on gram-positive Staphylococcus aureus and gram-negative Escherichia coli bacterial strains, as representatives of the human microbiome. Computational analysis showed that the peptide has an α-helix secondary structure. In addition, the computationally predicted antimicrobial activity was estimated to be between 20% and 30%. The results of the lab experiments showed that the IC50 concentration of the peptide had a minimal antimicrobial effect against both S. aureus and E. coli, which is not significant. The average inhibition rate of the peptide was 14.7% on S. aureus and 9% on E. coli. Accordingly, it can be concluded that the potential anticancer peptide can be considered safe on the microbiological level and will not disrupt the human microbiome. Thus, further investigation can be done on the peptide to use it for cancer treatment.

Abstract Name: Studying the Electrochemical Activity of Methanol Dehydrogenase in Lanthanide-Modified Methylobacterium extorquens

Recent studies have demonstrated that some enzymes in bacteria isolated from lanthanide-rich areas use lanthanides as metal cofactors in place of more common metals like calcium and that these lanthanide-enzymes have enhanced catalytic properties. For example, Methylobacterium extorquens is a methylotroph that conducts redox chemistry using methanol dehydrogenase (MDH). MDH is a type of quinoprotein that contains a pyrroloquinone and either a lanthanum (La3+) or calcium (Ca2+) metal cofactor. Here, the bioelectrocatalytic activity of MDH from M. extorquens grown in La3+ rich media is compared to MDH from M. extorquens grown in typical Ca2+ rich media. Biochemical assays have shown that La3+-MDH has higher activity than Ca2+-MDH. However, the bioelectrochemical activities from these bacteria have not been compared. If La3+ grown M. extorquens has higher bioelectrochemical activity than Ca2+ grown M. extorquens, then improved biofuel cells and sensors can be created. M. extorquens is grown in two separate cultures, one with La3+-rich media and one with Ca2+-rich media. Methylene blue is polymerized onto the surface of a glassy carbon electrode, then harvested bacteria or isolated enzyme is immobilized on the electrode by casting a mixture of the bacteria and tetrabutylammonium bromide (TBAB)-modified Nafion® onto the electrode surface. The bioelectrochemical activity for oxidation of methanol to formaldehyde is measured by cyclic voltammetry and amperometric i-t curves for various concentrations of methanol in a tris-HCl buffer. In addition to comparing the bioelectrochemical activity of the La3+-MDH and Ca2+-MDH, the activity of the whole bacteria and isolated enzyme electrodes will be compared along with the electrode lifetimes.

Abstract Name: The Effects of Gonadal Steroid Hormones on Perineuronal Nets and Parvalbumin Cells in the Ventromedial Hypothalamus and Bed Nucleus of the Stria Terminalis in c/57 Mice

Adolescence is a sensitive period for the organizing actions of gonadal steroid hormones on social behavior. However, the neurobiological mechanisms underlying steroid-dependent brain and behavioral maturation during adolescence are largely unknown. The development of extracellular matrix structures in the brain, perineuronal nets (PNNs), are associated with the timing of sensitive periods for experience-dependent plasticity in sensory systems. The current study is an important first step in understanding the role of PNNs in steroid-dependent organization of the brain during adolescence. We tested the hypothesis that adolescence is a sensitive period for steroid-dependent development of perineuronal nets in the ventromedial hypothalamus (VMH), a region of the hypothalamus important for social and reproductive behavioral function, and the Bed Nucleus of the Stria Terminalis (BnST), a limbic structure critical in endocrine function. We predict that gonadal steroid hormone exposure during the adolescent period, but not before or after, will increase the number of PNNs found in the VMH and the BnST. To further investigate this finding, we also analyzed Parvalbumin (PV) cell expression. PV cells are GABAergic inhibitory interneurons often surrounded by PNN's. In this study, male and female c/57 mice were first gonadectomized prior to puberty at 22 days of age. Subjects were surgically implanted with steroid hormone-containing or vehicle (blank) silastic capsules either before puberty (23-30d), during adolescence (40-47d), or after adolescence (63-70d). Female mice received estradiol-filled capsules, and male mice received testosterone-filled capsules. Brains were collected after seven days of steroid hormone or vehicle treatment for histological processing and analysis. Preliminary analysis of a subset of data reveals that female mice have more PNNs, on average. However analysis is still in progress for density of PNN and PV cell expression, and changes to the area size of these brain regions, of which the results will be presented at the conference.

Abstract Name: **Using Subsurface Imaging to Search for a Holocaust Mass Burial in Liepāja, Latvia**

Antisemitism and fascist indoctrination contributed to the genocide of millions of Jewish and other outcast people in the Holocaust before and during World War II. Today, the remains of thousands of people are missing. Liepāja, on the western Baltic coast of Latvia, is the only known Holocaust site to have video footage of one of the massacres. The footage depicts people being shot in a large trench and covered in sand with the local lighthouse visible, but the exact location of the burial was unknown. Ground penetrating radar (GPR), witness testimony, aerial photos, and coastal erosion analysis were used to attempt to locate the mass burial seen in the historical footage.
GPR antennae direct electromagnetic radio waves into the ground and record their returning reflections in lines. GPR lines are a form of subsurface imaging, which can be used to determine possible features in non-invasive archaeology by detecting subsurface contrasts. In Liepāja, a Sensors & Software pulseEKKO high frequency GPR system and Topcon self-leveling laser/receiver topography system were used. Data was collected using a 500mhz antennae in parallel lines, spaced every 0.25m, with a 0.02 step size in three grids sized 22m x 27m, 9m x 38m, and 11m x 13m and adjusted for changes in elevation. GPR lines were examined using EKKO_Project 5 software to locate features in subsurface materials.
A subsurface anomaly aligns with the position of the trench in the video. GPR lines, witness testimony, erosion analysis on the site, and aerial photos indicate the location of the trench. The located mass grave will be left undisturbed due to the Jewish religious custom of not exhuming the dead; however, those killed can now be memorialized by the local community. Further study is recommended to determine if other anomalies detected in GPR profiles are additional burials.

Abstract Name: **Detecting Bias in Intelligent Autonomous Hiring Systems**

This project analyzed if artificial intelligence (AI) hiring systems demonstrate prestige bias, and how that bias may be mitigated. We chose to look at prestige bias since the quality of a candidate's education will naturally be reflected in their skills and experience; a school's reputation should not additionally be factored into a hiring decision. Of note, this project analyzed prestige bias against Historically Black Colleges and Universities (HBCUs). The majority of students attending HBCUs are people of color who are already marginalized members of society. We examined how hiring site Indeed utilizes AI to list candidate resumes by relevance and measured the relationship between a candidate's resume ranking and the university they attended. We expect to find a negative association between HBCU status and ranking, which is stronger than the association between ranking and other confounding variables such as experience type, degree level, field of study, etc. Subsequently, we will develop our own AI system, utilizing hiring decision data that we collected from Indeed, to observe if it will present a similar bias. If so, then we will apply debiasing techniques to our model to create a new AI hiring system that is not biased against HBCU applicants. With businesses considering AI as a tool for hiring, companies must understand that AI hiring systems can perpetuate the same biases found in human hiring on a larger scale.

Abstract Name: **Exploring the Mediating Role of Social Dominance Orientation in Stigmatizing Attitudes Exhibited in Sports Fans**

While previous studies on sports fan environments reveal correlations between high sports fan identification and endorsement of sexist attitudes, the effect of sports fan identification on negative attitudes towards issues related to gender and sexuality outside of fan environments have not yet been investigated. In this study, we aim to examine the link between levels of sports fan identification and negative attitudes towards women, homosexual individuals, and transgender individuals. We predict that higher levels of sports fan identification will correlate with more negative attitudes toward women, homosexual individuals, and transgender individuals as compared to those with lower levels of sports fan identification. With level of sports fan identification as the predictor variable and stigmatizing attitudes as the outcome variables, correlational analyses will be performed to assess relationship between sports fan identification and attitudes toward women, homosexual individuals, and transgender individuals. The predictor variable will be measured using a composite score obtained from two measures evaluating sports fan identification, and the outcome variables will be obtained from three measures each separately designed to measure sexism, homophobia, and transphobia, respectively. Consistent with our hypotheses, we expect to find correlations between levels of sports fan identification and the specific attitude measures. Additionally, we will investigate political orientation and social dominance orientation as possible mechanisms underlying the connection between sports fan identification and attitudes towards women, homosexual individuals, and transgender individuals. These mechanisms will be investigated via mediation analyses; for example, we will explore whether the link between sports fan identification and attitudes toward women is mediated by social dominance orientation. This study is currently in progress and has received IRB approval. Data collection is scheduled to begin January 23, 2023 and conclude March 1, 2023. We anticipate all data analyses and report writing will be completed prior to the conference.

Abstract Name: **Dual Function Antibody Conjugates (DFAC) as a Photoacoustic Imaging Probes for Image-Guided Oral Cancer Therapy**

Close to 50,000 Americans will be diagnosed with oral cancer this year. Despite using molecular targeted 2-dimensional fluorescence imaging to delineate tumor margins, the presence of residual microscopic diseased tissue, post-surgery, often leads to tumor recurrence. This is in part due to the inability of fluorescence imaging to accurately determine tumor depths. We here report the development of a dual function antibody conjugate (DFAC) comprising of a fluorophore (AF647) and a photoacoustic dye (IRDye800) conjugated to an anti-EGFR antibody (cetuximab) to compliment fluorescence imaging with 3-dimensional photoacoustic imaging to overcome this limitation.As DFACs usually interact with their target cells through receptor-mediated-endocytosis (RME), we recapitulated different steps of this process, in vitro, and evaluated the fluoresce and photoacoustic signals at timepoints representing its different stages: Free DFAC – mimicking DFAC in circulation, DFAC-NAL (DFAC conjugated to liposome surface) – mimicking target cell-surface-bound DFAC, and NAL-DFAC (DFAC encapsulated inside liposomes) – mimicking endocytosed DFAC. The presence of DFAC on the nanoliposomal surface in DFAC-NAL was confirmed by determining binding specificity to A431 cells (EGFR-positive) through confocal fluorescence microscopy and flow cytometry. DFAC and DFAC-NAL showed high binding to A431 cells, in contrast, the binding of NAL-DFAC was found to be significantly lower validating DFAC presence inside the liposomes. While the fluorescence signal for the different formulations showed minimal variations, photoacoustic signals for NAL-DFAC showed a significantly lower signal than the rest.In conclusion, our study indicates that DFAC conjugated on the surface of nanoliposomes produces a better photoacoustic signal than DFAC encapsulated inside nanoliposomes, suggesting that photoacoustic imaging performed at early timepoints of the RME process, when DFACs are bound to the cell-surface, could yield higher intensity signals. The broader implication of this study is to consider microenvironmental effects and timing of imaging of such probes for delineating tumor margins.

Abstract Name: **Wolbachia-Mediated Protection Fails Against the Fungal Pathogen, Beauveria Bassiana**

Aphids are destructive pests of many economically important crops. Parasitoid wasps and fungal pathogens are natural enemies of aphids that are often utilized to control their populations in agricultural settings. Aphids have established relationships with symbiotic bacteria which provide them with life sustaining nutrients or defense. The symbiont,Wolbachia, can protect the banana aphid,Pentalonia nigronervosa, a vector of the BBT virus, against the aphid-specific fungal pathogen,Pandora neoaphidis. However, symbiont protection is often species specific. To evaluate the specificity ofWolbachia'santi-fungal protection, a lab assay was conducted usingBeauveria bassiana, a generalist fungus used to control a wide range of insect pests. Cohorts from fourWolbachia-infected (W+) and four uninfected (W-) banana aphid lines were exposed toBeauveriausing two different methods: a spray and dunking method. The number of aphids that survived, sporulated, or died from exposure were recorded over ten days. Results show that W- and W+ aphids were equally susceptible toBeauveria, experiencing similar rates of sporulation and survival, $t(34) = 2.03$, $p = .72$. This finding highlights the specificity of symbiont-mediated protection and suggests thatWolbachia'santi-fungal defense is not effective against all entomopathogenic fungi. Understanding how endosymbionts in aphid species influence host-pathogen interactions may lead to the development of more effective biological control strategies.

Abstract Name: **Effectiveness of Steel Wires in Compressed Stabilized Earth Bricks (CSEB)**

The purpose of this research project is to contribute to the development of interlocking Compressed Stabilized Earth Bricks (CSEBs) by studying crucial engineering properties (e.g., strength) of various highly compressed soil/stabilizers mixes of CSEBs. One of the many approaches involves steel wires' effect on the compressive strength and absorption of CESBs. We will examine three sets of samples with varying mix proportions (soil with 70% sand and 30% fines), then stabilize them with 10% Portland Cement. Two of the three sets will contain 1-inch cut steel wires. Afterward, our soil samples will be compressed with a (16-20) MPa hydraulic pressure compactor. Through experimentation and examination, the study will contribute to the knowledge of this evolving, aspiring green technology manufacturing environmental-friendly CSEBs. Unlike ordinary and modern construction materials like concrete and Fired Clay Bricks (FCB), which foster environmental degradation, manufacturing CSEBs poses a potential solution for effective, environmentally friendly building materials. Furthermore, they are energy efficient and economical compared to the production of FCBs that significantly damage our environment (e.g., global warming and Ozone depletion) due to the high energy levels. Along with being environmentally friendly, there are numerous other benefits of CSEBs. For instance, they lower transportation costs, promote local resources, develop the local economy rather than spending on import materials and improve access to quality housing for many people. Ultimately, our goal is to contribute to developing CSEBs as green construction materials through mechanical and chemical stabilization techniques. The anticipated results are that incorporating steel wires in CSEBs will reinforce compression and absorption.

Abstract Name: Seussical, an Audience that Grew Three Sizes: Community Engaged Learning and Studies in Audience Development

As campuses build new arts facilities to attract students of all disciplines, those seats need filled with audiences from the campus and larger community. Not only does this require the talents of a creative team to provide the art, but alsothe research and creative inquiry of other disciplines, such as marketing and community engagement. This short talk will share the experience of developing and teaching the course Studies in Audience Development using community engaged learning techniques in order to promote Slippery Rock University Department of Theatre's musical production of Seussical. According to theNational Endowment for the Arts, a direct correlation exists between arts participation and higher levels of education ("2017 Survey of Public Participation"). Therefore, in order to build future audiences, it is imperative that the arts be central to all education levels. Students in the course will use the Doug Borwick's Building Communities, Not Audiences: The Future of the Arts in the United States, Bob Harlow's, Taking Out the Guesswork: A Guide to Using Research to Build Arts Audiences, and the Arts Education Navigator to research, write, and implement a marketing plan aimed at cultivating young audiences, as well as identifying and addressing barriers to arts education and participation in schools. Students will interview and survey partner schools to create services thataddress these barriers. One objective is to fill the university's 700-seat newly remodeled Miller Theater with elementary and middle school students in two matinee performances. The larger goal is for undergraduate researchers to engage the community increating audiences of the future.The short talk will document the process of identifying campus and community partners, receiving designation as a community engaged learning course, the undergraduate student research process and findings, and student learning outcomes.

Abstract Name: The Architectural History of Marietta, Georgia's No. 1 Engine House

The transition from volunteer-run to professional fire departments in mid to late 1800's America led to a dramatic shift in the architectural style of new fire stations. Marietta, Georgia's No. 1 Engine House, built in 1886, reconciled a heroic volunteer department with an architectural style influenced by the professional departments of its time in larger cities. Unlike many other historic buildings in Marietta, the No. 1 Engine House, which has a similarly long and venerable history, has been of little scholarly interest. This is likely due to its architecture resembling an ordinary commercial building rather than an integral part of an Antebellum town. This case study of Marietta's No. 1 Engine House was conducted by comparing historic local documents and photographs against general trends in American fire station design of the time. Towns are rarely shaped by their own needs. In this case, nationwide trends compelled the small town of Marietta to adopt an architectural style contrary to its own aesthetic needs.

Abstract Name: **Deliver Website "Atlantic"**

Researcher: Dabana Intenque Presentation title: Atlantic websiteResearch Focus: Computer Science School: Bridgewater State University Presentation Type: Oral Presentation Abstract: Developing the "Atlantic website" to facilitate, help and support individuals online with easy and fast access to the product.Dabana Intenque, Bridgewater State University. Today the internet and cellphone play a huge role in our daily life. Most of the time cell phone can be helpful when you want to buy any product online. It is easy on some continents and harder on another continent. Ex: In Africa. Growing up in west Africa, I witnessed the difficulty there a lack of online websites in my native country. The "Atlantic website" focuses on solving the problem of the countries that do not have an online service in Africa.Using Amazon, Walmart, Apple, and Target as a prototype. Used full stack, including both the client and server side. Node.js as the main framework. Looking into different applications came up with the conclusion of using JavaScript, React, type script as a programming language, and many other technologies, such as HTML, CSS, Bootstrap, GIT, MySQL database, and Heroku cloud web hosting services provided by salesforce.In addition, the goal is to publish the Atlantic website to a cloud web hosting service and keep the Atlantic secure so users can benefit from the research work. The "Atlantic website" will improve people's daily life. In places that lack online services. It will cost less, is easy to access, and is fast for users to get the products at home.

Abstract Name: **ASSOCIATIONS BETWEEN SHAME AND GUILT, SELF-ESTEEM, AND HEALTH RISK BEHAVIOR AMONG UNDERGRADUATE STUDENTS**

Health Risk Behavior (HRB) is defined as behavior that increases the likelihood of adverse outcomes: injury, morbidity, or mortality. University students are particularly susceptible to HRB due to their age, academic pressures, social environment, and newly unsupervised lifestyle. Despite major efforts by university campaigns to make students aware of the potential health risks of HRB, students continue to consistently engage in behavior that risks both their short-term and long-term health. Previous literature indicates the importance of self-esteem in positive decision-making and the inhibiting role of shame in increasing withdrawal and social isolation. Shame and guilt are distinct self-conscious emotions often evoked in similar circumstances: shame often debilitating, and guilt adaptive. The purpose of this study is to examine the associations between HRB and the affective emotions of shame and guilt and self-esteem to better understand HRB determinants. Utilizing a cross-sectional design, data werecollected from students using a Qualtrics form containing demographic and HRB questions. The Personal Feelings Questionnaire-2 (PFQ2) and the Rosenberg Self-Esteem Scale (RSES) assessed shame and guilt pronenessand global self-esteem, respectively. Mean data analyses, frequency tests, and one-way ANOVA analyses revealed associations between HRB and the three tested affective emotions. Results of this study indicated HRB is associated with higher negative emotion: higher shame and guilt proneness and lower self-esteem. With further research, this information can guide more effective clinical and educational interventions in reducing HRB and subsequent preventable diseases by targeting emotional risk factors in the university population.

Abstract Name: **Rise and Shine': Professional Trajectories of Women Cancer Scientists: ?A Qualitative Study of Career Narratives**

In recent years, women consistently outnumber men in medical school enrollment, with women making up 52% of enrollment in 2021 (AAMC, 2021). Yet women are not equally distributed across medical specialties. Specifically, only 35% of the academic medicine oncology faculty are women (Chowdhary, 2020). It is well documented that a diverse workforce has many important benefits including the potential to improve health and healthcare disparities along with enhancing education for future professionals. The purpose of this research was to determine what experiences have benefited and prevented women from advancing into cancer careers. We conducted qualitative interviews of seven women from diverse backgrounds and experiences who had a professional role in the field of oncology. Interviews were recorded and transcribed verbatim. The research team reviewed the transcriptions and independently coded for patterns, comparing perspectives and experiences across the participant narratives. To ensure coding fidelity, the team met weekly, reviewing the codes and clarifying disagreements. These career narratives included a resounding awareness in having good mentors in tandem with other structured, social, and academic support systems. Networking, communication skills, and level of confidence emerge as essential skills and beliefs. The research revealed that the current challenges in oncology are limited access to resources and time to fulfill research responsibilities. Addressing barriers to the academic advancement of women in cancer careers may facilitate equity and improve collaborative research efforts, given the value that diversity brings to team endeavors.

Abstract Name: **Identification of bacterial genes involved in polysaccharide biosynthesis**

The surfaces of all bacterial cells have specialized polysaccharides that display incredibly diverse material properties due to their complex chemical structures. Each strain secretes its own unique polysaccharides built by distinct biosynthetic pathways.The short-term goal is to extract the polysaccharide to study the sugar composition, identify each glycosyltransferase and its sugar substrate, and understand the pathway of the polysaccharide production of Rheinheimera. Once these complicated polysaccharides are fully understood, the long-term goal is to form customized polysaccharides-based material that could be used to seal open wounds or burns, and waterproof adhesives. Colonies from bacterium Rheinheimera sp. B1H13, isolated from Lake Mendota in Madison, Wisconsin, appear mucoid on agar plates leading us to hypothesize that the bacterium produces novel polysaccharides. In this current project, transposon mutagenesis was used to identify the genes involved in polysaccharide production. Colonies that appeared non- mucoid and matte-looking suggested that genes involved in polysaccharide production were disrupted. Non-mucoid mutants were selected for further studies. A mapping method was used to identify transposon insertion sites in the disrupted genes. The results indicated 11 transposon insertions in the sensor histidine kinase, one insertion was found in the UTP-glucose- 1-phosphate uridylyltransferase, and one was found in the wzy gene. wzy-pathway is the most common pathway and produces the most complex products.We predict that Rheinheimera uses a wzy-pathway for polysaccharide production

Abstract Name: **Effect of Seed Priming and Fortification for Baby Food Formulation in Finger Millet (Eleusine coracana L.) Germplasm in Kenya**

Food insecurity affects 2.3 billion people globally, impacting 3.1 million Kenyan children under five. Finger millet, (Eleusine coracana L.) can fill nutritional gaps and generates income. It is high in calcium (0.38%), fiber (18%), and phenolic compounds (0.3–3%), with anti-diabetic, anti-tumorigenic, atherosclerogenic, antioxidant, and antimicrobial properties. It is also drought-tolerant with few post-harvest pests. However, as a neglected and underutilized crop (NUS), it ranks sixth behind wheat, maize, and rice, with little or no agricultural innovation worldwide. The three research objectives were determining seed priming's effect on germination, nitrogen fertilizer's effect on plant development, and biofortifying protein in traditional baby food. All three studies used U-15, Early Duration, and Snapping Green genotypes at Egerton University in Njoro, Kenya. Study 1 analyzed germination rates using gibberellic acid (GA), 6-benzylaminopurine (BAP), and indole-3-acetic acid (IAA). In study 2, genotypes were grown in PVC tubes with varying nitrogen fertilizer concentrations before harvest and chlorophyll and root structure analysis. Study 3 measured the nutritional composition of baby food containing malted and unmalted pigeon pea (Cajanus cajan) and peanut bases (Arachis hypogaea). Tests for phosphorous, zinc, calcium, magnesium, iron, and protein were done. Gibberellic acid had the highest rate of germination (90+%). Malting increased calcium and magnesium availability, but no statistically significant increase in protein was observed. Fertilizer study results are pending. In the future, metabolic profiling via HPTLC and HPLC and expanding baby formula protein sources will be done to increase finger millet's nutritional foundation and combat food insecurity in Kenya and worldwide. The research was completed over the summer of 2022 at Egerton University in Njoro, Kenya under the supervision of Primary Investigator Dr. Anne Osano of Bowie State University and Dr. Paul Kimurto of Egerton University, with assistance from graduate student Anne Amayu of Egerton.

Abstract Name: **Energy Storage Systems Using 2D Carbon Based Nanocomposites as Electrodes**

Different allotropes of carbon, such as graphene and carbon nanotubes, have the potential for use in applications such as clean energy storage systems, aerospace, and energy conversion. In this work, the development of graphene-based nanocomposites (GNCs) for use in an ultracapacitor is investigated. GNCs can be used in ultracapacitors because of their superior electrochemical properties providing superior energy storage performance. Device miniaturization is also possible to facilitate a vast number of applications. In this experimental work, GNCs will be synthesized using an electrochemical deposition technique and the performance of the electrode will be evaluated using various electrochemical studies in the presence of an aqueous electrolyte. Distinct Faradaic and non-Faradaic charge transfer mechanisms will be investigated using cyclic voltammetry (CV), electrochemical impedance spectroscopy (EIS), and galvanostatic charge-discharge (GCD) studies. Results of different rates of deposition during synthesis and their effect on performance will be presented. The role of different substrates, electrolytes, and their effect on the performance of the device will be discussed. Mechanisms of charge storage and transfer between the electrolyte and GNC surface will be presented.

Abstract Name: Communication Ability Profile for Employees and Employers

The purpose of this study is to analyze the development of the Communication Ability Profile for Employees and Employers (CAPE) as a tool that may help potential employees with a disability detail how they communicate and advocate for the ways employers and co-workers should communicate with them in the workplace. The CAPE details an overview of the employee's communication strengths, workplace qualities, communication modalities, accommodations, and beneficial ways to connect with fellow employees. According to the U.S. Bureau of Labor Statistics (2020) in 2019, 19.3% of persons with disability were employed compared to 66.3 percent of people without a disability. While the labor market has improved, the degrees of improvement are lower for people with disabilities compared to people without disabilities. Furthermore, McNaughton and Arnold (2010) completed a metanalysis and found that the keys to success in employing people with disabilities include developing employee knowledge and skills that are valued in the workplace, matching the skills and interests of the individuals who use AAC, and continue to maintain and ensure needs are met for each employee to be successful. Participants for this IRB-approved study were recruited through an emailed script, the CAPE protocol, and a Qualtrics survey link sent to 16 potential participants of which nine subjects consented and completed the survey. An analysis of the data from the study of the CAPE will inform a final version of the protocol. This data will allow us to accurately reflect on the best ways to inform the protocol to foster successful communication in the workplace for people with disabilities. Furthermore, through analyzing and shaping the CAPE we hope to answer how the CAPE identifies communication strengths and needs compared to a traditional employment application form and how participants' perspectives of benefits and recommendations vary across parent and professional disciplines.

Abstract Name: Temporal Analysis of Deep Sea Vent Microbial Communities

Deep-sea vents are one of the most biologically intriguing sites on Earth, as their microbial communities represent a plethora of novel species that continue to shape our understanding of anaerobic metabolic processes, global chemical cycling, and the origin and evolution of life on Earth. However, because they are so difficult to reach, exactly how these dynamic locations and their associated microbiota change over time is unknown. This project aims to characterize the change in environmental conditions through time and how this affects the microbial community in the sediment of the Pescadero Basin hydrothermal vent site in the Gulf of Mexico. Here we show – through the analysis of geochemistry, temperature data, and 16S DNA sequencing data from samples collected in situ across three years – that vent regions are not temporally stable systems. There were changes in the hydrothermal activity and geochemistry of the site between 2018 and 2021 that led to changes in the abundance of species, particularly in families of ANME (anaerobic methanotrophs). We also incubated sediments from both a hydrothermally active site, measured to be 80°C, and a colder background site, measured to be 4°C, at various temperature conditions to attempt to mimic this microbial community shift in vitro. Changes in the geochemical composition of the incubations were visible within as little as two weeks. As one of the first temporal studies of vent site sediment microbes, this project will contribute to developing a general understanding and prediction of vent community stability in the face of environmental change.

Abstract Name: **Functional characterization of a novel platform to study organotypic tissue slices from human appendiceal cancer**

Appendiceal cancer is a rare malignancy that has an incidence rate of one in one million people per year. This disease remains challenging to study given its low incidence, frequent mucinous histology and the absence of a comparable organ in mice for disease modeling. Recent studies have shown that appendiceal cancer is genetically distinct from colorectal cancer and as a result there is a need to develop novel tumor models to study this disease. Our objective here was to characterize how long, and at what time points appendiceal tissue slices are most suitable for use. To determine if the tumor slice cytoarchitecture changed during slice culture we photographed slices at days 0, 1, 4, and 7. We determined that tissue surface area decreased by 40% over 7 days. We also assessed cell viability over a 7-day period among different donor tumor slices through live cell imaging. We found that day one had the largest percentage of viable cells, with an average of 80% across all donors. The maximum proliferation rate was found to be 15% at days 4-5. Our findings indicate that tissue slices are functional for one week in culture. This study demonstrates a novel approach to study appendiceal cancer in a pre-clinical setting.

Abstract Name: **The Bonus Expeditionary Force: US Military Veterans March on Washington**

Suffering in the Great Depression, veteran Walter W. Waters organized a 15,000-member nationwide march entitled the Bonus Expeditionary Force (BEF) to lobby the Hoover administration for the payout of the 1924 Adjusted Compensation Act on March 15, 1932. The march ended with a violent crackdown by the Hoover Administration enacted by the US Army and FBI. Soon after, Mr. Waters organized a fascist group named the Khaki Shirts to take the government back away from his definition of special interests. How did an egalitarian and service-oriented group become a fascist organization in three months? The BEF failed to progress as a social movement as march leadership lost track of their original objectives, falling prey to internal and external tensions that embracing fascist policies only hastened. Social movement theory is the best framework to analyze the movement's progression and destruction.Movements progress based on their ability to counter internal tension and outside influence while maintaining mainstream appeal. Using over 30 primary source documents taken from newspapers, government officials and march leaders, my work will analyze the devolution of the Bonus Army from a service-oriented protest organization to a violent fascist group. Historians have extensively researched the history of the BEF up to its shutdown by the US Army. Understanding how the BEF leadership grew to embrace tenants of fascism and failed to grow as a social movement is an understudied aspect of the Bonus Army and deserves more focus in the historical field.

Abstract Name: **IL-4 and IL-33 Gene Expression Correlates with Colon Cancer Tumor Growth**

Colon cancer is the third-most diagnosed cancer in the United States. Additionally, 100,000 colon cancer patients are newly diagnosed each year. The possibility of developing colon cancer is reliant on genetic factors, environmental factors, and the body's immune capabilities. Having a healthy gut microbiome is relevant in homeostasis and maintaining a strong immune system. When there are gut microbial imbalances, it leaves room for the initiation of chronic diseases such as cancer. Particularly, when there is an abundance of probiotic bacteria in the body system, they are capable of increasing production of anti-inflammatory cytokines which are relevant to the fight against cancer cells because they hinder carcinogenesis and can lead to elimination of early-stage cancer cells. This research compares the interactions of pro-inflammatory cytokine receptor genes on gastrointestinal cancers, specifically colon cancer. To conduct this research, the NCI Genomic Data Commons website was used to gather and identify national data on colon cancer patient cases;including their demographic information, the severity/stage of the cancer, the procedures/treatments conducted on patients, and the gene expression of IL-4 and IL-33. IL-4 and IL-33 are cytokine receptors, known for their role in cancer cell growth and progression of the cancer cell cycle. The work presented here compares and analyzes the expression of the IL-4 and IL-33 genes in tumor versus normal samples (of which was shown to be statistically significant), gender, tumor stage, age, and history of polyps. We hypothesize that when cytokine receptor gene IL-4 and IL-33 are low, normal tissues and less tumor growth will be prevalent and when IL-4 and IL-33 are highly expressed, colon cancer tumor growth will be enhanced.

Abstract Name: **Impedance Spectroscopy Sensors to Detect Biofilm in Maple Sap**

Biofilm, an assemblage of surface-associated microbial cells enclosed in an extracellular polymeric matrix (EPS), are known to have pervasive effects in the food processing industry. Specifically, unwanted biofilm growth occurring in maple sap lines reduces the economic syrup value. One technique to monitor biofilm growth in real time is with the use of microfabricated electrochemical impedance spectroscopy (EIS) sensors. EIS is a method which involves applyingsinusoidal perturbations over a range of frequencies across an interface and the responses are recorded. We integrated these sensors into sap lines to continuously measure biofilm growth, temperature, and microbial-specific concentrations, allowing producers to accurately track sap quality in real-time and make decisions on sanitation practices to improve maple syrup quality and economic value. Experiments were performed both abiotically and biotically over a 72-hour time frame in a laboratory-controlled environment, where elemental conditions were closely regulated. In order to observe the effect of humidity and temperature on the sensors, similar experiments were performed outdoors, in an uncontrolled environment. For biotic experiments, EIS data followed trends that suggest microbial growth and confocal microscopy confirmed a biofilm monolayer on the surface of the sensor. Our study suggests that microfabricated EIS sensors can establish a reliable in situ quality control system and effectively aid in the mitigation of biofilm growth in sap lines.

Abstract Name: **Examining Resiliency and Mindfulness as Moderators of Stress in College Students**

Stress is a common experience for many individuals. From the recent COVID-19 pandemic to managing daily demands, situations that induce stress are common. Etherton et al. (2022) noted that college students, in particular, undergo an abundance of stressful experiences, such as rising tuition rates, high academic standards, money management, and concern for grades. According to Hudd et al. (2000), stress negatively impacts students, such that students under greater stress exhibited lower self-esteem, increased drinking, difficulty sleeping, lack of energy, and reductions in overall health. This can impact college students' ability to perform academically and meet various demands. As the number and intensity of stressors in college continue to increase, we chose to research the impact of stress on academic performance and well-being. Additionally, we explore how aspects of positive psychology (resilience, empathy, self-efficacy, mindfulness) may moderate stress in college students. According to Allan et al. (2014), resilience predicts academic performance, such that increased resilience is correlated with higher grades. Therefore, this study aims to investigate how resilience relates to perceived levels of stress in college students via a survey measuring behaviors related to their academic and everyday lives. We created a survey which was distributed electronically to college students, with a goal of obtaining at least 100 responses across different school levels and other demographic characteristics. We began data collection in fall semester 2022 (current N = 50) and will continue collecting data throughout winter and spring of 2023. We hypothesize that the college students who have higher levels of resilience, mindfulness, and empathy will also report lower stress and higher achievement in academics.The analysis will aid us in understanding the relationship between stress and resilience in current students at our university.

Abstract Name: **Finding a Greener Solvent for an Undergraduate SN2 Reaction**

My research attempts to replace N,N-dimethylformamide (DMF) with a solvent that is less toxic in a bimolecular nucleophilic substitution (SN2) reaction. SN2 reactions are done in organic chemistry laboratory courses at the University of Wisconsin-River Falls. A specific substitution reaction done on the UWRF campus yields hexyl acetate from 1-bromohexane and potassium acetate. I have experimented with two safer solvents: dimethyl carbonate (DMC) and N-butylpyrrolidinone (NBP). Using infrared spectroscopy and proton nuclear magnetic resonance spectroscopy, I can determine if dimethyl carbonate and N-butylpyrrolidinone are possible replacements for N,N-dimethylformamide because the spectra generated can show the specific stretches or peaks for the desired product, hexyl acetate. DMC did not yield enough product to be used in place of DMF, but NBP has resulted in the formation of hexyl acetate. However, the method used to reflux the reaction is difficult to do with NBP because the boiling point is higher than the boiling point of the starting material. The reaction burns because the reagents cannot be refluxed at the high boiling point of NBP. Instead of using a reflux apparatus as outlined in the laboratory manual for the Organic Chemistry I laboratory course at UWRF, I have experimented with using a water bath to heat the reaction with NBP as the solvent. In a water bath, the reaction does not reach a vigorous boil because the water bath is heated below 100°C. Using NBP as the solvent and utilizing a water bath has shown promise in the synthesis of hexyl acetate by a bimolecular nucleophilic substitution mechanism.

Abstract Name: Expressions of Cultural Identities

How might expressions of cultural identities take shape through language, stories, and other learning experiences in an elementary classroom? If preservice educators listen intentionally to the expressions of elementary students, will those studentsshare about their diverse backgrounds and cultural identities? Can these conversations support the classroom in an effort to be more culturally responsive? We will partner with a local elementary school and spendtime on site conferring withstudents about theirperceptions and contributions, connecting students' cultural knowledge to themselves and others through multimodal learning experiences, and gatherdata that will influencefuture teaching practices. Multimodal instruction is instruction that uses social and cultural resources such as drawings, technology resources, picture books, and storytelling. Student voice is listening attentively to students' perceptions and contributions.Cultural identity is the perception of self and others, and how children see themselves as a member of a group.

Abstract Name: Art as Transfiguration and the Philosophy of Limit in Albert Camus, La Peste: What matters is to know how to see

Albert Camus' La Peste (1947), is a novel about the French-Algerian town of Oran devastated by the bubonic plague in 194-. As a novel about an epidemic, there was a resurgence in interest in La Peste during the Covid-19 pandemic. While, La Peste, can be seen as straightforward reading about the bubonic plague, Camus encouraged a reading on multiple levels.Traditionally, scholarship has coalesced around two additional levels of interpretation, namely, an allegory for French occupation by the Nazi's during WWII and a metaphysical allegory on the nature of evil. Subsequently, historic scholarship has criticized La Peste for its messyand disjointedinterpretations or abandoned entirely an attempt at formulating a unity between interpretations; while current scholarship has dismissed or misappropriated its relevance to Covid-19. Conversely, this article argues for a unification of interpretations. To do so, this article first constructs a framework around two interrelated lines of thought. First, the absurd, the duplicity of abstraction, and the human plague of nihilism. Second, the role of the artist and the privileging of art as an antidote for nihilism through transfiguration and imaginative unity. Through this framework, a close reading of the characters reveals a unifying theme exemplified in Camus' philosophy of limit. Furthermore, Camus separates himself from the Existential thought of histimeby providing a bridge beyond its limitations. The Existentialfocus on the individual evolves in La Pest'sc ontextualization of individual freedom within our relations to others cementing the role of honest communication in achieving human solidarity.In conclusion, La Peste demonstrates a prophetic delineation of the existential state of the human condition and offers a way of seeing its transfiguration which transcends its historical time and strict academic interpretation. Furthermore, it exemplifies a significant relevance to the non-academic reader in evaluating our post-Covid-19 world.

Abstract Name: Proposing an RNA Interference (RNAi)-based Treatment for Human Immunodeficiency Virus (HIV) by Analyzing the Post-Transcriptional Gene Targeting of SARS-CoV-2, Hepatitis C Virus, and A549 Lung Cancer Cells

Human Immunodeficiency Virus (HIV) is a retrovirus that infects CD4+ T cell lymphocytes in humans, leading to development of AIDS. While current treatment methods, including antiretroviral combination treatments, effectively limit HIV replication, HIV can evade these treatments due to its high mutation rate. Long-term antiretroviral treatment can be toxic to patients, meaning a new mechanism of HIV treatment would benefit HIV patients. RNA interference (RNAi) is an antiviral pathway found in mammals, plants, and insects that involves a small-interfering RNA that binds to viral mRNAs and cleaves them using the RNA-induced Silencing Complex (RISC), reducing viral gene expression. RNAi is a promising method of treating HIV/AIDS, since it has been found to adapt to changing viral sequences in insects and can target highly-conserved sequences. RNAi has been successfully used to inhibit replication of Hepatitis C Virus, A549 lung cancer, and SARS-CoV-2 in mammalian cells using variations of RNAi. RNAi treatments have also been approved for use in humans, including Patisiran, a treatment for polyneuropathy, setting a precedent for the possibility of a HIV RNAi treatment for humans. However, an RNAi treatment for HIV has not yet been designed or developed. This paper aims to consolidate research on RNAi mechanism of viral inhibition, possible HIV target sequences, delivery mechanisms for RNAi treatment, and counters for HIV RNAi suppressors, in order to propose a comprehensive potential RNAi treatment for HIV. RNAi could effectively inhibit HIV replication by containing two siRNAs with the sequences 5'-UUAAUACUGACGCUCUCGC-3' and 5'-UGUAUUGAUAGAUAACUAU-3' that target highly-conserved sections of the p17 and Reverse Transcriptase genes, respectively, delivered within a solid lipid nanoparticle composed of equal amounts of DOTAP and DODMA cationic lipids and containing LFA-1 antibody on the surface for receptor-mediated endocytosis, and cotransported with Rev and GagPol HIV proteins to limit the anti-RNAi function of RRE and TAR.

Abstract Name: ORION: OBSERVATORY FOR CYBER-RISK INSIGHTS AND OUTAGES OF NETWORKS

Cyber-attacks present some of the most severe security threats to a nation's critical infrastructure. Early detection of these cyber threats can provide network security analysts valuable insights into ongoing malicious activities so that they can effectively mitigate them. One source of such threat intelligence is data provided via Network Telescopes or "Darknets" designed to collect unsolicited traffic towards large unused Internet IP spaces. Darknet data can help researchers obtain a global perspective on Internet behaviour and the origins of cyber attacks (e.g., malware, viruses, network scanning, and internet outages). However, analysis of data from such a large data source makes the transformation of captured information into meaningful insights challenging. To address this challenge, researchers at Merit Network, and at theUniversity of Michiganhave developed the ORION Network Telescope. The ORION infrastructure organizes the collected Darknet data and uploads meaningful events (such as detected scans and "backscatter" activities) into Google's BigQuery data warehouse. This allows researchers to easily query the data and compile features about the activities of Darknet scanners that could be then used to construct Machine Learning and AI models to categorize the data into meaningful clusters based on the attack origin, the magnitude of the problem, and attack tactics. The end goal of this project is to apply the ORION infrastructure on an ongoing, real-time basis to help detect real-world, high-impact cybersecurity incidents such as the onset of several anomalous, not-previously-seen, cluster formations.

Abstract Name: Genius is in the Eye of the Beholder

Do women have to be naked to get into the Met. Museum? A poster by the anonymous activist group Guerilla Girls truly bares all. According to a study done by the feminist activist group that aims to create awareness about the gender gap in the art world, 76% of the nudes featured in the museum are female—yet only 4% of the artists in the Modern Art section are women. We might not give much thought to who the artist is behind the brush, but it's about time we do. When we think of artistic masterminds, the names Leonardo da Vinci, Claude Monet, and Pablo Picasso often come to mind, and rightly so. They undeniably revolutionized each of their respective styles of art, but we often fail to recognize the impact women have had on the artistic world too: Lavinia Fontana was the first woman to have a career as an artist during the Renaissance; Hilma af Klint created some of the first abstract artworks ever documented; and Edmonia Lewis produced sculptures of US Presidents Abraham Lincoln and Ulysses S. Grant. The failure to understand their importance is a failure to understand the true meaning behind the art. They say that beauty is in the eye of the beholder, and the same thing is true for genius: society determines who exactly is one. Historically, it's mostly men whose genius gets cultivated and recognized. But in order to understand the true picture of society and the true potential our diverse world holds, we must recognize women's importance in every field—and this is especially true for art. We need to change our perception of genius in order to understand the important contributions women have made to the world of art.

Abstract Name: Socioeconomic Vulnerability and Environmental Inequalities: a Case Study of Climate Change Impacts in Egypt's Delta Agricultural Sector

Egypt's Nile Delta has historically had a significant impact and drawn a sizable population because of its abundant resources and trading opportunities. The Nile Delta faces a significant risk of being severely damaged due to flooding brought on by extreme climate change. Temperature increases, unpredictable rainfall patterns, and increasing sea levels are some of the effects of climate change on these cities. When we start to look deeper at the impacts of climate change on different groups of people, a question begins to pose itself. How are the effects of climate change distributed, and is it proportional to the level of contribution to emissions? The objectives of this research are to identify the detrimental effects and threats of climate change on farmers in Egypt's delta agricultural sector and the vulnerability of farmers. A hybrid methodology and system mapping were used to accomplish these objectives. Farmers and other internal and external stakeholders, including professionals, government officials, and NGO representatives, were also interviewed. The results of this study show and prove that farmers in Egypt's delta region are highly vulnerable due to ineffective practices and weak and inadequate government communication. The study also demonstrates that households with lower incomes and less access to natural resources are more vulnerable to the risk of flooding and sea level rise. Income disparities and asset distribution at the community level tend to be greater at higher risk exposure levels, suggesting that households with higher individual vulnerability also have higher collective vulnerability.

Abstract Name: **Stop the Swimmers! Inhibiting Flagellar EF-Hand Calcium Binding Domain Containing Protein 9**

Sperm cells are a vital component of fertilization and maintain a complicated and multiplex anatomy that enables motility, survival, and protection for important genetic information. Following an extensive literature review, we identified a testis-specific protein that is advantageous for inhibition to produce reversible sterility in males without detrimentally impacting non-target tissues and cells. This protein, EF-hand CAlcium Binding Domain Containing Protein 9 (EFCAB9), is a major constituent of the flagellum in sperm cells. EFCAB9 is necessary for sperm cell mobility, motility, and controls the influx of calcium into the sperm flagellum to allow for hyperactivation and penetration of the ovum. EFCAB9 is an ideal target for reversible inhibition to cause temporary male sterility, because the protein expression pattern is localized in the testis and is vital for the systematic and intricate motion and hyperactivation of sperm cells. Molecular modeling and virtual docking software facilitates the structure-function-based drug design process to create small molecule inhibitors of the EFCAB9 protein. Additionally, miRNA silencing of the EFCAB9 mRNA strand prior to protein synthesis is explored as another method of inhibition. This work could lead to decreased sperm motility and male infertility that can be easily reversed. Ultimately, the development of male birth control will expand upon the currently-available options of condoms and vasectomies, and enhance individual sexual health and autonomy.

Abstract Name: **Next Generation Organoids: Root Vascularization and Accurate Organ Shape**

Organoids are 3D, miniature cultures made from stem cells or primary tissue that mimic the function of nativeorgans, making them a useful platform to study the organ pathology of a disease or determine how drugs can impact a whole organ system.Organoids have the advantages of more accurately recapitulating cell to cell and cell to matrixinteractions compared to 2D cell cultures. One issue in organoid culture is the development of a necrotic core because the diffusion of nutrients and oxygen through passive diffusion is limited to the periphery of the organoid. Most organoids lack vascularization, which in vivo is essential to supply nutrients, oxygen, and remove waste deep in the organ. Additionally, organoids are usually shaped into a spheroid. However, in vivo, there is an immense variety in organ shapes across the animal kingdom. In the human body, there is evidence that organ shape dictates function. We aim to improve organoid function in three aims. First, I will learn the techniques to make several organoids and spheroids. Second, I will investigate the shape and dimensions of the human adrenal gland to bio-print 3D scaffolds in the ideal adrenal gland shape and seed them with human stem cell-derived cells. The goal will be to compare such engineered organoids to the original organoids to determine if there is improved function. Third, to address the organoids' necrotic core, I will use an interdisciplinary approach to combine plant biology and stem cell cultures. I will use Arabidopsis roots as vasculature scaffolds that will be surrounded by the stem-cell derived cells to form organoids with improved nutrient/oxygen transportation. My ultimate goal is to optimize organoid function through accurate native shape and root-based vascularization.

Abstract Name: **Can the Line Cook Speak: A critical discourse analysis of the voice and representation of Canadian restaurant staff.**

Over the course of the Covid-19 pandemic, restauranteurs and wage-earning restaurant staff found themselves positions as the focus of an immense amount of mainstream media attention. Never has the restaurant industry been the recipient of such frequent and consistent coverage, yet scholars have yet to critically engage with the available media discourse. This research explores the mainstream media depiction of the restaurant industry and challenges journalistic practices which prioritize the voices and ideological perspectives of those atop the restaurant industry hierarchy. To demonstrate this phenomenon, I engaged in a critical discourse analysis of 55 published online news articles through the theoretical lens proposed by Gayatri Spivak. The sample was examined to demonstrate who was afforded the discursive space to utilize their voice and share their ideological disposition as well as the ways in which the discursive voice found within the sample shaped a representation of wage-earning restaurant staff. The primary findings of this paper reveal that wage-earning restaurant staff, within the selected sample, were discursively silenced and not provided with an adequate opportunity to share their experience of working in a customer-facing position throughout the Covid-19 pandemic. Wage-earning restaurant staff were rarely afforded the opportunity to speak, however, they were spoken for. I argue throughout this paper that the voice of wage-earning restaurant staff is crafted by those atop the restaurant industry hierarchy and that this phenomenon serves to validate traditional restaurant industry hierarchical structures and reinforce hegemonic ideological perspectives. This study emphasizes the need for journalists to embrace the theoretical disposition of a standpoint theorist and strive to ensure that members of subordinated populations are not subject to the imposition of an inauthentic voice.

Abstract Name: **The impact of Nop1 on the presence of aggregation and growth rescue of FUS yeast**

Amyotrophic lateral sclerosis (ALS) is a progressive, fatal neurological disease that is characterized by a loss of motor neurons in the brain and the spinal cord which lead to muscle atrophy and paralysis. ALS has been linked to various gene mutations. A notable gene mutation occurs in fused in sarcoma (FUS), leading to mislocalization of FUS protein in the cytoplasm resulting in protein aggregation and neuronal death.How protein aggregation leads to neuronal death has not been completely elucidated. Epigenetic mechanisms such as histone post-translational modifications might be involved in this connection. We have previously discovered that FUS yeast display decreases in acetylation levels on Lysine 9 (H3K9ac) and Lysine 14 (H3K14ac) on Histone H3. Furthermore, treatment with histone deacetylase inhibitors restored H3K9ac and H3K14ac levels and improved cell growth even in the presence of FUS aggregation. We also found FUS does not directly interact with histones or histone deacetylases. Instead, we find that FUS interacts with Nop1, a histone glutamine methyltransferase, which might mediate indirect interactions with other histone modifiers.Here, we explore the role of Nop1 in FUS aggregation impact on cell survival and the epigenome. We hypothesize that Nop1 knockdown will lead to improved cell growth even in the presence of FUS aggregation by interfering with mechanisms leading to changes in histone modifications . Our findings will showcase the potential for modulation of histone post-translational modifications in neurodegenerative disease treatment.

Abstract Name: **Creation of Fiber-Based Brain Phantom for Diffusion Tensor MRI**

Diffusion Tensor Imaging (DTI) is a powerful tool at the disposal of medical professionals since it allows them to observe the fibrous connections within brain white matter. However, DTI is much more sensitive than traditional MRI techniques and requires better means of calibration. Current phantoms available to medical professionals are simplified and far from accurately representing the brain. The goal of this research was to improve upon previous studies done on creating brain phantoms for DTI using Dyneema® fibers. Bundles of Dyneema® serve as a substitute for brain matter because of their small fiber size and hydrophobicity. This study was done by testing different kinds of Dyneema® fibers, fiber bundle sizes, and fiber orientations in order to most accurately mimic brain white matter in MRI techniques. A key part of this research was the utilization of additive manufacturing to create phantom-scaffolds to hold bundles of Dyneema® fibers. In total, five phantoms were created using water as a surrounding and one was created with agar gel as a surrounding. It was determined that air removal, accounting for the movement of water within the MRI machine, fiber bundle wrapping, and the settings of the MRI machine were key factors to consider during the production of an effective phantom for DTI.

Abstract Name: **How do Viruses in Extremophilic Fungi Impact Their Host?**

The study of fungi has prompted great discoveries, but there is still much to learn by studying fungal biodiversity. A specific unstudied group of fungi is extremophiles who exhibit resilience and growth in extreme environments. They also, like all organisms, host viruses that may impact them. In this project, extremophilic fungi are tested to find mycoviruses. The effects of mycoviruses on the fungi will be assessed through growth experiments in different conditions after each species is cured. The Stress-Gradient Hypothesis states that organisms will tend to cooperate rather than compete in stressful environments, so it is expected that there will be a mutualistic relationship between the fungi and their viruses. To test this hypothesis we will 1) culture pure samples of extremophiles and use them in dsRNA virus screening through RNA extraction and cellulose chromatography, and by using the products of the chromatography, viruses will beindicated by high-weight molecular bands when analyzed in gel electrophoresis, 2) the host fungi will be grown with cycloheximide and subcultured to cure the strain of any mycoviruses, 3) once the strains are cured of mycoviruses, virus-positive and virus-free strains will be cultured separately and measured for daily radial growth. The growth of virus-positive and virus-free strains will be compared. This growth assay will be repeated under various environmental conditions. Through the comparison of virus-positive and virus-free strains, we expect to find a mutualistic relationship between the extremophiles and their mycoviruses. The mycoviruses are expected to serve the fungi in extreme environments more than in stress-free environments. Furthermore, virus-free strains are expected to grow less efficiently in extreme conditions when compared to virus-positive strains. These findings can be used in further research to establish these extremophiles as biocontrol agents in a plethora of problems such as oceanic oil spills, plant species extinction, and others.

Abstract Name: **Updated Annotation of Platyhelminth G-Protein Coupled Receptors**

Parasitic schistosome flatworms (Schistosoma haematobium, Schistosoma mansoni, and the zoonotic parasite Schistosoma japonicum) are responsible for the disease schistosomiasis which affects >200 million people. There is a need to identify new druggable targets in these parasites, given that there is no human vaccine and the current reliance on praziquantel monotherapy raises the potential for the emergence of drug-resistance. G-protein coupled receptors (GPCRs) are a logical starting point, since they control important aspects of schistosome biology such as neuromuscular function and reproduction. These targets are also highly druggable; over 1/3rd of FDA approved therapeutics act through these receptors. Updated genomes for several important species of flatworms have recently become available, providing significant improvements over previous drafts. There are likely additional GPCRs in these improved genomes that were not annotated in previous versions. Here, we have bioinformatically predicted the GPCRs present in these updated flatworm genomes using tools such as HMMER3 and BLAST, and used tree-building approaches to classify these additional receptors. These new annotations will assist drug discovery efforts by expanding our knowledge of parasite druggable targets, as well as enable improved analysis of omics datasets to better understand the mechanisms of existing therapeutics.

Abstract Name: **Investigating Job Satisfaction in Iowa Veterinary Clinics**

A veterinary medicine career has many stressors, including low wages, long hours, client complaints, management responsibilities, euthanasia procedures, educational debt, and poor work-life balance. With these stressors, veterinary professionals are at high risk for burnout, compassion fatigue, depression, and suicidal ideations. Our aim with this study was to investigate the prevalence of these conditions within Iowa veterinary clinics. We sent a survey to over 400 clinics to collect information using three widely used, standardized survey tools: the ProQOL 5, PHQ-9, and SBQ-R. We also included questions about demographics, job-related factors, and job satisfaction. We received and analyzed a total of 94 responses. We found no support to indicate different levels of burnout, compassion satisfaction, or secondary traumatic stress between veterinarians and support staff, but support staff was found to have increased levels of depression and suicidal ideations compared to veterinarians. Based on this data, we believe that both veterinarians and support staff have elevated levels of burnout, depression, and suicidal ideations, but support staff suffers from higher levels. Despite this, Iowa veterinary professionals remain compassionate about their work and desire to stay in the veterinary medicine field.

Abstract Name: Political Divide

The current climate in the US is more than contentious. The current state of the us verses them attitude divided along the political lines is ever worsening. What informaiton is fact and what is political rhetoric? How can the divide be bridged? What are the potential dangers of such a divide in a powerful country? This research is designed to study how the political attitudes across the US are shaped by unfriendly dialog and news media bias. The goal is to understand how the varying forces around the political disconnect predict the perspective of adults in the US. This research will focus on political knowledge, willingness to connect with people of differing views, commitment to current political views, and news seeking behaviors when identifying underlying reasons for the unwillingness to accept otherswith different viewpoints and what can be done to mediate the negative behaviors creating an even wider divide between the groups. How does having friends with widely different political views impact inter-political group discourse? What communication skill sets can be cultivated to foster necessary listening and dialogue techniques? Data analysis will be completed in the spring semester of 2023.

Abstract Name: Analyzing Sexual Health and Consent Policies Among Greek Life Organizations

Sexual violence is an ongoing phenomenon on and off campus, especially among college-aged individuals. While some universities have implemented bystander intervention programs, I believe not many individuals are aware of these programs, especially when it comes to greek life organizations. As a current member of a multicultural greek sorority, I have seen, firsthand, the misconceptions and stigmatization of bystander intervention. Which lacks the basic concepts as well as knowledge of sexual health and consent. My plan is to analyze the varying policies major universities have on sexual health and consent, especially when it comes to greek life organizations. Additionally, I plan on hosting a roundtable discussion regarding sexual health and consent within greek life organizations, by unifying representatives from various greek life councils.

Abstract Name: **Strategies for Increasing Student Engagement in Undergraduate Research and Creative Activity While Promoting Diversity and Inclusion**

There are many tangible and intangible benefits to student participation in undergraduate research and creative projects. Students who engage in research are transformed by the experience; in addition to exploring their field of interest, they gain confidence, learn and master transferable skills, network with others, and hone their written and oral communication. Furthermore, it is well-established that participation in undergraduate research leads to increased retention and a sense of community. At Westfield State University, a small public liberal arts institution, we recognize the importance of supporting student and faculty engagement in research and have prioritized this initiative through the formation of a Center for Research and Creative Activity (CURCA). One of the major goals of CURCA is to increase the diversity of students that participate in this high-impact practice. This includes diversity in race, ethnicity, gender, socioeconomic status, and field of study; we feel that any student in any major should have the opportunity to conduct undergraduate research. In this FAN session, we will detail approaches we have taken and will continue to take to achieve diversity and inclusive excellence and discuss challenges and obstacles faced, both from the perspective of a Director of the center and the Faculty Coordinator. Throughout the session, we will incorporate participant feedback and experience using the formative assessment tool “Plickers” cards. Furthermore, we will engage with participants in discussions related to our process of institutionalizing undergraduate research and share insights into lessons learned and future directions to take. This session aligns with “Expanding the participation of underrepresented groups in undergraduate research and creative inquiry”.

Abstract Name: **The Fluid Nature of Piracy in the 19 Century South China Sea**

Ghulam A. Nadri The Fluid Nature of Piracy in the 19 Century South China Sea Maritime piracy is generally understood in the literature as attacking and plundering ships at sea. Eastern piracy is often overshadowed by Western Piracy. This paper seeks to examine pirate identity and argues that the fluid nature of pirate identity contributes to their efficacy. The paper also argues that the pirate identity and lifestyle challenged the social norms and legitimacy of the local government. This paper also contrasts Eastern piracy with Western piracy. It argues the Western idea of piracy is too rigid to be applied to Eastern piracy. Incidents from China and Vietnam are used to provide a thorough examination of Eastern piracy

Abstract Name: Measuring Grassland Ecosystem Productivity: Assessing Effects of Invasive vs Native Grass and Forb Dominance in the Texas Hill Country

Native prairies in Central Texas once harbored a vast diversity of plants and animals, but many have experienced declines due to exotic species invasion and woody encroachment. Prescribed fire and seeding treatments were used on private and public land in the Texas Hill Country to restore grassland communities. Ecosystem services and functions, such as productivity, disturbance regulation, nutrient cycling, and soil erosion control can be improved through restoration efforts, but these functional responses have not yet been quantified at many sites. We measured aboveground productivity in grassland sites dominated by the invasive grass King Ranch bluestem (Bothriochloa ischaemum) and nearby restored grassland sites dominated by little bluestem (Schizachyrium scoparium) at three sites: Commons Ford Metropark, Cemetery field at Spicewood Ranch, and West Winding field at Spicewood Ranch. We collected aboveground biomass at 4 plots per site (n=24), in three 20 X 50 cm2 quadrats per plot in spring (May-June) and fall (Oct) of 2021 and 2022, which allowed us to compare vegetation response to restoration in a wet (2021) and extremely dry (2022) year. During the wet year, restored sites were twice as productive as invasive-dominated sites, at 305 ± 161 g m2 compared to 150.55 ± 54 g m2 . We are still analyzing data from 2022. Results from the dry year will provide insight into how resilient restored sites are to extreme drought, which is predicted to occur more frequently in Central Texas due to climate change.

Abstract Name: Using Visual Graphics of Mass Wasting for Community Outreach

Port Washington, Wisconsin, is a community along the shore of Lake Michigan. Their scenic view makes it a popular destination for tourists. Their shoreline is subject to lake erosion, and increased rainfall leads to landslides within the city. However, the general public seems mostly unaware of the various factors that can cause slope failure events in their own communities. Unless bridged, this knowledge gap can lead to potential death and property damage as people may fail to take appropriate and timely slope stabilization measures to protect their communities. The United States Geological Survey has released a Landslide Handbook, however, the terminology used throughout is difficult to understand without expert commentary. Simply finding the information you are looking for becomes a game a “Where’s Waldo”. The glossary of landslide terms is found on page sixty of the handbook rather than at the beginning or the end. This makes the first fifty-nine pages incomprehensible to a general reader.To address this issue, we have designed a simple visual graphic of different types of slope failures, with explanations of causes, effects, and general descriptions of each. Community outreach is important when talking about landslides because people need to be prepared so they can be proactive in protecting their own property and the community's economy.This past summer the community experienced a slump on their North Park Beach.We shared the graphic with Port Washington city leaders and were met with a positive response. This project is part of an ongoing conversation between our team and the Port Washington community. The purpose of creating this poster for the Port Washington community is to bridge the gap between specialists and the general public.

Abstract Name: **Functional evolution of the KLK2 and KLK3 proteases in hominoid primates**

The kallikrein-related peptidases (KLKs) are a large family of proteins that code for proteases, many members of which are expressed in a tissue-specific manner. The KLK2 and KLK3 proteases are highly expressed in seminal plasma and are responsible for the breakdown of extracellular coagulum to mobilize sperm for subsequent fertilization. The KLK2 and KLK3 genes arose from a gene duplication approximately 40 million years ago in the ancestor of the catarrhines (apes and Old-World monkeys). In humans, these genes both show prostate-specific expression but with different substrate specificities. While most catarhines retain functional KLK2 and KLK3 genes, genomic deletions have occurred independently in both gorillas and gibbons. This has resulted in chimeric genes (KLK2/3) where the first four exons are derived from KLK3 and the last exon from KLK2. In order to determine whether the resulting chimeric proteins of gorillas and gibbons function more similarly to KLK2 or to KLK3, we cloned their coding sequences into a mammalian expression vector with a hexahistidine tag. These constructs were then transfected into HEK-293T cells, purified through affinity chromatography. Their ability to cleave two different fluorescently labeled synthetic peptide substrates were subsequently quantified. Human KLK2 and KLK3 served throughout as positive controls. The observed differences in enzyme kinetics on the different substrates will be discussed in light of the evolution of the primate KLK gene family.

Abstract Name: **Biochemical Analysis of Non-Protein Coding RNA LINC00298 and Its Expression in Early Onset Alzhimers.**

Alzheimer's is a terminal-neurodegenerative disease which causes neuronal loss in the brain. This disease affects 5.6 million people a year over the age of 65 and is the most common diagnosis among Dementia patients. Data meta-analysis of Alzheimer's patients has found that specific genes, when expressed, may lead to the development of Alzheimer's. One gene of interest is LINC00298 which is a non-protein coding RNA in the brain that is present in Early-Onset Alzheimer's. Very little is known about the impact of this gene during development. Our research team's focus is to biochemically and biophysically analyze LINC00298. Working in collaboration with the School of Pharmacy at North Dakota State University, using Circular Dichroism and Cell Mobility Shifts, researchers were able to identify that the gene depends on Mg2+ using the electrostatic interactions to undergo significant structural changes upon binding. Additionally, through the use of Mass Spectrometry in coordination with the University of Minnesota Minneapolis, Center of Mass Spectrometry and Proteomics. The LINC00298 gene was biotinylated at the 3' end and bound to streptavidin beads. This testing allowed for an understanding in its interactions with enzyme metabolism as well as protein translation. This new information gives insight on the importance of the gene and will potentially assist in finding solutions for Alzheimer's in the future.

Abstract Name: **Adolescent social isolation stress enhances nicotine conditioned place preference and disrupts stress coping behavior.**

Adolescence is a sensitive period in brain development that is marked by increased susceptibility to the effects of chronic stress, which may enhance vulnerability to neuropsychiatric conditions such as depression and substance use disorders. In the present study, we used an animal model to examine the effect of adolescent social isolation stress on coping behavior and nicotine reward. During the adolescent period from postnatal day (P)35-P49, male and female C57BL/6J mice were exposed to either social isolation (SI) stress or standard rearing (SR) conditions, as well as nicotine exposure (0.35mg/kg) four times between P35-P49 during a nicotine conditioned place preference (CPP) procedure. On approximately P50, stress-coping behavior was examined following a 6-minute forced-swim test (FST). Our behavioral results show that both male and female SI mice more rapidly develop nicotine CPP compared to SR mice, that SI mice exhibit increased levels of immobility in the FST, and that prior nicotine exposure during social isolation decreases immobility in the FST. These results suggest that adolescent social isolation stress enhances the rewarding effects of nicotine and negatively impacts stress-coping behavior. To determine whether adolescence is a sensitive period for these effects, ongoing research efforts are aimed at comparing these results to adult social isolation and nicotine exposure. Furthermore, we are examining stress-induced functional (c-fos expression) differences in the brains of SI versus SR mice in response to the FST via immunohistochemistry of the dorsal raphe ascending serotonergic system. Collectively, these analyses will help determine neurological correlates of adolescent susceptibility to the negative effects of chronic social isolation stress and inform our understanding of adolescent brain development and vulnerability.

Abstract Name: **High wind impacts on the Wasatch Front - Saratoga Springs Utah**

The Wasatch Front Range has experienced major windstorms causing Utah citizens to be concerned about how future events could affect them. In our research project, we concentrated on the city of Saratoga Springs, Utah. The methods we used for gauging wind event impact involved researching statewide weather information utilizing local news and historical weather information with a focus on Saratoga Springs. Our goal was to develop information on what the public could do to prepare for a wind event and what to do during the event. We then compiled an informational document that could be potentially used on a web-based platform. After additional research and recommendations from future cohorts of students with a focus on other cities along the Wasatch front. These findings could then be consolidated and offered for use to different emergency sites, which currently have no materials that are specific to wind events such as BeReady Utah. (https://beready.utah.gov/)

Abstract Name: **Using Community-Based Participatory Action Research Frameworks to Enhance Undergraduate Research and Connect Students to Historically Excluded and Exploited Communities**

Community-based participatory action research models (CbPAR) are unique research frameworks that involve the community of interest (CoI) in the research process. The aim is to address concerns of interest and value to the CoI, which increases investment in the research by the CoI. CbPAR should always be founded in the needs of the CoI, informed by community knowledge, and aimed to lead to community and social changes. Unlike traditional research models, CbPAR focuses on empowering the CoI, amplifying their voices, and sharing their unique stories. These aims are especially important for historically excluded and exploited communities (e.g., the LGBTQIA+ community and Veterans) in research. Within these communities, there is a high degree of distrust and disenfranchisement towards the scientific community due to historical and current exploitation. CbPAR methods are a first step towards mending relationships with these communities. It also connects undergraduate students to these communities in a meaningful way. Students learn to empathetically listen and connect to the stories of the community, becoming more than consumers of knowledge, but rather stewards of that knowledge to promote mutually beneficial change in their communities. Additionally, these qualitative, CbPAR research frameworks provide students with hands-on learning opportunities with interview techniques, transcription, and analyses. CbPAR allows students the unique experience of working directly with the CoI through the phases of the research. Too often, traditional service-learning opportunities in the classroom benefits the insular culture of academia more than the community itself. Through CbPAR, students learn how to connect with the community from a scholar-activist perspective, which emboldens them to to affect social and political change in their communities. We argue that CbPAR methods are mutually beneficial to faculty, students, and the community and should be used more often to allow for research to be less exploitative in our drive to advance science.

Abstract Name: **Machine Learning to Develop Models for Analyzing Stress in an Academic Environment**

This paper demonstrates the significance of readily available machine learning (ML) platforms like IBM Watson machine where the user can develop ML models to analyze the data and predict the outcome with high accuracy by using various algorithms. This platform provides a great opportunity to new users with limited computing and/or data analysis experience to run a machine learning problem. This is achieved by offering the user an option of automated selection of various algorithms and other relevant parameters (hyper parameter values) under both supervised and unsupervised learning. In the current work, we are analyzing the data collected from an academic institution in Pakistan to evaluate the impact of various parameters on students' average grades by developing ML models on Watson platform. The data was collected right after the COVID peak by distributing a questionnaire among students. The aim was to obtain information on various relevant parameters that were grouped in four sections as "General Information", "Perceived Stress Scale", "Cognitive Assessment", and "Social Dependency". Watson ML platform was used to develop a model under "supervised learning" option and by incorporating various algorithms including Extra Trees Classifier and Random Forest Classifier. The machine proposed two best performing pipelines corresponding to Random Forest Classifier that gave an accuracy of 66.4% (Cross-Validation) in which feature enhancements were performed including hyper parameter Optimization and feature engineering. The paper includes details on various aspects of using ML Watson-platform and the outcome of the ML-model for the analysis of the current data. Results shows that among all impacting parameters, cognitive performance, self-study hours, and number of class absentees played a dominant role in predicting the student's average score. This presentation will describe the questionnaire, statistics, and ML models employed to conduct the study. Suggestions to improve the model's accuracy will also be discussed.

Jiang, Menglu

Abstract Name: **Acute Effects of Aerobic Activity Compared to Sauna Exposure on Plasma Uric Acid Concentration**

Aerobic exercise provides multiple health benefits, some of these benefits are modulated by increased body temperature, vasodilation, sweating, and others. Previous studies have shown that exercising results in plasma uric acid (UA) increased concentrations. In this study, we sought to investigate if a 30-minute session of sauna-induced heat therapy has similar effects as exercising aerobically for the same amount of time on plasma UA. We hypothesize that heat therapy and exercise will increase concentrations of plasma UA.Plasma from fourteen participants (age 23 ± 2 y, ht 1.74 ± 0.08 m, wt 80.9 ± 19.7, BMI 26.5 ± 5.5 kg/㎡) was collected and tested. Each participant completed a randomized crossover, counterbalanced control study. This trial consisted of a 20-minute resting period lying supine that was followed by 30 minutes of either sauna heat therapy (SAU: ~132°F/~56°C), cycling exercise (EXER: ~40-50% HRR), or upright sitting that served as the control (CON: control). At the completion of the trial, participants completed a 60-minute recovery period lying supine. Plasma samples were taken both pre- and post-completion of each activity for research evaluation.Cycling exercise was the only treatment to increase UA concentration, EXER (pre 3.52 ± 0.16 vs post 3.67 ± 0.15; P = 0.03), SAU (pre 3.70 ± 0.17 vs post 3.73 ± 0.15; P = 0.85), CON (pre 3.90 ± 0.18 vs post 3.74 ± 0.14; P = 0.11).Cycling for 30 minutes (40-50% HRR) was enough to increase UA levels. This is in accordance with previous studies showing that exercise increases vasopressin which concentrates plasma UA; in addition exercise results in lactic acid build up that prevents plasma UA excretion.Sauna heat therapy for 30 min at ~132°F/~56°C did not affect plasma UA levels. Longer exposure or/and intensity may be required to observe noticeable changes in this marker.

Abstract Name: **Exploring The Impact Of Educational Exchange Activities Between UWEC And CIT Project**

With the development of educational internationalization, more and more Chinese students choose to study abroad. While ample studies discuss international students, less research examines exchange programs. To better understand the impact of exchange activities on international students and scholars, this case study explored the positive experiences and challenges faced by students and exchange scholars in the University of Wisconsin Eau-Claire (UWEC) and Changshu Institute of Technology (CIT) 1+2+1 program.The research team adopted surveys and interviewers to collect data from exchange students, visiting scholars, and administrative personnel. The results revealed both external and internal factors that accounted for the participants' experience, such as students' perceptions of values in speaking up, sense of fitting in, and the importance/lack of a multilingual classroom environment. The participants shed light on gender, identity, language, culture, education, and communication style. Additionally, results showed that the study abroad experiences influenced students' networking with diverse friends and a better understanding of their own cultural values and prejudices. This project aims to offer implications for future exchange programs between Chinese and American universities, advocate for thoughtful and mutually beneficial cross-cultural communication, as well as offering suggestions for exchange students.What made this research project distinctive and meaningful was that the entire research team consisted of international students and a faculty mentor from China. Both the topic of the project and the background of the researchers represent an effort to promote equity, diversity, and inclusion locally and globally. The research team was able to bring in an authentic, culture-relative, and empathetic lens to examine the gains and challenges experienced by the participants. This project hopes to inspire more international students to engage in faculty-student research experience, enhance their professional and career skills, and amplify their voices.

Abstract Name: Social Media and Self-esteem

Social media, what did we do before it existed? Were we better off before or are we now? The debates around social media use are endless. There are strong viewpoints on both sides. Some believe it is literally the demise of human society, contributing to the delinquency of minors and providing negative information that molds the minds of the young. Others believe it is entertainment and provides no harm to society and has no impact to the changing world we live in. Still others are cautiously in the middle. While social media has been around for some time now, we still know very little about the potential long-term impact. The population most influenced is the young. This research study explores the association between age of beginning use of soical media and the impact on various aspects of development.The key areas of interest are mental health, self-esteem, sexualization, achievement and addiction. Correlational analysis will be completed in the spring semester of 2023.

Abstract Name: Skeletons of Algebraic Surfaces in Grasshopper

Algebraic surfaces can be difficult to understand from a 2D view, such as on a screen, and creating an accurate physical model comes with many inherent problems, specifically at points of singularity which cause the model to break easily. Past attempts to solve this problem have included global and piece-by-piece solidification. This ongoing project attempts to create printable models piece-by-piece and place a plug and socket connection at connecting singularities, allowing the model to be taken apart and snaped back together. We previously used OpenSCAD, but it was unable to perform the necessary Boolean operations, so we opted to change tools. Related work done in Summer 2022 focused on porting code to Rhino3D and Grasshopper. The current project extends upon this work and aims to compute and print the skeleton of algebraic surfaces, incorporate the plug and socket connections, and add shells, allowing for the printing of larger and more intricate models of algebraic surfaces.

Abstract Name: **Testosterone Increase Caused by Winning and Higher Social Standing Lead to Lower Positive Utilitarianism**

The winning effect is when an animal wins an aggressive encounter, then is more likely to engage in and win aggressive encounters in the future. This effect has been studied in humans, specifically in athletic competitions, as well as in non-human primates (Bernstein et al., 1974; Page; Coates, 2017). The increases in testosterone after winning have been linked to changes in mood, dominance behavior, perception of physical dominance, and aggressive behavior (Mazur; Lamb, 1980; Mazur; Booth, 1998; Welling et al., 2016; Carré et al., 2017). Research has found that high testosterone levels are related to more negative utilitarian decision-making, especially when this decision involves aggression and social cost (Carney; Mason, 2010). The current research is exploring “social winners”: individuals who experience the winning effect from being high status. Participants who are higher status are more likely to make aggressive utilitarian decisions and participants who are randomly assigned to win a game of Tetris will show a shift toward aggressive utilitarian decisions. Participants will be randomly assigned to win or lose a competition playing Tetris, which has been previously validated (Zilioli; Watson, 2012), and then complete the Oxford Utilitarian Scale. Inferring previous studies, participants in the winning condition will make aggressive utilitarian decisions and score negatively on the utilitarian scale. Success in males increases testosterone, which may subsequently increase how likely they are to punish others. Understanding this relationship may help illustrate why individuals in leadership roles often make harsher decisions.

Abstract Name: **Low-cost Multispectral Camera for NIR Imaging Analysis**

Low-cost multispectral imaging is critical for applications in agriculture, infrastructure, and disaster planning by enabling detection of information beyond human vision or Red-Green-Blue (RGB) cameras. Most of these applications use an Unmanned Aerial Vehicle (UAV) as a platform to carry the sensor payload, and thus require lightweight and inexpensive imaging systems. The current study aims to develop and test a simple, low-cost, yet reliable multispectral camera payload for target detection. By extending the 400 to 700nm range of visible light, we can highlight features that are otherwise unnoticeable by the human eye or digital camera, such as soil moisture levels. Through the development of a low-cost multispectral imaging payload, we will harness near infrared wavelengths for target identification purposes. The camera is developed around a Raspberry Pi (RPi) 4B computer and four different Pi camera modules: two RPi RGB modules and two RPi NoIR V2 camera modules. A python script adapted from existing packages is used to trigger each camera synchronously, simulating flight computer-controller automated data capture. To highlight different wavelengths in the captured spectrum, the NoIR camera modules have been modified by adding either a red or blue gel filter. We will report on ground testing on targets of various sizes, materials, colors, and temperatures to determine detection accuracy. The captured images will be compared against the images taken from a commercial off-the-shelf multispectral camera.

Abstract Name: **Investigating the Relationship between Academic Stress, Trait Self-Control, and Compulsive Behaviors in College Students**

Stress amongst college students has been at an all-time high, contributing towards issues in coping, poor academic performance, and increased dropout rates. The American Psychological Association has even identified this population as vulnerable to high levels of stress. The current study aimed to explore relationships with academic stress, trait-self control, and various compulsive behaviors including disinhibited eating, cyberloafing, and compulsive online shopping. In total, 164 college students were surveyed utilizing convenience sampling to take part in this research by volunteering their time to fill out a 71-item survey. Survey packets included the Perceptions of Academic Stress Scale (PAS), the Brief Multidimensional Self-Control Scale (BMSCS), the Dutch Eating Behavioral Questionnaire (DEBQ), the Cyberloafing in Lectures Measure (CLM), and the Modified Bergen's Shopping Addiction Scale (M-BSA). In addition, several demographic questions and daily hours spent on Social media were asked. It was hypothesized that there would be negative correlations between academic stress and trait self-control. Furthermore, it was believed that there would be negative correlations between trait self-control and the various compulsive behaviors studied. Lastly, it was hypothesized that there would be positive correlations between academic stress and the compulsive behaviors studied. Results found significant moderate positive correlations between academic stress and cyberloafing and compulsive online shopping. Furthermore, a significant moderate negative correlation was found between academic stress and trait self-control. Trait self-control and the compulsive behaviors studied were unrelated. Correlations between academic stress and disinhibited eating were also not significant. Recommendations for future research, implications, and limitations are discussed.

Abstract Name: **Ribosome Biogenesis in Cancer Cachexia**

Cancer cachexia is a wasting syndrome characterized by the loss of skeletal muscle mass, which in turn is a predictor of poor prognosis and mortality in cancer patients. Maintaining skeletal muscle mass during cancer is also associated with longevity in this population. The synthesis of ribosomes, known as ribosome biogenesis, is a central mechanism regulating cell mass, including muscle cells. This investigation aims to determine whether ribosome biogenesis and ribosomal abundance in skeletal muscle is impaired during cancer cachexia in a genetically modified mice model of pancreatic adenocarcinoma (the KPP mice) that resembles muscle wasting in humans due to cancer cachexia. The KPP mice will be used to test the hypothesis on whether ribosomal abundance is affected in cancer cachexia and whether lower ribosome synthesis precedes the onset of cancer cachexia. Understanding the molecular mechanism of muscle wasting in cancer cachexia will allow us to design better therapeutic approaches.

Abstract Name: **A limit to the prosocial spending effect: Parents are not happier spending money on their children than themselves.**

The finding that spending money on others (vs. the self)—particularly close others—promotes happiness has been well established.However, no research has investigated whether this prosocial spending effect emerges for parents when spending on their children. Testing this question is important for both the prosocial spending and parental well-being literatures. In a separate study, we found preliminary support for the hypothesis that parents are happier after spending on a child than themselves, but the study was only correlational and had some sampling issues. Therefore, in the current research we conducted an online experiment in whichparents (N= 228) were randomly assigned to recall and describe a memory in which they spent $20 onthemselves (personal spending), another person (prosocial spending), or on their child (child spending). After the manipulation they reported their positive emotions. Controlling for baseline positive emotions, parents were happier after reliving a time they spent money on someone else than themselves—the well-established prosocial spending effect. In contrast to our prediction, parents reported being similarly happy after reliving a time they spent money on themselves as in their children. As a stronger test of this hypothesis, future research should replicate this study with three improvements: 1) modify the writing prompt to focus on discretionary spending, 2) increase sample size, and 3) include a measure of inclusion of other in the self. Although prosocial spending is a strategy people can use to increase their well-being, it may not apply to parents spending on their children.

Abstract Name: **The Effects of Socioeconomic Status on Childhood Obesity Rates**

This presentation examines how socioeconomic status affects childhood obesity rates and evaluates socioeconomic status as a determinant of health within the United States. Socioeconomic status does not only affect children's access to healthy foods but also affects what type of community they live in, physical activity spaces, and school resources available for their families. Through this research, I was able to evaluate the quality of life of children with obesity, the impact of race and ethnicity, and current intervention programs that address this issue. Prior research has studied the development of intervention programs across the country to explore the gap in health as it pertains to socioeconomic status, but research is limited to the results of community-specific programs. When addressing the issue of childhood obesity, health professionals must consider their holistic health to improve the lives of children. This issue must be addressed as a barrier for adolescents, but also their families and communities to increase the number of healthy habits and lives. Future research should focus on the implementation of nationwide obesity prevention programs in low-socioeconomic communities that address environmental and nutritional issues through various methods.

Abstract Name: **Using low-cost sensing technology to assess ambient and indoor air quality in Queens, New York during and after the COVID-19 Pandemic**

Air pollution is a leading cause of death in the U.S. Although ambient air quality improved during the COVID-19pandemic, indoor air pollution (IAP) remains a concern yet data are seriously lacking. Understanding the role of respiratory illnesses is critical. Americans generally spend about 90 percent of their daily lives indoors. With no indoor air quality (IAQ) health standards, high IAP levels imply greater health risks among vulnerable groups especially children, the elderly and persons suffering chronic respiratory and cardiovascular diseases. This study utilized the AirBeam2, to measure concentrations of particulate matter with a diameter of 2.5 micrometers (PM2.5) to investigate the differences between indoor and ambient PM2.5 levels in Queens, New York during the COVID-19 pandemic in winter, spring and fall of 2020 at six private homes, and in fall 2022. Meteorological parameters: temperature and relative humidity were monitored simultaneously. IAP levels were more than two times greater than ambient levels. Indoor spaces with little or no ventilation and direct emission sources such as smoke from cooking, particularly in kitchens and basements, resulted in higher PM2.5 levels that momentarily exceeded outdoor levels and those in more ventilated areas. Indoor PM2.5 concentrations were significantly higher than outdoor levels, p = 0.05. High ambient PM2.5 levels were attributed to vehicular traffic at street-facing sampling sites. Even under normal conditions, infiltration of PM2.5 through ventilation systems could further degrade IAQ. The identification of PM2.5 sources in this study can be useful in devising control strategies for improvement of IAQ and consequently, the alleviation of respiratory health effects. Further, these findings may be used as a basis for in-house modifications including natural ventilation and the use of air filters to reduce exposures, mitigate future risks, and prevent potential harm to vulnerable residents.

Abstract Name: **Finding our place with Being here.**

Martin Heidegger’s concept of Dasein, quite literally, Being here, is remarkably similar to thecore values of deep ecology, justly, what is our place within nature and how do we orientourselves around that place. By understanding our Beingness within the framework of Heideggerian philosophy that deep ecology is rather unknowingly biased off, we can better understand that our Being is the same as all Beings around us and thus conceptualize a world thatis non-Anthropocentric as we are all the same Being. The presence of “hyper objects” things thatwe can conceptualize but are unable to fully comprehend play into this greater sense of Being-in-the-world, as one can conceptualize one's role in an ecosystem, but struggles to understand whythe Being-in an ecosystem is so important as well.

Abstract Name: **The Influence of Trisomy on Neurodevelopmental Milestone Achievement in the Ts65Dn Mouse Model of Down Syndrome**

Down syndrome (DS), caused by the triplication of human chromosome 21 (Hsa21), is the most common genetic cause of intellectual disabilities. The Ts65Dn mouse model of DS has a freely segregating chromosome that contributes a third copy of ~100 genes homologous to those found on Hsa21 and has similar phenotypic abnormalities such as reduced brain volume and body size. Little is known about how trisomy affects early brain development and how this alters the ontogeny of behavior in this mouse model. Assessing behavior during the postnatal period of rapid neurodevelopmental maturation may provide information on the influence of trisomy of Hsa21 on neurobehavioral milestone achievement. We hypothesize that the Ts65Dn mouse model will display delayed behavior and milestone achievement compared to the wildtype littermate mice. A series of neurodevelopmental assessments are administered on a rolling timeline for the first three postnatal weeks in trisomic and wild type pups. Assessments include weight (measuring physical growth), cliff aversion (measuring strength and coordination), and ultrasonic vocalization (measuring the number of calls and power of calls emitted). Preliminary results indicate trisomic mice display an approximate three-day delay in reaching growth and developmental milestones when compared to wildtype littermates. Delayed or altered brain development in the Ts65Dn mouse model has the potential to reduce performance on the neurodevelopmental tests given, indicating neurobehavioral deficits in the mouse model. Results from this study provide a baseline for future behavioral studies in DS developmental research and to better understand how trisomy affects developmental delay.

Abstract Name: **Reusable polymers for the selective separation of metals from aqueous solutions**

What do smartphones, vehicles, and medical imaging devices have in common? Aside from being crucial components of a functional modern society, none of them could function without metals. As the demand for these technologies rises, so does the accumulation of metal waste. Recycling metals is a difficult task, and current recycling methods lack the selectivity required to separate them efficiently. In pursuit of improved recycling techniques, we are developing a series of polymers that can selectively absorb and release metals from aqueous solutions.
By introducing charged functional groups onto the polymer backbone, we can use the polymer to attract metal ions from aqueous solutions. This attraction between the metal ions and the polymer is called chelation. We can coax the polymer to selectively chelate one metal over another by changing the type of charged functional group on the polymer backbone. Synthesizing a library of polymers with different functional groups that have different binding preferences is our ideal goal, as it would allow us to isolate one metal from a solution of electronic waste, leaving the other metals behind.
We control the chelation and release of metals by changing the pH of the solution that surrounds the polymer. In a high pH solution, our polymer can chelate heavy metals, specifically copper, cobalt, and nickel, exhibiting a visible color change after metal uptake. After decreasing the pH, the polymer releases the metals. Our polymers can be reused to chelate and release metals for multiple cycles. By designing functional groups with highly selective, pH-dependent binding preferences, we can use this polymer system to recycle electronic waste, repurposing these useful metals. With the rise of modern technology, the development of improved metal recycling methods like these is becoming increasingly important.

Abstract Name: **Population Diversity and Density Framework: DNA Barcoding of Indiana Predators**

Predators play a crucial role in maintaining a healthy ecosystem. Sitting on top of the food chain, predators keep prey population under control, thus initiating a cascade effect for maintaining biodiversity in an ecosystem. In Indiana, reported predators include coyotes, bobcats, and gray and red foxes. The data on the exact estimate of these predators' population in Indiana is lacking. This project was proposed to supply valuable information regarding predator diversity and population density. Predator species were identified using a DNA barcoding approach. DNA was first extracted from noninvasive samples of scat and hair of predators in Indiana using the QIAamp Fast DNA Stool Mini Kit. PCR was then performed using primers HCarn200 and CanidL1 and Taq 5X Master Mix. PCR products were purified using Zymo Genomic DNA Clean and Concentrator kit and samples were then sequenced by Genewiz. Finally, individuals were identified using a SNP based assay and the genotypes of each sample were used for calculating population genetic statistics, such as allele frequency, heterozygosity, and FST, which are indicators of population genetic health. The new knowledge generated through this study will be used in a broader modeling framework to estimate predator density and predator home ranges.

Abstract Name: **Looking in when you're left out: Regulating emotions following social exclusion**

As humans, we have a fundamental need to belong. When that need is threatened, it can lead to negative emotions, such as depression, self-doubt, negative or pessimistic thoughts, and more. Past research has found that the awareness of internal body signals (interoception) moderates the effects of exclusion. Our study extends this past work and focuses on the connection between social exclusion and interoception. We will use the experimental task Cyberball to induce feelings of exclusion and ostracism. Cyberball is based off the playground game, catch: the participant and two internet characters pass a virtual ball to each other and, eventually, (in the exclusion condition) the other characters stop throwing the ball to the participant. This induces the feelings of exclusion. Past studies have found that higher interoceptive awareness increases the effectiveness of the coping strategies used, such that the individual uses more effective emotion regulation for handling negative emotions from exclusion. This can be critical when strong emotions arise from social exclusion. We plan to replicate and extend past research on exclusion and interoception. We predict that individuals with greater interoceptive awareness will be less negatively impacted by social exclusion, induced via Cyberball. Pilot data and future directions will be shared based on preliminary findings from spring 2023.

Abstract Name: **Race Predicts Reactions to Controversial Information About Racism in Policing**

Humans are not impartial receivers of information. Several cognitive biases are known to influence individuals' evaluations of new information. For example, individuals' assessments may be influenced by the identity or lived experience of the person presenting such information (i.e., a messenger), as well as the individual's own identity or lived experience. We investigated the degree to which people's reactions to scientific information about a controversial issue, racism in policing, are influenced by three factors: 1) participants' own racial identity (black or white), 2) the messenger's racial identity (black or white), and 3) the news platform on which the messenger presents their information (MSNBC or Fox News). In this study, participants were asked to read a handout containing a set of bulleted statistics that run counter to prominent narratives about the ubiquity of racist policing. For example, the handout included a breakdown of the number of unarmed white (26) and unarmed black (12) people that were shot and killed by the police in 2019, and it described data showing that many people drastically overestimate the number of unarmed black people that are shot and killed by police. Participants were led to believe through random assignment that the information came from either a black or white police chief who appeared on either Fox News or MSNBC, for a total of four experimental conditions. We hypothesized that participant racial identity, messenger racial identity, and news platform would independently predict participants' reactions to the information and also interact to affect participants' receptivity to the information. Contrary to expectation, the manipulations (messenger race and news platform) did not influence participants' reactions to the handout; however, one robust pattern in the data was that white participants viewed the message more favorably and were less inclined to censor it than were black participants.

Abstract Name: **Impact of COVID-19 on Student-Teaching Practices: How Undergraduates Utilized and Researched Mursion Simulations to Bridge the Field Experience Gap**

Globally, COVID-19 was described as the biggest disrupter in the lives of individuals, including student teachers (Pokhrel; Chhetri, 2021). Student-teachers faced uncertainties, especially in field experiences, when schools, colleges, and universities were closed. Third-year student-teachers faced the challenge of having no field experience in their second year and third year of training. COVID-19 drove educators to utilize E-learning technology tools, such as Mursion simulations to continue teaching and learning (Aucejo, French, Araya, Zafar, 2020).This qualitative research presentation provides a comprehensive summary of how undergraduate student-teachers used Mursion simulation to bridge the field experience gap during the COVID-19 pandemic. Student-teachers answered the research questions (1) What was your experience teaching Mursion avatars and (2) In what way(s) did this teaching experience bridge the field experience gap?Undergraduate student-teachers applied the participatory action research (PAR) approach (Raynor, 2019) to this research. A total of 47 student-teachers completed the mandatory field experience using Mursion mixed reality simulation. Each student-teacher taught avatars thrice, for thirty minutes each time. There was one mandatory teaching episode recommended by the class professor, and student-teachers selected two other scenarios from the library of scenarios in Mursion. Following each teaching episode, student-teachers had a debriefing session with the simulation specialist. Finally, student teachers completed a personal reflection in Google Docs after each teaching episode. This research summarizes the results of the 47 student-teachers who participated in this research, using Mursion simulation.Student-teachers indicated Mursion was beneficial to future teachers' interactions with students and parents, realistic, intuitive to learning, a vital part of the teaching job, and Mursion bridged the teaching gap. The use of technological advances such as Mursion simulations can enhance the training of student teachers, similar to using simulations in the military, medicine, and aviation.

Abstract Name: **UVR2 and UVR3: Candidate Regulators of the Chaperone-Protease System in Chloroplasts**

The CLP protease system is conserved in bacteria, mitochondria, and higher plant plastids, such as chloroplasts, and maintains protein homeostasis by degrading a wide variety of substrates. Several CLP protease components have been identified in chloroplasts; however, more components are believed to be involved in regulating this complex degradation system. Previous affinity purification and mass spectrometry experiments identified the proteins UVR2 and UVR3 to be enriched in a stabilized CLPC1 chaperone-protease complex, distinguishing UVR2 and UVR3 as candidates for regulating CLP proteolysis. These proteins are especially of interest as UVR2 and UVR3 have no previously characterized function but contain UVR motifs, which are also found in three proteins already identified to be involved in the chloroplast CLP protease system: CLPC1, CLPC2, and CLPF. Furthermore, in bacteria, adaptor proteins regulate assembly and activation of CLP chaperones through direct interactions with their UVR motifs. As such, this study aims to understand the role that UVR2 and UVR3 play in the chloroplast CLP protease system. The objectives were to test whether UVR2 and UVR3 form dimers and interact with CLP proteins in vitro–as predicted by my homology modeling–as well as to determine if these proteins serve a redundant function in stress response. To test UVR2 and UVR3 interactions, I used restriction cloning to generate recombinant UVR2 and UVR3 proteins for future in vitro pull downs with recombinant CLP proteins. UVR2 and UVR3 have an almost (81%) identical protein sequence. To determine if these proteins serve a redundant function and a role in stress response, I established a double null uvr2uvr3 t-DNA insertion line, which will be used for future stress response phenotype studies. Characterizing the function of potential regulators of the CLP chaperone-protease system is significant, as unraveling the mechanisms of CLP substrate selection is key to understanding chloroplast proteostasis.

Abstract Name: **Rehydration of fluid preserved vertebrate natural history specimens.**

Fluid fixation and storage is one of the most common methods of preserving vertebrate natural history specimens to be used in research and teaching, especially for fishes, amphibians, and reptiles. Storage of such specimens requires well-sealed containers and/or periodic replenishment of the storage fluid to prevent desiccation. In many collections, however, especially college teaching collections, container failure and/or lack of regular curation can lead to specimens becoming dehydrated, which limits their utility for either teaching or research. A technique developed by John E. Simmons in which dehydrated specimens are exposed to high humidity has had success in restoring such specimens. We are investigating the efficacy of this technique by comparing rehydration in a chamber using Simmons' original protocol versus one in which the humidity within the chamber is boosted by the use of a saturated salt solution as the source of the humidity. We are using American Toad (Bufo americanus) specimens which were collected in 1965, but subsequently experienced dehydration at an undetermined date prior to the experiment.

Abstract Name: Expressing and Purifying Type IV CRISPR Accessory Proteins

CRISPR (Clustered Regularly Interspaced Short Palindromic Repeats)-Cas (CRISPR-associated) adaptive immune systems defend bacteria and archaea against phages, plasmids, and other mobile genetic elements. Each Type IV CRISPR system contains a subtype-specific gene and is hypothesized to be essential for function. The Type IV-A system encodes ATP-dependent 5'-3' DNA helicase called CasDinG, while the Type IV-B systems encode a putative pyrophosphatase named CasCysH. Here we investigate the function of the type IV CRISPR systems by expressing, purifying, and characterizing the accessory proteins from the Type IV systems. This project is a first step towards understanding the structure and mechanism of Type IV systems and the possibility of repurposing Type IV systems in future applications.

Abstract Name: Experimental investigation of the radiated waves from variable-shape wave energy converters

Optimal control solutions of the conventional fixed-shape wave energy converters result in bidirectional power behavior (reactive power), which means that the power take-off unit harvests energy at certain times and acts as an actuator at other time instants to create resonance in the system. Power take-off units that provide reactive power are complex and expensive. Variable-shape wave energy converters were recently introduced to eliminate or reduce the need for this reactive power requirement of the power take-off unit. This work proposes a design for the variable-shaped buoy, and an experimental radiation test was conducted. The experiment uses a buoy setup where an inflatable/pressurized spherical buoy was semi-submerged by using an external weight (plate). Four 3-D printed arms with lengths equal to the radius of the buoy were connected to this plate from one end and to the buoy's shell from the other end. Servo motors were connected to these arms such that when these servo motors rotate, the buoy's shape changes in a controlled manner. Wave gauges and accelerometers were used to measure the waves and buoy responses. A comparison of the radiated wave amplitude and the buoy heave response for the variable-shape wave energy converter and the fixed-shape wave energy converter was conducted. Also, the effect of varying the internal pressure of the inflatable buoy is investigated on its response. Results show that the heave response and the radiated wave amplitudes from the variable shape buoy are higher than the fixed-shape buoys.

Abstract Name: **Starting a mouse lab from the ground up: A compliation of tools, experience, and campoarison of DNA sampling options for genotyping**

Mice have been used in laboratories for more than a century. Their physiological similarities to humans, short life expectancy, quick reproductive cycles, and ease of care make them model organisms. Research-intensive universities typically have pre-established vivariums with hundreds of mice and dedicated vivarium staff. Although some of this knowledge is available in published resources, some of it is difficult to find, or not available all in one place. Additionally, resources like The Guide for the Care of Use of Laboratory Animals are great for establishing IACUC protocols, it is not an all-inclusive tool for those trying to start a lab from the ground up. In this presentation, we will share information that we collected as we started a new mouse laboratory in August 2022. We will include what is needed before the mice arrive; IACUC protocols, equipment, and space preparation. The recommended quarantine protocol and parasite screening will also be discussed. We will also examine how to start a breeding program: prenatal care, birthing, post-natal care, and weaning. In addition, we will present data on how other types of DNA sampling (cheek swabs and hair follicles) compare to the common tail-tip amputation for genotyping purposes.

Jones, Elizabeth

Discipline: **Visual Arts/Performance Art**

Author/Contributors:
Elizabeth Jones

Abstract Name: **Feminine Heritage Within Stitches**

My project is comprised of two parts. The first part will be the creation of a quilt using a pattern my great-grandmother had published in a 2004 quilting magazine, though the pattern was made by her and her mother 54 years earlier in 1951 for her son's wedding. Most crafts have the same baggage, but I chose to analyze quilting because it is the craft I have the most expertise on and has been described as painting with fabric, thus providing an effective medium to compare to the fine arts. Through studying quilting as an ever-present art form, I will analyze and present concepts of gender, identity, and the perceived value of art, craft, and Women's Work.For the second part, I will research and write a historical over-view of American quilt making that includes personal anecdotes from my family history interwoven into the narrative with a particular focus on who did/does create quilts and when/why they are recognized and praised for quilt making both in the past and today. Quilts are often divided into functional quilts and artistic quilts. This disallows functional quilts from being a form of artistic expression and thus, created by artists. The reality is that even though traditional quilts have a purpose, they are not devoid of artistic expression; their creators imbue their work with messages, colors, forms, and balance intentionally while remembering the needs of their intended function. This paradigm of artistic value defines traditional quilts on a basis of lack, implying their lowered status when compared to the fine arts. I seek to describe and challenge this frame of mind through a braided essay referencing the quilt I will create.

Abstract Name: **Ester hydrosilylations via a titanocene borohydride-PMHS reagent system**

An efficient and environmentally friendly way to reduce carbonyls.Carbonyl reductions are an important and fundamental reaction in organic chemistry. Synthetic organic chemists have routinely applied this transformation to form basic motifs in multi-step syntheses of complex organic molecules. An efficient and environmentally friendly way to reduce esters via carbonyl hydrosilylations with a titanocene(III) borohydride-PMHS system was carried out on a Schlenk-Line under inert atmosphere. It was discovered that the use of isopropanol as an additive accelerated both the formation of the active catalyst and the hydrosilylation of esters. The breadth of this approach was investigated by probing the reduction of a variety of esters with different steric and electronic properties. The product yields were measured using a variety of analytical techniques such as GC-MS, NMR, and FTIR. Overall, the optimized procedure for ester hydrosilylations via a titanocene borohydride-PMHS reagent system was successful for a large variety of substrates, and preliminary mechanistic studies indicate a titanocene(III) hydride species is formed in situ and this new complex is responsible for subsequent carbonyl hydrosilylations.

Abstract Name: **The Importance of Play in Parent-Child Relationships**

While play is often misinterpreted as a trivialor optional part of childhood, research suggests that play has an essential role in the development of children and attachment. Previous research has also found that parental participation and perceptions of play can affect the attachment with their child. This current research study investigated the importance of play and parental involvement in play as it pertains to the parent-child relationship. Data was collected using two questionnaires examining parental play involvement and parent-child interactions. They were administered to parents of children under the age of 12 through an online survey. A total sample of 52 parents responded to the questionnaire. My results did not find a statistically significant relationship between the frequency of parent play and parent-child acceptance. However, the study did find that there was a significant correlation between parental attitudes toward play and parent-child interaction acceptance. Parental attitudes towards play were also positively related to the frequency of parent-child play. This study suggests that parents who have apositive outlook on the value of play are more likely to also have greater acceptance in their relationship with their child. This research demonstrates the importance of play in creating healthy family dynamics and typically developing children.Keywords: Parental play involvement, parent-child interactions, attachment, parent-child relationship, family dynamics, questionnaire

Abstract Name: **Parental status, beliefs about verbal ability, and support for behaviorist ideas on language development**

Parents and non-parents may differ in their support for the behaviorist approach to language acquisition. Behaviorist theory posits that preschool children learn language as a result of caregivers' modeling, shaping, and rewarding of correct verbal behaviors. In a previous study conducted in our lab, parents unlike non-parents, on average, did not endorse the behaviorist approach. It is not clear why this difference emerged, but an earlier study showed similar trends in beliefs about child development whereparents were less likely to attribute children's behavioral tendencies to "nurture" and more likely to associate these with their inherent nature. Further, the behaviorist theory is comparable to a controlling, pedantic style of parenting as opposed to an autonomy-supportive style. This is an important comparison as previous research has demonstrated that individuals who adopted a controlling style of parenting also believed that the verbal ability of their children was highly fixed, that is less malleable. We examined our survey data of 451 participants (226 parents and 225 non-parents) to determine if parental/non-parental status and beliefs about fixedness of verbal ability (via a pre-validated scale) predicted the overall endorsement of behaviorist statements on language development. We also included income and educational status as predictor variables. In addition to parental status, beliefs about fixedness of verbal ability emerged as a significant predictor but not income or education. Parents were less supportive of behaviorist statements than non-parents. The stronger the fixedness beliefs of individuals (regardless of parental status) the stronger the support for behaviorist statements on language development. We discuss these findings from a multidisciplinary perspective.

Jones, Faith

Abstract Name: **The Effects of Religion and Spirituality on the Social Work Profession**

This research study examines the topics of religion and spirituality in the social work profession. For years, social work educators and practitioners have reported grappling with the concepts of religion and spirituality. The comfortability levels of practicing social workers when it comes to addressing religion and spirituality with clients are vastly and starkly different. Social workers are often wary when discussing such topics due to concerns over crossing personal boundaries or ethical violations, or solely because the social worker themselves may not feel adequately educated on the subject or hold strong religious and/or spiritual beliefs. Although every client may not be religious or spiritual, those who are can have religion or spirituality as a pillar of their identity and often like to use this part of themselves in recovery or in their sessions. Social work is rooted in faith and yet faith is scarcely talked about in both social work education and social work practice. Following IRB approval, electronic surveys were sent to social work students and practicing social workers in order to learn more about their attitudes and behaviors when it comes to the topics of religion and spirituality in their practice. The research findings supported the researchers initial hypothesis that many social work students and social work practitioners do not have high levels of confidence when discussing faith or spirituality with clients. In addition, many do not feel adequately prepared or educated to do so. Therefore, social workers should be equipped in knowing how to handle or communicate in said situations and be able to readily adapt to whatever level of faith the client possesses. Moving forward, the researcher plans to further explore these topics in order to shed light on the importance of religion and spirituality in the future of the social work education and the profession.

Jones, Nadeem

Abstract Name: **Whole Genome Analysis of Isolated Congenital Diaphragmatic Hernia**

Congenital diaphragmatic hernia (CDH) occurs when the diaphragm muscle fails to close during prenatal development, and the abdominal organs (stomach, intestines and/or liver) move up into the chest through the hole in the diaphragm. This congenital difference is clinically classified as being either isolated or syndromic. While a majority of CDH cases are classified as isolated (>60%), underlying genetic causes of these cases are rarely found (<5%). Therefore, our objective is to identify possible genetic diagnoses for isolated CDH. We hypothesize that most genetic contributors to isolated CDH will be caused by either mutations in genes whose function is limited to diaphragmatic development, mutations in regulatory elements of CDH genes that regulate those gene specifically in the developing diaphragm, or mosaicism (post zygotic) mutations in CDH genes with tissue limited mosaicism primarily in the diaphragm.Using whole genome sequencing of blood, skin, and diaphragm tissue of CDH patients, anin-silicoanalysis ofde novovariants was performed to identify possible contributors to CDH using various genetics databases. Integrative Genomics Viewer (IGV) was utilized to analyze the presence of mosaicism mutations between tissues.After the whole genomes of 15 CDH patients were analyzed for contributors to isolated CDH, a frameshift variant was identified in the rare known CDH gene, ZFPM2. Notably, this variant was observed only in the diaphragm tissue, indicating that it was a mosaicism mutation with tissue limited mosaicism primarily in the diaphragm. Our finding represents the first ever mosaicism mutation identified as contributing to the development of isolated CDH. This discovery can be implemented directly into clinical practice to provide recurrence risks of CDH for families. It can also indicate if future patients' CDH is syndromic or isolated which impacts management and prognosis for the child.

Abstract Name: **Investigating the use of 3D Printing to Enhance the Capabilities of Electrochemical Machining**

In the past few decades, several non-traditional manufacturing techniques have been advanced to the point where they are now commonly used in industry. Electrical discharge machining (EDM) and 3D printing are two examples of such technologies that have matured and revolutionized industrial manufacturing. The electrochemical machining (ECM) process machines metal in a similar way to EDM and offers several advantages over the EDM process. ECM is a cold process that does not create a heat affected zone in parts and it is capable of creating better surface finishes in parts than EDM. This research is focused on the design and construction of 3D printed plastic tool blanks to allow rapid development of ECM tools in order to reduce the cost of manufacturing and to create tools with geometries that are difficult to produce with conventional machining techniques. The process for creating ECM tools involves first 3D printing a part that has a surface designed in the shape of an ECM tool before electroplating that surface with copper to create a conductive electrode. The current focus of our investigation is to demonstrate that a 3D printed tool blank can be successfully coated with copper, and subsequently used in an ECM process. Anticipated outcomes include observation of processes and tool blank characteristics that enable or inhibit copper coating, and description of features machined by a 3D printed tool via the ECM process.

Abstract Name: **Developing a Novel Fluorogenic-Based Assay to Measure Chaperone Mediated Autophagy Activity in Cells and Tissues**

Pathologies including cancer, neurodegenerative, and cardiovascular diseases, are caused by the accumulation of misfolded/damaged proteins. Intracellular protein degradation mechanisms play a critical role in the clearance of these disease-causing proteins. Chaperone mediated autophagy (CMA) is a protein degradation pathway that employs chaperones to bind proteins, bearing a unique KFERQ-like motif, for delivery to a CMA-specific Lysosome Associated Membrane Protein 2a (LAMP2a) receptor for lysosomal degradation. To date, steady-state CMA function has been assessed by measuring LAMP2a protein expression. However, this does not provide information regarding CMA degradation activity. To fill this dearth of tools / assays to measure CMA activity in cells and tissues from preclinical models, we generated a CMA-specific fluorogenic substrate assay. Methods: A novel CMA substrate fluorogenic probe (KFERQ-FP) was designed. KFERQ-FP when cleaved generates fluorescence. Using an inhibitor of lysosomal proteases, i.e., E64D [L-trans-Epoxy-succinyl-leucylamido(4-guanidino)butane)], responsible for degrading CMA substrates, the actual CMA activity was determined. Essentially, CMA activity = (substrate)fluorescence - (substrate+E64D) fluorescence. To confirm specificity of KFERQ-FP for CMA, scrambled CMA substrates were designed. Results: Heart, liver, and kidney lysates containing intact lysosomes were obtained from 4-month-old adult male mice (n=6 tissue samples/group). First, lysates incubated with KFERQ-FP displayed a time dependent (0-5 hour) increase in fluorescence vs. lysates incubated with scrambled substrates. These data validate the specificity of KFERQ for CMA. Of note, liver exhibited the highest CMA (6-fold; 0.05) > kidney (2.4-fold) > heart (0.4-fold) at 5-hour. Second, E64D prevented KFERQ-FP degradation, substantiating that KFERQ is degraded via lysosomes. Third, cleavage of KFERQ-FP and resulting fluorescence was inhibited in H9c2 cardiac cells transfected with LAMP2a vs. control siRNA. These data suggest LAMP2a is required for KFERQ degradation. Conclusion: We have generated a novel CMA activity assay for use in cells and tissues in a variety of experimental contexts.

Abstract Name: **Using low-cost sensing technology to assess ambient and indoor air quality in Queens, New York during and after the COVID-19 Pandemic**

Air pollution is a leading cause of death in the U.S. Although ambient air quality improved during the COVID-19 pandemic, indoor air pollution (IAP) remains a concern yet data are seriously lacking. Understanding the role of IAP in respiratory illnesses is critical. Americans generally spend about 90 percent of their daily lives indoors. With no indoor air quality (IAQ) health standards, high IAP levels imply greater health risks among vulnerable groups especially children, the elderly and persons suffering chronic respiratory and cardiovascular diseases. This study utilized the AirBeam2, to measure concentrations of particulate matter with a diameter of 2.5 micrometers (PM2.5) to investigate the differences between indoor and ambient PM2.5 levels in Queens, New York during the COVID-19 pandemic in winter, spring and fall of 2020 at six private homes, and in fall 2022. Meteorological parameters: temperature and relative humidity were monitored simultaneously. IAP levels were more than two times greater than ambient levels. Indoor spaces with little or no ventilation and direct emission sources such as smoke from cooking, particularly in kitchens and basements, resulted in higher PM2.5 levels that momentarily exceeded outdoor levels and those in more ventilated areas. Indoor PM2.5 concentrations were significantly higher than outdoor levels, $p = 0.05$. High ambient PM2.5 levels were attributed to vehicular traffic at street-facing sampling sites. Even under normal conditions, infiltration of PM2.5 through ventilation systems could further degrade IAQ. The identification of PM2.5 sources in this study can be useful in devising control strategies for improvement of IAQ and consequently, the alleviation of respiratory health effects. Further, these findings may be used as a basis for in-house modifications including natural ventilation and the use of air filters to reduce exposures, mitigate future risks, and prevent potential harm to vulnerable residents.

Abstract Name: **Short term measurements of formaldehyde, moisture, and environmental PM near Georgia Southern University Buildings**

With the increasing use of carpet as flooring in buildings around Georgia Southern University and Statesboro's significant rainy weather, the environmental exposure levels of moisture via carpets are also increasing. The purpose of this study aimed to measure airborne moisture levels at various times of the day in the interior and exterior settings of University buildings to determine levels of exposure in relation to temperature, humidity (both hidden and pin-type), moisture, and overall microbial activities in carpet. Procedures/Methods: Samples will be collected at five different locations between 8:00 - 9:00 AM , 1:00 PM - 2:00 PM, and 4:00 PM - 5:00 PM on Tuesdays and Thursdays in the Fall 2022 and Spring 2023 semesters. Formaldehyde, and total particle concentration will be determined by the use of the DT-988 Particle Counter. Chlorine gas will be measured with the Aeroqual Series 500 Monitor (S-500). The total microbial activity in carpets will be determined by an ATP by the SystemSURE Plus V.2 Hygiena.·ResultsThe microbial activity range 0 to 2025, which was the peak value. The particle and ranges showed no particular trend between buildings depending on location and time of the day.·ConclusionThe preliminary data collected so far did not provide any trends for pollutants, probably due to low levels of pollutants released in the cold temperature of winter. Higher TVOCs were detected on the rainiest days of the study. We expect some variations of data in the measurements of next several months at elevated temperatures.

Abstract Name: **EFFECTS OF ATYPICAL ANTIPSYCHOTICS IN RATS TRAINED TO DISCRIMINATE BETWEEN 22 AND 2 HOURS FOOD DEPRIVATION**

In humans, weight gain is a side effect of atypical antipsychotics. In rats, clozapine increases eating, but reduces food-related, operant behaviors. Ziprasidone has smaller or no effects on eating in rats. Given the short half-life of clozapine in rats, we tested the effects of acutely administered clozapine and ziprasidone on the discriminative stimulus effects of food deprivation. Male, Sprague-Dawley rats were trained to discriminate between 22 and 2 hrs (hours) of food deprivation in a two-lever operant task. Under 22 hrs deprivation, left lever presses were reinforced by a 45 mg food pellet. Right lever presses were punished with 8 seconds of darkness. Under 2 hrs deprivation conditions, the contingencies were reversed. Training sessions lasted until 10 reinforcers were earned or 15 minutes elapsed. Training continued until rats emitted 80% or greater condition appropriate responding before the first reinforcer was earned for 8 out of 10 sessions. After acquiring the discrimination (M = 71, SEM = 6 sessions), subjects were food deprived for 2 or 22 hrs and injected subcutaneously with either clozapine (1.0-5.6 mg/kg), ziprasidone (0.32-1.0 mg/kg) or vehicle (1.0 ml/kg). For the 5 minute or 5 reinforcer test sessions, responses toward either lever were reinforced under the FR 15. Test trials were conducted every 15 min for 2 hrs. After test session, food intake was recorded for 1 hour. Clozapine and ziprasidone did not induce hunger-like responses under 2 hrs deprivation. After 22 hrs food deprivation, clozapine (1.0-5.6 mg/kg) significantly reduced hunger-like stimuli induced by 22 hr deprivation, whereas ziprasidone had no effect. Under both deprivation conditions, clozapine decreased food intake, but ziprasidone did not. These data indicate clozapine decreases feeding-related behaviors in rats. Atypical antipsychotic medications have different effects on food-related behaviors in rats and humans

Abstract Name: **Dietary preferences of invasive red swamp crayfish (Procambarus clarkia) from the Patuxent Research Refuge, Maryland**

Invasive species are a leading cause of environmental degradation in freshwater ecosystems. Invasive crayfish, for example, can displace native crayfish and consume large quantities of both aquatic macrophytes and native animals. While Maryland is home to three invasive species of crayfish, relatively little is known about their impacts to local food webs. Here, we collected invasive red swamp crayfish (Procambarus clarkia) from the Patuxent Research Refuge in Laurel, Maryland and performed a feeding experiment to understand their dietary preferences and likely influence on refuge food webs. Crayfish were housed in 20 x 12 x 10-inch glass tanks equipped with air stones and polyvinyl chloride pipes for refuge. They were offered native plants and animal matter in three separate week-long trials, and their diet preferences were quantified based on the percent of food mass remaining at the end of a trial. We also used the stable carbon and nitrogen isotopic composition of wild red swamp crayfish to understand how their dietary niche compares with that of a common, native omnivore, the eastern painted turtle (Chrysemmys picta picta). Our feeding experiment showed that on average, red swamp crayfish preferred smartweed (Persicaria sp.) over other species of aquatic plants and animal matter over native plants. We also documented substantial variation among individual crayfish – a finding echoed in wild crayfish's variable nitrogen isotope values. Finally, we observed considerable overlap between the red swamp crayfish's isotopic niche and that of the eastern painted turtle. These results provide insight into the impact of an invasive species within one of the largest green spaces in the Washington, D.C.-Baltimore corridor.

Abstract Name: **The Effects of Animal Assisted Therapy in the Stress and Anxiety of Nursing Students**

Background: Nursing students experience stress and anxiety with a curriculum requiring study in both the didactic and clinical setting, adaptive style testing, and being held to a higher grading standard in order to move forward in the program. These high levels of stress and anxiety can inhibit the students' learning resulting in poor academic performance, serious health issues, and decreased emotional well-being.Purpose: The goal of this project is to explore the impact of animal-assisted therapy in the stress and anxiety levels of nursing students. Studies have shown AAT to be an effective intervention in relieving feeling of stress and anxiety by stimulating the release of neurotransmitters that promote relaxation, calmness, and general well-being. Pet therapy is a form of social support found to be effective in minimizing stress and anxiety in students.Methods: Nursing students in a baccalaureate program will interact with a therapy dog for thirty minutes prior to taking an exam. The participants will then complete a survey tool, The Human Animal Link: Modification of Stress in the Higher Education Setting, describing their experience with the therapy dog as well as the Pre-Exam Animal Visitation Program Student Survey (PASS) to evaluate the effectiveness of AAT.Discussion: Stress within nursing school is a given, but it is important for the nursing student to implement an effective stress reduction intervention to move forward in the program, graduate, and prevent early burnout with stressful experiences as a new graduate. In the classroom, ATT can provide a positive, stress-free environment to facilitate learning. Using AAT in university nursing programs can provideas an inexpensive intervention for students to cope with feelings of stress, anxiety, and depression related to higher education.Key words: animal-assisted therapy, stress, anxiety, nursing students.

Abstract Name: The Conquest of the Latinidad: Historical and Contemporary Colorism in Hispaniola

The research paper “The Conquest of the Latinidad: Historical and Contemporary Colorism in Hispaniola” has been composed under the subset of Race, Gender, and Sexuality Studies. Historically, Latinidad was used as a blanket term to encompass various Latine identities: however, it has come under fire for its lack of inclusion towards race in recent years. Race has become engrained to Latin American society, as a leading result of the European colonization of Latin America. Specifically, a multi-ethnic, radicalized society has been created in Hispaniola as a result of the combination of European, African, and Amerindian identities. This research seeks to answer “To what extent has colorism impacted Haitian and Dominican society?” The purpose of this research is to analyze the foundations of colorism in Hispaniolan society, as well as its contemporary effects. Since inception, Latin America has existed as an amalgamation of identities. Europeans arrived in Latin America in the fifteenth century, leading to a mixture of identities. The Spanish created Las Castas in order to divide these identities into subsects (i.e. mestizo and mulatto).The implementation of this system can be seen on the microcosm that is Hispaniola, which represents the modern-day Dominican Republic and Haiti. In Haiti, the French established Code Noir to outline Black freedmen and slaves treatment on the island.As a result of these systems, colorism dominated early Hispaniolan society, with its ramifications continuing contemporarily through instances such as antihaitianismo sentiments in the Dominican Republic.The research methodology for this paper is the usage of previously written academic sources, interviews with academics, and surveys to create conclusions regarding colorism. The expected conclusions are that Hispaniolan society was built upon a foundation of colorism due to Code Noir and Las Castas and has become an integral part of Hispanolan identity due to the commodification of race.

Abstract Name: Neighborhood Effects: An Ethnographic Study of the South Loop, Pilsen, and Austin Neighborhoods in Chicago

Place is more than just the physicality or location of something. It is also a productof buildings, streets, the people who surround it and occupy that space. Place cannot exist without the actors and the actors cannot exist without the place. Both play an essential function in understanding neighborhood effects and the necessary equipment for living. It is important that people develop the necessary knowledge and equipment for living to function and make the best of their daily interactions that take place in society.Chicago is composed of many different neighborhoods;however, each neighborhood poses different challenges with respect to the equipment for living or the practical routines individuals need to figure out and make their way through each community. This study draws upon first-hand observations, demographic analysis, and interviews to understand and compare these different routines in the South Loop, Pilsen, and Austin community areas of Chicago. Through this study it was found that these communities vary greatly in terms of access to clean and healthy food, relationship with the police and the community,diversity, homelessness, and access to everyday resources. These findings help to understand the importance of building a relationship with the community around you and why it is important for people to understand the daily equipment for living in these neighborhoods in Chicago.

Abstract Name: Development and Implementation of a Tailored Breast Cancer Awareness Program at a University in the Midwest

Breast cancer (BC) is the leading cause of global cancer. Early diagnosis through screening has decreased mortality rates; however, the population's awareness of BC screening is unclear. Members of university settings are particularly an advantageous target population for increasing BC awareness because they are primarily active adults, potentially strong disseminators of knowledge, influencing the community around them.This project aimed to design and implement a breast cancer awareness program tailored to the needs of a community at a Midwestern university. During the 2021-2022 academic year, an online survey on breast cancer awareness was emailed to all undergraduate/graduate students, faculty, and staff of a university located in the Midwestern U.S. The participants' responses were critically reviewed and organized into categories (phase 1), and data were used to plan activities to promote breast cancer awareness in the following academic year (phase 2). Phase 1: Over one thousand university community members responded to the survey, and approximately 200 participants shared specific suggestions on what information they perceived as needed and how they would like to receive it. Survey results suggested the need for awareness activities related to BC risk factors and screening measures. Participants also shared their interest in learning through posters, presentations, apps and shared stories, besides understanding university resources related to BC. Phase 2: The team developed a series of events for 2022 Pink October, consisting of breast cancer awareness tables to share the information signalized by survey participants, opportunity for conversations with health providers, and group meeting with faculty/staff who shared personal stories about BC experience. Students, faculty, and staff were invited to participate in all events. Results will be used to inform awareness strategies for 2023 Pink October activities.

Abstract Name: The Associations between Belongingness, Trust, and the Willingness to Donate to One?s Alma Mater

Donations are a vital part of keeping universities up and running across the globe. Thus, it makes sense that universities have a vested interest in fostering relationships with students that will generate future donations. This study examines the degree to which feelings of belongingness, trust, and engagement in campus activities affect an individual's willingness to donate to their alma mater. The 72 participants in this study represent a diverse group of students at the University of Wisconsin-Eau Claire. The findings indicate that feelings of belongingness with the university and the belief that one can trust the university are more strongly associated with a willingness to donate. Engagement in campus activities was not significantly associated with a willingness to donate. Thus, we learned that while it is important for a university to provide opportunities for students to engage in campus life, the university should spend equal time fostering a sense of belongingness and trust with their students.

Abstract Name: **Synthesis of Doxorubicin-Protein Conjugates Via Cobalt Coordination Chemistry: Conjugates of Transferrin and Immunoglobulin G**

Protein-drug conjugates are a rapidly expanding family of therapeutics that hold significant potential to ameliorate off-target toxic effects commonly observed in patients undergoing chemotherapy. In this context, the protein acts as a nanoscale delivery vector that alters the biodistribution of the drug upon administration by restricting its unhindered distribution in vivo. Researchers at TWU are exploring the use of cobalt coordination chemistry in the synthesis of doxorubicin-protein conjugates. Previous work has shown that cobalt can be used to crosslink amine-containing molecules in a reversible reaction that only utilizes the lone pair of electrons on nitrogen to form a dative bond with cobalt. Doxorubicin was chosen for initial studies because it contains a primary amine that could be crosslinked with lysine residues on a protein to form a protein-drug conjugate. Conjugates of dox with albumin, transferrin, and immunoglobulin G were investigated to demonstrate the broad applicability of the method for bionconjugation reactions. Drug loading was investigated by HPLC and the conjugates further characterized by dynamic light scattering, mass spectrometry, and calorimetry. Details of the effects of reaction conditions on synthesis of stable conjugates will be discussed.

Abstract Name: **Systematic review of ?7 nicotinic acetylcholine receptor on anti-inflammatory effects against T-helper 2 cells induced inflammation**

The nicotinic acetylcholine receptor (nAChR) is an ionotropic receptor that accepts acetylcholine as the primary ligand. Nicotine, a stimulant in the central nervous system (CNS), can also bind to nAChR as the receptor's name suggests. The activated nAChr regulates the cation flow such as Na+, K+, and Ca2+ through the plasma membrane, which is fundamental for neural signaling. nAChr is a pentamer composed of five subunits among diverse subunits: α1-10, β1-4, γ, δ, and ε. Amongst the numerous possible pentamer combinations, α7 homo-pentamer is the principal type that has been studied the most. The α7 nAChR is also present in nonneuronal cells (such as blood cells) throughout the human body as well as the CNS and PNS. These α7 nAChR are thought to play a quintessential part in terms of neuroimmunomodulation as they are involved in physiologically crucial pathways such as the cholinergic anti-inflammatory pathway (CAP). This study explores the participation of α7 nAChR in other anti-inflammatory pathways such as the T-helper 2 cell (Th2) response, to investigate its mechanism of action and potential modulation paths in allergic inflammation.

Abstract Name: **Meeting the Monster: A Creative Exploration of Korean Culture and Mythology**

My project unravels my identity and relationship to Korean culture as part of the Korean diaspora, specifically as a Korean born in the Philippines, who grew up in predominately Papua New Guinean and white-American communities. I explore how Korean culture impacts me by incorporating Korean folklore and myths into my original creative writing piece, a hybrid of short fiction and memoir. By reclaiming Korean folklore and myths as a part of my own story, I gain insight into the relationship between my inner world and ancestral history while showing the relevancy of a nation's ancient narratives to a wider audience. Korean folklore and myths, such as the legend of Barikongjoo and the tale of Shim Cheong, cradle the lives of my ancestors. They show the Koreans' fears, anger, and desires. It is undisputable that the emotional, spiritual, and societal challenges a nation and family generations dealt with in the distant past impact the lives of individuals today. To see how I am directly shaped by my ancestor's past lives, both psychologically and spiritually, despite living amongst non-Koreans, I recast the stories that my ancestors created, deemed as important, and orally passed down to me. Even as a third culture kid who was born and grew up outside of Korea her whole life, I find a burning desire to connect to Korean culture when I read and listen to Korean folklore and myths as I try to form my own identity amidst non-Korean cultural environments. By braiding my own personal narrative with Korea's famous folklore and myths, I will show the parallels and interactive relationship that my own story has with the greater stories of Korea itself and why the world needs to retain and revive the culture these ancient stories have been preserving for us.

Abstract Name: **Markers for viable donor hearts during long term normothermic ex-vivo perfusion**

The average donor heart will last for approximately four to six hours when preserved with static cold storage, adding another limiting factor to the donor organ supply. This research aims to identify markers of a viable donor heart as it perfuses for extended durations of time outside of the host. After standard heart procurement under anesthesia, pig hearts are placed in a normothermic ex-vivo perfusion apparatus (M-Flow), which provides O2 and nutrients and removes CO2 and toxins for 24 hours. Oxygen is provided via a blood-derived solution infused into the coronary arteries via the aorta, and venous blood from the heart is collected from the pulmonary artery. We analyzed data from four hearts (241-282 g) preserved for 24 hours with the MFlow system. Left ventricular systolic pressure (LVSP, ideal: >25mmHg), heart rate, cardiac rhythm, lactate (ideal: <4.5 mmol/L), and glucose (ideal: 80-120 mg/dL) were monitored continuously and collected hourly. All hearts were perfused successfully with M-Flow for 24 hours. The heart rateswere between 60-120 bpm, and one heart required pacing. LVSP was maintained >25 mmHg (25-86 mmHg) while lactate values were <4.5 mmol/L (1.1-4.4 mmol/L) throughout the whole experiment. Glucose was within normal values except for one experiment that required higher supplementation of glucose throughout the study. The use of the M-Flow system to perfuse and preserve hearts for 24 hours proves to be successful as all cardiac function variables (heart rate and LVSP) and biomarkers (lactate and glucose) were sustained in a similar and consistent fashion to published studies by our group. Therefore, the M-Flow apparatus is a novel device that uses artificial intelligence to autoregulate blood flows and oxygen delivery based on algorithms.

Abstract Name: Designing a Uniform Magnetic Field for nEDM Experiments

According to the Big Bang Theory, equal parts of matter and antimatter should have been created in our Universe. Now, it is predominantly matter. Understanding the differences between particles and anti-particles through CPT symmetry could lead to insight into our existence and reshape the Standard Model of physics. This matter – antimatter imbalance can be explained with the detection of a non-zero electric dipole moment within the neutron (nEDM), which violates these symmetries. To detect annEDM, an extremely uniform magnetic field is required because neutrons are hypersensitive to magnetic fields. The main goal of this project is to design a uniform magnetic field that will be used measuring thenEDM. This magnet will be a double cosine theta coil. The design includes a cylindrical, double layer aluminum skeleton that will serve as the base of the magnet and skins to surround it. These skins will contain clips which will secure the wires in place and make the field more uniform. Once the design of the magnet has been finalized and all components have been 3D printed, the magnetic field can be mapped using a robotic mapper and MATLAB. This could then be used to understand what adjustments would need to be made on a design level to improve the electromagnet's uniformity.

Abstract Name: Unconscious Bias or Trainable Attitudes? Training Implicit Biases That May Be Detected in the Implicit Association Test

Implicit Association Tests (IAT) are intended to measure beliefs that people are unable to admit (Project Implicit).Architects of the IAT acknowledge that results are onlyweakly correlated with measurable behaviors.The purpose of the current research was to determine whether a neutral implicit association could be trained into participants and subsequently be detected on an IAT.Participants were trained to associate negative words with angular shapes, and positive words with rounded shapes. Training sessions presented angular or rounded shapes, followed bypositive or negative words. Participants had to press "correct" or "incorrect" buttons depending on the shape and word association shown. After completing all training sessions, participants were given an IAT to determine whether they showed an implicit preference for rounded shapes. The IAT was created using the experimental design utilized by the IAT Website according to the methodological designs provided by the authors (Project Implicit) and replication studies (Jain et al, 2022). Data collection is currently ongoing.During the training session, trainees' reaction times were tracked to measure the strength of the associations being developed between shapes and positive and negative stimuli.After completing the IAT, trainees' scores on the rounded/angular shape IAT will be analyzed using the standard chi-squared analyses to identify the presence and strength of implicit associations.Additionally, using a X2 test of independence, trainees' IAT scores will be compared to scores of untrained participants who complete the same IAT.If results indicate that trainees exhibit implicit associations between rounded shapes/positive words, and angular shapes/negative words, and do so to a greater extent than control participants, this will suggest that implicit associations detectable by IATs can be formed quickly, and with relatively few exposures to previously nonexistent associations.These findings hold implications for understanding implicit associations and contribute to conversations on developing bias awareness training.

Abstract Name: Linguistic Nationalism in Hispanic Country Constitutions

As the “law of the land,” a country’s constitution defines the institutions and values that it finds essential to a functioning society. Among the plethora of these themes discussed in a constitution is the issue of language, particularly the official status of a certain language and its function in society. When the rights and powers of a certain language make it dominant over other languages in the country, it creates a dynamic known as linguistic nationalism, where language is used as a tool to exert control over other groups in a country. Particularly prominent examples of linguistic nationalism exist throughout the Hispanic world, where the Spanish language was imposed on indigenous societies during the period of colonialism. Although the Spanish language remains the de facto lingua franca in much of the Spanish-speaking world in the post-colonial world, each of the countries approached its relationship to a country's collective national identity. This often translates to the Spanish language exerting continued dominance over indigenous languages. Employing Critical Discourse Analysis methodology, this study explores the role of the Spanish language in Hispanic constitutions, bridging linguistic discursive elements to the ideology of a constitution’s framers. Through this methodology, three separate cases of Spanish’s role in society emerged. The first is Spanish’s role as the sole official language, maintaining its hierarchy over indigenous languages. The second places Spanish as a co-official language, creating equity between indigenous communities and Spanish. The third is the lack of any language as official, removing Spanish’s dominance over society through intentional linguistic ambiguity. This application of Critical Discourse Analysis develops the understanding of the Spanish language’s status in post-colonial Hispanic constitutions, and how linguistic nationalism is engendered and institutionalized through these documents.

Abstract Name: Attosecond electronic excitations in molecules

Light-induced electronic excitations are at the basis of many fundamental physical processes, from the photoelectric effects in materials, to light harvesting in photosynthetic organisms, to cancer-inducing radiation damage in organic tissues. These processes unfold at the ultrashort time scale of a few attoseconds (1 as is one billionth of a billionth of a second). Only recently, with the development of new laser technology capable of delivering isolated extreme ultraviolet pulses with a duration of only a few tens of attoseconds, has it become possible to experimentally observe these electronic excitations in real time. To interpret the results of these experiments, however, the assistance of advanced quantum-mechanical calculations is required. Indeed, sophisticated theory is needed to draw the connection between the detailed motion of electrons, at the microscopic scale, and their signature in the macroscopic observables recorded in the lab. In this work, we present a theoretical time-resolved study of the electronic dynamics triggered in carbon monoxide, CO, by an ultrashort pulse of ionizing radiation. To do so, we use ASTRA, a new molecular ionization code developed in our group, to reproduce the absorption by CO of an extreme ultraviolet attosecond pulse (pump), in the presence of a delayed infrared dressing field (probe), as a function of the pump-probe delay. The pump pulse causes the valence electrons in carbon monoxide to slush back and forth across the molecule. By perturbing the system at different times, the probe IR pulse is able to reveal the stage of this periodic oscillation, thus allowing us to reconstruct and even control it.

Abstract Name: **Spider functional community assembly along a stress gradient in Northern and Southern Wisconsin forests**

Ecological communities are smaller subsets of overall larger species pools.Ecological selection can cause a community to have less than expected functional trait diversity, narrowing it to a small subset of features (trait clustering). There are also processes, such as competition, that can cause communities to have greater than expected trait diversity (trait overdispersion), especially where ecological stress is low (i.e., the stress-dominance hypothesis). Ecological selection can also alter the mean trait values of communities.There has been considerable work on the functional assembly of plants and fish, but little is known about assembly of terrestrial invertebrate animals. We placed three pitfall traps in 40 locations in Northern forests (i.e., mainly evergreen conifers) and Southern forests (i.e., mainly deciduous trees) across a strong gradient in soil moisture. We measured the size and asymmetry of spider body, leg, eye, and mouthpart traits because they are related to resource acquisition. We used Monte Carlo simulations to estimate the amount of functional trait diversity and mean trait values that would be found if community assembly was caused by random ecological drift. The simulations used three species pool scales: regional (all species), within Northern or Southern Wisconsin forests, within specific forest types. Overall, trait diversity was less than expected by chance, but the effect size was smaller when using smaller species pools.Spiders were larger in Southern forests, but mean trait values were unrelated to soil moisture.Size trait diversity increased with moisture in Northern forests, but not in Southern forests.This partially supports the stress-dominance hypothesis.Asymmetry trait diversity was also unrelated to moisture.Functional community assembly differed in Northern versus Southern forests, and so there are unique assembly rules for each region.

Abstract Name: **Backwards and in High Heels: How Sexism Has Been And Continues to Be Portrayed on Screen**

Everyone's heard that Ginger Rogers did everything Fred Astaire did, but in high heels and backwards. How has the double standard of higher expectations affected women on screen? How has it changed over time? Through a feminist critique, my paper analyzes representative mainstream films and the way in which women are portrayed. It also discusses and evaluates the historical context within which our cultural values evolve. In order to examine their portrayal, I evaluate the effect of patriarchy, the male gaze, and enlightened sexism. The patriarchy is a social construct in which limitations are placed on women and can be most easily seen in the media. The male gaze also affects the ways in which women are portrayed, especially on screen where the camera directs the audience's eye. Enlightened Sexism is the concept of how embracing femininity and sexuality is seen as a way for women to take back their power but in actuality ignores the history of female sexual oppression. This paper draws on previous work: How Societal Structures Contribute to Means Girls (2004) and Mean Girls: The Musical (2018): A Feminist Critique of Mean Girls, and expands the scope of films analyzed to include films such as Top Hat (1935), Star Wars: A New Hope (1977) and Little Women (2019). As an interdisciplinary undergraduate student my analysis combines Communication and History. This feminist critique demonstrates a correlation between the patriarchy and societal values in how women are portrayed on screen. As the portrayal of gender has changed in films, we would expect to see a change in cultural values.

Abstract Name: **Comparing Historic Artifacts from Two Archaeological Sites on the Red Cliff Indian Reservation, Gaa-Miskwaabikaang**

My research took place in Red Cliff, Wisconsin, as part of Gete Anishinaabe Izichigewin Collaborative Archaeology Project (GAICAP), a community-based effort that brings archaeology under the control of local Ojibwe people. Under the direction of the Red Cliff Tribal Historic Preservation Officer, Marvin DeFoe and professional archaeologists, I conducted field and laboratory research during summer 2022. In doing this I compared glass, metal, and ceramic artifacts from two roughly contemporary late 19th and early 20th century archaeological sites on tribally owned lands: Frog Bay Tribal National Park and the Old Pageant Grounds. This research has identified differences in the kind of artifacts present at these two historic sites and helps determine what each area was used for within the community. Outcomes include narrowing time-frame of usage and identifying specific objects and their purposes. All of this is done in the interest and at the request of the Red Cliff community to increase their knowledge of their sites in order to better protect them.

Abstract Name: **Using Remote Sensing to model suitable habitats for Rusty Patched Bumblebees in Rock Island, Illinois**

Species biodiversity is an important foundation for healthy ecosystems. When a species is endangered/threatened, it is a sign that the ecosystem is slowly failing. This is especially important for the Rusty Patched Bumble Bee because as a pollinator, they contribute to our food security and the healthy functioning of our ecosystem. In 2017, the Rusty Patched Bumble Bee was federally listed as endangered; therefore, more work needs to be done to conserve this species. Since habitat loss and degradation has been a key factor in the decline of this species, my research has focused on finding suitable habitats for the Rusty Patched Bumble Bee. My research uses Image Classification in Remote Sensing technology to identify diverse floral resources in people's yards, road edges, arboretums, and even in forests within the city of Rock Island, Illinois. The Rusty Patched Bumble Bee has been found to do really well in urban/suburban landscapes, which is somewhat unique for a rare species. However, with its recent listing, there is not much known about them; therefore, this research will help identify habitat needs and thresholds, identify potential areas to survey, and find potential conservation zones for the species.

Abstract Name: **Implications of LRRK2-G2019S Mutation on DARPP32 Phosphorylation and Cortical Physiology in Parkinson's Disease**

Parkinson's Disease (PD) is a neurodegenerative disease characterized by degeneration of dopaminergic neurons in the substantia nigra pars compacta (SNpc) of the midbrain. Over 10 million people worldwide are currently diagnosed with PD, and about 15% of PD cases are familial and majority of these are attributed to mutations in the leucine rich-repeat kinase 2 (LRRK2) gene. LRRK2 is highly expressed in medium spiny projection neurons (SPNs) of the striatum. SPNs express either D1 or D2 dopamine receptors that relay information to the basal ganglia and thalamic nuclei about motor decisions that are then sent to the cortex. The LRRK2-G2019S mutation influences SPN excitability by inhibiting activity of protein kinase A (PKA) and regulates its ability to phosphorylate dopamine and cAMP-regulated phospho- protein Mr 32,000 (DARPP32). Selective phosphorylation of DARPP32 regulates protein phosphatase-1 (PP-1) activity and may play a key role in regulating activation of AMPA and NMDA receptors, both of which affect long term potentiation (LTP). Revealing a connection between the LRRK2-G2019S mutation and glutamate receptor activity via the phosphorylation of DARPP32 will be groundbreaking in allowing researchers to explore the mechanisms by which the basal ganglia pathways and PD dopaminergic signaling pathway is affected by the LRRK2-G2019S mutation. Preliminary results indicate a consistent reduction of DARPP32 in the cortex of LRRK2-G2019S knock-in mice, and I am further investigating the effect of the mutation on glutamate receptors in primary mouse models.

Abstract Name: **Utilizing Machine Learning algorithms trained on Recent Music-Listening Activity in Predicting Big Five Personality Traits: A Novel On-going Investigation**

Music has been important to everyday life since long before modern civilization and has been a subject of study for many years. It has been known to be a positive predictor of personality traits due to the individuality of personal preference. These personality metrics are typically evaluated using a Big 5 trait inventory that measures personality into 5 categories: Openness, Conscientiousness, Extraversion, Agreeableness, and Neuroticism. The study will attempt to assess the prediction quality of an individual's Big Five personality traits from a week worth of recent participant music listening activity from the Spotify Application Programming Interface using machine learning (ML). The created dataset will allow for correlating each of the 5 Ten Item Personality Inventory dimensions with music genres, artists, year, beats per minute, energy, danceability, loudness, length, acoustic, popularity, and other features in a vector. The dataset will be standardized and used to train on ML models such as Random Forest, Decision Tree, K-Nearest Neighbors, Logistic Regression, Support Vector Machine, etc. Prediction accuracy will be compared to previous works. Metrics include accuracy, FPR, TPR, and ROC/AUC scores. Both regression (continuous numeric value) and classification (Likert scale) will be used. A full literature review showed this is the first study to use both Spotify API data, rather than self-reported music preference, and ML classification, rather than traditional statistical tests and regression models, to predict the personality of a college student demographic. Applications of this study include custom advertisement recommendations and music therapy. Approval has been granted to administer the survey by Irvine Valley College's Institutional Review Board.

Abstract Name: **A Deep Learning Model for Pancreatic Ductal Adenocarcinoma Chemotherapy Outcome Prediction**

Pancreatic Ductal Adenocarcinoma (PDAC) is an aggressive abdominal malignancy, with an overall 8.5% 5-year survival rate. PDAC is often detected too late for surgical resection and is associated with resistance to chemotherapy and radiation. To minimize ineffective chemotherapy treatment, the ability to identify tumor characteristics and predict chemotherapy response is essential. Morphological characteristics of PDAC tumors can be extracted from CT scans and are associated with tumor characteristics and behavior. In this research, a deep-learning system for predicting chemotherapy outcomes based on CT scans is being explored. To establish the foundation for this system, a segmentation model is being developed and optimized. The effects of novel data augmentation techniques, including window-leveling, histogram matching, five-fold cross-validation, and YOLO bounding-box-based cropping on segmentation accuracy are examined. The morphological characteristics of PDAC tumors, upon initial inspection, revealed that over 50% of Radiomic features are statistically different between normal and abnormal patient populations. By establishing techniques for standardizing CT scans from different datasets and using a flexible segmentation model, we aim to create a pipeline for pancreas segmentation followed by tumor extraction using Radiomic texture analysis.

Abstract Name: **Neurodiversity, Personality, and Mental Health Challenges**

Prominent variations of neurodiversity include autism spectrum disorder (ASD), attention deficit hyperactivity disorder (ADHD), and dyslexia. Institutions of higher education should foster an inclusive environment for these individuals, which includes understanding common behavioral attributes, limitations, predictors, prevalence, and desirable adaptations.Participants in our pilot study were 23 females and 8 males (31 total), drawn from convenience and student sources. The primary goal in this first foray into investigation of neurodiversity in higher education was to focus on personality and related associations with common attributes of these three forms of neurodiversity. Follow-up with larger samples is planned to investigate their prevalence and effects / limitations in the college environment.Results found that openness to experience correlated negatively with typical ASD symptoms such as difficulty with social norms (r = -.52, .01). Neuroticism correlated positively with ASD symptoms (r = .46, .05), and individuals higher on neuroticism were more likely to suffer burnout (r = .74, .00001). Participants endorsing ADHD symptoms also reported higher burnout (r = .50, .01), and participants not reporting ADHD symptoms reported higher levels of self-care activities (r = -.46, .01).Although this pilot study focused on associations and not causality, our results nonetheless identify several correlates of neurodiverse symptoms and provide direction for follow-up research. The potential benefits of enhanced understanding of neurodiversity in higher education include targeted resources, classroom adaptations, and counseling resources. In short, continued research offers great potential to afford neurodiverse students the same opportunity to succeed as neuro-normal students.

Abstract Name: Breakthrough or Quackery?: An Exploration of Yoga within US Economy and Healthcare

Over the past century, “spirituality” as an alternative to “religion” has absorbed many non-western practices. In the contemporary United States, yoga has transcended the world of “spiritual” practice and implicated itself into a diversity of contexts as a method of practicing spirituality and mindfulness outside the bounds of institutionalized religion. Yoga has also come to be perceived as a method of healing and has been absorbed into practices of alternative medicine. It has also become a popular form of exercise for those who shy away from aggressive exercise practices, like bodybuilding. Furthermore, the capitalist spirit of the United States has taken all of these iterations of yoga and turned them into a product which is marketed and sold to those willing to explore its purported benefits.In this presentation, I will examine why yoga has become so popular within the fitness and wellness industries as opposed to the US healthcare system, which is still substantially reliant on biochemical treatments. Who is attracted to yoga as a practice? As business empires built on yoga have flourished for decades, what continues to drive the customer base? I will argue that one of the main attractions of yoga and related practices is the healing sense of community that they generate. Sharing a path with others towards a similar goal, whether it is physical or spiritual mindfulness, makes the journey easier because every achievement and setback can be appreciated in a collaborative environment. Whether the collaboration is virtual or in person, yoga as both a spiritual and a healing practice is sustained by shared experiences that validate struggles while also testifying to the triumphs of said practices. Given the success of yoga and similar practices as forms of alternative medicine, what can we learn about implementing alternative medicine within the US healthcare system?

Abstract Name: Is Sleep Quality a Factor Influencing Clinical Self-efficacy During Undergraduate Nursing Students' First Clinical Experience?

BACKGROUND: Undergraduate nursing students' first clinical experience is essential because it affects their outlook on their profession. In the existing nursing literature, nursing students have struggled during their first clinical experience which caused some students to leave the profession. Students’ personal health such as sleep quality is noticed to affect their academics and clinical performance. The purpose of this study is to examine undergraduate nursing students’ sleep quality as a factor influencing clinical self-efficacy beliefs during their first clinical experiences.
METHODS: The objective population for this cross-sectional survey was undergraduate nursing students with first clinical experience who were enrolled in clinical courses at three universities. The survey consisted of demographics, sleep quality (Pittsburgh Sleep Quality Index (PSQI) score), and clinical self-efficacy beliefs (Self-Efficacy Clinical Performance (SECP) scale. SPSS software was used to analyze the data with Pearson’s coefficient being calculated to find the correlation between sleep quality and self-efficacy beliefs.
RESULTS: Among the 37 participants, the mean age was 20.92 years and 91.9% were female. Participants reported poor sleep quality (M=7.60±2.831) and high clinical self-efficacy beliefs (M=38.06±9.227) during first-time clinical experiences. Pearson correlation test showed no statistically significant correlation (r = 0.138) between both variables. However, the results of this study showed that 77% of participants reported that they had poor sleep quality during their first clinical experience (PSQI>5). Additionally, the participants reported lower clinical self-efficacy beliefs in the nursing diagnosis (M=6.87±2.178) and evaluation (M=7.17±2.204) stage of the nursing process.
CONCLUSIONS: The study revealed poor sleep quality during undergraduate nursing students' first clinical experience. This evidence should raise nursing educators' awareness of students' personal health and recognize the potential defects of poor sleep quality, Moreover, nursing educators should implement ways for improving students' sleep health and clinical judgment skills during their first clinical experience.

Abstract Name: **The Mesoscale Conditions that Contributed to the development of the Morton, Texas Tornado on 23 May 2022**

On 23 May 2022, the participants of UW-Whitewater's Field Course on the Forecasting and Verification of Extreme Weather witnessed a tornado in west Texas. The official tornado report had tornadogenesis occurring at approximately 0007 UTC 24 May 2022 (7:07 pm CST 23 May 2022). Based on synoptic-scale (i.e., large scale) conditions most of west Texas from the US-Mexico border into the Texas panhandle were under the threat of severe weather on this day. While in the field and in the post-mortem analysis of this day it was determined the mesoscale conditions were the main factor as to why a significant tornado occurred in the west Texas region near Morton. Mesoscale conditions were evident during the course's morning weather briefing using various mesoscale forecast models. As the day progressed and conditions changed slightly, adjustments were made by the course participants that allowed them to witness the development of the thunderstorm that would end up producing a dust storm (with straight-line wind gust up to 80 mph) and large hail (1.5 – 2.5 inches in diameter). In the post-mortem analysis, a detailed analysis of the mesoscale conditions was performed with additional data from mesoscale networks around the west Texas region. This post-event analysis did find that a localized area of enhanced shear formed near the Morton area due to a surge of dry air out of eastern New Mexico. Preliminary results show that this surge of dry air interacted with an outflow boundary from the earlier developing thunderstorms. The interaction of these differing boundaries created a small area of enhanced lift and wind shear that allowed one of the on-going thunderstorms to intensify and produce an EF2 tornado that occurred 7 miles north of Morton, which the course participants witnessed.

Abstract Name: **Genetic Control of Lamina Glia Migration in the Drosophila Visual System**

The development of the brain depends on the specification of several cell types, their interactions, and connections. In the optic lobe of the Drosophila visual system, glial cells constitutea significant portion oftotal cells (up to 10%) and play important roles in establishing structure and function. The purpose of this project is to understand the genetic control of lamina glia cell migration in the optic lobe. We have decided to study the roleof known regulators of cell migrationin the context of glial cell migration.Our investigation focused on the Rho family of small GTPases (Rho1, Cdc42, and Rac1).We did not observe a clear reduction of the migratory potential of lamina glia when knocking down Cdc42 and Rac1 activity, however a subtle defect in glia orientation was observed. Knocking down Rho1 activity resulted in the death of our experimental line, therefore a modification of methods should be explored.Furthermore, to understand the genetic regulation of lamina glia migration, we have analyzed scRNA-seq datasets that include lamina glia transcriptomes at different stages of development. As a result, wehave identified a list of genetic markers specific for lamina glia,including promising candidates that can play a role in the process of lamina glia migration.

Abstract Name: "I get physically ill when I think about us?: Making sense of memorable breakup messages

All relationships have a beginning; some have an end. The experiences we have as we disengage from relationships influence our understanding of those relationships. To better understand the memorable messages that individuals received during romantic relationship breakups, we sought to answer the following questions: What is the significance of memorable breakups? Which words or phrases are consistently remembered during a breakup? Do memorable messages usually come from the person breaking up or the person being broken up with? To answer these questions, the research team conducted 16 semi-structured interviews; participants were recruited via convenience sampling. Thematic analysis techniques (Nowell, Norris, White; Moules, 2017) were used to identify the following themes: Many of the reasons for a breakup appealed to an individual's desire for independence as they looked toward the future. Many memorable breakups also had connections with an individual's family or friends' disapproval of the relationship. In general, negative or harmful relationships yielded negative breakup memories while healthy relationships usually yielded more positive or mutual disengagement conversations. As participants reflected on a memorable breakup and pondered future breakup communication they would execute, every individual mentioned something they learned from in their memorable breakup.

Abstract Name: Shining a Light on Experimental Theatre Practices: A dissection of Neo-Futurism as it is and how it is applied in a modern performance context.

This project seeks to explore the tenets of an experimental style of theatre in a modern performance context while working with passionate students to help expand their means of artistic expression. Neo-Futurism is an active creative force and is continuing to evolve within the theatrical community. I will be basing my project on the work of The Infinite Wrench,a neo-futurist ensemble that is based in Chicago, Illinois. They are an ensemble of writers, directors, and actors that perform thirty plays in sixty minutes, all while following the four basic tenets of neo-futurism: no suspension of disbelief, speed and brevity, scripted and planned, reliance on chance. My goal is to create an ensemble of students at UWEC that mirrors this aesthetic of truthful communication between the audience and the performer. The main research questions I want to explore are 1. What exactlyisfuturism? 2. How did it evolve into neo-futurism? 3. How can we, as writers and performers, apply this specific style in a modern performance context and 4. How does a theatre practitioner develop this style of theatre? My objective for myself and the ensemble is to break out from the robotic tendencies of realism based writing and thinking and creating a new heightened theatrical sensibility. I want the audience to leave with a newfound appreciation for experimental theatre. In addition, I want our plays to evoke a particular atmosphere that challenges the audience to think for themselves. Moreover in executing this project, I want to gain dexterity in performing, writing, and directing within an experimental environment while also developing my skills as a leader amongst fellow creators. Lastly, I would like to develop this material into something suitable for a possible confrence presentation, a poster and/or a short performance at NCUR.

Abstract Name: Shakespeare and the #MeToo Movement

How have sexual violence and harassment – normalized behaviors in Elizabethan England – aged in a modern climate through literature and performance? Stephen Greenblatt defines “strategic opacity” as key elements left out of Shakespeare’s plays so events can unfold in a particular way. Utilizing his understanding of strategic opacity, I examine how opacity in textual moments – such as the lack of stage directions and ambiguousplot points – influence performance choices through our changing societal views of sexual violence. In tracing how the #MeToo movement has influenced the social climate, I am hoping to better understand how performance choices of Shakespearian plays are received by audiences. This analysis should contribute to filling the literary gap connecting Shakespeare to modern feminism by analyzing texts, performances, and literary discourses.While Shakespeare’s plays often enforce silence upon women who have been wronged, emerging cultural shifts condemning non-consensual sexual behaviors and the #MeToo movement give more powerful voices to victims who wish to share their stories. This cultural shift creates a critical discussion in Shakespearean studies as these plays have carried significance throughout time and are still taught to developing teenagers today. Tracing the variations in performance choices, textual strategic opacity, and audience reactions through a #MeToo lens will illuminate how early modern plays influence the modern societal acceptance of behaviors.

Abstract Name: Exploring the Suffocating Regimes of Totalitarianism Design

Judging a book by its cover has been a statement that is repeatedly said to avoid the miss lead judgment that could exude the imagery that could be potentially translated into so many interpretations. Judging a book by its cover can devalue the indirect and symbolic meaning of a metaphorical and internal message. In totalitarianism, judging a book by its cover has never been so apparent. Abiding by this traditional principle becomes near impossible due to the pure purpose of totalitarianism design. This direct communication through design has been part of totalitarian regimes. This authoritarian regime has taken over and adopted a fascist ruling over a long list of dictators through the years. Present and past dictators thrived on the use of the totalitarianism design in their campus, warfare, and, most importantly, day-to-day imagery of their people. Most countries and governments have engaged in several totalitarian propaganda and its distinctive art form. Historians have recognized that the most iconic rulers have obtained their positions in the public eye due to the use of visual power as a communicative strategy through poster design. Govern countries and their dictators that inhabited this style in their years of oppression would be Mussolini's rule over Italy, Stalin's communist rule over the Soviet Union, and in recent years, Saddam's domination over Iraq. One can see totalitarianism presented in democracy and other forms of politics. Nevertheless, dictatorship is the only type of political regime that glorifies design, creating vivid totalitarian imagery that leaves a powerful impression.

Abstract Name: **Stratigraphic Analysis of Paired Vegetated Linear Dunes in the Nebraska Sand Hills Using Ground Penetrating Radar**

There are three models of linear dune formation, and there is no agreement on which theory best explains their formation. The research focuses on the stratigraphy, the internal sediment layering, of the Nebraska Sand Hills' paired linear dunes in north-central Nebraska to determine how the dunes there were formed. Sand dunes are given their shape by wind velocity and sand supply. Therefore, the shape of dunes and the internal layering of sediment within them are indicators of the former wind regimes and dune movements during formation and can be used to determine the correct formation model.
The ground penetrating radar (GPR) data was collected in herringbone-shaped transects centered in the trough between paired linear dunes, extending over the crests. The pattern maximizes the visible internal layering within the dune. Sensors and Software's Pulse EKKO Pro GPR system was used as a non-invasive, high-resolution means of viewing stratigraphy. Topographical data was collected every 2 meters using Topcon RL-H4C laser level. The GPR data was collected using a frequency of 100 MHz antenna frequency, maximizing image depth while maintaining image resolution. The GPR transmitter and receiver were separated 1 meter apart and traces collected every 0.25 meters. The transects varied from 45 meters to 150 meters long. GPS points were plotted at the beginnings and ends of transects to accurately record GPR data locations. Results show some dune stratigraphic layers being superimposed over dune's, which indicates different periods of deposition. This would support a bimodal wind theory over windrift or helical roll vortices theory. The southern dune of the pairs compared to the northern are larger, suggesting two separate formational periods for each dune. Further GPR investigation and Optically Stimulated Luminescence (OSL) dating on sediment cores should be conducted to confirm ages of stratigraphic layers to provide further evidence of our results.

Abstract Name: **The Trials of Tinder: The Allocation of Attention and Selection of Dating Profiles**

This study explored how visual attention is allocated within multimodal (textual and visual) profiles, and how its role is modulated by the user's dating goal orientation. Given the serious cognitive limitations on visual processing and short-term working memory, processing the complex and bountiful information provided on dating apps necessitates an efficient and selective allocation of visual attention. Eye tracking coordinates and survey data were used to analyze how the different components of the profile (free-text and photo) draw attentional focus as measured by eye movements, as well as the influence that they have on participant responses. The study proposed that high photo attractiveness and more complex free-text biographies would generate more positive participant responses (right swipes). In addition, it was postulated that an individual's interest in either short-term or long-term dating would alter how they attended to the various components of dating profiles. This study also hypothesized that participants interested in long-term relationships would allocate more attention to the biography section than those interested in only short-term. The visual and textual components both played separate, but complementary, roles in influencing participant responses. Although both were expected to have a positive impact on participant responses (right swipes), the physical attractiveness of the profile photos had a much stronger impact. With millions of users utilizing mobile dating apps every day, the psychological mechanisms underlying dating decision-making have serious implications for the process of finding love on the internet.

Abstract Name: **Yeast Genetic Screen to Identify Regulators of Numtogenesis**

The process of nuclear mtDNA transposition (NUMT) results in the integration of mitochondrial DNA into the nuclear genome, a phenomenon termed “numtogenesis”, thatis positively correlated with mortality in colorectal cancer. In yeast, the YME1 gene functions as a numtogenesis suppressor, indicating the existence of a gene regulatory network that protects against the transfer of mtDNA into the nucleus. Mutations in thehuman homolog of Yme1 are further implicated in colorectal tumorigenesis and disease progression. Using a NUMT reporter system unique to yeast, we will systematically discover other YME genes that regulate numtogenesis by screening the genomic library of yeast gene deletion strains (YGDS). To do this, a yeast strain has been constructed that is auxotrophic for tryptophan biosynthesis due to deletion of the nuclear TRP1 gene, but contains the gene integrated into the mitochondrial genome. The synthetic genetic array (SGA) method is used to systematically derive all haploid double mutants from the YGDS library, introducing the deletion of nuclear TRP1 and themitochondrial genome with the complementing nuclear TRP1 gene into the deletion strain. Only strains that have undergone NUMT willgrow on media lacking tryptophan, as TRP1 cannot properly be translated from the mitochondrial genome. To identify new YME genes, we will use a high throughput growth curve profiling technology, named quantitative high throughput cell array phenotyping, to measure increased growth on tryptophan dropout media among the double mutant YGDS-derived library. Based on the integration of mitochondrial-encoded TRP1 into thnuclear genome, increased NUMT frequency can be detected. Human homologs of genes that regulate numtogenesis will then be surveyed for their role in cancer, as a proxy for the contribution of numtogenesis to oncogenesis, using bioinformatic (e.g., cancer genomics data analysis) and experimental (e.g., cell line and mouse xenograft models) approaches.

Abstract Name: **The Female in Frankenstein: Man's Attempt to Abort Femininity**

In her first novel, Frankenstein, Mary Shelley casts the burdens of motherhood and creation onto her male protagonist, Victor Frankenstein. By telling a creation story through the eyes of a male protagonist, Shelley subverts the patriarchal model of narrative form while still speaking to an audience attuned to patriarchal ideologies that might otherwise dismiss the issues if presented from a female voice. Frankenstein’s challenges and obligations after he creates life parallels the absence of control in a woman’s life when she becomes pregnant, and how pregnancy obliges women to a sphere of life that struggles to reach beyond the scope of the home. Depicting Frankenstein’s creation as a monster hyperbolizes the ordinary struggles women go through when they enter motherhood, acknowledging a struggle that went primarily unseen at the time, and still fails to garner public attention today. In a sense, Frankenstein wishes to abort his creation therefore retaining the life he held before. Frankenstein’s desires parallel the plight of women dealing with unwanted pregnancy and, once they have children, are forcefully placed into a life of confinement and domesticity. Through the creation of Frankenstein’s monster, Shelley challenges the expectations of patriarchal society that requires women to risk their lives in childbirth and forfeits their autonomy for a life molded by their creations.

Abstract Name: **A Critical Ethnography Of Mad Children**

The 1984 documentary “Children of Darkness” is a primary historical source, that illustrates adolescent carceral mental health care in the era of “mass institutionalization.” This research uses the film “Children of Darkness” to create a speculative ethnography that asserts a framework of symbolic interactionalism to examine the adolescents filmed in “Children of Darkness” self-reported symptomology, staff/ patient ideology, and differing ontologies of “mental illness ” endorsed by the differing staff/patient groups. Further, this research utilizes critical theories of madness and gender to assess the documentarian’s positionality and impress upon the readership that the legacy of mass institutionalization asserts a number of relevant implications to social theory, public health, and social justice.

Abstract Name: **Modeling human observer detection for varying data acquisition in undersampled magnetic resonance imaging (MRI)**

Undersampling in the frequency domain (k-space) in magnetic resonance imaging (MRI) accelerates the data acquisition. We used a fixed one-dimensional undersampling factor of 5x where 20% of the k-space lines are collected. The fraction of the low k-space frequencies that are fully sampled were varied from 0% where the primary artifact is aliasing to 20% where the primary artifact is blurring. We conducted a human observer two-alternative forced choice (2-AFC) task with a known signal for each of the acquisitions. In the 2-AFC study, a synthetic signal was placed in the center of one of two anatomical backgrounds of the brain. The observer had to choose which of the two images had the signal. Each of the 4 observers conducted 200 such trails for each experimental condition. In the 2-AFC studies, it was clear that the observers performed better with more low frequencies being fully sampled. In other words, blurring is preferable to aliasing for this task. Our goal is to develop a mathematical model that will predict these experimental results. To achieve this, we modified the three-channel sparse difference of Gaussians model observer (S-DOG). The S-DOG model uses frequency domain channels to model the human visual system. Adding a fourth channel improved our prediction of human performance. Noise models are used to account for uncertainty in human decision making. We implemented an independent noise model, rather than the previously employed proportional noise model. The independent noise model introduces the same uncertainty for all images and the proportional model has noise that depends on the image. The independent noise model more accurately predicted the average human performance. Our future research includes modeling a detection task where the observer needs to search for the signal in the anatomical background and developing a mathematical model to predict the experimental results.

Abstract Name: **Machine Learning to Develop Models for Analyzing Stress in an Academic Environment**

This paper demonstrates the significance of readily available machine learning (ML) platforms like IBM Watson machine where the user can develop ML models to analyze the data and predict the outcome with high accuracy by using various algorithms. This platform provides a great opportunity to new users with limited computing and/or data analysis experience to run a machine learning problem. This is achieved by offering the user an option of automated selection of various algorithms and other relevant parameters (hyper parameter values) under both supervised and unsupervised learning. In the current work, we are analyzing the data collected from an academic institution in Pakistan to evaluate the impact of various parameters on students' average grades by developing ML models on Watson platform. The data was collected right after the COVID peak by distributing a questionnaire among students. The aim was to obtain information on various relevant parameters that were grouped in four sections as "General Information", "Perceived Stress Scale", "Cognitive Assessment", and "Social Dependency". Watson ML platform was used to develop a model under "supervised learning" option and by incorporating various algorithms including Extra Trees Classifier and Random Forest Classifier. The machine proposed two best performing pipelines corresponding to Random Forest Classifier that gave an accuracy of 66.4% (Cross-Validation) in which feature enhancements were performed including hyper parameter Optimization and feature engineering. The paper includes details on various aspects of using ML Watson-platform and the outcome of the ML-model for the analysis of the current data. Results shows that among all impacting parameters, cognitive performance, self-study hours, and number of class absentees played a dominant role in predicting the student's average score. This presentation will describe the questionnaire, statistics, and ML models employed to conduct the study. Suggestions to improve the model's accuracy will also be discussed.

Abstract Name: **Spray Integration in the Cooling of High Heat Flux Electronics**

Spray cooling is an efficient cooling technique for high heat flux applications like metal forming and electronic cooling. However, without fundamental knowledge of fluid mechanics in these applications, spray cooling can be ineffective due to dry-out at low spray rates, or excessive liquid accumulation at high spray rates. In electronics like computer chips, these errors can cause crucial and expensive failures. The purpose of this research is to further understand the fluid mechanics and heat transfer processes behind spray cooling, enhance the ability of the process, and develop a phase diagram of collected data. The first technique researched was single droplet impingement. To obtain data, a high-speed camera was used to take detailed videos of microdroplets produced from a piezoelectric nozzle. Microdroplets of various liquids, including ethanol, isobutanol, and isopropanol, were dropped onto a heated copper surface, with the surface temperature ranging from 60 to 200 degrees Celsius. Droplet diameter, velocity, and resident time were tracked, as well as the associated behavior of evaporation, boiling, or leidenfrost, and the rate at which this occurred. These results contribute to the understanding of mechanical properties of microdroplets, discovering which combinations of droplet diameter, velocity, and liquid properties will improve their function in spray cooling. Another aspect researched was the ability of multi-droplet sprays to cool a heated surface via impingement and evaporation. An experimental setup was developed and assembled consisting of a pressurized air and water supply connected to an ultrasonic atomizer nozzle, heated plate, and thermocouples that relayed results to a data acquisition system. Preliminary results determined that cycling nozzle operation yielded similar cooling results to continuous spray, while saving up to 70% of fluid consumed. Future variables to explore include recycling atomized vapor, determining optimal timing of cycles, and testing additional liquids.

Abstract Name: Assessing Pain Behaviors in a Rat Unilateral Anterior Crossbite Model

The current popular animal models used to study temporomandibular pain disorders (TMD) rely on chemicals to develop the disorder, while clinical cases ordinarily result from wear and tear at the joint. The objective for this investigation is to develop and characterize the unilateral anterior crossbite (UAC) model, a more holistic and clinically relevant animal model to study TMD pain as opposed to chemical injections. Characterization of this model will allow for future research that emulates pain in humans.First, we recorded baseline behaviors on a battery of pain behavior tests. We used an electronic von Frey rigid tip to apply pressure and measure mechanical allodynia at the temporomandibular joint and the periorbital region to test for specific TMD and craniofacial pain, a common comorbid symptom. We tested for generalized pain or hyperalgesia with thermal and mechanical hind paw testing. One day after concluding baseline testing we cemented the prosthesis. The UAC prosthesis (n=8) and sham (n=4) were cemented using Metabond quick luting cement according to their protocol. The UAC prosthesis consists of 13 gauge needles, filed down and cemented to the maxillary incisor and 12 gauge needles, filed down, bent at a 130 degree angle, and cemented to the mandibular incisor. The sham crowns were cemented to the incisors, but the mandibular crown was not bent. Behavior testing resumed the following week and was conducted over two days every week for one month.Our results for the UAC model indicate TMD is developing and causing pain. After two weeks there is a sharp increase in mechanical allodynia at the joint. Results were insignificant in testing the periorbital region as well as for thermal and mechanical hyperalgesia in hind paw testing, indicating the model alone is not enough to create widespread pain. Future projects will add stress to testing.

Abstract Name: PATIENTS WITH VENTROMEDIAL PREFRONTAL CORTEX DAMAGE HAVE INCREASED EXPLICIT ETHNIC PREJUDICE

To reduce racially motivated behavior and hate, it is critical to understand the psychological and neurological mechanisms of ethnic tolerance and prejudice. Research has shown that ethnic tolerance requires cognitive effort and executive function resources. One leading hypothesis indicates that to exhibit ethnic tolerance individuals must inhibit unintentionally activated stereotypes and prejudicial thoughts. The ventromedial prefrontal cortex (vmPFC) is critical for executive function and inhibitory control. Moreover, the False Tagging Theory (FTT) argues that the vmPFC is necessary to disbelieve propositions. Early work has shown that damage to the ventromedial prefrontal cortex via stroke or tumor resection increases credulity to information generally. Thus, damage to the vmPFC should decrease inhibitory control and increase general belief in extreme ideas (epistemically suspect ideas that most people doubt or disbelieve), such as ethnic prejudicial beliefs. Here, we examined 72 health individuals, 15 patients with vmPFC brain damage, and 49 patients with brain damage outside the prefrontal cortex (brain damaged comparisons, BDC). These individuals were given the American Ethnic Prejudice Scale (AEPS). In support of the FTT, patients with ventromedial prefrontal cortex damage reported increased ethnic prejudice relative to the BDC group and healthy individuals. This research may offer a neurobiological explanation for the increase in ethnic prejudice during elder aging. Older adults (>65 years old) express greater prejudice (than younger adults) and tend to have structural and functional declines in the vmPFC. This work suggests that education and interventions designed to facilitate vmPFC functioning (such as inhibitory control/executive function) may decrease racism.

Abstract Name: **Identification of Beneficial Bacteria Associated with Plants Grown Alongside Birmingham Sidewalks**

Urbanization poses adverse conditions for plant growth, as it has been shown that concrete can change the pH and nutrient content of the soil, in turn changing the microbiome composition. Identifying beneficial bacteria in endogenous plants may allow increased crop resiliency in such suboptimal conditions, potentially addressing food insecurity in urban areas. One root and one leaf sample were collected from a single plant found growing on a sidewalk in Birmingham city. Two morphologically different bacterial colonies were selected from both leaf and root spread plates for a final round of streaking, resulting in single colony isolation. Polymerase Chain Reaction (PCR) was performed using 16S rRNA primer sets to yield two leaf bacteria amplicons and one root bacterium amplicon. Samples were sequenced using the Sanger sequencing technique at the Heflin Center for Genomic Sciences at UAB. Two leaf bacteria and one root bacterium were identified using NCBI BLASTN. One of the bacterial colonies isolated from the leaf sample showed a 99.06% sequence similarity to Leifsonia xyli and Leifsonia shinshuensis. L. xyli has been found in the vasculature of Bermuda grass and of corn plants and has previously been genetically engineered to improve plant growth. The second bacterial strain isolated from the leaf sample displayed a 95.24% sequence similarity to an uncultured bacterium, which may potentially be a novel, beneficial microbial strain. Bacteria isolated from the root sample showed 82.52% sequence similarity to Klebsiella pneumoniae, which has been shown to reduce plant susceptibility to nematode infection. The results for the root bacterium are limited by the low sequence similarity. Further plant inoculation studies are required to support a causal relationship between the aforementioned microbes and plant growth.

Abstract Name: **Elimination of Multi-Drug Resistant Candida auris Utilizing a CRISPR-Cas9 System**

Candida auris (C. auris) has recently become a cause for concern in healthcare facilities around the world due to its ability to cause severe infections and its resistance to a limited arsenal of antifungals including azoles, amphotericin B, and echinocandins. Utilizing clustered regularly interspaced short palindromic repeats (CRISPR) along with CRISPR associated proteins (Cas) it may be possible to eliminate C. auris without the need to rely on antifungals and can potentially eliminate the resistant fungi. Little research has been done in regard to utilizing CRISPR-Cas mechanisms to abrogate resistance or promote apoptosis in multi-drug resistant yeast such as C. auris. The goal of this research is to identify potential genes necessary for crucial cellular function and development and study the effects of removing or manipulating these genes to see if the changes will lead to elimination of C. auris. To test this hypothesis there will be five groups of C. auris isolates, two control groups and three modified groups that will be plated on selective media and media impregnated with antifungals specific to yeast. The control group will be multi-drug resistant unmodified C. auris while the modified group will be the C. auris altered via a CRISPR-Cas system specifically targeting genes coding for resistance and genes necessary for the organism's survival. Each group will be plated in succession to monitor growth in the presence and absence of antifungals to see if the organism can be eliminated.

Abstract Name: **Human vs. Faunal Bone: Less-destructive Identification using Scanning Electron Microscope**

In the medico-legal field of forensic anthropology, the most common task, and the first step in any case is determining if a suspected bone came from a human. This detail is crucial to get right, if an animal bone is mistaken as human a lot of time and resources can be wasted chasing an unwarranted forensic case, and if a human bone is mistaken for faunal the deceased may never be identified or recovered. On fragments or non-morphologically distinct bone, currently, standard practices for human vs faunal bone fragment differentiation involve cutting a section of the bone sample off or grinding down a sample into powder; both of these techniques include destroying the bone. In our research project, we analyzed various human/non-human bones and bone fragments to determine if we can accurately differentiate between human and faunal(animal) on non-morphologically distinct bone, in a less-destructive way using a Scanning Electron Microscope (SEM). Using a SEM, samples can be directly placed inside the microscope for analysis and do not necessarily need to be thin or severely altered in order to image, thus leading to a less destructive (and often non-destructive) method of bone cell analysis. Less/Non-destructive analytical techniques are beneficial for many reasons; one main reason is that when a sample is destroyed, further analysis of that sample is halted, which means that after the sample is analyzed, no new information can be obtained. This can run a case dry or impede the investigation process. Another reason, and arguably the most important reason, is that as scientists and Forensic Anthropologists we have an ethical duty to maintain the integrity of the remains we are working on out of respect for the individual and their culture/kin.

Abstract Name: **Personality and Social Influences on Personal Relationships and Daily Behaviors among University Students**

Social media has become a large network of vast amounts of information. Amongst the many types, misinformation has become an issue of current psychological interest. Misinformation, which isinformation that is made to deliberately deceive people by being untrue or inaccurate, has generated much research into the phenomenon of falling for misinformation, such as the research on emotion, personality, engagement, media presentation, etc. Notwithstanding the past several years of data backed toward this issue and its recent upswing from COVID-19 and the 2020 US Presidental election, more research must be directed towards the individual characteristics of those more likely to be susceptible to fall for misinformation, and the potential influences it can have on those individuals interpersonal lives. The present research focuses on the two previousfactors by investigatingreligious fundamentalism, personality, and interpersonal competenceas predictor variables to explore the psychosocial impact that misinformation has made since the COVID-19 Pandemic.To measure the previous constructs, this study uses the Religious Fundamentalism scale, M5-50 Personality Assessment, and the Interpersonal Competence Questionnaire to measure personal characteristics. Then to measure misinformation susceptibility, this study uses the Susceptibility to (Mis)information Scale (SIS), which categorizes participants into one of four phenotypic types of individuals susceptible to information ormisinformation: Consumers, Doubters, Knowers, and Duffers, respectively. By collecting data through this means, the current study usesa multiple-regression model to explore the relationshipsbetween exposure to (Mis)information and how people perceive their personalrelationshipsto better understand howinformation on social media and psychosocial factorsimpacts their lives. Additionally, this researchaims to learn more about what personal characteristics are more likely to accept misinformation on social media.

Abstract Name: Utilizing Machine Learning algorithms trained on Recent Music-Listening Activity in Predicting Big Five Personality Traits: A Novel Ongoing Investigation

Music has been important to everyday life since long before modern civilization and has been a subject of study for many years. It has been known to be a positive predictor of personality traits due to the individuality of personal preference. These personality metrics are typically evaluated using a Big 5 trait inventory that measures personality into 5 categories: Openness, Conscientiousness, Extraversion, Agreeableness, and Neuroticism. The study will attempt to assess the prediction quality of an individual's Big Five personality traits from a week worth of recent participant music listening activity from the Spotify Application Programming Interface using machine learning (ML). The created dataset will allow for correlating each of the 5 Ten Item Personality Inventory dimensions with music genres, artists, year, beats per minute, energy, danceability, loudness, length, acoustic, popularity, and other features in a vector. The dataset will be standardized and used to train on ML models such as Random Forest, Decision Tree, K-Nearest Neighbors, Logistic Regression, Support Vector Machine, etc. Prediction accuracy will be compared to previous works. Metrics include accuracy, FPR, TPR, and ROC/AUC scores. Both regression (continuous numeric value) and classification (Likert scale) will be used. A full literature review showed this is the first study to use both Spotify API data, rather than self-reported music preference, and ML classification, rather than traditional statistical tests and regression models, to predict the personality of a college student demographic. Applications of this study include custom advertisement recommendations and music therapy. Approval has been granted to administer the survey by Irvine Valley College's Institutional Review Board.

Abstract Name: Serious Play: Near-Peer Mentorship in UW-Madison's Undergraduate Research Scholars (URS) Program

Over the past 25 years, the Undergraduate Research Scholars (URS) program has successfully supported early undergraduate students, many of whom academic institutions have historically marginalized, in rich research and creative practice placements across campus. The URS program includes two key components: 1) partnerships between undergraduate students (Scholars) and campus researchers & artists (Mentors) and 2) a seminar-based, interdisciplinary learning community that centers near-peer mentorship by upper-level undergraduate researchers and artists (Fellows).
In this session, you will join current URS Research Fellows in an exploration of what we know about peer-leadership and mentorship within an undergraduate research program and its impact on both the peer mentors and the students they support. Fellows will share their approaches to building Scholars' resilience and sense of belonging at a Predominantly White Institution (PWI). Fellows will also reflect on pedagogical and practical strategies that contributed to their development. This includes the program's ideological framework of interdisciplinary "serious play" and intellectual emancipation, the student-led curriculum development process, and the model of academic and administrative support that makes their work possible.
Near-peer mentorship is a core element of the URS program. It is this near-peer component that is so often missing from other undergraduate research experiences in higher education. Research indicates that students' sense of belonging is enhanced by exactly this kind of mentorship, and this is especially true for students from historically underrepresented groups. In this way, URS offers a unique contribution to the landscape of belonging efforts on college campuses as well as undergraduate research participation. We hope this panel discussion will help faculty members and administrators understand how comprehensive near-peer mentorship can enrich undergraduate scholarship, especially for students from historically underrepresented groups.

Abstract Name: Evaluating the Effect of Drought Conditions on Foraging Activities in Northern Leopard Frogs (Rana Pipiens)

Drought is one of the biggest ecological dangers facing the Midwest. With wetlands being lost to both agriculture and climate change, organisms who rely on them are decreasing at alarming rates. Northern Leopard Frogs (Rana pipiens) are a species that historically has thrived across the Midwest and are now seeing drops in numbers. As average temperatures increase and precipitation decreases, wetlands can't keep up with these new demands. To understand how drought is affecting Northern Leopard Frogs and their behavior we looked at how these stressors change their foraging behavior. Tadpoles were collected from wetlands across eastern south Dakota during summer 2022. These tadpoles were raised in the lab until Gosner stage 26 and from there randomly assigned to a drought group. Trail groups included control (0%), low (40%), high (70%), and extreme (90%) loss of water. Water levels were lowered at a consistent rate each week, over an 8-week period. Two trail blocks were created with a one week difference. As tadpoles, algae pellets were used for foraging trials and as adults, meal worms or crickets were used. Foraging trials lasted 15 minutes as tadpoles and 10 minutes as adults with an observer taking notes. The reason for observing foraging behavior is to understand if there is a positive relationship of drought as a stressor and consumption of more food. Mass, length, weight and Gosner stage of each individual were taken each week throughout the entirety of the experiment period. Preliminary results suggests no significant change in feeding behavior or consumption of food based on water loss. However, results do show a positive correlation to timing of metamorphosis and body size.

Abstract Name: Decolonizing Honor Killings

In this article, I compare the cultural manifestations of violence against women in Palestine through honor killings and in the United States through crimes of passion. This article provides a comparative study of the current laws that mitigate both the nature and punishment of the crime of gender violence in Palestine and the U.S. Using historical perspectives, current U.S. criminal statutes, and Palestinian legal codes. I examine the connections between honor killings and crimes of passion, including comparisons between legal concepts, case studies, and Ancient Roman societal norms influence on gender violence. By analyzing recent cases since the 1990s, I suggest that these crimes, while culturally, historically, and geographically distanced from one another, share universal patriarchal values that socially normalize violence against women, as demonstrated in both criminal justice systems. Past and current quantitative and qualitative trends are utilized to develop recommendations on decreasing the frequency of the rate of violence against women by identifying cultural norms that maintain patriarchal systems of repression and making policy recommendations to criminal justice laws on honor killings and crimes of passion.

Abstract Name: **Characterizing an Exoskeleton Device for Leg Muscles Rehabilitation**

Stroke patients very often suffer from disability and are unable to walk freely. To regain their mobility, they need rehabilitation exercises. Commercial exoskeleton devices are availble but these are either very expensive or do not fulfil the patient's particular exercise requirements. An ongoing project at the San Jose State university is engaged in designing and developing an exoskeleton knee brace that will be cheap and will be user friendly [IMECE 2020, 2021, 2022, SCCUR-2022]. This knee brace relies on the fluidic muscles (Festo Corp) that use air pressure to mimic the leg muscles movement. The device consists of two parts, an upper brace for the front of the thigh holding the fluidic muscles and a lower brace behind the calf. The operating system includes a central control box that contains multiple solenoids and valves that are controlled by a central microprocessor (Arduino). The central system was activated by EEG sensors that were mounted on a human leg to activate the exoskeleton device. The EEG sensors' response was further processed for the noise reduction and was amplified by using an amplifier. Five fluidic muscles were characterized and calibrated before mounting them on a mannequin leg. Further experiments helped to optimize the knee brace design to mount it on a human leg. Experiments were performed to characterize the device operation by measuring the average leg rotation time and the maximum rotation angle as a function of applied pressure. Experiments show that the average time to reach the maximum rotation angle varied from 18 to 36 degrees where the rotation time varied from 1.58 to 1.23 seconds as the pressure increased from 30 to 60 psi. The presentation will detail the design and the operation of the exoskeleton device and will also describe the experimental results in a greater detail.

Abstract Name: **Effect of Neighborhood Densities on Fruit Removal and Frugivore Interaction with Pokeweed**

The density of neighborhood densities of pokeweed between frugivore interactions has not been tested before. A neighborhood is defined as a pokeweed plant with another pokeweed plant within close range. Pokeweed either grow is clusters or in isolation. These types of neighborhood densities can be a factor for the interactions between frugivore and the species. Clustered plants are known to have more berries on their racemes, which might be a reason for why frugivore will target these clustered plants more favorably than isolated plants. It was hypothesized that clustered plants will have a higher interaction rate with frugivore and a higher berry consumption rate throughout time when compared to pokeweed plants of isolation. There were cameras placed at ten clustered and ten isolated pokeweed plants throughout September 2022 to February 2023 to document the number of frugivore interactions with the plants. Clustered plants were plants that had other plants within five meters of it, and the isolated plants were plants with no other plant within five meters of it. The average contact duration recorded for clustered and isolated plants were tested throughout time. Also, there were three racemes on the 20 pokeweed plants being recorded to document the number of fruits being removed on the different types of pokeweed plants. There were four categories of berries when recording the berry consumption: unripe, ripe, missing, and shriveled. The percentage of fruits removed on both isolated and clustered plants was documented throughout time. The isolated plants did not have many berries removed from their racemes as compared to the clustered plants. The clustered plants also had a higher percentage of frugivore interactions throughout time when compared to the isolated plants.

Abstract Name: **A Community-Focused Analysis of the Heat Mitigation Techniques in Hunting Park, Philadelphia**

Along with rising temperatures, the number of days over 90 degrees is rising in Philadelphia, Pennsylvania. Historically, Philadelphia averaged 21 days at 90 degrees or higher yearly; however, July 2020 recorded 21 days in the nineties. Projections show Philadelphia will double the number of 90-degree days by 2030. Increasing heat unequally impacts low-income communities and communities of color. The Hunting Park neighborhood of mostly Hispanic and Black residents records surface temperatures more than 22 degrees hotter than greener areas in the city. The inequitable heat leads to an increase in health risks in the neighborhood. Drexel University, the Philadelphia Office of Sustainability, and the non-profit Esperanza, funded by the William Penn Foundation, collaborated to install cooling structures of umbrellas and planter boxes in the neighborhood to combat heat. This study initiates the quantitative analysis needed to examine the effectiveness of the cooling structures. Comparisons of temperatures between blocks in the focus neighborhood analyzed the capability of the cooling structures to reduce the overall heat. With help from Civic Scientists, the localization of urban heat islands was determined to help assess areas within Hunting Park with an increase in heat disparity, so that future cooling structures can be implemented more strategically.

Abstract Name: **Populist rhetoric that overshadows journalistic objectivity: Fox News ideological influence in the start of Covid-19**

Using two Fox News newscasts from the spring of 2020, this thesis examines their presentation of the start of Covid-19. Using Cluster Agon Analysis, the ideological assumptions of Fox News are examined as they are revealed through their language choice. This strategy analyzes rhetoric by extracting key terms that are frequently used, clearly described, or used in multiple contexts and thus can be associated with other terms to reveal the motive of Fox News. It is further discussed to what extent the rhetoric creates identification and divisions with the audience during the start of Covid-19. Furthermore, Fox News journalistic responsibility and its function as a Fourth Estate are discussed by showing their journalistic methods.This rhetorical study assesses the influence of Fox News on their audienceregarding the perception of Covid-19 facts; their objectivity in journalism and their subsequent influence. Cluster Agon and Ideological Analysis are used to argue for the hypothesis that Fox News presents Covid-19 facts in a populist biased manner and does not represent journalistic objectivity. Populism here means that Fox news creates clear images of identity during the start of Covid-19, where they define themselves and their listeners by distinguishing themselves in opposition to supposed political enemies. Fox News also discusses the responsibility for Covid-19, although this has not yet been scientifically explained at the time. Finally, a comparison is made with scientific facts about the start of Covid-19 and the strategies of Fox News to manipulate by rhetorical means and framing the presentation of alternative or false facts.

Abstract Name: Impact of Biological Sex on Cognitive Decline in Healthy Older Adults: A Cross-sectional Study

Alzheimer's disease is a growing problem both in the United States and in Arkansas specifically. As the populaton ages, the disease is becoming more prevalent which is creating a strain on the economy and producing an increased demand for caretakers. In order to prevent and manage the disease it is important to understand what risk factors are associated with Alzheimer's. One factor under investigation is the impact of biological sex on cognitive decline. Studies have shown a wide variety of results which can lead to confusion and prevent the improvement of medical care. If there is a difference between males and females, early detection and intervention techniques can be modified to more accurately address cognitive deficits. This study used a cross-sectional design to determine if there was a difference in cognitive function between individuals of each sex spanning the ages of 45-75. The study used a total of 31 male-female pairs that were matched based on age and total ANU-ADRI score. Differences were determined based on 12 individual cognitive assessments within the RBANS test that span five different cognitive constructs. Analysis was performed using a two-by-five mixed factorial ANOVA with pairwise comparisons to detect biological sex and age cohort subgroup differences. Of the twelve assessments, eight displayed no significance in age or sex. Picture naming, list recall, and story recall had a sex-pooled effect for age cohort. The coding and list recall assessments had an age-pooled main effect for sex, but there was no further interaction between age and sex.

Abstract Name: Does parent education affect children's discussion of their thoughts and feelings?

Research suggests that hearing and using mental-state talk – words that refer to thoughts, wants, and feelings – is important for the development of children's understanding of others' thoughts, feelings, and relationships. Due to its high influence, it is important to understand the factors that influence this talk. Prior research studies have shown that parental stress and socioeconomic status (SES) is related to parents' mental state talk, but there is a lack of research regarding how these factors influence children's mental-state talk. This study examines the question, do parental stress and SES impact children's mental-state talk and understanding? This study used pre-existing videos of parent-child interactions as well as data regarding parental stress and SES. In these videos, the parent and the child (3.5- to 5.5-year-olds) look at a wordless picture book designed to elicit talk about mental states. We coded how frequently children used mental-state terms, what type of mental-state term they used (cognition, desire, emotion), whose mental state they referenced, as well as whether it was a statement or a question. Our results showed that higher educated parents produced children that use more cognition terms. This is important because more cognition terms implicate a higher social cognition skill. In addition, both the parents and the children referred to the child's mental state more. What these results are showing us is that higher-educated parents are going beyond what the picture book shows and they are relating it to their child's own experiences and feelings. These findings are significant in the further understanding of children's social-cognitive development and their reliance on a beneficial parental input.

Abstract Name: **Sustainability of Resources for College Food Pantries**

Over 40% of college students are food insecure. Students in need are 43% more likely to fall behind in classwork and drop out of college. Students with food insecurity are also more likely to develop severe mental health conditions like depression, anxiety, low self-esteem, and loneliness. This study seeks to explain what factors contribute to sustainability of resources in university food pantries. The purpose of sustainability research is to find new and efficient ways to meet the needs of students who are food insecure in college. The student researchers explore the issue of sustainability of resources within college settings and how it impacts the resources obtained by grants and donors. The student researchers developed the following question: What are the factors involved in the sustainability of resources within college food pantries? The student researchers used 16 scholarly journal articles to inform their research on the factors that contribute to the long-term sustainability of food pantries in institutions of higher learning. Researchers using purposive and snowball sampling to identify a minimum of 100 participants with the help of the public directories to complete the questionnaire.The student researchers identified three common concepts within articles: factors of sustainability of food pantries, barriers and obstacles to successful food pantry use, and pantry development. The information gathered from the articles assisted the student researchers in question development for their survey.This research aims to identify the factors in sustaining a college food pantry through increased use. This information is important in attaining the researchers' overall goal of aiding the Tarleton Purple Pantry in developing a plan to sustain resources through Tarleton State College's rapid growth in enrollment.

Abstract Name: **Biochemical and Biophysical Analysis of LINC00298, A Non-protein Coding RNA Gene That When Expressed, Causes Early Onset Alzheimer's Disease**

Early onset Alzheimer's disease is a form of progressive dementia that affects people under the age of 65. There are several causative factors ranging from genetic to environmental, this study focuses on one of the genetic factors. LINC00298 RNA gene has consistently been expressed in patients of Early Onset Alzheimer's disease, as such, the goal of this study is to determine the binding partners of the LINC00298 RNA gene. LINCOO298 forms secondary and tertiary structural elements when bound to Mg2+. Biophysical analysis carried out using gel mobility shift assays confirmed this. When bound to Mg2+, LINC00298 forms a more compact helical structure as compared to Apo LINC00298 when run. Affinity chromatography was used to biochemically identify the binding partners of LINC00298 by using lysate from the hippocampal neuronal cells of mice. Mass spectrometry was consequently used for further analysis and identified the binding partners of LINC00298 to be the 40s and 60s ribosomal proteins in the neurons of mouse hippocampus cells.

Abstract Name: **Attitudes on Loneliness and Technology as an Intervention in University Students**

Across the world, loneliness has been increasing in the populations, with young adults within the university population, ages 18-24, experiencing the greatest rises in the amount of lonely individuals and amount of loneliness experienced by these individuals. These experiences can be due to risk factors such as social minority statuses, social transition, increased responsibility, and perceived or real isolation from peers. Social technologies, in the form of artificial agents, may be capable of aiding young adults in managing their feelings of loneliness. The purpose of this study is to evaluate the perceptions of loneliness through an extensive overview of the collegiate population. Within this study, I seek to identify the individuals most vulnerable to chronic loneliness, decipher the associated outcomes, and determine if technological services could serve as a viable method of intervention for some or all populations.
The study will be conducted through a survey with university students. Within the study, I hypothesize that 1) Population will exhibit significant amounts of loneliness in the amount of lonely individuals and in how lonely the individuals are, 2) Individuals in societally minoritized groups (racial minorities, sexuality and gender minorities, disabled individuals, etc.) will exhibit greater amounts of loneliness than that of their societally majority peers, 3) Individuals with greater amounts of loneliness will endorse maladaptive coping skills more often than individuals with lower amounts of loneliness, and 4) Individuals with greater amounts of loneliness will rate interventions involving technology more highly than those with lower amounts of loneliness.

Abstract Name: **Idiopathic Facial Aseptic Granuloma: a Case Report and Review of a Developing Pediatric Entity**

Idiopathic facial aseptic granuloma (IFAG) is a rare, anomalous pediatric entity characterized by asymptomatic erythematous nodules that are primarily located on the eyelids or cheeks. The infrequency in which it is encountered makes it an arduous diagnostic challenge. We describe the rare presentation of a 3-year-old male who was referred to the dermatology clinic with an asymptomatic facial nodule that had been present on the right zygoma for 3 months. The patient was diagnosed with idiopathic facial aseptic granuloma, based on clinical reasonings. Treatment was initiated with topical corticosteroids and topical calcineurin inhibitors. After 8 weeks of treatment, the patient showed marked improvement. The objective of this case report is to highlight the clinical aspects of this atypical entity to avoid the inaccurate diagnosis and raise awareness for the management of this condition, for which we propose a novel treatment combination of topical corticosteroids and topical calcineurin inhibitors.

Abstract Name: **AI Modelling for the Impact and Contribution of Various Factors on Heart Attack Casualties**

Previous studies reveal that many prevailing health indicators/variables can play a significant role in heart attack-based causalities. These variables include blood pressure, age, anemia, smoking, serum sodium, ejection fraction, serum creatinine, platelets, diabetes, and creatinine phosphokinase. With the increasing computational power, it is now possible to use different algorithms to develop a predictive model that will take the input data related to various factors to predict the outcome in term of survival or death of the patients. Developing these models is time consuming task that may take a lot of effort and resources. This can be eased by using machine learning tools that be able to develop a predictive model by incorporating multiple algorithms for an optimized solution predicting the final outcome with a high accuracy. In the
current work, an open-source data from Kaggle was obtained that incorporated multiple variables for 300 patients including the final outcome for these patients [https://www.kaggle.com/datasets/heart-failure-clinical-data]. We used IBM Watson platform to conduct this study. IBM machine model first analyzed each variable by conducting a statistical analysis on each variable. Then it used random Forest Classifier and LGBM Classifier with and without multiple enhancements including HPO-1/HPO-2/FE. The developed model can predict the outcome with an accuracy of 86.6%. Important variables
contributing to the outcome predicted by LGBM forest included platelets-76%, Ejection Fraction-58%, Creatine Phosphokinase-52%, Serum Creatine-49%, Serum Sodium-34%, and Age-27%. On the other hand, the corresponding variables contribution predicted by the Random Forest included serum creatinine-50%, ejection fraction-30%, creatinine phosphokinase-25%, age-19.00%, and platelets-18%. This presentation will highlight the
medical implications for selected variables contributions and will provide information on various algorithms' pros and cons along with the confusion matrix, ROC curves, and summary effects predicted in this study.

Abstract Name: **Modeling and Simulation of Compliant Mechanisms in MATLAB Simscape**

Compliant mechanisms are the mechanisms that transfer the input force, displacement, or torque from one point to another through the deformation of its compliant members and flexible body rather than the joints such as ball bearings. They have superiorities over the traditionally designed mechanisms such that since they can be designed and manufactured as a single piece using injection molding or additive manufacturing, they are light weighted, and no need for assembly and have no friction loss. Thus, the compliant mechanisms have better performance and accuracy and find application areas in the design of locomotive robots, grippers, medical robots, and microelectromechanical (MEMs) devices. Despite all the advantages, deriving the mathematical model of compliant mechanisms is much more challenging compared to traditional rigid body mechanisms as the complexity of the design increases. Although there are several methods available to find the load-deflection curves of flexible members such as pseudo rigid body modeling (PRBM) and the first and second of the Elliptica theory, they are limited to the simple geometries including fixed-free, fixed-guided, and fixed-fixed buckling beams. In this study, we present the design, modeling, and simulation of several compliant mechanisms in MATLAB Simscape. We adopted two approaches: the model can be created using the Simulink library blocks or by importing the cad model and then introducing the flexibility using discrete beam elements. We created the models of a fully compliant five-bar mechanism including 4 rigid bars connected by large deflecting flexure hinges, a compliant dwell mechanism incorporating buckling beams, a slider, and a rail, and a compliant bistable mechanism consisting of 6 rigid bars, a slider, and fixed-free flexible beams. The Simscape models not only provide kinematic insight but also visualizes the displacement and motion of each mechanism in the mechanics explorer.

Abstract Name: Stereotypes of "Research"

Research on the term “research” and the stereotypes it holds in academia is limited. Subjectively, scholars in the arts and humanities use different terminology to describe their studies (scholarship, creative endeavors, etc.), often leading to a lack of participation in programs/events labeled as “research.” In the current study, a survey examining how professors of varying nationalities identify with the term “research” depending on their discipline was distributed utilizing academic webpages and faculty email lists. Questions on the survey included demographics, preferred terminology for disciplinary work, individual and department-based identities with the term “research” and rating various scenarios based on how well they coincide with “research.” Some of the scenarios included were scenarios involving a musician doing transcribing work versus a biologist studying cancer cells. Based on preliminary results, the arts are associated the least with the term “research” while the natural sciences are associated most strongly with this term. However, on a scale out of 6, the social sciences tend to associate both their field and themselves most strongly with the term (5.43), while the natural sciences (5.20) lie closer to the humanities (5.13). Interestingly, all disciplines scored relatively high on this scale, pointing towards some form of identification with “research” among all fields. However, these findings indicate the humanities identify less with the and appear to prefer the terminology “scholarship.” Ironically, the natural sciences scored relatively low in personal identification, but scored the highest in regards to their scenarios (2.95 oout of 3). Further analyses will be conducted, including qualitative sorting of responses to open ended questions from the survey. The results of this project will allow adaptation of research programs/offices to better include these underrepresented fields, bridging the gap between disciplines by incorporating different terminology and expanding project requirements to better accommodate nontraditional projects.

Abstract Name: The Evolution of Ancient Egyptian Hieroglyphics and Their Impact on Design

Ancient Egyptian hieroglyphics are a complex writing system that was used in burial and funerary practices, as well as to honor the ancient Egyptian gods and goddesses. As the writing system developed over time it evolved to include three main types of symbols. These symbols are pictograms, signs that mean exactly what they represent, phonograms, signs that represent sounds, and ideograms, signs that represent broader, more complex and, sometimes abstract concepts. Hieroglyphics can be seen most commonly in ancient Egyptian society in temples, tombs, or in other religiously significant works such as the book of the dead. Their impact on design is seen even in modern society today such as with things like public restroom signs and emojis.

Abstract Name: **Longterm exposure to Bacillus subtilis 6D1 CFE negatively impacts Staphylococcus aureus fitness in planktonic and biofilm competitions**

Antibiotics have helped reduce bacterial infections since the creation of penicillin in 1929. However, biofilm is a self-adhering community of bacterial cells enveloped in a self secreted extracellular matrix, serving as additional protection from certain antimicrobial treatments, like antibiotics. As antimicrobials are unable to penetrate the matrix, the bacteria can develop a resistance, survive and persist in a variety of environments. It has become important to find alternatives to eliminate biofilms and reduce antibiotic resistance. In previous work done in our lab, cell free extract (CFE) of Bacillus subtilis 6D1 was shown to break down the biofilm of Staphylococcus aureus ATCC 29213. However, it is unknown how long-term exposure to B. subtilis 6D1 CFE drives S. aureus ATCC 29213 evolution and subsequent fitness. For this reason we subjected S. aureus ATCC 29213 to different treatment lifestyles for 11 days (80 generations) (Table 1). To test how B. subtilis 6D1 CFE affects S. aureus evolution, we evolved the S. aureus ATCC 29213 with and without it, in both a planktonic(free swimming)and biofilm enviroment. After, the evolved strains ofS. aureus were subjected to competitions withB. subtilisin both aplanktonic and biofilm environment to test for long-term effects of CFE onS. aureus. Our results suggest, that S. aureus populations evolved in the presence of B. subtilis 6D1 CFE were less fit against B. subtilis in both a planktonic and biofilm environment, suggesting long term exposure to CFE decreases the ability of S. aureus to produce biofilm.

Abstract Name: **In Silico studies and Synthesis of Modified Nucleoside Analogues for Pancreatic Cancer Therapeutics.**

Pancreatic ductal adenocarcinoma (PDAC), the most prevalent type of pancreatic cancer with a high mortality rate due to a lack of early detection techniques, leading to diagnosis at a terminal stage and limiting treatment options. The nucleoside analogue Gemcitabine, while the most effective chemotherapeutic, faces drug resistance that hinders its therapeutic potential. We propose nucleoside analogues that feature a polyethylene glycol amino (PEGA) modification. This modification reduces the hydrophilic nature of the drug. The PEGA group is also hypothesized to serve as a chelating agent for both zinc and iron ions required for RNR activity. We have done computational studies including molecular docking using the internal coordinate mechanics algorithm (ICM), SWISS Absorption, Distribution, Metabolism and Excretion (SWISSADME), and prediction of activity spectra for substance (PASS), utilizing way2drug online application. We have also begun synthesizing the intended compound and plan on performing biological and enzymatic assays afterward.The edock scores, the root mean square deviation (RMSD), and the H-bonding formation were analyzed on ICM. Edock scores showed a higher binding affinity than gemcitabine, with an average value of -48.52 KJ/mol and an average RMSD value of 2.69. The PEGA moiety indicated a strong binding affinity to a known substrate binding residues in the catalytic sites such as amino acid Asn211, a vital component to the catalytic processes. The pharmacokinetics and toxicity were assessed through SWISSADME which demonstrated excellent solubility scores of logS -0.37 and showed non-toxic interactions to CYP isoenzymes. Through PASS prediction, the biological activity of the compound showed high potential as an RNR inhibitor with a probability of activity (Pa) to probability of inactivity (Pi) of 0.174 to 0.011. In conclusion, the proposed analogues demonstrated improved target inhibitions making them strong candidates for further investigation via in vivo and in vitro studies.

Abstract Name: **The Relation Between Prenatal Stressor Exposure and Autoimmune Disorder Risk**

Stress is ubiquitous in daily life and has been linked to detrimental effects on both physical and mental health. Countless studies have been conducted to evaluate the impact of acute and chronic stressors on the incidence of depression, anxiety, cardiovasculardisease, and autoimmune disorders. Cumulative stressful experiences are thought to lead to deterioration on physiological systems via a process known as allostatic load. Over a period of time, this can increase the risk for diseases. Similar to the way stressors impact health, there is evidence that suggests that stressors experiencedby one's mother during pregnancy can influencethe offspring's health in adulthood. Prenatal stressors confer maternal immune activation, which is also linked to negative health outcomes in offspring. Although links between prenatal stress and general health of offspring are relatively well researched, the relation between acute prenatal stress and autoimmune disorder diagnoses in offspring is less established. The current study analyzed relations among self-reported measures of prenatal stressor exposure, demographic factors, and both autoimmune and general health diagnoses. Prenatal exposure was measured using the Stress and Adversity Inventory for Adults (STRAIN), and stress-related health diagnoses (both non-autoimmune and autoimmune health disorders) were recorded using diagnoses by medical professionals. A poisson generalized linear model was usedto evaluate the results, while controlling for covariates. It was found that prenatal stressor exposure was correlated with more general health issues and autoimmune disorders, and that this association held despite controlling for relevant covariates of age, sex, race/ethnicity, sex, socioeconomic status, negative affect, and social desirability. Further analyses were done for each individual diagnosis to determine significant relationships. These results provide an insight into the dynamics underlying stress in relation to disease risk and sets the framework for further research into the specific mechanism of autoimmune disease risk.

Abstract Name: **Evaluating Conditions for Implementing Urban Ecology Centers in New Communities**

Milwaukee's Urban Ecology Center (UEC) is a non-profit organization that is founded on urban environmental education, community building, neighborhood renewal, and land restoration. The ability to cultivate such an immersive connection between nature and society has caught the attention of leaders and change-makers in cities around the nation. Directors of non-profit organizations, administrators of municipal programs, and educators at all levels have reached out to the UEC with the aspiration to develop their own version of an urban ecology center to prompt positive change in their community. Research in this study is focused on identifying demographic commonalties between cities across the U.S. that can help to foster the relationship between urban living and connection to the natural world through the development of UEC-based programming. A crucial factor in the development and success of an urban ecology center is its location, with the goal to optimize conditions that bring a community together. The key data for finding a best-fit location is formulated by considering the overall city population, the school density, and additional geographic features. Community organizations with aligned missions serve as potential partners, which can also be a consideration in determining the best site for a UEC. Data for this study is gathered from publicly available records, then organized into a database allowing for comparative analysis and to recognize trends in cities. Using GIS software, the collected data is converted to a digital map which aids in identifying a best-fit location relative to the number of parks and the school density found within a specified distance buffer. The goal of the research is to establish a guide to creating deeper relationships for initiating urban ecology center programming in any city.

Abstract Name: NCUR Murals Project (Collaborative Artistic Project)

I am a studio artist, with a focus on painting, inspired by both the natural world around me and the man made issues of our society. My painting style is one I like to call fantastical surrealism, where I startby just putting a few blocked colors on the canvas then build up layers and layers of detail through techniques like dry brushing and stippling. I have painted on a variety of materials such as canvas, wood, and fiberglass.I have also used other mediums such as sculpture and assemblages to hit on issues such as women's rights, censorship, and societal controls. Based on this I would be interested in the Equity/Diversity/Social Justice theme. Recently I was a part of another collaboritave paintingproject for the community, the Downtown Naperville Alliance Truck Project. For this project two other artistsand I painted a sculpture of a truck with a retro theme. The project took place over the course of two weeks andwas commissioned by a local business, whowe worked directly withto develop and finalize our design. While I go to school in Illinois, I am from the Greater Orlando area. I have been involved in multiple exhibitions in galleries both in Illinoisand Florida.

Abstract Name: Smartphones, Attention, and Brain Electrical Responses

Given concerns about how distracting smartphones can be, we are interested in how they affect attention-related brain electrical activity. Previous research suggests that the mere presence of one's smartphone can negatively impact behavioral performance on an attention-related task. The aim of our ongoing study is to investigate whether simply having one's smartphone present and visible (although shut off) influences attention-related EEG (electroencephalographic) activity. We are assessing this in two ways. First, subjects perform an oddball task, which requires attention and responses to occasional target stimuli ("oddballs") among many task-irrelevant stimuli ("standards"). The P3, a late component of the event-related potential (ERP), is typically larger to oddballs (which receive more attention) than standards; we predict an attenuation of this oddball effect in the presence of one's phone versus a control non-phone object (tile). Second, we are looking at EEG power in the beta range (13-30 Hz) as subjects passively view their phone versus the control object. Since beta activity is positively correlated with alertness and attention, we predict greater beta power in the phone condition. Furthermore, we predict a correlation between beta power in response to one's phone and attenuation of the P3 oddball effect by one's phone; that is, the more attention is garnered by one's phone the more we think their phone will distract from a phone-irrelevant attention task. Preliminary data suggest increased beta activity in the presence of the phone and replication of the classic P3 oddball effect, but are unclear about an impact of smartphone presence on P3 amplitude.

Abstract Name: **How Gender Influences Gym Comfort Level in UCO Students, Staff and Faculty**

Background. Physical activity and its positive effect on overall health has been studied for decades. The goal of this research is to understand if there are observable differences in gym comfort level between self-identified genders. Methodology. Researchers curated an online questionnaire to measure one's comfort level in the gym. Data collection spanned over 6 weeks during the summer of 2022. The participants (N = 290) were 24.83% cis men, 65.52% cis women, and 9.66% transgender/gender-non-conforming (GNC). Results included students, staff and faculty with several cross-tabulations functions performed through SPSS 28.0 to examine differences between self-identified genders. Results. Notable results indicated that on a scale of 1-10 (lower scores indicating less comfort) the average result for cis men being 7.90, cis women at 5.21, and GNC individuals at 6.14. Percentages listed indicate a "yes" to if participants are comfortable in certain settings. 83.33% of cis men were comfortable participating in weight training activities in contrast to 35.79% of cis women and 53.57% for GNC individuals. When asked about cardiovascular training, 100.00% of cis men were comfortable as opposed to 76.32% cis women and 75.00% of GNC individuals. Those who were comfortable in the gym in terms of social setting were: 80.56% cis men, 37.37% cis women and 46.43% GNC. Discussion. Through data collected, researchers have been able to support the hypothesis that there are differences in gym comfort levels between gender identities. One limitation was confronting how to protect transgender or non-cis individuals because the response was very low. To do this, all non-cis people were grouped into one category (though researchers acknowledge that there are differences between trans/gender fluid/non-binary individuals). Possible outcomes to this result could be future improvement on making public and private gyms feel more open and comfortable to all genders.

Abstract Name: **Conformational Dynamics and Function of?Escherichia coli?Prolyl-tRNA Synthetase in Crowded Environments**

Conventionally, enzymes are studied in vitro under dilute conditions. However, in vivo conditions are different; enzymes are surrounded by the crowded cellular milieu that contains a variety of molecules of different shapes and sizes. Crowding impacts the structure, function, and dynamics of enzymes, the molecular mechanism of which has remained only partially revealed. In the present study, the crowding mechanism was investigated by replicating the intracellular crowded environment using synthetic polymers and their monomers. The model enzyme utilized was Escherichia coli prolyl-transfer RNA synthetase (ProRS), a multidomain enzyme involved in catalyzing the ligation of proline to tRNAPro during protein biosynthesis. The conformational dynamics and function of ProRS in crowded conditions were probed using intrinsic tryptophan fluorescence spectroscopy, molecular simulations, and enzyme kinetics. Results of this study are expected to shed light on the molecular mechanism of crowing and aid in structure-based drug design. Preliminary results of the study will be presented.

Abstract Name: Identifying Cognate RNA Sequences of Non-Structural Protein 9 in SARS-CoV-2

As an RNA+ virus, SARS-CoV-2 infection (COVID 19) leads to direct translation of viral RNA to produce non-structural proteins (Nsp) responsible for viral replication. For example, Nsp 7 and 8 are thought to act as a helicase, Nsp 9 as a single stranded RNA binding protein and Nsp 12 as the replicase essential to the proliferation of the virus. Studies of homologous, Nsp 9 proteins in HSV, MERS, and SARS-CoV-1 indicate this protein binds both DNA and RNA sequences. In SARS-CoV-2, Nsp 9 contains an unusual OB, greek key motif thought to keep RNA single stranded for efficient replication in other viruses. Together these results suggest, Nsp 9 may function in SARS-CoV-2 to keep the viral RNA linear for replication by Nsp 12; however, little is known about the RNA binding requirements or structural contacts and interactions in this protein-RNA complex. Tryptophan fluorescent studies of Nsp 9 have been developed to identify cognate RNA binding sequences and structures. Initial studies indicate binding of an RNA pseudoknot structure in the 3'-untranslated region of the viral RNA. Further analysis of RNA structural requirements for stable Nsp 9 binding will be important in further deciphering the role of Nsp 9 in SARS-CoV-2 as pseudoknot structures in the 5' and 3'-UTR have served as a switch from viral RNA translation to replication and may serve as a handle for control of this ever infecting and mutating virus.

Abstract Name: Investigation of electronic and hydrodynamic properties of fluorescent probe molecules in reverse micellar environment

The electronic and hydrodynamic properties of fluorescent Texas red dyes have been investigated in confined and crowded reverse micellar environments. Various steady-state and time-resolved spectroscopic techniques such as UV-Vis absorption and fluorescence emission as well as Dynamic Light Scattering (DLS) were employed to determine various photophysical parameters such as band shift and fluorescence quenching etc. The results obtained in confined environments were compared with the results in aqueous environments. Our experimental observation shows that Texas red behaves very differently in a reverse micellar environment as compared to an aqueous environment. Furthermore, our results show that the dye undergoes aggregation inside reverse micelles.

Abstract Name: **Comparative Analysis of Centella asiatica Components in Cosmetics Using Solid Phase Micro- Extraction (SPME) and Gas Chromatography-Mass Spectrometry (GC-MS)**

The cosmetic industry regularly markets new lines of products focused on the latest trendy ingredient. Recently,skincare companies advertised ointments and balms with pseudo-pharmaceutical benefits under the portmanteau of "cica"-care.The supposed plant ingredient,Centella asiatica, is well-documented in medicinal texts across the Asian continent. While most prevalent in Ayurvedic and traditional Chinese remedies, this flowering herb also originates incountries such as Malaysia, Brazil, Nepal, and Kenya. Contemporary studies have suggested properties of wound healing, anti-inflammation, and improved cognition.C. asiaticais best recognized by its eponymous centelloids, or its pentacyclic triterpenes and triterpenoids. However,a comprehensive profile of its smaller secondary components was used in this project as a basis of reference in testing cosmetics for the plant ingredient. This system of comparison was quantified by giving each tested product a point formonoterpenoids, monoterpenes, or sesquiterpenes found in the plant leaves alone. Aggregated lists of detected compounds were also juxtaposed with lists produced after testing non-"cica"-care topical products. Samples were run using a solvent-free and low-preparation extraction method known as SPME, or solid phase micro-extraction. The volatiles were adsorbed onto a specially coatedfiber, exposed within the headspace of a sample vial. These analytes were desorbed for analysis when thefiber was re-exposed within the injection chamber of a gas chromatography-mass spectrometry instrument. This method was used to compare volatilecompounds foundin the plant leaves, in a selection of popular "cica"-care products, and in a number of comparatively cheap and dermal creams. The resulting rankings decreased confidence in the majority of the productlabel claims, and called into question the validityof the marketed hype.

Abstract Name: **Exploring the Raman Scattering Response of Meteoritic Fragments**

Raman spectroscopy is a technique that has been used extensively on different kind of samples (carbon allotropes, semiconductors, polymers, microplastic particles, microorganisms, cells, etc.) since it is a nondestructive tool that provides information about their structure and material composition. In particular, it has been employed on meteoritic samples which in general are mainly composed of micro/millimeter sized inclusions, surrounded by a matrix of microparticles, that date from around the time of the formation of our solar system. The study of the physical properties of these relics using Raman spectroscopy can help to understand how planets formed since they can give evidence of the conditions (e.g., thermal, temporal and barometric) in which the materials found in the meteoritic samples developed in our solar system. However, not all the constituents of meteoritic samples have a Raman signal with a high signal-to-noise ratio, or other phenomena present in those materials (e.g., fluorescence) can hide some Raman features. In this work, we examine several meteoritic fragments that have recently been acquired by our group, such as carbonaceous chondrites Northwest Africa (NWA) 7184 and Aguas Zarcas, using this experimental technique. We explore the surface of these samples carrying out Raman spectroscopy measurements on numerous inclusions and surrounding matrix to find materials with high signal-to-noise ratios to analyze the mineralogical composition of the fragments. We correlate these results with other experimental techniques (e.g., optical microscopy, scanning electron microscopy, energy dispersive X-ray spectroscopy and/or atomic force microscopy) to look for signatures of the physical processes that drove the formation of these meteorites.

Abstract Name: **Role of Regulatory mRNA Structures in the Expression of Cancer-Related Genes**

Messenger RNA (mRNA) translation, the synthesis of proteins based on genetic code, is an essential process in gene expression. Translation is often inhibited when cells are under stress, but there are mechanisms that allow certain genes to bypass stress-induced inhibition. Prior studies have identified a list of genes that disregard stress signals to continue mRNA translation using regulatory RNA structures to hijack the translational machinery. We hypothesize that stress-signals must alter the RNA structure to trigger structure-mediated mRNA translation. Our target genes include oncogenes HIF1A, FGF2, and tumor-suppressor gene TP53. We aim to amplify regulatory mRNA regions previously reported for each gene from A549 lung carcinoma cell lines. Next, we will build and compare structure models for regulatory regions under three conditions: (a) cell-free, (b) in-cell unstressed, and (c) in-cell stressed. For structure modeling we use SHAPE-MaP, a chemical-probing strategy analyzed using next-generation sequencing (NGS). We have successfully extracted, probed, and amplified the target regions using gene-specific primers, reverse transcription (RT), and polymerase chain reaction (PCR). We analyzed PCR products using gel electrophoresis. Here we describe our experimental workflow along with data from NGS library preparation. Applying NGS using the Illumina MiSeq platform on target mRNAs, we will build RNA secondary structures with Shapemapper2 and SuperFold software packages. Our long-term goal is to describe structure-based mechanisms by which translation of cancer-causing mRNAs can be blocked, and how translation in cancer-fighting mRNAs can be reengaged.

Abstract Name: **Computational Chemistry on Investigating Copper, Nitrogen-doped Graphene Catalyst for CO2 Reduction Reactions**

With the growing use of fossil fuels, CO2emission is also sharply increasing. This increase directly correlates to the recent global warming issues, affecting the environment, human survival, and development. Although plants undergoing photosynthesis may regulate carbon dioxide levels, the severity of the current CO2 emissions is not sufficient to stabilize the CO2 concentration. However, the CO2 reduction reaction(CO2RR) is a potential solution to reducing CO2 levels by converting CO2 into fuels and raw materials. CO2RR will not only be environmentally sustainable but will also economically sustainable. A CO2 reduction reaction is a series of chemical reactions that converts CO2 into potential products and applications. The products of CO2RR include C1 products, such as CO, HCOOH, and CH4, and C2+ products, including C2H4, ethanol, and so on (see attached figure). However, not all CO2RR products are of equal importance and have similar applications. For example, aC1 product, such as CH4, is mainly used in natural gas and metal smelting. On the other hand, a different C1 product, CO, carbon monoxide, is used directly as fuel. Therefore, the selectivity of catalysts toward CO2RR is crucial. Out of various catalysts, Cu stood out from the many catalysts for CO2RR because of its appreciable CO2RR catalytic performance. In our project, we use Cu@4N graphene material for CO2RR by density functional theory(DFT) computations. We investigate different reaction pathways and products to see their reaction energies and find whether Cu@4N graphene is an ideal catalyst for CO2RR. If Cu@4N graphene is a suitable catalyst, we can also study which C1 product is the most favorable on Cu@4N.

Abstract Name: **The Search for HIV Latency Reversing Selective HDAC3 Inhibitors Through Virtual Screening**

There are numerous antiretroviral therapies (ARTs) developed for treating HIV, lowering the viral load to undetectable levels, thereby inhibiting transmission of the disease. However, HIV remains incurable due to the presence of latent HIV reservoirs that are not treatable with the current ART. In addition, the life-long use of ART by patients results in chronic side effects, thus a cure is needed. Herein, we report the use of Computer-Aided Drug Design (CADD) approaches to identify latency-reversing agents (LRAs), like histone deacetylase 3 inhibitors (HDAC3Is), that can be included in the ART regimen. Concomitant activation of latent reservoirs with an LRA and inhibition of viral replication with ART, via the “shock and kill” method, is one approach to potentially curing HIV. Although there are class I HDACIs on the market, they are not selective and cause drug-induced adverse effects. To overcome the challenge of selectivity by the well-known LRA HDAC3I, which plays a significant role in HIV latency, we took advantage of the presence of un-conserved regions of the allosteric corepressor site of HDAC3. HDAC3 activation requires exclusive complexation with the SMRT/NCoR corepressor to carry out its catalytic function, so inhibition of HDAC3-SMRT/NCoR complexation by small-molecule(s) results in enzyme inactivation. Towards this end, we conducted molecular docking to screen our in-house and ZINC chemical libraries to identify potential hits. The top hits identified were then assessed in vitro for their HDAC3 inhibitory activity and selectivity. Thus far we have identified an HDAC3 inhibitor with an IC50 of approximately 5.11μM and we are continuing our exploration to identify other diverse scaffolds.

Abstract Name: **Adult Perception on Outcomes of Child Custody Cases**

Custody cases are meant to find the best possible option for the child, the process the child experiences lead to negative mental developmental outcomes.Throughout the family court process the families often face challenges that may consist of stress, role confusion, financial struggles, depression, anxiety and many transitions and changes to their everyday lives. One major obstacle for many families that have to deal with family court orders are the financial overloads placed on families. Private information often causes tension in families and households. This mixed methods study focuses on adults who have experienced a child custody case at any point during their childhood using a pre-developed Perception Survey.The survey consisted of 15 questions including demographic, multiple choice and open ended. Twelve articles were reviewed by the student researchers focused mainly on parental alienation, including factors associated with child custody cases and family court proceedings and how they affect the child involved.The student researchers used the literature review to aid in developing their research. This exploratory study explores the effects of child custody cases on mental development of children. The student researchers plan to study the impact of child custody cases by identifying the mental development outcomes of adults, who were a part of a child custody case. The student research group developed the following research question: (1) What are the mental development outcomes of children who were part of a child custody case? The study includes participants older than 18, who were involved in a child custody case when they were under the age of 18. Through purposive sampling, the researchers survey 75 participants to gain a better understanding of their perception of their childhood experiences during their child custody case.

Abstract Name: Reality is Virtual: A Content Analysis of Eric Whitacre's Virtual Choir Compositions "Sleep" and "Sing Gently"

This research investigates musical, lyrical, and audience reaction aspects of virtual choir composition to determine whether these aspects are uniting or discrepant and will contribute to the virtual choir's continuing popularity and originality as an art form, and staying potential as the world moves on post-pandemic. Virtual choirs, ones in which performers record their individual parts and editors compile the parts into a production aired on an online platform such as YouTube, have increased in visibility because of the COVID-19 pandemic. The popularity of virtual choirs within the context of COVID-19 calls into question virtual choir's staying power post pandemic. First, definitions of virtual choir formatting and substance are given and a discussion of virtual choir's current limitations and explosion in popularity associated with the COVID-19 pandemic is held. Next, a content analysis of prominent virtual choir composer Eric Whitacre's pre-pandemic written "Sleep" and post-pandemic written "Sing Gently" compositions is conducted in order to highlight strengths of Eric Whitacre's virtual choir in continuing and transforming the art. Additionally, comments posted to YouTube on the original postings of "Sleep" and "Sing Gently" were analyzed to garner audience reactions. This research reveals that the virtual choir format in generality and Eric Whitacre's compositions in specificity are most translatable as a stand-alone art form for their synchronicity between lyrics and music, and relatability to personal experience. These findings enhance the healing potential of music to include music aired in the virtual choir format, demonstrating that unity among people, just as unity between music and lyrics, provides the best chance for originality to thrive.

Abstract Name: Harm Reduction in West Virginia: Awareness in Action

As the nation grapples with the continuing opioid epidemic, it has become increasingly obvious that more intensive interventions must be made in order to save lives. Harm reduction has arisen in recent years as an excellent methodology that destigmatizes and humanizes people in addiction. West Virginia is widely considered the epicenter of this epidemic and has experienced widespread negative societal impacts as a result. Formalized harm reduction programs have been in action in the state for the past decade, but many principles have been at work for decades in various forms. I discuss this with a case study on a West Virginia University organization established in 1969 called the Council on Drug Information. This interdisciplinary community organization centered at the university provided evidence-based information on drugs and drug use through a comprehensive educational program and a 24-hour phone line with a citizen-based crisis response team. Their work outlined what we now know as harm reduction decades before the principles were outlined.The purpose of this research is to overview the principles of harm reduction, compile a brief history of the opioid crisis in West Virginia, and argue for the expanded implementation of harm reduction principles in response to this crisis. This study utilizes an interdisciplinary literature review on harm reduction and the opioid epidemic and archival source analysis.

Abstract Name: **Microstructural origin of mechanical damage in REBCO superconducting tape**

Rare-earth doped barium copper oxide (REBCO) is a superconducting tape made of multiple thin-film oxide layers that is capable of carrying large electric currents at magnetic fields exceeding 20 Tesla. This allows REBCO to be used in advanced high-field magnet systems in nuclear fusion reactors, which is done by combining multiple tapes into a single high-current cable. The cabling process requires bending the tape around small radii, and this process can introduce mechanical damage in the tape. In this study, we examine tapes that passed or failed a cabling bend test, in order to understand the microstructural origins of the damage induced by the bending. To do this, we imaged the surface of the tapes using a violet-laser scanning confocal microscope and a scanning electron microscope with EDS capability in both backscatter and secondary electron modes to understand the microstructure and surface homogeneity of the samples. We further used nanoindentation to assess the relative mechanical properties of good and bad tape samples. By identifying the structural and mechanical differences between the tapes that passed the bend test and those that failed, we can provide design guidance back to the manufacturer of the tape, so that they can improve the quality and reliability of the manufacturing process. This in turn, should help ensure that the REBCO superconductor can be a reliable conductor for a wide variety of high-field magnet applications.

Abstract Name: **Use of Waste Plastic Bottles as a Modifier of Asphalt Pavement Materials**

Over fifty billion plastic bottles of water were used in the US in a year and only less than one-third of those bottles were usually recycled. It takes up to a thousand years for each bottle to decompose. The use of plastic waste in road construction has recently come to the limelight. Several previous studies reported that when plastic was melted and coated on the surface of the aggregates, the molten plastics showed very good adhesion properties. However, the main concern of this application using waste plastic in road paving is that heating plastic over its melting temperature can often release toxic fumes. This study investigates the potential of utilizing waste plastic bottles as reinforcing fibers through the dry process without melting them to improve the performance of asphalt pavements. Adding the fibers into asphalt pavements is expected to improve the tensile resistance of asphalt pavements and might result in potentially reducing the thickness of the asphalt layer, reducing material cost, and increasing the use of waste to protect the environment. This study involves laboratory tests including fracture test, rutting resistance test, and moisture susceptibility test to assess the performance of the asphalt mixture. The results of the tests are then compared with the results of the asphalt materials without plastic additives. This study also explores the physical and mechanical properties of asphalt mixtures containing different waste plastic types. The findings of this research study will not only provide insight into the potential of utilizing waste plastic modifiers for sustainable construction but also provide valuable information for pavement engineers and contractors to optimize asphalt mixture performance.

Abstract Name: **Exploration of Undergraduate Biology Students' Engagement in Metacognition**

How a student utilizes a study method, comprehends a subject, and prioritizes learning can all be used to differentiate how students engage in metacognition. Metacognition is the process of thinking about one's own thinking and understanding; when a student is aware of their own understanding, they can make improvements to study plans, and make adequate changes to improve comprehension of material.At our university, there are five core biology courses required for the biology major; students in each course participated in surveys and interviews during the course, answering questions related to the principles of metacognition. In our analysis of the responses, we asked the following research questions: (1) What are the individual characteristics of different levels of metacognitive engagement?, (2) What is the relationship between the four levels and three dimensions of metacognition?, and (3) How do metacognitive levels and dimensions vary depending on students' grades?.Responses from individual students were classified into four metacognitive levels as proposed by Stanton et al. (2015): Not Engaging, Struggling, Emerging, and Developing. We examined trends in responses within each of the four levels to identify any defining characteristics. We found that there are three overarching concepts that vary between all four levels: 1) the ability to identify poor study habits and capability to make changes, 2) the emphasis placed on grading and how it affected study effort, and 3) the focus on comprehension rather than rote memorization. We then explored the presence of the three dimensions of metacognition, as defined by Grotzer and Mittlefehldt (2012): Intelligibility, Plausibility, and Wide-Applicability. In this presentation, we will discuss the trends found among students in each of metacognitive levels and the overarching trends of metacognitive dimension presence in relation to student grades. These findings will be of benefit, further defining how metacognition develops and exemplifies in students.

Abstract Name: **Heavy Metal Analysis of Wetlands in Northern Wisconsin**

Copper, lead, and zinc are common toxic heavy metals that are found in contaminated soils. The primary sources of heavy metal contamination are industry, agricultural runoff, sewage that is improperly treated, and atmospheric deposition. There is currently no baseline for zinc, copper, or lead levels in wetlands in Northern Wisconsin. I analyzed wetland soil core samples that are surrounded by agricultural and urban land use to determine if there is heavy metal contamination coming from those sources. In addition to urban and agricultural land uses, I analyzed soil from a natural wetland to determine base levels of heavy metals. Zinc was found in the highest concentration in every sample collected. Lead was consistently found in the lowest concentration. Copper was found to be variable in all soil cores.The wetlands surrounded by urban land use had the highestconcentrations of the heavy metals analyzed. Wetlands surrounded by agricultural and natural land uses had similar heavy metal concentrations.

Abstract Name: NCUR Murals Project (Collaborative Artistic Project)

I am a studio artist based in Chicago, Illinois. I find inspiration from the outside world and mix it with my individual experience. Looking inward is just as crucial as looking outwards. As a feminist artist, my process includes taking life lessons learned about the culture in which I live and putting my surrealist spin on it. My process starts with picking a topic I want to portray, then I create collage-like digital renderings. From there, I take those renderings and paint them on stretched canvases. I mainly work in oil paint, but I work in acrylics as well. My specialty includes equity, diversity, and social justice. I use these topics in all of my artwork. These conference topics fit perfectly for me since these themes are my main focus as an artist. My collaboration skills are also perfect for this conference since I always surround myself with fellow artists whom I look to for inspiration and critiques. An example of teamwork is when I worked alongside my peers to paint a fiberglass truck for a company in downtown Naperville. We spent two weeks painting the truck and communicating with the client. We ensured the work we were doing was up to their standards. Obtaining the opportunity to collaborate with artists of different styles and backgrounds will be conducive to a motivating environment. I am always looking to enhance my experiences as an artist and sharpen my group skills.

Abstract Name: Relating Patterns in Mathematics & Statistics Tutor Center Use to Student Success

Our research explores usage patterns of the mathematics and statistics tutoring services provided by a regional comprehensive university, and how these patterns relate to student success. Tutor service is available at no charge to students and supports 100- to 200-level courses and is staffed by undergraduate and graduate students. General trends are explored, and statistical models are built to identify connections between student success and frequency of attendance. Our data set consists of date and timestamp information per student visit to the mathematics and statistics tutoring center at a regional comprehensive university during the Spring 2022 semester. The visit information is joined by ID number to other details (class standing, GPA at the semester of interest, demographic information, major/minor, and overall grade in the class that they received support for). A comparison group of students in the same classes that did not attend the tutoring center during the semester was gathered. The same variables excluding timestamps were recorded for this group. Students are matched between tutoring and comparison groups by similar characteristics (e.g. GPA, major) and analyzed. Statistical models (ordinal and logistic regression) are created to relate student success to how often they attended tutoring. By including a comparison group, we can compare success rates between those who attend tutoring and those who do not. Our research provides a foundation for the university to continue monitoring relationships between tutor center use and student success. Our results highlight how student success metrics link to the tutoring center service provided by the university. Generalized student use patterns and metrics are shared to provide recommendations to better staff the tutoring center and answer other questions. Results will be reanalyzed each semester in the center with additional data. Similar methods can be applied to tutoring centers in other subjects or at other universities.

Abstract Name: **The Effect of an IPE Simulation on the Self-Efficacy and Knowledge of PT, OT, and SLP Students**

The implementation of interprofessional education (IPE) for students is an important learning opportunity where they can gain skills that will help facilitate successful collaborations with various professionals in their future careers. Measurement and documentation of student learning is critical to justify ongoing implementation of these IPE experiences. Most tools that are used to assess student learning about IPEand interprofessional practices (IPP) are self-efficacy scales that measure students' own perceptions. Measurement of change in student knowledge associated with IPE is rarely reported in the literature but would lend more support to the value of IPE. The purpose of this study is to determine how students' self-efficacy compares to their actual knowledge before and after participating in an IPE simulation. Speech language pathology (SLP), occupational therapy (OT), and physical therapy (PT) students willwork in interdisciplinary groups to complete a co-evaluation of a simulated stroke patient, with opportunities for discussion and feedback during the process. The students will complete the Interprofessional Collaborative Competency Attainment Scale (ICCAS) and answer knowledge-based questions before and after the simulation in a Qualtrics survey. Student self-efficacy and knowledge-based scores will be reported as quantitative data. Students will also complete a reflection on the event, providing qualitative data about their learning and growth. The results of this study will help determine whether this type of IPE simulation is effective in increasing students' knowledge about working in interprofessional teams.

Abstract Name: **The Determinants of Income Inequality in Rural Wisconsin and Policy Implications**

Rural communities in Wisconsin are currently facing many economic challenges, namely high levels of poverty, declining population, lack of high-quality services, and poor infrastructure. These are issues that call for innovative and creative approaches and require prompt attention. This project is a collaboration of three faculty members at the Department of Economics at our institution. Our project has three main goals. First, we propose to measure regional, particularly rural, income disparities while identifying the main explanatory factors with American Community Survey data and quantile regression analysis. Second, we will examine and quantify the impact of entrepreneurship, growth of immigrant populations and access to broadband on rural incomes in Wisconsin. Third, we will offer insights and recommendations to Wisconsin policy makers. Our research findings will help assess economic needs and resources and provide policy options to address challenges facing rural communities.

Abstract Name: **Diagnostic, Perinatal, and Medical Features of Turner Syndrome with Trisomy X Mosaicism: An InsighTS Study**

Objectives: Turner Syndrome (TS) occurs in ~1 in 2000 females who have partial or complete absence of the second sex chromosome. Half of the girls with TS have a single monosomy X cell line (45,X) and ~20% have typical female chromosomes in some cells (45,X/46,XX), while mosaicism for a trisomy X cell line (45,X/46,XX) occurs in only ~3% of girls with TS. Data on mosaic 45,X.47,XXX are limited. The aim of this study was to describe the phenotype of 45,X/47,XXX and compare to TS with 45,X and 45,X/46,XX.
Methods: The InsighTS Registry has enrolled 325 females with TS across the US and obtained histories from medical records. Those with 45,X/47,XXX, 45,X/46,XX, and 45,X were included in this analysis. For medical diagnoses, each subject with 45,X/47,XXX was age-matched to a subject from each of the other two groups (1:1:1). Outcomes including timing and reason for TS diagnosis, birth history, and medical diagnoses were compared between groups.
Results: For participants diagnosed postnatally, age of TS diagnosis was older in those with 45,X/47,XXX compared to 45,X. Indications for postnatal genetic testing were different between groups with the 45,X/47,XXX group being more likely to be diagnosed due to delayed puberty/amenorrhea compared to non-mosaic 45,X and less likely to have lymphedema as a neonatal complication. Compared to the non-mosaic 45,X group, girls with 45,X/47,XXX were less likely to have a diagnosis of short stature and eczema. Compared to the 45,X/46,XX group, the 45,X/47,XXX group was more likely to have structural heart disease or ovarian insufficiency.
Conclusions: This large TS registry suggests mosaicism with a 47,XXX cell line may be more common in girls with TS than previously reported. In addition to expected differences between girls with 45,X/47, and non-mosaic 45,X, we identified several differences between mosaic 45,X/47,XXX and 45,X/46,XX individuals for the first time.

Abstract Name: **"All the Faded Roses Shed": Beauty, Mortality, and Divinity in Paradise Lost**

Given that Milton uses "beauty" so many times in Paradise Lost to describe Eve, it is perhaps easy to assume that she is characterized primarily as an objectified counterpart to Adam. But Eve is central to Milton's narrative about choice, free will, and knowledge—and the narrative relies on her choice to eat from the tree of knowledge. My analysis illustrates how Milton crafts a definition of "beauty" unique to Eve that is both holistic and empowering. References to Eve's beauty do not always line up with her inferiority to Adam. While her beauty is gentle, this gentleness points not to her weakness but to her understanding of her self love and to her potential mortality. Eve's greater removal than Adam from God's image lends her more free will, humanity, and potential to fall. Since her beauty has the potential to deteriorate if removed from the image of God, it is both a mark of her divinity and the possibility of mortality granted to her by free will. I suggest that her beauty is not simply a veneer—if it is not a reflection of some internal virtue, then she is nothing but a trap that God has set for Adam. Ultimately, it is the fact that Eve's uniquely feminine beauty is not enough that she eats from the tree of knowledge. I conclude that after the fall, while she and Adam's beauty will fade as they approach death, its continuance is a reminder of their potential for divinity and the virtue they may still achieve in their mortal states.

Abstract Name: Printing Bronze with a (Cheap) 3D Printer

Metallic additive manufacturing (MAM) techniques that can print metallic parts with high dimensional accuracy have been around for 30 years now, but typical industrial setups can cost anywhere between $100,000 and $500,000 dollars or more. Fused deposition modeling (FDM) is a similar additive manufacturing process that includes building up prints layer by layer using various thermoplastics, and the average small-scale machine can cost anywhere from $200 to less than $10,000.
Using an FDM printer and a hybrid thermoplastic-bronze particle filament, parts can be printed and processed to produce a completely metallic part. This procedure includes up-scaling and printing the desired part, then debinding the plastic mass and sintering the metallic mass through two separate cycles. This project's focus is on the complete manufacturing process of such parts, as well as their mechanical functionality. Dimensional control of the finished parts is difficult, with the finished accuracy being largely determined by the accuracy of the printer as well as part geometry, which can cause unexpected degrees of shrinkage during debinding and sintering. Wall thickness also impacts the accuracy of post-processing, with thin walls being preferred to allow volatized plastic to exit the part during debinding without bloating or rupturing the part geometry.
In mechanical tests, the finished bronze parts currently fail at or slightly above one third of their expected UTS. Using scanning electron microscopy, white light microscopy, tensile testing, hardness testing, and a custom program written to calculate the actual density of a cross-sectional area from visual graphics, improvements are being made to the sintering step of post-processing to improve the mechanical viability of this vastly cheaper MAM procedure.

Abstract Name: Music, Memory, and Murder: An Investigation into Murder Ballads as Monuments

Murder ballads are a type of folk music which tells the story of a murder, and they have a richhistory in both England and America. As with other forms of folk music, murder ballads naturally adapt and change over time as they are transmitted to different communities. However, murder ballads also serve as vessels for the historical memories of crime, whichpresents a tension between the preservation of memory and changes caused by folk transmission. This paper investigates how murder ballads perserved and altered memory accrossdifferent communities. I explored this phenomenon by comparing "Knoxville Girl", as performed by the Louvin Brothers in 1956, to "The Berkshire Tragedy", an 18th century manuscript of a British ballad based upon a historical murder. According to the academic consensus, these two ballads are variations of a single ballad because of the narrative similarity they share. I also examined archival records and diaries that indicate a factual basis for the events in "The Berkshire Tragedy" and studied other documented variants of the ballad. I analyzed both the historical records and the differences between the two ballads to understand how the memory within the ballads changed over time. This analysis demonstrated that while "Knoxville Girl" preserved the central narrative memory within "The Berkshire Tragedy" across continents and centuries, the ballad altered details such as geography, relational dynamics and the fate of the criminal as a result of organic variations in oral transmission and songbooks. These changes in memory primarily reflect the need for the ballad to entertain, resonate with, and be relevant to the community that constitutes its audience and underscores that memory is largely determined by the community that perpetuates it. Performance environments have a considerable impact on the memory preserved within artistic media, especially that within folk traditions.

Abstract Name: **Lake Eutrophication: Natural vs Anthropogenic Phosphorus?**

Lake eutrophication in western Wisconsin results from excessive nutrient loading (P, N), and mitigation of the issue requires quantification of the ultimate nutrient source. Lake eutrophication events are not consistent across the region, but seem to vary with bedrock geology, hydrogeology, and land use. Lake eutrophication is assumed to be the product of nutrient overload associated with agricultural runoff. A regional surface water study shows elevated concentrations of P across the region. Seasonal values vary between peak agricultural months (July: ~160-180 ppb) and the winter months (November: ~20-95 ppb).
The same study analyzes groundwater, documenting extremely elevated levels of P, which is problematic because it is believed that agricultural P does not enter the groundwater system due to absorption by the soil profile. The ultimate source of P in groundwater is unclear and discerning the role of anthropogenic vs natural P is difficult.
Aquifers in the region are largely hosted in Cambrian bedrock, which hold more P (~2000 ppm) than groundwater (~ 0.5-1.6 ppm), and surface water (<.2 ppm). Sequential extraction demonstrates that P is bound with Fe-Mn oxides, which suggests that anoxic conditions in aquifers could lead to the influx of P from Paleozoic bedrock. Bedrock derived P may lead to elevated concentrations in groundwater, and therefore contribute to lake eutrophication. It is feasible that agricultural P may not be the primary driver of lake eutrophication.

Abstract Name: **Results of a Ruptured Logjam on Macroinvertebrate Diversity and Stream Quality: Comparisons of 2 years**

The addition of large woody debris to streams and rivers is a popular restoration technique to combat ecological stress. These logjam additions break down from natural stream conditions, so understanding how a logjam rupture impacts nearby microhabitats could provide insight into future stream conditions after woody debris jams are changed or removed. Macroinvertebrate populations and taxa diversity are associated with stream health; after a rupture, stream quality was predicted to decline due to fewer habitats and different dominant taxa. The objective of the study was to compare Van Horn Woods East, Plainfield Illinois's data using the Illinois RiverWatch protocol and documentation of the previous years' Macroinvertebrate Biotic Index (MBI), Shannon Diversity Indices (SDI), and dominant taxa individuals. Riffle and snag samples were taken from the stream to collect the macroinvertebrates. 2020-2021 samples were taken in low velocity (0.3 m/sec) or pools with no velocity (0 m/s). The 2022 Logjam sample was from a break where water passed through, creating a high-velocity flow (0.7 m/sec). A chi-square analysis was performed with the subsampled data from EPT (Ephemeroptera, Plecoptera, Trichoptera) and pollution tolerant/intolerant individuals. 2020, 2021, and 2022 showed significant differences ($p < 0.001$) between all comparisons except the upstream sample and the logjam of the same year. Taxa dominance and SDI differed between samples, and MBI showed reduced stream quality over the study. Although many environmental factors may be interacting in changes observed between 2020 and 2022 there was a general decline in stream quality, and changes in EPT/nonEPT, pollution intolerant/pollution tolerant, and dominant taxa and diversity observed over time.

Kline, Maranda

Maranda Kline

Abstract Name: Autobiographical Episodic Memory and Personality

There are differences in the way individuals recall past episodes. The purpose of this experiment is to examine the link between autobiographical episodic memories and the Five-Factor Model personality traits. Students from Westminster College were asked to recall a positive and a negative event in as much detail as possible and rate the vividness and clarity of the recollection using an autobiographical memory questionnaire. Participants were also asked to complete the IPIP-120 Personality Test. The results from their self-reported memories were run through LIWC software to analyze metrics like cognitive processes, emotional tone, and word count. Based on previous research, I predict that the biggest differences in memory reliving will come from the specific personality facets within the traits rather than the broad personality trait itself. Previous research suggests that neuroticism will result in more detailed and vivid negative memories and that scoring high in extraversion and openness to experience will result in less vivid memories overall. Research has also found that the higher the use of emotion words, the more immersion in the event, so I predict that higher scores in emotional tone in LIWC analysis, the more vivid and accurate the recall will be in AMQ analysis of confidence/clarity.

Abstract Name: Analyzing the Coyote-Fox-Domestic Cat Relationship

Previous studies have established that the relationship between coyotes and red foxes tends to be negative, correlating to a decrease in red fox populations. The interaction between red foxes and domestic cats has also been studied, demonstrating in their coexistence, cats shift their diets to not overlap with red foxes. I wanted to investigate how coyotes (Canis latrans) may impact the activity/temporal patterns of red foxes (Vulpes vulpes), gray foxes (Urocyon cinereoargenteus), and domestic cats (Felis catus). I studied this using the 2019 and 2020 data sets from Snapshot USA, a nationwide project with over one hundred different sites collecting trail camera data through September and October. To analyze the data, I used the R statistical program with the packages 'tidyverse', 'lubridate', 'lutz', 'overlap', and 'activity' to create graphs of the activity patterns for each species in the presence or absence of coyotes. Domestic cats, red foxes, and gray foxes were more likely to be seen at deployments without coyotes than with. Of the three species, red fox activity is the most affected by coyote presence. Gray fox and domestic cats shift their activity patterns less than expected in the presence or absence of coyotes.

Abstract Name: **Aqueous electrocatalytic reduction of nitrite using a copper-containing catalyst**

Nitrogen oxyanions are being found in increasing amounts in water sources, in particular due to the overuse of fertilizers. The presence of nitrogen oxyanions in drinking water and wastewater has been shown to adversely affect natural environments and human health. Of these nitrogen oxyanions, nitrite is the most detrimental to marine life due to its toxicity to fish. Excessive nitrite in water also leads to eutrophication and anoxic water which can culminate in areas such as the dead zone seen in the Gulf of Mexico. Conventional methods for the removal of nitrite include reverse osmosis and ion exchange filtration. Electrochemical methods can be used for the reduction of nitrite and are more desirable due to their sustainability. Nitrite electroreduction can produce gaseous products which are easier to remove. These products can include nitric oxide, nitrous oxide, or nitrogen gas. The reduction is proposed to involve a proton-coupled electron transfer (PCET) process.This project focuses on developing electrocatalysts capable of mediating the PCET processes underpinning the reduction of nitrite in water. The complexes chosen to perform this reduction are bioinspired copper catalysts. Here we report on the effects of pH on the electrocatalytic reduction of nitrite. These studies contribute to determining the underlying nitrite reduction mechanism that is occurring with the chosen catalyst. The mechanistic data informs future work in the electroreduction of nitrite, especially future catalyst design.

Abstract Name: **The Relationship Between Cerebrovascular Dysfunction and Behavioral Abnormalities in Rats Exposed to Alcohol In Utero**

The purpose of this study was to determine a relationship between cerebrovascular dysfunction and behavioral abnormalities in rats exposed to alcohol in utero. Maternal consumption of alcohol during pregnancy is an established risk factor for fetal alcohol spectrum disorder (FASD), which causes lifelong intellectual and behavioral disabilities, as well as cerebral and cardiovascular dysfunction. FASD is estimated to impact 2% to 5% of children in the United States. While studies have shown impairment in functional responses of cerebral resistance arterioles in rats exposed to prenatal alcohol, no studies have examined the association between impaired cerebrovascular function and behavioral abnormalities. We tested the hypothesis that in utero exposure to alcohol causes cerebrovascular dysfunction, decreasingblood flow and oxygen delivery to the brain, which may contribute to a decline in memory and motor coordination. We fed Sprague-Dawley dams a liquid diet with or without alcohol (3% ethanol) for the duration of their pregnancy (21-23 days). We then performed short-term memory (Novel Object Recognition [NOR]) and coordination (Rotarod) assessments on the offspring during adolescence (4-6 weeks) or adulthood (14-16 weeks). Following the behavioral evaluations, we examined cerebral arteriole reactivity to nitroglycerin (NOS-independent), adenosine diphosphate (ADP; eNOS-dependent), N-methyl-D-aspartate (NMDA; nNOS-dependent), and iloprost (BK channel-dependent). All tests were examined in control male and female and prenatal alcohol male and female. We found impairment in eNOS-, nNOS-, and K-channel-dependent dilation of cerebrovascular arterioles in rats exposed to alcohol in utero. Furthermore, we found short-term memory impairment in rats exposed to alcohol in utero, as well as modest motor learning differences in adolescent, alcohol-exposed rats. Based on the findings, we suggest that impaired cerebrovascular function, resulting in decreased blood flow to essential areas of the brain, may contribute to impaired short-term memory and learning differences exhibited by rats exposed to alcohol prenatally.

Abstract Name: **Characterizing Architecture of a Biomimetic Bone Scaffold**

Biomimetic bone scaffolds are widely studied for applications in wound healing via grafts and for improving microenvironments for in vitro studies. Previous scaffolds mimicking cancellous bone, the porous bone that is most susceptible to damage during aging and disease, have prioritized mimicking either composition (protein and mineral components) or architecture (dense vs. porous) but not both simultaneously, despite the importance of both properties in bone function. As part of a larger study, we created porous, mineralized protein scaffolds to mimic both composition and architecture, and our objective for this work was to analyze the pore characteristics of these scaffolds to determine if they are similar to cancellous bone. Scaffolds of varied composition were created by freeze-drying solutions of three different collagen:chitosan weight % ratios (10:0, 8:2, 6:4) to create pores. Scaffolds were carbodiimide-crosslinked, mineralized for 14 days, and then scanned using nano-computed tomography (1.5-µm voxels) to create a reconstructed 3D image. Using Dragonfly software (Object Research Systems), a small box region (1,284 x 2,017 x 2,302 µm) of interest in each scaffold was segmented, and the average pore size and percent porosity (void volume %) were measured. Analysis is ongoing, but preliminary data across the scaffold formulations show average pore sizes of 43.3 µm for 10:0, 51.8 µm for 8:2, and 57.4 µm for 6:4 and percent porosities of 88.3% for 10:0, 92.3% for 8:2, and 85.2% for 6:4 formulation. Scaffold pore sizes are slightly smaller than the 100-200 µm pores in cancellous bone, and scaffold porosities are a bit higher but comparable to the average porosity of 70-80% for cancellous bone. Scaffold formulations can be further optimized to produce a more accurate model mimicking both composition and architecture of native cancellous bone, which is essential for studying the cellular microenvironment in models of injury and disease.

Abstract Name: **Effects of multiple diets on metabolic response in mouse models of SMA**

Spinal muscular atrophy, or SMA, is a neuromuscular disorder that causes morbidity and mortality inbabies and young children. SMA is caused by reduced levels of SMN protein in the body as a result ofmutation of the SMN1 gene.Recently developed treatments are effective at increasing lifespanand are specific to the nervous system. Due to this,new questions have arisen about how additional organ systems are eliciting responses to the disease. One of the potentially disrupted responses is the function of the metabolic system. Initial reports indicate that SMA may alter fatty acid metabolism, cause fatty liver disease, and glucose intolerance. To study SMA, mutant forms of the SMN1 gene have been introduced into research mice to create mouse models of SMA. Our study focused on using mouse models to examine potential disruption of metabolic responses in SMA. Specifically, we usedamild mouse model that has onset of neuromuscular symptoms later in life and is useful as a model for SMA patients that receive treatment. This study focused on observing the effects of diet on SMA mice. We performed this study using three different diets given to both normal, control mice and SMA mouse models. The dietsincluded a normal control feed, a high fat feed, and finally a high sugar feed. Mice were fed these different diets and tested over time for changes in weight and motor function. Motor function was tested using a Rotarod assay. Experiments are currently ongoing and preliminary results will be presented. If our hypothesis is correct, we expect to see abnormal weight gain and motor disfunction in the high calorie diets. If this is observed, this would give insight into the need for treatment of SMA regarding metabolic response.

Abstract Name: Expressions of Cultural Identities

How might expressions of cultural identities take shape through language, stories, and other learning experiences in an elementary classroom? If preservice educators listen intentionally to the expressions of elementary students, will those studentsshare about their diverse backgrounds and cultural identities? Can these conversations support the classroom in an effort to be more culturally responsive? We will partner with a local elementary school and spendtime on site conferring withstudents about theirperceptions and contributions, connecting students' cultural knowledge to themselves and others through multimodal learning experiences, and gatherdata that will influencefuture teaching practices. Multimodal instruction is instruction that uses social and cultural resources such as drawings, technology resources, picture books, and storytelling. Student voice is listening attentively to students' perceptions and contributions.Cultural identity is the perception of self and others, and how children see themselves as a member of a group.

Abstract Name: From the Graveyards to the Laboratories: The Legal History of Cadaver Use in American Medical Schools

Due to the critical nature of healthcare, many issues within the domain have attracted controversies, sometimes veering into the unethical practices of preserving the sanctity of the human body. For years, academics in American bioethics have explored the subject of human testing and the murky ethics that allowed horrendous experiments such as the Tuskegee syphilis study and Project MKUltra to be funded and carried out. At the forefront of these experiments lies the American medical schools, and despite the extensive research linking the role of higher institutions to human testing and the protection of the human body, there is a lack of exploration into the institution's role in conserving the integrity of human corpses. Following the explosion of scientific knowledge in the 19th century and the introduction of the anatomy and physiology subfields, American medical schools were highly competitive and filled with unbridled authority. Only the top school offered such classes, and only the most elite institutions allowed their students to have hand on experiences with human cadavers to give them a competitive edge. However, due to the rise in medical students and the limited laws regarding the ethical sourcing of human cadavers, medical schools turn to Night Doctors. Night Doctors – or body snatchers – were frequently employed by elite schools, many of which happen to be modern-day ivy league universities, to rob and remove the bodies of the societally unprotected. This rhetoric cemented the idea that dead bodies, especially those of lower socioeconomic status, were nothing more than economic commodities and created a dark, hidden medical marketplace, thus reinforcing the privileged status of heroic medicine in American society.

Knox, Victoria

Victoria Knox

Abstract Name: **The Power in Regulating Victorian Women in Prostitution**

During England's Victorian period, the Contagious Diseases Acts were established, which regulated women's bodies and represented the intersectionality of gender, class, and power. Before the CD Acts, England began to grow rapidly during the Industrial Revolution, which was in part made possible by the work of underpaid and undervalued working-class women. One option for women to earn an income was prostitution. Men who worked as sailors and soldiers were common customers in prostitution, which contributed to the rapid spread of venereal disease throughout the British Empire. In the spirit of protecting men, the first CD Acts were passed in the 1860s. The CD Acts allowed any woman who was suspected of being a prostitute to be legislated, policed, and held hostage by men in the medical field. As a result of the targeting of women's bodies, men and women unified to protect the rights of prostitutes against the unjust CD Act's policies. By analyzing newspapers, speeches, and essays revealing the sexist and classist ideologies supporting the CD Acts' legislation and those of its dissenters, this project will explore how men legally exercised control of women, and how those actions were justified by society's perception of medicine, policing, and the social status of its practitioners, thereby maintaining their elite status through regulation. I will also address how women and allies worked together against the CD Acts in an effort to progress women's rights. It is important to recognize the levels of bodily autonomy women have had, and why the regulation of working-class women has continued to adapt to protect men in positions of authority. This research is significant to understanding the use of women's bodies in legislation and how the CD Acts and its repeal would later work in establishing feminist movements that crossed political, class, and power boundaries.

Abstract Name: **Characterizing Sprays using High-Speed X-ray Imaging and Image Analysis**

Sprays are commonly found in many industrial applications, from chemical applications for agricultural use to fuel injection in gas turbine engines to powder formation for 3D printing. Spray characteristics can easily be assessed in the mid- and far-field regions, well after liquid sheet breakup and droplet formation, using various optical/laser diagnostic techniques. The conditions in the near-field region can influence mid- and far-field characteristics; however, near-field measurements are extremely challenging because the spray in this region is typically optically dense where optical/laser diagnostics are ineffective. X-ray imaging is one technique that can be used to view inside the optically dense region. In this study, high-speed X-ray images are captured of an airblast coaxial two-fluid atomizer, and then image analysis is completed to characterize the spray operating under different flow conditions. It will be shown that an unstable crown forms at high gas flow rates, and flapping frequency and intact length are influenced by momentum flux ratio, gas-liquid swirl ratio, and ambient pressure.

Abstract Name: **Minorities in the Healthcare System: By Angel Kobaly**

Under the Human Rights Laws, everyone has the right to proper healthcare. It is known that minorities are treated unfairly in the healthcare system. Not having access to proper healthcare can cause long-lasting physical and emotional effects. Black women have always been treated differently from their white counterparts. Infants born to black women are twice as likely to be born stillborn than their white counterparts. Transgender people face insurance conflicts because some insurance compaines don't cover Gender Conformation Surgery they see it as a cosmetic. Not the life changing surgery it is. Gay men are also affected by unfair treatment in the healthcare system. Since 1978, 40.1 million people have died from AIDS/HIV related illnesses since the epidemic began. People died from it because they didn't seek out medical treatment in fear of judgment from professionals. Being gay in the 1980's was very frowned upon, so many of men suffered in silence. Hispanic people are also a minority affected by unfair treatment, they are also some of the highest people to not have health insurance. In regards to the mental health aspect of unfair healthcare treatment for minorities, it can make someone hostile, and increase risk of depression. People choose unhealthy ways to cope with the stress of it all, like drinking alcohol or smoking cigarettes. 54% of minorities have reported their mental health declining due to these unfair treatments. In order to show this research I plan on gathering this information by providing interview data of minorities who have had similar experiences within the healthcare system. The goal of this research is to examine these inequalities and bring more awareness to the situation.

Abstract Name: **On the n-attack Roman Dominating Number of a Graph and the Impact of Infinite and Finite Resources**

The Roman Dominating number is a widely studied variant of the dominating number on graphs. Given a graph G = (V, E), the dominating number of a graph is the minimum size of a vertex set, V ′ ⊂ V , so that every vertex in the graph is either in V ′ or is adjacent to a vertex in V ′. The Roman Dominating function of G is defined as f : V → {0, 1, 2} such that every vertex with a label of 0 in G is adjacent to a vertex with a label of 2. The Roman Dominating number of a graph is the minimum total weight over all possible Roman Dominating functions. In this paper we analyze a new variant: n-attack Roman Domination, particularly focusing on 2-attack Roman Domination (n = 2). The n-attack Roman Dominating function of G is defined similarly to the Roman Dominating function with the additional condition that for any j ≤ n, any subset S of j vertices all with label 0, must have at least j vertices with label 2 in the open neighborhood of S. The n attack Roman Dominating number is the minimum total weight over all possible n-attack Roman Dominating functions. We introduce properties as well as an algorithm to find the 2-attack Roman Domination number. We also consider how to place dominating vertices if you are only allowed a finite number of them. Finally, we discuss the 2-attack Roman Dominating number of infinite regular graphs that tile the plane. We conclude with open questions and possible ways to extend these results to the general n-attack case.

Abstract Name: **Sustainability and the Salton Sea: Multi-stakeholder Perspectives on Sustainability**

Over the past several decades, the Salton Sea in southern California has suffered from environmental degradation and lack of support for remediation leading to one of the largest environmental disasters in California. This environmental disaster was caused by unsustainable agricultural and real estate practices and has widened economic and health disparities among Latino and Indigenous residents in the area. To restore the Salton Sea, multiple parties across the private, public, and non-governmental sectors are collaborating to develop sustainable solutions. Given the diversity of stakeholder backgrounds and lived experiences, a constructivist approach was used to understand how Salton Sea stakeholders conceive of sustainability. Data gathered from recorded meetings and in-person interviews were analyzed to characterize stakeholder conceptions of sustainability. Findings from this study are then applied to inform a multistakeholder framework for sustainable development. This study is particularly relevant to the United Nations Sustainable Development Goal (SDG) 17, Partnerships for Implementing Sustainable Development. If multistakeholder partnerships are to succeed, then understanding various conceptions of sustainability among parties is critical to identify shared interests and to support collaborative decision-making.

Abstract Name: **Mechanical Properties of Organic-Inorganic Composite Films: Comparing the Impacts of Flexible vs. Rigid Organic Components**

A series of organic-inorganic composite films composed of alkanethiol-capped gold nanoparticles and dithiol crosslinking molecules were assembled upon the air-water interface within a Langmuir trough. The mechanical properties of films containing conformationally flexible alkanedithiols were compared to those containing rigid bi- and terphenyl dithiols via measurement of minimum collapse pressures. The results of this study address the specific role of nanoscale materials components,further enabling the rational design of nanoarchitectures with specific chemical, physical, and mechanical properties.

Abstract Name: **Testament of Youth: The World War I and Women**

This presentation discusses how Vera Brittain's experiences in the First World War reshaped her feminist perspective and helped develop her pacifistic views in her memoirTestament of Youth. The presenter argues that having worked as a nurse during World War made Brittain an advocate for changes against entrenched and archaic gender norms based on Victorian values that treated women as children and made them feel incompetent. Furthermore, the presenter maintains that Brittain's experiences in WWI also helped develop her pacifistic views, as she openly expressed her opposition to killing, warfare, and violence and ultimately became a strong proponent for peace to prevent wars from recurring or breaking out again. Finally, the presenter argues that one insight we can draw fromTestament of YouthbyVera Brittain is that we should all stand up against any war because war is "pointless and the sacrifice of life and property benefited none of the countries involved." Let's help stop all the wars in our contemporary time!

Abstract Name: **Review on Usage of Deep Learning and Machine Learning Algorithms with Behavioral and Physiological Biometrics based Smartphone Security**

Throughout the past decades, mobile devices have evolved in capability and popularity at growing rates while improvement in security has fallen behind. As smartphones now hold mass quantities of sensitive information from millions of people around the world, addressing this gap in security is crucial. Recently, researchers have experimented with behavioral and physiological biometrics-based authentication to improve mobile device security. Continuing the previous work in this field, this study identifies popular dynamics in behavioral and physiological smartphone authentication and aims to provide a comprehensive review of their performance with various Deep Learning and Machine Learning algorithms. Throughout this paper, the benefits, limitations, and recommendations for future work will be discussed.

Abstract Name: **The Role of Transcriptional Regulator MeCP2 in Motor Learning and Memory in Mouse Model**

Methyl CpG binding protein 2 (MeCP2) is an X-linked methylated DNA-binding transcriptional regulator that plays a role in the epigenetic regulation of many genes. The loss of regulation due to the lack of MeCP2 is involved in many Rett syndrome (RTT) symptoms, including motility deficit, epileptic activity, and cognitive dysfunction. However, the effect of MeCP2 in motor learning is not well defined. We hypothesize that knocking out MeCP2 in mice interferes with motor learning capabilities. This hypothesis will be tested by performing the following experiments: (1) I will use transgenic MeCP2-knockout mice to determine the pellet-reaching capability and compare these results to a wild type control group of mice; (2) I will use pharmacological, optogenetic, and immunofluorescent approaches to examine the behavioral and cellular consequences of knocking out MeCP2. Motor learning paradigms will be performed, including accelerating rotarod and single pellet reaching tasks. These results will provide novel information regarding the role of MeCP2 in motor learning, uncovering fundamental brain mechanisms involved in the processing and integration of motor learning capabilities in the motor cortex. The results from the proposed experiments will expand our understanding of neurodevelopmental diseases and many other disorders that affect motor learning, including Parkinson's disease, Huntington's disease, Rett syndrome, and Tourette syndrome.

Abstract Name: **Building Belonging and Creating Community: Intentional Alignment of Research Programming at a Women-centered, Minority-serving Institution**

St. Catherine University is a women-centered, minority-serving institution located in Saint Paul, MN. As a University founded by and for women, our collaborative research programs aim to build a supportive scholarly community and provide robust year-long research opportunities to underrepresented students. Two such examples of complementary programs that work to build scholarly identity among our students are the Summer Scholars Program and the Assistantship Mentoring Program (AMP). Both programs foster mentored research through funding collaborative projects between faculty and students across any department within the College for Women - either through 20 hours/week for 10 weeks in the summer or through 10 hours/week for one or more academic semesters. Students in both programs participate in additional professional development and all opportunities are compensated to provide accessibility and sustainability. Notably, recent data indicate an increase in student retention following engagement in mentored research with AMP students demonstrating an average 98.2% return rate to the university in the past two academic years. This return rate is 8.5% higher than the overall University rate of 89.8% during this same timeframe. Through a short talk about our collaborative research programming and University-wide research infrastructure, we hope to engage audience members in a discussion of best practices that build identity and belonging among underrepresented women in research.

Abstract Name: **Development of Whey Protein-Lignin Based Film Materials for Food Packaging Applications**

Whey protein (WP) and lignin are by-products of cheese industry and the pulp and paper industry, respectively. This project aims to combine WP, glycerol, and lignin to develop biodegradable films with improved water barrier and mechanical strengths for food packaging applications. Reconstituted WP solutions (6% w/v) were held in a water bath with glycerol and lignin (if applicable) at different temperatures (60-95°C) for 30 mins to induce different levels of WP denaturation.SDS-PAGE showed that the film-forming solution prepared at 90°C for 30 min resulted in 88.7% WP denaturation, while it was only 12.3% for WP prepared at 60C for 30 min. Further results revealed that WP denaturation increased available thiol groups, which were likely responsible for forming the polymeric structure of WP films. With altered polymeric structures, different levels of WP denaturation altered film properties such as film thickness, water vapor permeability (WVP), and water solubility. Both WVP and water solubility were inversely correlated with the percent denaturation of WP.WVP of 60°C and 90°C WP films was 2.20 ± 0.34 mg·m-1·hr-1·kPa-1 and 1.83 ± 0.41 mg·m-1·hr-1·kPa-1, respectively. WVP of 20°C film could not be measured as the film started to rupture within 3-4 hrs of the WVP measurement, indicating its inability to block moisture due to its extremely hygroscopic nature. As for water solubility, 20°C and 60 °C WP films were completely dissolved within 24 h, whereas the water solubility of 90°C WP films was 58.36%±1.8% after 24 h. The results indicate that WP denaturation is critical to the properties of the resultant WP films. Lignin-incorporated WP films are prepared and currently being tested to study the effects of different types and concentrations of lignin on improving film properties, especially mechanical strength, light barrier and antioxidative properties.

Abstract Name: **Aquafaba Characterization and Evaluation**

Eggs are nearly ubiquitous in American households. They serve as a source of protein and other nutrients. For baking, eggs often serve as an emulsifier, a stabilizer, a binder and a foaming agent. However, eggs are a major allergen, and with many consumers opting for a plant-based diet, the demand for plant-based egg substitutes has grown. Aquafaba has emerged as a possible alternative for eggs. Aquafaba, latin for “bean water” typically refers to the brine from cooked chickpeas. Intriguingly, aquafaba exhibits foaming and emulsifying properties similar to eggs. Recent research into aquafaba has focused on optimizing its properties and applying it in recipes that would traditionally include eggs like sponge cake, meringues, and mayonnaise, but there is still much to be known about this fascinating food ingredient. One issue that emerges in the literature is the important of standardization, and in particular the many factors that affect the composition and performance, and the need for a method to characterize the aquafaba composition to predict performance, which will be important for the implementation on a commercial scale. In this study, aquafaba is characterized using size-exclusion HPLC and correlated to foaming capacity in order to both create a method that can accurately and efficiently characterize the protein composition of aquafaba, and to understand how the composition indicates performance. Multiple brands of the brine of canned chickpeas were analyzed in addition to prepared aquafaba with varying cook times. Using these methods, qualitative and quantitative data was collected about the types of proteins and other compounds present, and the specific role of high molecular weight proteins on foaming was examined.

Abstract Name: **Impact of invasive jumping worms on soil microbial density and species composition**

In 2019 non-native invasive species of earthworms were identified in Minnesota (Amynthas sp.). These worms have deleterious consequences on farm, forest and garden ecosystems with no scientifically identified solutions. We aimed to examine jumping worm impact on microbial density and species composition. Soil samples with and without jumping worms were sampled in Rochester, MN locations during winter and summer seasons. Using 16S rRNA microbial communities were characterized. Using standard techniques including serial dilutions and viable plate counts, microbial colony forming units were estimated. Our results indicate that bacterial colony forming units were greater in soils with jumping worms. In addition, species composition varied between soils with and without jumping worms.

Abstract Name: **Familial Conflicts of Second Generation Indian Women in Interracial Marriages**

In the United States, the rates of interracial marriage have grown in most cohorts due to the growingly progressive nature of our society. However, that is not a comfortable reality for many second-generation Indian American women living in the United States. After a review of the literature it has been examined that due to the remaining presence of ideologies from the Indian caste system, which promote staying in ones social class, the majority first-generation Indian parents actively discourage interracial marriage. One reason is that parents believe that if their children marry someone from a different race or caste, their children's offspring will be less culturally Indian causing them to experience cultural dilution, which will eventually lead to the culture's extinction. A study conducted on Asian-American women found that due to the difference in cultural ideologies between parents and their children it has caused familial conflicts. The biggest cultural difference is that first-generation Indian parents have grown up in India, a collectivist society that promotes prioritizing one's family and family values above all else, compared to second-generation children who have grown up in an individualistic society like the US where their needs and wants are prioritized. As a result of the disparities between the two cultures, second-generation Indian women are more likely to face depression and anxiety due to the pressures they face from their parents to maintain traditional norms. Despite this, there has still been a raise of Indian women entering interracial marriages because they have grown up seeing interracial marriage as something that is a cultural norm even though it goes against their parent's beliefs. By further studying women who have entered marriages their parents were against, it opens the possibility to more research regarding the differences between second-generation women in interracial marriages versus intraracial marriages.

Abstract Name: **Low Cost Filter Media for the Removal of Phosphorus in Agricultural Runoff Treatment Systems (ARTS)**

Seasonal hypoxia of lakes in the Midwest, Gulf of Mexico, and surface waters around the world as a result of excessive algal production, has a detrimental effect on the local aquatic species, environment, and recreation. Despite investments in point source reductions, seasonal hypoxia is persistent, in part due to non-point agricultural sources of phosphorus (P) (35% of total P load to Lake Michigan). Agricultural runoff treatment systems (ARTS), consisting of sedimentation basins and phosphorus removal structures, are an effective field treatment to reduce nutrient pollution .pollution. Numerous media (>80) for phosphorus removal structures have been investigated for their P removal potential and the hydraulic conductivity; Ca, Fe, Mg and Al content of media are important factors. Reactive media derived from waste products would create a product from waste, extending time prior to disposal, supporting a circular economy. Waste residuals (e.g. drinking water treatment residuals, wood waste, vegetative waste) will be modified (through metal additions, heat treatment, pelletizing, and binder addition) for and evaluated for dissolved P removal from agricultural runoff.. Treatment potential of modified waste media will be measured using flow through lab scale reactors constructed out of 0.75-inch diameter PVC pipe. Columns will be completed in triplicate for each media. Influent and effluent samples will be collected every 5 to 10 hours until effluent P is >50% of influent P. Ortho-phosphorus will be measured in collected samples using a discrete analyzer (Seal AQ300) at UWGB. Media will be designed to maximize P sorption capacity, hydraulic conductivity, mechanical strength, efficacy in high flow systems (< 10 min retention times), and reuse potential; minimize toxic side effects, energy consumption, and cost, critical to

Abstract Name: **Perfusion-Fixation Protocol for TEM Imaging of Brain Tissue in Mice**

Proper fixation is critical in transmission electron microscope (TEM) studies because of the artifacts created in poorly fixed (i.e., dying) tissues. This is especially true with brain tissue, due to the fatty myelin of the brain. To prevent tissue breakdown from lack of oxygen and nutrients, perfusion fixation must be used to rapidly and completely fix the tissues for high-resolution TEM images. Briefly, perfusion fixation is a method of circulating fixative via the circulatory system. It consists of replacing the blood of a deeply-anesthetized animal with physiological saline via the heart, then replacing the saline with fixative — in this case, a mixture of paraformaldehyde and glutaraldehyde. These trials have been conducted to refine the mouse perfusion fixation technique in brain tissue. The subsequent preparatory steps — post-fixation, dehydration, embedding in plastic, thin-sectioning, and staining — are all well-known. Using the optimized perfusion-fixation protocol, we obtained high-resolution TEM images of the hippocampus and cerebellum from mouse brain. Future studies will use this technique to determine the effects of acute colitis on the ultrastructure of the hippocampus and cerebellum in mice. Previous studies of acute colitis in mice demonstrated that biochemical compounds from the inflamed intestinal tract induce important pathophysiological changes on the brain, most notably, the brain vasculature. This protocol will serve as a method to visualize and characterize the vascular, neuronal, and glial cell changes within the hippocampus and cerebellum of animals with induced colitis. The information from this work may contribute to effective therapies for colitis-related diseases.

Abstract Name: **Adversarial Analysis of Fake News Detectors**

In recent years, machine learning models have been developed to mitigate the problem of fake news. One example is dEFEND, a state-of-the-art natural language processing (NLP) model that utilizes news contents, comments, and the relation between the two to detect fake news. We aim to expose vulnerabilities in the model so that it can be strengthened against attempts to use manipulated data to mislead it.Attacks on fake news detection models are a growing concern and an active area of research. One product of this is MALCOM, a malicious comment generator that ostensibly forces misclassifications of news with success rates upwards of 93%. MALCOM generates stylistically similar and topic-relevant comments to the input text, alleviating common problems with attacks on NLP models (e.g., producing nonsensical examples). However, these comments are recognizable as being computer-generated. We instead use real comments from the same dataset, so that they are indistinguishable from the rest. This approach aims to match Le et al.'sresults in a less complex and computationally expensive way.Using the FakeNewsNet dataset, we develop an attack by grouping articles and their preexisting comments into topics, and then computing their pairwise similarity. This enables us to identify both generic and topic-specific comments that can sway dEFEND's classification of an article. For comparison, we implement CopyCat, a baseline attack used by Le et al.that randomly selects comments from relevant articles. Attack success rates – the percentage of time an attack fools dEFEND into misclassifying an article – indicate that our novel attack techniques outperform our implementation of CopyCat in most cases (Table 1).An ongoing area of research is creating a defense to mitigate these attacks, e.g., by filtering comments post-training, based on properties identified as being adversarial.

Abstract Name: **Unraveling the metabolite richness of underexploited Amaranth using Metabolomic approaches.**

The United Nations designated grain amaranth (Amaranthus spp) as "The Future Crop." This plant has been overlooked and undervalued yet the grain amaranthis a leafy vegetable with a lot of health-promoting properties and therefore cannot be overlooked at a time when gluten-free, protein-rich, high-fiber and high nutritional qualities are becoming attractive labels in supermarkets throughout the world. The plant is reported to have anticancer, antivirals, and antioxidants properties. Documentation on environmental effects on secondary metabolites profiles in amaranth is missing. Symbiotic endophytes associated with plants are known as resources of novel metabolites. Fungal endophytes of the Amaranthaceous family have received inadequate attention. We hypothesis that endophytes contribute to the synthesis of metabolites in the amaranth plant. The objective of this research was therefore to isolate the fungal endophytes from different tissues of grain amaranth and use metabolomics approaches to understand the role the endophytes play in metabolite synthesis. The further objective was to study the effect of the environment of metabolite synthesis in Amaranthus. Plant samples were collected from Africa and different states in the USA. Metabolomics approaches of High-Performance Thin Layer Chromatography (HPTLC) and Proton Nuclear Magnetic resonance (1H-NMR) were used for the analysis of metabolite components. The HPTLC results showed the presence of flavonoids in the leaves. The endophyte study revealed fungi in the stalk (Fusarium spp) and the leaves (Fusarium spp) and (Eppicoccum spp). The metabolite rutin was detected in modest amounts from NMR results. More studies are ongoing on the role of endophytes on metabolite synthesis in grain amaranth. This research was completed over the summer of 2021 at Bowie State University under the supervision of Dr. Anne Osano, Dr. Elizabeth Arnold of the University of Arizona, and Dr. Eike Reich of the HPTLC Association.

Abstract Name: **Characterizing novel mechanisms underlying serotonin dependent influences on behavior**

Mood disorders, such as depression, affect over 40 million people in the US. Despite the use of an array of therapeutics for mood disorders, current understanding of the mechanisms underlying these processes and the specific targets of each therapeutic remains unclear. This results in variable success of the existing treatments, along with very little specificity toward an individual. More recently, there has been a deeper focus on understanding serotonin targets involved in mood and mood disorders. We use the nematode, Caenorhabditis elegans, to investigate the behavioral effects of serotonin and the neural mechanisms and intracellular pathways that mediate serotonin's effect on the brain. Our present study specifically investigates, 1) the novel targets of serotonin, and 2) how serotonin-dependent behaviors may vary across different species within the Caenorhabditis genus. We have found that known serotonin effects on worm behaviors including paralysis and stimulated egg laying, were significantly different across worm species that originate from distinct geographical locations. This implies the possibility of characterizing intracellular pathways and the factors that contribute to the differing behaviors, to understand the extent of pharmacological drug specificity toward an individual suffering from mood disorders. In further research, we intend to discover the targets of serotonin in nematodes across different genera to assess the fundamental variation in the alternate behavioral responses to both serotonin and serotonin targeting therapeutics, which continues to be of high importance in understanding human neuropsychiatric disease, like depression, addiction, and bipolar disorder.

Abstract Name: **Heavy Metal Exposure Induces Senescence as a Mechanism of Dopaminergic Neurodegeneration in a Parkinson's Disease Model**

Parkinson's Disease (PD) is the most common movement disorder, affecting over 10 million people worldwide. It is marked by dopaminergic neuron loss and alpha-synuclein (αSyn) aggregation, but 90% of diagnoses do not have a known cause. Environmental exposures may play a role as heavy metals have been epidemiologically implicated in the etiology of neurologic diseases of aging such as Parkinson's Disease. Despite this well-known connection, the mechanisms behind metal-induced neurodegeneration remain unclear. Work from our lab suggests that a common feature of toxicant exposure in neurons is the induction of cellular senescence, which accelerates aging, promotes inflammation, and impairs protein degradation. We hypothesized that environmental exposure to heavy metals induces senescence and its negative effects.To assess this, we used an in vitro platform within the dopaminergic neural N27A cell line that express human αSyn, and treated neurons with 5 μM manganese (MnCl2), 2.5 μM lead (PbNO3), or vehicle for 24 hours. Using immunocytochemistry, we detected significantly elevated levels of p21, a senescence cell-cycle regulating protein, in dopaminergic neurons following both manganese and lead treatment (0.0001). As senescent cells are reported to have autophagic impairment, we assessed lysosomal function via the Lysosomal Membrane Associated Protein (LAMP)-1, which was significantly decreased following manganese and lead exposure (0.0001). Furthermore, we observed an accumulation of αSyn within N27A cells, suggesting that heavy metal-induced senescence caused a reduction in protein degradation pathways that promoted αSyn aggregation.Together, these data suggest that heavy metal may induce senescence and accelerate neurologic aging and neurodegeneration. These data indicate that inhibition of senescent proteins such as p21 may be effective at protecting neuronal damage from exposure to heavy metals such as manganese and lead. Experiments to block senescent pathways to preserve autophagy and limit αSyn accumulation are currently ongoing in our lab.

Abstract Name: **Cyanobacterial Harmful Algal Blooms and Phytoplankton Nutrient Limitation in a Pair of Hypereutrophic Reservoirs in the Red Cedar River Watershed**

Eutrophication and the proliferation of cyanobacterial harmful algal blooms (cHABs) are a significant problem in the waters of Wisconsin. In western Wisconsin, a history of intensive agriculture and naturally occurring phosphates in rocks lead to an overabundance of nutrients in lakes supporting an overgrowth of cyanobacteria in many reservoirs. Cyanobacteria produce toxins that are hazardous to human and pet health and limit recreational activities in lakes with blooms. To manage waterbodies for improved water quality and reduced cHABs, it is critical to identify whether phosphorus or nitrogen needs to be reduced to limit phytoplankton growth. Lakes Menomin and Tainter located near Menomonie, Wisconsin are hypereutrophic impoundments of the Red Cedar River. Both water bodies experience annual cHABs composed of the potentially toxin producing taxa, Microcystis spp. and Aphanizomenon spp. Watershed nutrient management in the Red Cedar River watershed has reduced the amount of phosphorus entering the lakes over the last decade but nitrogen levels are increasing. The objective of this study is to determine if cyanobacterial toxins are present in the lake and whether nitrogen or phosphorus is limiting phytoplankton growth. In the summer of 2022, a group of researchers from UW Stout conducted regular sampling of lakes Menomin and Tainter to determine how the algal blooms developed over the summer. Water was collected bi-weekly for analysis of cyanobacterial toxins and nutrient limitation status. Over the course of the summer an intense cyanobacterial bloom formed across both lakes. Ongoing data collection will allow us to gain a better understanding of the toxin dynamics in the blooms and suggest further management interventions at both the reservoir and watershed scale.

Abstract Name: Efficiently executing Discontinuous Galerkin Finite Element Method (DG-FEM) workloads on GPUs via data flow graphs

Numpy contains the primitives to express the computation cleanly for DG-FEM operators (typically used in electrodynamics, fluid mechanics and plasma physics workloads). However, it is not the first choice for deploying production scale applications. This is due to a combination of targeting only CPUs and under-utilizing the hardware's resources. We address these problems by developing a novel system where the user writes Numpy-like code while executing operations concurrently on a GPU. We do this by mapping the array operations onto a precise data-flow graph and exposing that to a GPU via NVIDIA's CUDAGraph API. To evaluate the soundness of this approach, we port a suite of complex operators that represent real world workloads to our framework and compare the performance with a version where the array operations are executed one after the other. To make this work accessible to a wider audience, we are in the process of integrating this into PyCUDA, a tool that has been broadly adopted across computing communities. We conclude with some insights on NVIDIA's runtime scheduling algorithm using a set of micro-benchmarks to propose a roofline-model for task-graph based parallelism on GPUs.

Abstract Name: Beyond Translation: A Qualitative Inquiry Study for Refining a Culturally and Linguistically Adapted Health Coach Intervention for Latina Breast Cancer Survivors

Background: Latina breast cancer survivors historically lack linguistic and culturally tailored coping and management interventions. Traditional adaptation of English education materials for a Latina audience often address surface cultural features such as language, but lack nuances garnered through formative research with the target audience. This study implemented a collaborative community-academic partnership to develop a multi-module health coach intervention and coinciding workbook tailored to the needs of Latina breast cancer survivors (LBCS). All materials used in development were adapted from nationally recognized guidelines for cancer survivors. Thus, this study aimed to gather qualitative data assessing cultural relevance of the transcreated (translated + culturally adapted) health coaching intervention for LBCS. Methods: Following best practice for cultural adaptations, English materials were reviewed by cancer survivorship experts and transcreated into Spanish. Two focus groups (6-8 participants each) were held in Spanish to assess the cultural relevance of the transcreated materials to LBCS. Focus group guide questions were informed by two theories (Social Cognitive Theory, Help-Seeking Behavior Model), learner verification (a methodological approach for education message design). Guide also included questions on feasibility. Transcripts were translated into English and analyzed using thematic analysis. Community expert review confirmed findings.Results/Discussion: Emerging themes included content relevance, applicability, saliency of messages for comprehension, and areas for further refinement.Verification checks with our community partner confirmed content revision and solutions for incorporating participant feedback in future implementation. Data from focus groups allowed for further verification of acceptable content and method expansion prior to piloting with LBCS as a final refining step in the transcreation process. Conclusion: Reflection of cultural reality during program development is crucial for intervention adaptation in diverse populations while building social capital. Transcreation allowed for a collaborative process guided by the integration of cultural nuances, while participant first-hand experiences led modules toward cultural accuracy.

Abstract Name: **Transforming Taboo: Discursive and Generic Uptake in South Asian Mental Health Recovery Narratives**

Mental health in South Asian communities is urgent, unaddressed, taboo, and needs further study. Studies show that South Asian immigrants across ages and genders are disproportionately affected by depression, anxiety, insomnia, and eating-related psychopathology (Karasz et al., 2019). According to the South Asian Public Health Association, 1 in 5 US South Asians report experiencing a mood or anxiety disorder in their lifetime. A review of relevant research identifies finding culturally sensitive approaches as a pressing need (Karasz et al., 2019). Developing a culturally-relevant approach, however, requires understanding the lived experiences of members of that culture. The mental health recovery narrative genre, an emerging variation on the illness narrative, provides one record of these lived experiences. Illness narratives have been studied by medical anthropologists like Arthur Kleinman (1988), who writes that they intimately share the "innately human experience of symptoms and suffering" (p. 3) which is "culturally shaped" (p. 5). With this understanding, my research asks what mental health recovery narratives from South Asian communities can reveal about the South Asian mental health crisis. This presentation will share my genre analysis of eight samples of South Asian mental health recovery narratives from the platform Mann Mukti, meaning mental liberation in Hindi. Taking a rhetorical genre studies lens, my research identified five recurring rhetorical themes and moves: the regaining of control, call to actions, enargia, the completeness of narratives, and anonymity. These patterns are especially meaningful when interpreted through the South Asian cultural context, including collectivist culture, immigration and globalization struggles, and other factors contributing to mental health stigma. Overall, I argue that this genre has transformed a personal need to be heard empathetically and uninterruptedly into a recurrent social exigence recognizable to other South Asians. Ultimately, it is a hopeful genre communicatinga culturally situated solution for a seemingly intractable problem.

Abstract Name: **The Effects of COVID-19 on College Students: Pre- and Post-Vaccine**

This research examined the impact of COVID-19 on college students resource loss and stress levels by offering a comparison across pre- and post-vaccine phases of the pandemic. Two research studies will be presented.In spring 2021 (n=155) and spring 2022 (n=256), business school students completed an online surveyassessing their resource loss, stress, physical and psychological health, well-being, academic performance and moreduring the global COVID-19 pandemic. In support of COR theory, the 2021 "results demonstrated that students with lower resources (i.e., lower socioeconomic status) reported significantly more resource loss; increases in resource loss were significantly associated with increases in stress; and stress was significantly and negatively related to physical health, psychological health, and well-being. Reevaluation of resources served as a buffer in the relationship between resource loss and stress." (Murphy et al., 2022, p. 125-6). The 2022 post-vaccine resultsshowedcollege students reportedover<u>five</u>fewer resource losses, but thesame levels of stresscompared to the pre-vaccine sample. In support of hypotheses from Hobfoll's (1989) Conservation of Resource (COR) theory as well as Hobfoll and Lilly (1993) work on types of resources, students reported a negative impact on stress and resource loss from the COVID-19 pandemic regardless of vaccination status. Further, the effects were more negative for females than males as well as for upper-class students (juniors, seniors, super seniors) compared to lower-class students (freshmen, sophomores). This is one of the first studies to test the differential impact of resource type (personal characteristics,conditions,energiesandobjects) on the relationship to stress – finding thatpersonal characteristicswere the key component explaining most of the variance in stress. Overall, this is the first series of studies to explore the effects of resource loss or gains at two critical points in a global pandemic.

Abstract Name: **A Brief Literature Review in Deepfake Detection**

In recent years, fake news and false information in media has become an incredibly important and threatening issue in society. Deepfakes, a relatively new type of fake media, have emerged as a major contributor to that threat. The creation of deepfakes utilizes deep learning techniques to create realistic fake videos or images. These deep learning-based deepfake generation models can combine, merge, replace, and alter videos of people to create fake versions that are difficult to distinguish from real videos. The core threat of deepfakes is that they give anyone the ability to portray someone doing or saying anything without their consent. To combat this, extensive research into deepfakes and the creation of deepfake detection models has been conducted by various universities, major technology corporations, and independent teams.In this project, we conducted a literature review of 21 deepfake detection papers. We provide a summary of each method along with advantages and constructive critiques. The methods reviewed all use machine learning techniques with many using more specific types of machine learning such as deep learning and statistical learning. With our review, we seek to analyze the recent status of deepfake detection research. Most of the literature works we reviewedapproach the detection task using deep neural networks which achieve high performance scores but suffer from high complexity and poor generalization ability. We also noticed a lack of a benchmark datasetand evaluation system which makes comparing models difficult. Almost all the literature covers video and/or image deepfakes but does not consider audio fakes. In addition to these findings, we also provide suggestions for future research such as creating a benchmark evaluation system and focusing on generalization.

Abstract Name: **The effect of mechanical perturbation on rapid goal-directed interception task**

Most people perform daily tasks through dynamic coordination of their eyes and hands while maintaining posture. For example, catching a pass during a game of football, grabbing a rebound during a game of basketball, or catching a bouquet of flowers at the end of a wedding night.During instances where an opponent provides a mechanical disturbance, our visuomotor system must make rapid adaptations to successfully achieve the desired goal. However, how the visual and motor system coordinate to intercept a moving target after a mechanical disturbance of the upper limb while upright is not well understood. In this study, we investigated the long-latency reflex (75-110 ms for upper limb and 75-119 ms for lower limb) effect on visual processing and whole-body balance through a goal-directed reaching and interception task with mechanical perturbation of the upper limb. Participants used a robotic manipulandum (KINARM) to reach a stationary target or intercept a moving target while standing on a force plate sensor. The force plate measuresground reaction forces to quantify balance and helpsus understand postural sway through the center of pressure (COP). On some trials participants experienced a force towards or away from them as they performed a reaching movement. We hypothesized that there is a distinct difference in the relationship between saccadic (fast) and smooth pursuit (slow) eye movements on muscle activation of the upper and lower limbs when there is a mechanical perturbation. Our initial findings show that COP begins to shift 80-100 ms before movement onset as anticipation for movement. We also found that across 4 random successful trials the average points of interception occurred 570 ms from target onset and 13.35 cm from the point of fixation. We expect to find a strong correlation between eye movement speed and the long-latency reflex.

Abstract Name: **Dominus Vobiscum: Ritual Experience and Engagement Among Converts to Catholicism**

A great deal of work has been done within cultural anthropology studying religious ritual, but comparatively little of this has focused on the ritual experiences of converts to the Catholic Church. Such converts enter the Church with a range of ritual and religious backgrounds which have the possibility of impacting how they view ritual within a Catholic context. The unique perspective of converts in this realm, drawn from multiple ritual vantage points, is particularity instructive regarding how ritual experience changes over time. This project will focus on how converts to Catholicism experience and engage with ritual with a special emphasis being paid to the Mass. When applicable, their previous ritual experience will be brought in as a point of comparison regarding change in ritual experience and its effects on ritual engagement. This project will use data collected from participant observation, surveys, and semi-structured interviews. Data will be collected primarily at two Catholic churches in La Crosse, Wisconsin, although given the scope of the research, data from other Catholic sites in Wisconsin will not be excluded. The experiences of converts to Catholicism, particularly the comparisons and contrasts between their current and previous ritual experience and engagement, provide a unique emic perspective on comparative ritual study that hasnot been, as of yet, explored in depth. Thus, this paper will offer, through its analysis of ritual participation among converts to Catholicism, a window into such emic perspectives that can give valuable insight into how ritual is experienced and engaged within religious communities.

Abstract Name: **EPR Characterization in the Liquid Solution Phase of Isomeric Copper-Bound Linkage Isomers with Anti-Cancer Activity.**

Two isomeric linkage isomers of Cu(II) complexes with phenylglyoxal bis(ethylthiocarbamate) with equatorial CuN2S2 coordination are differentiated by liganding via either a 4-, a 5- and a six-membered chelate ring (L3) or three 5-membered chelate rings (L4) (Inorg. Chem. 2022, 61, 7715-7719). Both isomers exhibit qualitatively similar but quantitatively distinct preferential antiproliferation activity towards lung adenocarcinoma cells (EC50 ~ 0.1 mM) compared to non-malignant cells (EC50 ~ 1 - 2 mM). Here, electron paramagnetic resonance (EPR) was employed to answer some outstanding questions: (i) How do the electronic structures of the isomers differ? (2) Do the physical and electronic structures of the isomers in liquid solution correspond to those in the solid and frozen solution states? (iii) Do the isomers interconvert under mild conditions in liquid solution? (iv) Are the electronic and/or physical structures affected by the nature of the solvent or detergents? The study additionally prompted a critical evaluation of methods for simulating EPR spectra with high anisotropy in g and A in the liquid phase and the effects of viscosity on the line shapes.

Abstract Name: **National Socialist Propaganda in the Third Reich: The Iconography of Youth**

The National Socialists used many tools in their rise to power, but among the most important to both achieving and maintaining their power, was propaganda. One of the previously unexplored facets of this propaganda is the regime's manipulation of the iconography of German youth as a means to achieve the goals of their propagandistic messaging. These adolescents were both a valuable target and symbol for the National Socialists to use to further the guise of their control. All in one, this population was the tool and object of National Socialist violence. They became the propagandistic tool with which party leaders maneuvered German adults into conforming while simultaneously being the generation that could be molded into this same form from their inception. The goal of the party was to form this next generation's mind and body -- to take them from the meek and timid creatures which they were depicted as for their parents' sake, and turn them into the ideal battle-ready, obedient youth they were depicted as to entice them into the service of der Führer. Children were the perfect vessel with which the National Socialists could mask their insidious agenda of racial hygiene behind the guise of "protection". In many cases, the party would be depicted as a "protector" keeping the ideal German family or child(ren) safe from the impending doom of the other. In this way, children had become both a weapon of objective violence and the victim of subjective violence -- as defined by Slavoj Žižek. Using a compilation of the party's propaganda posters, video footage depicting Hitler Youth organizations' activities, and informed by the tactics of the National Socialist Party and Slavoj Žižek's works, I have crafted a critical analysis of German youth's role in the propagandistic success of the Third Reich.

Abstract Name: **A Quill in Honor of The Nation: Rustaveli's Knight in the Panther Skin and Whitman's Starting from Paumanok**

The Georgian poet, Shota Rustaveli, and the American Romantic writer, Walt Whitman,celebrate and discuss the identity of their countries, in their respective poems The Knight in the Panther Skinand "Starting from Paumanok."Rustaveli's use of Georgian rather than the dominant languages of the12th century, such as Latin, suggests his devotion to his country. The two protagonists, Avtandil and Tariel, are imbued with the core Georgian values of friendship, heroism, and true love. Belonging to different kingdoms, these knights develop a strong bond through the similarity of their stories and display their willingness to sacrifice for their belovedroyals,Tinatin and Nestan-Daredjan. The empowerment of women in Rustaveli's poem reflects the reign of Georgia's first female monarch, King Tamar, during the country's Golden Age. Rustaveli also mentions God and the Christian values that inspire his compatriots. Similarly, "Starting from Paumanok" exhibits Whitman's patriotism. He wants his poetry to be democratic and accessible to all, regardless of social status. Although aware of the individual nature of human beings, he is sensitive to their interconnectedness, hence his desire to write about the whole rather than the parts. As Whitman recognizes the diversity of America, his verse is inclusive, as exemplified by the use of"Paumanok,"which is the Native American name for Long Island. He also explores the ideals upon which his country was founded and emphasizes one of the essences of America, democracy. Furthermore, "Starting from Paumanok" praises the resources with which America is naturally endowed while acknowledging the imperfection of theUnited States. By successfully highlighting the cultural identityand uniqueness of their homelands, Rustaveli and Whitman become revered national bards whose works transcend the boundaries of time and region.

Abstract Name: NCUR Murals Project (Collaborative Artistic Project)

I am a studio artist, with a focus on painting, inspired by both the natural world around me and the man made issuesof our society. My painting style is one I like to call fantastical surrealism, where I start by just putting a few blocked colors on the canvas then build up layers and layers of detail through techniques like dry brushing and stippling. I have painted on a variety of materials such as canvas, wood, and fiberglass.I have also used other mediums such as sculpture and assemblages to hit on issues such as women's rights, censorship, and societal controls. Based on this I would be interested in the Equity/Diversity/Social Justice theme. Recently I was a part of another collaboritave paintingproject for the community, the Downtown Naperville Alliance Truck Project. For this project two other artistsand I painted a sculpture of a truck with a retro theme. The project took place over the course of two weeks andwas commissioned by a local business, whowe worked directly withto develop and finalize our design. While I go to school in Illinois, I am from the Greater Orlando area. I have been involved in multiple exhibitions in galleries both in Illinoisand Florida.

Abstract Name: Detection and Removal of Lead from Water Using Nanocomposite Film Electrode

Lead (Pb2+) is a heavy metal that is toxic when consumed, especially in high quantities. The United States Environmental Protection Agency (EPA) recommends that water contain less than 15 parts lead per a billion parts water to be safe for consumption. Screen printed electrodes (SPEs) were chemically modified and used as Pb2+ detectors in water with very low concentrations of Pb2+ present. Previous studies have shown that these sensors can detect lead in concentrations as small as 0.07 ppb, but further studies must be conducted to verify the consistency of the sensors with different concentrations of lead. The modification of the SPEs begins with the synthesis of cysteine-functionalized graphene oxide (sGO). A solution of sGO and polypyrrole (PPy) was electrochemically deposited onto the surface of the SPE, causing a nanocomposite film to grow on the electrode surface. The sensor detects Pb2+ in water by first depositing Pb2+ on the working electrode surface. Then, anodic stripping voltammetry is used to collect a range of signals that can be interpreted to determine the amount of Pb2+ in a sample of water. Results from previous studies indicate that the sensors are effective in adsorption and removal of Pb2+ in water samples. The sensitivity of the synthesized sGO/PPy nanocomposite makes it an effective method for the detection and monitoring of heavy metal ions in water.

Abstract Name: "No"

I'm stuck in the middle and I want to find my way out. Don't you see how I sit there? I just listen and listen with the uncomfortable stare. Don't you see how I sit there? I question every word before it comes in the air. Don't you know how I'm afraid of you, how you steal and how you cheat and how you lie to me too.I never wanted for all this to get here but you've taken and taken from me, my dear. So tell me, tell me, something new. What are you hiding? Why do I have to rip it from you? Tell me, tell me, something new. I'm not tryna hold any grudges on you, but I'm sick and tired of all these dirty lies. I cannot barely even look you in the eyes. Anymore. Anymore. Anymore. Anymore. Anymore. Anymore. Anymore.Oh how did we get here? It's been a ride. It's been a ride. Why do I want to run and hide? To run and hide. I'm afraid. I don't know. I freak out. But I'm tryna let go of the past. Oh-oh. Don't you know? How this is the end, how this ends? Oh, how this ends, oh-oh. Don't you know? How this is the end, how this ends? Oh, how this ends, oh-oh. It's gotta end. It's gotta end,oh-oh, it's gotta end. It's gotta end. So tell me,tell me, something new. Whatare you hiding? Why do I have to rip it from you?You've taken enough from me. You've taken it all. I was lost,and I was scared, but now I'm making the call. So now, I'm saying no. I said no. I said no. I said no. I said no. I said no. I said no. No.

Abstract Name: **Detection of Radon and Gamma Radiation in Basalt Samples and Geothermal Springs**

Radon is produced by the parent element uranium. Uranium initially decays into radium, and finally radium decays into radon atoms. In the conversion from radium to radon, two protons and two neutrons, also known as an alpha particle, are lost. These elements are considered radioactive, because they are continually decaying. However, it is the decay of radon into other elements that pose the greatest risk. Elements such as polonium, which is produced from the decay of radon, becomes trapped in lungs and can cause physiological issues. Such issues, including various forms of cancer, are a major concern. Radon is common in older igneous rocks such as basalt. The abundance of radon in basalt is a natural concern given the geological characteristics of Iceland. The vesicles and fractures that compose basalt allow for feasible emission of radon particles into the surrounding soil and air. The purpose of this research project is to analyze the abundance of radon particles around geothermal areas located around Iceland. Through the collection and assessment of this data the severity of the amount of radon can be determined, which can influence safety protocols and mitigation efforts for native Icelanders. In tandem with detecting radon in Iceland we will bring a geiger counter to detectbackground radiation data and gamma radiation frombasalt samples in Iceland. Gamma radiation in basalt is due to traces of thorium, we will measure radiation near various basaltic formations and geothermal springs. This will be compared to background radiation to determine the amount of gamma radiation that is being emitted.

Abstract Name: Comparison of pathways and detection strategies for Pancreatic Ductal Adenocarcinoma (PDAC) using genetically engineered mouse model (GEMM)

Pancreatic ductal adenocarcinoma (PDAC) is a deadly, invasive pancreatic cancer. Currently, there are five central models used to investigate PDAC, namely, human PDAC cell line, cell line xenograft, patient derived xenograft, genetically engineered mouse models(GEMMs), and organoids. Cell lines don't represent the heterogeneous nature of PDAC nor the pressures of the human immunesystem making them less relevant than other models. Xenografts have a low engraftment rate making the number of models available exceedingly small, and organoids are still in development and analysis phase. In this research, we focus on exploring GEMMs, themost useful in biomarker discovery and specific gene mutations. Using these GEMMs, an in-silico model will be developed for simulating PDAC. Steps would include, developing a model, genetically modifying it, and predicting how often PDAC develops in the model to understand the importance of that gene in PDAC progression. Preliminary research revealed several detection strategies like PanIns, CA 19-9, stromal-related circulating molecules, biomarkers, and mitochondrial DNA. Some gene activity or pathways toexplore may include COX-2, Notch pathways, MMP-7 expression, and MAPK pathway.

Abstract Name: Goal Attainment Scaling and Use of Retrieval Based Practice

Using goal-attainment scaling to promote the effective use of retrieval-based learning strategies among college studentsBackground: Retrieval-based practice is a learning strategy built upon an extensive body of research demonstrating that frequent and intentional recall of information results in more robust learning and memory over time. (Agarwal et al., 2020; Carpenter; Agarwal, 2020). Unfortunately, retrieval-based practice is underutilized among college students (Pinheiro et al., 2022). Methods are needed that help students successfully incorporate retrieval-based practices into their study routines. Goal attainment scaling (GAS) has been found effective in facilitating skill acquisition by employing self-monitoring to promote goal attainment (Hoepner et al., 2021; Turner-Stokes, 2009). The current study investigated the effectiveness of GAS in supporting online college students' independent use of retrieval-based practice.Methods: Students in two online undergraduate courses in communication sciences and disorders were taught how to use retrieval-based practices and given weekly tips on how to apply them to specific course content throughout the semester. Additionally, all students from one course utilized GAS to track their progress in acquiring retrieval-based practice as a skill. Students from both classes completed start-of-course and end-of-course rating scales that assessed self-efficacy related to the use of retrieval-based practices and the likelihood of continued use of the strategy in future courses. Rating scales were then used to evaluate the effectiveness of GAS in promoting retrieval-based practices among college students.Analyses have not yet been completed. We expect both groups to improve in their knowledge of and use of retrieval-based practices, although we anticipate the GAS group to improve at a higher rate and be more likely to use the strategy in the future. Relationships will be discussed related to the variables being investigated in addition to applications of findings that may help college students effectively utilize retrieval-based learning strategies.

Abstract Name: iScheduler - Intelligent Scheduling For Building Optimal Class Schedules

Effective course scheduling can serve to improve department resource management as well as reducestudent time to graduation.Scheduling is a complex decision-making process that requires identifying all possible options and finding optimized solutions based on degree requirements, prerequisite relationships, offering of courses, and availability of students with appropriate backgrounds and prerequisites. The development of the iScheduler (intelligent scheduling) was initiated in 2017 as a class project in an upper-level database course, and later extended by (Alavo et. al 2018) and more recently by (Garcialazo et. al 2022). Our work extends and complements the iScheduler system in two areas. The first areais an adaptivestudent and advisor portal that presents a student with personalizedcourse suggestions and allow them to choose coursesbased on his/her degree requirement, successful completion of prerequisites, and his/her availability. The second areahelps department administrators build optimal class schedules by presentingcandidate faculty members for each course that isplannedto be offered based on expertise, availability, preferences, and scheduling conflicts, to allow for the effective use of faculty resources and reduce the possibility of class cancellation.

Abstract Name: The Informal Power of Women in the Late Roman Republic

The end of the Roman Republic was dominated by the elite male population who controlled society. These male authors put forth a vision of the Republic as it began to crumble, but they do not detail the power of women who existed beside them. However, women had their own ways to manipulate politics and social relationships both within and outside thefemale standards of behavior. These techniques were forms of informal power and can be understood by analyzing the sources through what is implied by the author. Clodia Metelli is one example of a woman who exercised female informal power. Clodia had status and wealth but was subjected to intense scrutiny by Cicero's famous trial oration, the Pro Caelio. This scrutiny produced a vision of the villainous Clodia that lasted centuries and has even influenced modern scholarship that does not note the male author's bias. However, it is possible to discern Clodia as a powerful individual in the Pro Caelio and the private letters of Cicero. This paper uses Clodia as a case study to define informal power because of the number of sources that write about her. These sources offer alook at Clodia as a remarkable woman who influenced politics through social relationships and wealth while officially relegated to the background of Roman society. Understanding the power of status and wealth that Clodia Metelli and othershad can reveal how women were able to influence society in ways not overtly seen in the historical record. Women similar to Clodia in the Late Republic were not just passive actors as their male relatives decided the fate of the Republic as previously believed. This project concludes that they were influential individuals that worked for their own independent aims through informal power that influenced the end of the Roman Republic.

Abstract Name: **Pipeline to Success through Research and Community Connections for Underrepresented Women in STEM Majors**

Alverno College is the first Hispanic serving institution in Wisconsin with programs aimed to increase the population of STEM majors from underrepresented communities. In 2011, a pipeline was created with the Girls' Academy of Science and Mathematics program (GA) where high school girls work with the Natural Sciences, Mathematics, and Technology division (NSMT) faculty on Friday nights to participate in STEM activities, which encourages them to apply for undergraduate STEM programs. Since 2018, NSMT has increased its capacity to provide STEM undergraduates with on-campus summer research opportunities. Traditionally, these programs are designed for upper level students; however, Alverno's program is open to students of all grade levels. The main goal is to increase student self-efficacy in the laboratory, connect scientific research to the local community, and increase persistence in STEM majors. Alverno and the Milwaukee Riverkeeper has established a partnership in efforts to make a community-based connection and assist in water analyses researched each summer. Beginning-level students conduct water sample collection, analyses, and hypothesis building using chemistry and biology methods over a six week program. Upper-level students conduct more advanced water chemistry analyses, microbiological, and molecular biology research over eight weeks. Students attend weekly laboratory meetings and professional development sessions to learn about STEM careers, research/internship opportunities, and receive academic advising.GA has served over 730 students. The majority of participants are girls of color (96%) and those who qualify for free or reduced lunch (98%). Each year approximately 18-20 girls matriculate from GA to Alverno with about half majoring in STEM. The summer research program has supported 73 researchers (56 unique students), 65% who identify as women of color with a 95% persistence rate. A common themed found was an increase in personal identity as a scientist (self-efficacy). Furthermore, 54% of 2021 summer researchers applied for off-campus research opportunities.

Abstract Name: **Investor Sentiment During the Covid-19 Pandemic: Evidence from SPAC IPOs**

This study investigates how investor sentiment during the Covid-19 pandemic affects SPAC IPOs. A SPAC (Special Purpose Acquisition Company) is a company with no specified business operations otherwise referred to as a "Blank Check Company", the SPAC raises capital via an IPO (Initial Public Offering). The purpose of the SPAC IPO is to acquire a private company within a two-year period using the funds raised from the IPO. During the Covid-19 pandemic, expansionary monetary policies such as quantitative easing (QE), zero-federal funds rate, and the Economic Impact Payments (EIPs) augmented liquidity in the global financial markets. We find that investor sentiment (IS), which are the general beliefs investors have on a particular security, strengthens as investors with a money surplus experience FOMO (Fear of Missing Out). A money surplus mixed with a distressed economy caused many investors to invest in riskier assets such as SPACs due to FOMO. Using hand-collected SPAC data, we find that SPAC IPOs grew significantly in volume and size. During the pandemic, SPAC activities are positively associated with investor sentiment and consumer confidence. The results suggest that the enhanced investor sentiment boosts investor risk-tolerance toward much riskier investments such as SPACs.

Abstract Name: **A Survey on Deepfake Detection Methods**

A deepfake is an engineered photo or video of a person in which their image has been altered or replaced with an image of someone else. Some types of deepfakes include face-swapping (switching an image of a face with another), lip syncing (an audio method where the real audio is replaced), and face synthesis (creating a fake image of a face by altering features of a real face image). Deepfakes have the potential to cause a variety of problems and are often used maliciously. A common usage is altering videos of prominent political figures and celebrities. These deepfakes can portray them making offensive, problematic, and/or untrue statements. Current deepfakes can be very realistic, and when used in this way, can spread panic and even influence elections and political opinions. Even more concerning is that deepfakes are easier to produce than ever, and even someone with very little knowledge of technology can use premade methods to create them. There are many deepfake detection strategies currently in use but finding the most comprehensive and universal method is critical. So, in this project we will address the problems of malicious deepfake creation and the lack of universal deepfake detection methods. Our objective is to survey andanalyze a variety of current methods and advances in the field of deepfake detection.

Abstract Name: **A Culturally Informed Approach to Improving Forest Diversity in Bad River Tribal Lands**

Forest diversification is essential to creating and maintaining healthy, resilient forest ecosystems. Forest diversification buffers the effects of climate change, creates new habitats for plants and animals, and improves biodiversity increasing the speed of succession. Without forest diversification, plant and animal life are at higher risk of localized extinction. More species and populations of plants and animals thrive in an ecosystem that facilitates their habitat needs. In this project we worked with the Mashkiiziibii (Bad River) Natural Resources Department to diversify their forested lands. We acknowledge that the Mashkiiziibii tribal lands are of cultural significance and their cultural values play an important role within their community. For this project, we used LiDAR images and superimposed soil maps to locate sand lenses that have the potential to house new tree species and improve biodiversity. By collecting and analyzing samples from the study areas in the field, we were able to verify our observations from remotely sensed data.

Abstract Name: **Creation of Anxa2 Deletion Mutants in Zebrafish Using&#65533;CRISPR/Cas9&#65533;Gene Editing**

Annexin A2 is a calcium-dependent phospholipid-binding protein that facilitates angiogenesis via endothelial barrier maintenance and sprout formation. However, the functions of Annexin A2 are not well established in endothelial cells in vivo. The Annexin A2 gene in humans corresponds to a duplicated locus in zebrafish, called anxa2a and anxa2b. We are using CRISPR-Cas9 to make mutations of the Annexin A2 homologs in zebrafish to take advantage of the optical clarity of the early embryo to follow endothelial morphogenesis. Due to the possible overlapping functions of these homologs, we designed gRNAs that, when complexed with Cas9, targeted the 5' and 3' UTRs of both anxa2a and anxa2b. This was done to induce whole gene deletions instead of creating loss-of-function mutants through indel formation. These whole gene deletions would allow us to avoid genetic compensation induced by mutant transcripts. We also designed a tag-RFP construct flanked by short homology arms for integration into the deleted locus to visually track anxa2a and anxa2b expression during development. Here, we describe a whole gene deletion of anxa2a (14,172 base pairs) via CRISPR-Cas9 injection in fli1-egfp embryos. We have recovered a stable germline deletion in anxa2a. Our next steps are to induce a whole gene deletion in anxa2b for further functional analysis and create mutants homozygous for both deletions. This will allow for loss-of-function analysis of the Annexin A2 duplicated locus in zebrafish for a more complete phenotypic analysis and characterization of the genetic requirements of anxa2a and b during endothelial morphogenesis.

Abstract Name: **Role of Motivation on Academic Success**

The collegiate world is constantly discussing how student motivation is related to student success. How true is this correlation? Does the motivation importance change with the specific course or the format the course is taught in? Can the institution or instructor impact the student motivation level by understanding intrinsic and extrinsic factors that motivate students? The aim of this study is to determine what motivation in education is and how it impacts the academic success of college students. Factors that will be studied include intrinsic and extrinsic motivation factors, academic performance, familial college experience (1st generation students vs non 1st generation students), and the role of the institution and faculty. The study will be completed through a survey with a battery of questions adressing all the key areas mentioned above. Demographics will also be collected to compare possible inter-group differences. Correlational analysis will be completed through data collection in the spring semester of 2023.

Abstract Name: **Creative Ways of Broadening Participation in Undergraduate Research**

In this panel discussion, moderated by Prajukti (juk) Bhattacharyya (UW-Whitewater), three panelists will highlight innovative and effectivepractices for broadening participation in undergraduate research from the perspectives of faculty and administrators. These presentations will describe successful models of expanding participation from an administrator's point of view, as well as highlight the roles of community engagement, mixed-age mentoring, and seminars designed to develop students' identities as scholars.Catherine Chan from UW-Madison will highlight various barriers for expanding participation,and provide practical tools and effective collaboration strategies for overcoming those, based on her almost two decades of experience as a faculty mentor, grants administrator, program manager, and institutional administrator at different types of institutions. Angela Frey (co-author Jennifer Johanson) from Alverno College will showcase a mixed-age project where upper level students apply their STEM learnings to fulfill an unmet need of a community organization and disseminate their works through blog posts and presentations, while beginning students comment on those posts and personally reflect on the value of those projects conducted by upper-level projects. This presentation will focus on how the design of this project provides role models and leadership opportunities through community engagement, and ultimately leads to increased STEM identity and retention for students from underrepresented backgrounds.Alena Kubatova (co-authors Daphne Pedersen, Rebecca Simmons, Shaina Mattingly, Ka nishka Marasinghe, Gregory Vandeberg, Ryan Zerr) from University of North Dakota will describe a 1-credit science literacy seminar course paired with different curriculum-based research experiences (CURES) offered over the last three years. This presentation will focus on the impacts of these readings and discussions on beginning students on developing their STEM identities, interest in science topics, and formation of deep connections with faculty and peers.

Abstract Name: **Learning from Public Spaces in Historic Cities**

Successful public spaces in cities are key for enhancing social cohesion and improving health and safety. Learning from historic cities involves the development of representational and analytical tools aimed at capturing their essence as places of human interaction. The research reports findings of the spatial analysis of twenty Adriatic and Ionian coastal cities, which addresses the question of how the network of public spaces calibrates different degrees of spatial enclosure necessary for creating successful social interactions. Cities in the littoral region include well-preserved historic centers that are renowned for the successful integration of urban squares into the urban fabric. For the purpose of this study, we define urban squares according to areas visible from key public buildings and measure the compactness and convexity of their shapes. We then plot the plaza shapes of all twenty cities in a two-dimensional matrix and classify them into groups that represent various degrees of enclosure and spatial interaction. The study discovers the existence of three main classes of plazas found in cities along The Adriatic and Ionian coastline, suggesting the effect of specific regional and national influences on urban form. On the one hand, the study develops analytical methods for capturing the degree of spatial enclosure of public spaces, and on the other hand, it suggests principles of contemporary urban design based on historical precedents.

Abstract Name: Novel Estrogen Receptor ?? agonist EGX358 in a female mouse model of Alzheimerðs Disease

There are many contributing factors in the development of Alzheimer's Disease (AD), including age, biological sex, and apolipoprotein E (APOE) gene variants. While the APOE3 allele has been deemed a neutral risk factor in AD development, presence of one or two copies of the APOE4 allele results in a starkly increased likelihood of developing AD, especially in postmenopausal women, due to the loss of circulating estrogens. Although current estrogen therapies have been used to treat hot flashes, anxiety, and cognitive difficulty, activation of estrogen receptor has been shown to increase risk for both cancer and stroke. By targeting estrogen receptor (ER) instead, these harmful side effects may be bypassed without compromising the overall benefits of treatment using estrogen therapies. In order to test the efficacy of an ER agonist, a novel compound (EGX358) was administered in a female mouse model of AD. Mice expressed five copies of familial AD gene mutations, in addition to either two copies of the human APOE3, or one APOE3 and one APOE4 (E3FAD, E3/4FAD) gene. Vehicle (10% DMSO) or EGX358 (10 mg/kg/day) were administered orally via hydrogel for eight weeks. Mice were trained and tested for Object Recognition (OR) and Object Placement (OP) memory, anxiety-like behaviors, and senktide-induced hot flash-like symptoms. EGX358 improved memory in OR among both genotypes, and had little effect on anxiety-like or hot flash responses, although E3/4FAD mice spent more time in the center of the Open Fieldand had higher sensitivity to drug-induced hot flashes than their E3/3FAD counterparts. Interestingly, preliminary results show no clear difference in basal dendritic spine densities in the CA1 subregion of the dorsal hippocampus, a brain region highly implicated in episodic memory. Therefore, ER-selective treatments appear to be efficacious for some AD-related symptoms, with underlying mechanisms yet to be determined.

Abstract Name: Effects of Stereotype Threat on Executive Function

Activating age-related stereotypes, known as stereotype threat, can lead to a decrease in executive functioning in older adults (Hess et al., 2003). However, there is limited research on the effects of aging stereotypes on middle aged adults. We examine the effects of stereotype threat on executive function across three age groups: young, middle-aged, and older adults. All participants are randomly assigned to either a stereotype threat condition or a control condition. We plan to investigate the role of stereotype threat on an executive function task using the "Age Identification Scale" (Garstka et al., 1997) and the "Attitudes Towards Own Aging" questionnaire (Lawton, 1975) to establish stereotype threat and using the Digit Span Task (Blackburn; Benton, 1957) and the Wisconsin Card Sorting Task (Heaton et al., 1993) to assess executive function. We have completed our data collection and are starting our data analysis. We hypothesize that (1) middle-aged and older adults will have lower performance under the stereotype threat condition compared to their counterparts in the non-stereotype threat condition and (2) middle-aged and older adults will have lower performance on the cognitive tasks than younger adults in both conditions. We will use a two-way independent factors ANOVA to examine the relationship between stereotype threat and performance, age and performance, and the interaction between age and stereotype threat. Findings from this research expands the literature surrounding stereotype threat and executive function in middle age, which has not been extensively studied. Further, we will examine the influence of people's beliefs about their age and the impact of those beliefs on cognitive tasks that assess executive function. Findings from this research will have implications for how we understand executive function in the aging population.

Abstract Name: Impact of Personal Care Products on Tensile Strength and Structure of Hair

There is currently a lot of debate over hair products and the components within them. While sulfates and parabens have been the two most controversial components within hair products, there is very little public knowledge regarding how other common chemical components impact hair. The purpose of this research is to explore the chemical components citric acid, hydrogen peroxide, and sodium chloride found in shampoo specifically and evaluate the impacts that each of these chemical components can have on hair. This was quantified through measuring changes in tensile stress and strain after chemical treatment when compared to the initial dry hair and a deionized (DI) water soak control. A high-resolution tensile tester capable of measuring the strength of a single hair was constructed from commercially available components and sensors. The diameter of each hair was determined by optical microscopy after chemical treatment. Based on the results of this study, it does appear that there are measurable changes in hair strength and elasticity after some of the chemical interactions tested. Samples exposed to hydrogen peroxide and citric acid showed the greatest decrease in tensile strength while sodium chloride appeared to have a strengthening effect. Samples soaked in deionized water showed a marked increase in elasticity and elongation at break while exposure to sodium chloride decreased the observed elongation at break when compared to the dry untreated control. Further research needs to be done to elucidate the significance and repeatability of the observed effects.

Abstract Name: Storytelling Through Video Games - A Communication Study

In this paper, I explore the function of narrative in role playing video games and its relationship to players, as well as how it can connect and communicate with them on a deeper level through the effect of immersion—particularly in regard to those with mental conditions such as ADHD, anxiety, depression, and more. I do so by analyzing interview data I collected from research participants who play video games and have experienced this sense of deep narrativeimmersion by asking specific questions about their feelings, experiences, and interests regarding the topic. I also will be using Walter Fisher's narrative paradigm theory as a framework to understand video gaming as a mental health salve, exploring the effectiveness of narrative communication in this format. Finally, I analyze data from other published research to help understand and explain the reasons in which humans are able to connect with narrative in such a manner, and why video games could be considered a form of narrative communication no different than other forms of media such as books or movies/television.

Abstract Name: A Comparison Study of the Autism Spectrum Disorder Attention Profile in Detailing Attention

This research investigated the use of The Autism Spectrum Disorder Attention Profile (ASDAP) to assess attention in individuals with autism. The goal of this pilot study was to identify how the ASDAP quantifies and qualifies attention compared to the Childhood Autism Rating Scale (CARS) and the Gilliam Autism Rating Scale (GARS) for subjects who have, or are suspected to have, autism spectrum disorder (ASD).Attention deficit hyperactivity (ADHD) in individuals with ASD, considered comorbid in 50-70% of cases (Hours, Recasens,; Baleyte, 2022), is under-researched because it is not classified as a trait of ASD. Attention requires the filtering of information at the level of the basal ganglia (Awh; Vogel, 2008), amygdala (Avino, et al., 2018), and cingulate cortex (Libero, 2015). Additionally, the combination of genotypes, phenotypes, and epigenetics impact attention (Robinson, 2015; Peaston; Whitelaw, 2006). A review of the research and clinical practice informed the development of 15 ASDAP factors.The aim of the research was to determine differences in the quantity and quality of information yielded across the seven attention categories in CARS, three categories in GARS, and 15 categories in ASDAP. The researchers recruited participants with or suspected of having a diagnosis of ASD to participate in a two-hour long informal assessment either in their home or in the UWEC CCD clinic. Individuals (N = 5) were observed during interactive play, or a preferred activity. Observations and caregiver interview responses were completed for the three protocols. We expect to discover preliminary findings on the efficacy of measuring attention through the ASDAP both quantitatively and qualitatively. Furthermore, documented differences in the summary information from the ASDAP, CARS, and GARS is expected. Data will be presented showing how information obtained from the ASDAP is efficacious in understanding attention in individuals with ASD.

Abstract Name: Stabilizing the Dimer of Non-Structural Protein 9 in SARS-CoV-2

SARS-CoV-2 is an RNA+ virus that is directly translated by the host cell to produce non-structural proteins (Nsp 1-16) essential to the replication of viral RNA.One interesting non-structural protein, Nsp 9, contains an unusual OB-greek key motif known in other viruses to bind single stranded RNA working with the helicase to allow efficient replication. Additionally, this protein is thought to dimerize for efficient RNA binding; however, the specific mechanism of dimerization and the interaction between this dimer protein and a cognate RNA sequence are currently unknown. To better understand the requirements for dimer Nsp 9-RNA binding, we have made a cysteine mutant to covalently stabilize this dimer. Tryptophan fluorescent studies have been developed to determine differences in binding affinities of both RNA and DNA sequences to help identify requirements of complex formation between Nsp 9 and, an as of yet, unidentified cognate RNA. Initial studies indicate binding of an RNA pseudoknot structure could aid in sequestering Nsp 9 to untranslated regions of the viral RNA.

Abstract Name: Relating Hall Viscosity from Hall Conductivity in Quantum Hall Systems

Quantum Hall systems help create more accurate and precise measurements at the quantum scale. Moving electrons in 2-dimensional materials under a strong perpendicular magnetic field reveals an interesting phenomenon such as quantized Hall resistance, generically in low temperatures, these systems are called quantum Hall systems. The strong magnetic field limits the complexity of particles as though they are spinless and also breaks parity symmetry. When these particles move, they bend toward a preferred transverse direction. Computing transport coefficients, such as conductivities and viscosities, theoretically can become quite a task. When the electrons are under an inhomogeneous electric field as well as the magnetic field, there is a Lorentz shear response, referred to as Hall viscosity. This Hall viscosity theoretically exists yet, no experimental measurements have been made. There is an interesting relation between the Hall viscosity and the momentum-dependent part of the Hall conductivity. Our goal is to derive a relationship using a semiclassical approach using stress-energy tensor and the Kubo formula. We expect this study will provide insights into the mysterious Hall viscosity.

Abstract Name: "I get physically ill when I think about us?: Making sense of memorable breakup messages

All relationships have a beginning; some have an end. The experiences we have as we disengage from relationships influence our understanding of those relationships. To better understand the memorable messages that individuals received during romantic relationship breakups, we sought to answer the following questions: What is the significance of memorable breakups? Which words or phrases are consistently remembered during a breakup? Do memorable messages usually come from the person breaking up or the person being broken up with? To answer these questions, the research team conducted 16 semi-structured interviews; participants were recruited via convenience sampling. Thematic analysis techniques (Nowell, Norris, White; Moules, 2017) were used to identify the following themes: Many of the reasons for a breakup appealed to an individual's desire for independence as they looked toward the future. Many memorable breakups also had connections with an individual's family or friends' disapproval of the relationship. In general, negative or harmful relationships yielded negative breakup memories while healthy relationships usually yielded more positive or mutual disengagement conversations. As participants reflected on a memorable breakup and pondered future breakup communication they would execute, every individual mentioned something they learned from in their memorable breakup.

Abstract Name: **Adverse Childhood Experiences, Intimate Partner Violence, Anger, and Mental Health Symptoms Among Incarcerated Women**

Introduction:An alarming number of incarcerated women report histories of adverse childhood experiences (ACEs) and intimate partner violence (IPV), which can increase women's risk for negative mental health symptoms. Research is needed to examine mechanisms to explain the link between ACEs, IPV, and mental health symptoms among incarcerated women. Women who are incarcerated may have little choice, or little space, to express their emotions. The current study explored the role of state anger, including anger expression and anger control, in the association between ACEs, IPV, and mental health symptoms among incarcerated women.Methods: Data from a 2019 study at a multi-security prison was utilized, which included 832 women between the ages of 18 and 85 (M = 38). Women were racially diverse (50% White, 35% Black/African American, 15% Latina/x or another). A mediational path analysis was conducted to examine associations between ACEs, IPV, anger (i.e., state anger; expression and control of anger), and mental health symptoms (i.e., depression, anxiety, and post-traumatic stress disorder [PTSD]).Results: Approximately 60% of women reported four or more ACEs, and 70% had experienced IPV. Women reported clinically significant levels of depression (43%), anxiety (29%), and PTSD (65%). ACEs (B = .45) and IPV (B = .30) were both associated with higher levels of state anger. State anger indirectly explained the associations between ACEs and mental health symptoms, as well as between IPV and mental health outcomes.Conclusions: Women's anger has been both under-researched and over-pathologized. The current study examined the ways in which anger may contribute to the associations between adversity and mental health symptoms. By illuminating some of the root causes of anger, this research can assist practitioners and prison staff to better support the mental health of incarcerated women by understanding where their anger comes from and increase their quality of life.

Abstract Name: **The Effects of Hypoxia and Hypobaria on Sima (HIFa) gene expression in Drosophila melanogaster**

With the rising rates of global climate change, insects such as disease vectors and agricultural pests are migrating to higher altitudes. We are interested in how the model insect Drosophila melanogaster may respond under the related conditions of hypobaria (low pressure) and hypoxia (low oxygen). Typically, hypoxic conditions result in the persistence of hypoxia inducible factor proteins (HIFs) that then initiate physiological responses to the condition via the regulation of gene expression. The homologous protein to mammalian HIFa in insects is Sima. It in turn can be signaled for degradation under normoxic conditions by the proline hydroxylase protein Fatiga. Flies were exposed one of four treatment groups: normal oxygen at normal pressure (sea level), 10% oxygen at normal pressure (isolated hypoxia), normal oxygen at 50% pressure (isolated hypobaria), and 10% oxygen at 50% pressure (high altitude equivalent to 5400m ASL). 24 hours post-treatment, the flies were sexed, RNA was extracted and cDNA was produced via reverse transcription. Real Time PCR (qPCR) was conducted to quantify Sima against a tubulin internal standard. Results indicated that hypobaric and hypoxic conditions separately induced significant expression of the Sima gene. Interestingly, the high-altitude hypoxic/hypobaric flies appeared to express lower Sima levels than the isolated hypoxic or hypobaric flies suggesting. Future work will include an analysis of the different ways that females and males respond to these conditions, as well as their effects on Fatiga expression. This work may aid our understanding of how insect populations could adapt to climate change via vertical migration.

Abstract Name: Characterization of Quantum Dot Dispersions in Liquid Crystals

Liquid crystals are a phase of matter which have unique properties in between those of a conventional crystalline solid and conventional isotropic liquid. Their anisotropic properties have been exploited for applications such as liquid crystal displays, drug delivery nanocapsules, and smart windows. A past study conducted by Konshina et al. demonstrated that the optoelectronic properties of liquid crystals can be improved by adding small amounts of CdSe/ZnS quantum dots into the liquid crystal matrix. In particular, the switching time of liquid crystalsand the corresponding voltage needed to induce such switching both decrease upon quantum dot doping. However, aggregation and conglomeration of quantum dots limits the complete realization of these optoelectronic improvements. To address this stability obstacle, our study explores the nature of aggregation of CdSe quantum dots in a 4′-Pentyl-4-biphenylcarbonitrile (5CB) liquid crystal medium. Droplets of quantum dot dispersions in liquid crystals were placed on treated glass substrates and analyzed under a polarized optical microscope. Aggregation was quantified with an image analysis application and exploitation of the anisotropic nature of liquid crystals. Correlations between aggregation degree and quantum dot size, heating profile and duration, and solvent type were established. Our studies of quantum dot aggregation in 5CB liquid crystals contribute to current efforts to optimize the synthesis of stable quantum dot-liquid crystal dispersions for optoelectronic applications.

Abstract Name: Change in Gene Expression in Green Crabs in Response to Environmental Salinity Change

When exposed to low salinities, the green crab Carcinus maenas experiences elevated hemolymph levels of methyl farnesoate (MF), a putative hormone that may be involved incrab osmoregulation. The final step of the MF biosynthetic pathway is catalyzed by the enzyme farnesoic acid o-methyltransferase (FAOMeT). Previous work in our lab has identified a long isoform and a short isoform of FAOMeT in the green crab; the cDNA sequences of the two isoforms wereidentical, except that the short isoform had a 15 bp deletion. Sequencing of genomic DNA determined that there were no introns present in the area of the 15 bp deletion, which suggestedthat the presence of two isoforms of FAOMeT was due to gene duplication rather to than alternate splicing. In a time-course study of crabs that had been transferred to low salinity (10 ppt), the relative amount of mRNA for the short form increased after several hours of exposure to low salinity, whereas the relative amount of mRNA for the long form did not increase significantly until the crab hadacclimated to low salinity (21 days after transfer).

Abstract Name: Conformational Dynamics and Function of?Escherichia coli?Prolyl-tRNA Synthetase in Crowded Environments

Conventionally, enzymes are studied in vitro under dilute conditions. However, in vivo conditions are different; enzymes are surrounded by the crowded cellular milieu that contains a variety of molecules of different shapes and sizes. Crowding impacts the structure, function, and dynamics of enzymes, the molecular mechanism of which has remained only partially revealed. In the present study, the crowding mechanism was investigated by replicating the intracellular crowded environment using synthetic polymers and their monomers. The model enzyme utilized was Escherichia coli prolyl-transfer RNA synthetase (ProRS), a multidomain enzyme involved in catalyzing the ligation of proline to tRNAPro during protein biosynthesis. The conformational dynamics and function of ProRS in crowded conditions were probed using intrinsic tryptophan fluorescence spectroscopy, molecular simulations, and enzyme kinetics. Results of this study are expected to shed light on the molecular mechanism of crowing and aid in structure-based drug design. Preliminary results of the study will be presented.

Abstract Name: Studying the Electrochemical Activity of Methanol Dehydrogenase in Lanthanide-Modified Methylobacterium extorquens

Recent studies have demonstrated that some enzymes in bacteria isolated from lanthanide-rich areas use lanthanides as metal cofactors in place of more common metals like calcium and that these lanthanide-enzymes have enhanced catalytic properties. For example, Methylobacterium extorquens is a methylotroph that conducts redox chemistry using methanol dehydrogenase (MDH). MDH is a type of quinoprotein that contains a pyrroloquinone and either a lanthanum (La3+) or calcium (Ca2+) metal cofactor. Here, the bioelectrocatalytic activity of MDH from M. extorquens grown in La3+ rich media is compared to MDH from M. extorquens grown in typical Ca2+ rich media. Biochemical assays have shown that La3+-MDH has higher activity than Ca2+-MDH. However, the bioelectrochemical activities from these bacteria have not been compared. If La3+ grown M. extorquens has higher bioelectrochemical activity than Ca2+ grown M. extorquens, then improved biofuel cells and sensors can be created. M. extorquens is grown in two separate cultures, one with La3+-rich media and one with Ca2+-rich media. Methylene blue is polymerized onto the surface of a glassy carbon electrode, then harvested bacteria or isolated enzyme is immobilized on the electrode by casting a mixture of the bacteria and tetrabutylammonium bromide (TBAB)-modified Nafion® onto the electrode surface. The bioelectrochemical activity for oxidation of methanol to formaldehyde is measured by cyclic voltammetry and amperometric i-t curves for various concentrations of methanol in a tris-HCl buffer. In addition to comparing the bioelectrochemical activity of the La3+-MDH and Ca2+-MDH, the activity of the whole bacteria and isolated

Abstract Name: **Exploring the Role of Knowledge and Topic Interest in Predicting Mind-Wandering Among College Students in a Night Class**

Purpose: In this study, students self-rated topic interest, familiarity and mind-wandering during and after weekly class sessions. Attention and engagement during class is a crucial aspect of learning (Szpunar et al., 2013). Mind-wandering is a phenomenon that occurs when the mind shifts thoughts from the topic that is being presented to other internal thoughts (Smallwood; Schooler, 2006). Mind-wandering is associated with reduced academic outcomes, including reduced recall of lecture-based content (Risko et al., 2012), and is associated with working memory capacity, intentionality, motivation and increased time on task (Soemer; Schiefele, 2020). Further investigation into the effects of topic interest and topic familiarity may provide additional insights into modifiable factors influencing mind-wandering within the college classroom.Methods: For six consecutive weeks, students in an undergraduate night class were surveyed midway through each class and at the end of each class. At both points in each class session, students were anonymously surveyed regarding their interest level in the course content presented in that class, as well as their familiarity with the topic and the degree of mind-wandering that occurred during class. Mind-wandering was assessed via the five-item Mind-Wandering Questionnaire (MWQ; Mrazek et al., 2013).Relationships will be discussed related to the variables being investigated. Additionally, applications of findings to student self-efficacy, responsibility and metacognitive learning strategies will be discussed as will potential strategies to mitigate mind-wandering during class.

Abstract Name: **Mathematical Identities of Pre-service Elementary Teachers**

Mathematical identity is defined as “the ways in which students think about themselves in relation to mathematics and the extent to which they have developed a commitment to, are engaged in and see value in mathematics and in themselves as learners of mathematics” (Graven, 2019). The mathematical identities of pre-service teachers influence not only their own mathematical work as they prepare to become teachers, but also their future mathematics teaching (Lutovac, 2013). Research suggests that mathematical identities are formed by specific and memorable positive or negative mathematical experiences during the school years. In this study, I focus on comparing the mathematical identities of preservice elementary teachers at both the start and the end of their mathematics content sequence (the start of their math methods course). Preservice elementary teachers in three sections of a first university math course (Number Systems) and in a section of their math methods course completed a twenty-four question Likert survey that asked them to reflect on their mathematical experiences and views on mathematics. Once the initial data was collected, a select group of students holding either an overall positive or negative mathematical identity were identified to participate in interviews. In that interview, they were asked to reflect on their mathematical memories, to talk about what it means to be a “good math student” and a “good math teacher” and to reflect on how their beliefs about math changed during their math content sequence (if at all) and why. The data provides an understanding of how (and whether) mathematical identities evolve during teacher preparation, and to what participants attribute that evolution. In this talk, I will present the preliminary results of this work.

Abstract Name: **Plant cell-secreted growth factors for ex vivo massive production of red blood cells**

Ex vivo generation of clinically available red blood cells (RBCs) from hematopoietic stem cells represents a promising approach for overcoming the limitations associated with the use of donor's blood. Both expansion and differentiation of hematopoietic stem cells are highly reliant on erythropoietic growth factors. This project aims to develop a novel plant cell-based bioproduction platform for erythropoietic growth factors at significantly reduced cost. In addressing the low productivity bottleneck of plant cell culture technology, we are engineering hydroxyproline (Hyp)-O-glycosylated peptides (HypGPs) that function as a molecular carrier to boost the secretion of fused proteins from culture plant cells. Each of three key erythropoietic growth factors essential for the expansion and differentiation of hematopoietic stem cells, including erythropoietin (EPO), stem cell factor (SCF), and interleukin 3 (IL-3), were expressed in tobacco BY-2 cells as a fusion with a strategically designed HypGP tag, for example (SP)20 consisting of 20 tandem repeats of a "Ser-Pro" motif. The secreted protein yields were up to 500-fold greater than the expression of growth factors controls lacking a HypGP tag. The HypGP-tagged growth factors secreted from plant cells exhibited bioactivity in stimulating the proliferation of TF1 erythroleukemic cells. Furthermore, the plant cell-derived growth factors were able to stimulate the expansion and differentiation of umbilical cord blood-derived CD34+ cell towards RBCs. This project provides a new cost-effective bioproduction platform for erythropoietic growth factors, facilitating the manufacturing of stem cells-derived RBCs at a large scale for clinical applications.

Abstract Name: **Effect of Sound Exposure on c-Fos Expression in the Cochlear Nucleus of Fmr1-Knockout and Wild-type Mice**

Fragile X Syndrome (FXS) affects 1 in 4,000 males and 1 in 6,000 females in the United States and is the leading hereditary cause of autism and intellectual disability. The disorder is caused by a trinucleotide repeat expansion in the Fmr1 gene that leads to a loss of the protein product FMRP. Although it has been established that individuals with FXS exhibit auditory hypersensitivity, the relationship between sound exposure and neuronal activity remains sparsely examined. We hypothesize that Fmr1-knockout (KO) and wild-type (WT) mice respond differently to sound exposure. Using the expression of c-Fos (the protein product of an immediate early gene) as a marker of neuronal activity, we compared the responses between KO and WT to various sound pressure levels.Twenty, 14-day-old mice from each Fmr1-KO and WT strain were evenly distributed into four sound exposure groups. After two hours of habituation, each group was exposed to either 20, 40, 60, or 80 dB of sound for two hours. Following the sound exposure, mice were euthanized and perfused. Mice brains were harvested. Cryosections through the brainstem were immunostained with anti-c-Fos antibodies. The number of c-Fos stained cells in the cochlear nucleus were counted. An analysis of preliminary data revealed that c-Fos expression is sound intensity-dependent; as the magnitude of sound level increases, the expression of c-Fos increases. This is the first study to investigate sound pressure level and c-Fos expression correlation in Fmr1-KO mice. These findings suggest that auditory stimulation does lead to c-Fos expression in the cochlear nucleus of Fmr1-KO mice and that the expression occurs in a dose-dependent manner. Here we present the comparison of KO and WT mice.

Abstract Name: Femoral and Lumbovertebral Strength and Microarchitecture in the Dp1Yey Down Syndrome Mouse Model

Down syndrome (DS), affecting ~ 1 in 800 live births, is caused by the triplication of human chromosome 21 (Hsa21). Individuals with DS have skeletal features including craniofacial abnormalities and decreased bone mineral density (BMD). Lowered BMD can lead to increased fracture risk, and common fracture points are mainly in the femoral neck with some in the lumbar spine. While the femur has been studied in DS mouse models, there is little research done on the vertebrae. It is also important to establish when skeletal deficits occur to find a potential treatment timepoint. The Dp1Yey DS mouse model has all genes triplicated on mouse chromosome 16 orthologous to Hsa21 and displays deficits in femoral bone, including trabecular and cortical deficits in male but not female mice, at 12 weeks. We hypothesize that the long bone and lumbovertebral microarchitecture and strength will exhibit deficits in Dp1Yey mice compared to control mice at 6 weeks. The trabecular region of the 4th lumbar (L4) vertebra and the trabecular and cortical regions of the femur are analyzed via micro-computed tomography (micro-CT), compression testing, and 3-point bending in 6-week-old male and female Dp1Yey mice and wildtype controls. Trabecular and cortical deficits were observed in femurs from male Dp1Yey mice, but only cortical deficits were seen in femurs of female Dp1Yey mice. Preliminary results of the L4 show male and female Dp1Yey mice have significantly lower BMD compared to control mice. Additionally, male Dp1Yey mice show deficits in trabecular thickness and BV/TV. Our results indicate that skeletal deficits occur early in development, are sex dependent, and potential treatments should likely begin early in the development of mouse models of DS.

Abstract Name: Investigation of potential inhibitors of SARS-CoV-2 spike protein by molecular docking and molecular dynamics

On March 11, 2020, the World Health Organization (WHO) declared COVID-19 a global pandemic. Since then, the disease has had an immense impact at a global level. The WHO reports over 600 million COVID-19 cases and around 6.5 million deaths. COVID-19 is caused by a coronavirus called SARS-CoV-2, predominantly causing mild to moderate respiratory illness. SARS-CoV-2 contains proteins on its surface, Spike proteins, that attach to human cells through the angiotensin-converting enzyme 2 (ACE2). Their large role in transmission and prominence in solely coronaviruses make them an ideal drug target.The ZINC online molecular database provided 7.8 million molecules as a starting list of potential drugs for this project. These molecules were initially screened using a process called molecular docking where they are placed in the binding site of the protein by a computer program. The physical movement of these molecules within the active site under in vitro conditions is modeled with a technique called Molecular Dynamics (MD). The average binding affinity is calculated to assess binding favorability.Around 7.8 million molecules from the ZINC database underwent molecular docking. From these molecules, the top 100 molecules with the most favorable docking scores were further analyzed through 50 ns MD simulations. For all 100 simulations, an average binding free energy score was calculated. 10 molecules from these 100 simulations showed promising results from their favorable binding free energies. The top ten molecules with the lowest binding free energy scores were simulated for an additional 50 ns for a total of 100 ns, and these reproduced in triplicate.From the 7.8 million molecules obtained from the ZINC online molecular database, three molecules have been found to show exceptional inhibitory promise in ceasing the function of the spike protein in SARS-CoV-2.

Lamug, Isabelle

Abstract Name: **Investigating interactions between Sstx and other mouse X- and Y-linked amplified genes**

Genes essential for cellular viability are typically conserved acrossspecies. Interestingly, recently acquired (present in one or fewlineages) genes, Slx and Slxl1, on the mouse Xchromosome are essential for spermatogenesis, and thus male fertility. Slx and Slxl1 are thought to compete with a related and recently acquired Y-linked gene, Sly. This hypothesis is based on the transmission of the X versus Y chromosomes to the next generation, because loss of Slxl1 results in more male offspring and duplication of Slx and Slxl1 results in more female offspring. Thus, an imbalance of Slx/Slxl1 versus Sly can lead to male infertility, when both Slx and Slxl1 are lost, and sex ratio distortion when a subset is disrupted. To understand the mechanism of how Slx/Slxl1 competes with Sly to impact sex ratio, we will testSlx, Slxl1, or Sly interactions with the X-linked, amplified spindlin gene, Sstx, by performing yeast two-hybrid (Y2H) screens.We are testing for Y2H interactions with SSTX, because we have previously demonstrated interactions between proteins encoded by Slx (SLX), Slxl1 (SLXL1), and Sly (SLY1 and SLY2 isoforms)—with three other spindlin proteins — SPIN1 and SSTY1/2. We demonstrated SLX and SLY2 binding to SSTY2 andSLXL1 and SLY1 binding to SPIN1. We also showed two of these spindlins, SSTY1 and SPIN1, can bind to each other. We hypothesize that an additional, X-linked spindlin, SSTX will mimic this interaction and directly bind to SSTY2. However, it is plausible for SSTX to compete for binding to SPIN1 with SSTY1, or interact with SLX, SLXL1 or SLY1/2 proteins, and this conclusion will allow us to further investigate our currently known protein-protein interactions. Recognizing competition between X/Y-linked genes and their relationship to mice spermatogenesis will aid us in understanding the basic mechanisms of fertility.

Abstract Name: **Designing A Metastatic Breast Cancer Support Program**

Currently, there is a significant lack of community-based support groups for individuals living with Metastatic Breast Cancer (MBC). The majority of breast cancer support groups exist for those who are breast cancer survivors, inadvertently overlooking those given a terminal diagnosis. Additionally, only about 2% to 5% of the funds raised for breast cancer research is spent towards breast cancer metastasis studies. The goal of our research is to create a patient-led, community-based support program for individuals living with MBC. This will require the collection of resources that address the specific needs of this community, which were identified through extensive literary research and comprehensive surveys. The survey we created assessed their backgrounds, capabilities, needs, and desires. Additionally, we conducted 15 one-on-one interviews with MBC individuals to gather information on their past support program experiences and program structural preferences.With this qualitative and quantitative data, we are currently developing the Charlotte MBC Program and plan on officially implementing the program in the spring of 2023. We have partnered with Carolina Breast Friends, a Charlotte-based nonprofit organization centered around providing support and resources to those who are affected by breast cancer. Carolina Breast Friends does not currently have any specialized services for those with metastatic breast cancer and partnering with this organization allows them to impact more lives within the breast cancer community. We plan on housing our program at their Pink House, a unique respite center for breast cancer survivors.

Abstract Name: **General Microbiology Students Searching for Antibiotics in Minnesota's Wetlands**

As antibiotic resistant pathogens continue to emerge, there is a dire need for the discovery and development of new antimicrobial agents. In Fall 2021,University of Minnesota Crookston General Microbiology students collected soil samples from wetlands of Northern Minnesota. They isolated and characterized the microbes to see if they have antimicrobial activity. Nineteen students were able isolate cultures that showed antimicrobial activity against the safe relatives of the ESKAPE pathogens. The current aim of the research is to conduct a longitudinal study to isolate and identify antibiotic-producing bacteria from bogs and fens collected from the previous student work. We hypothesized that some of the pure culture isolates would produce antimicrobial substances and show inhibition against the ESKAPE safe relative pathogens.Procedures followed the general protocols of the Tiny Earth-Studentsourcing Antibiotic Discovery Initiative. Soil samples were further analyzed using standardized techniques to identify the presence of potential antibiotic-producing microorganisms. Bacteria from these samples were transferred to isolates and tested against ESKAPE pathogens to show signs of antibacterial activity. Streak plates were created for all isolates showing antibacterial activity and incubated at room temperature to further separate the microorganisms to purity. This process was repeated until cultures reached purity. Pure isolates were then tested against ESKAPE pathogens to demonstrate inhibition. Pure isolates that showed inhibition underwent chemical fixation using acetone. Further testing is needed to isolate and extract the antimicrobacterial component. Further characterization of the twelve pure isolates that have antimicrobial activity will be reported. Findings from this research could aid in the development of antibiotics with new antimicrobial properties that can fight off pathogens resistant to current medications.

Abstract Name: **Food Environments and Healthy Communities: An Assessment of the Food Environment on the University of Wisconsin-Eau Claire Campus**

The foods we eat are a determinant of health and wellbeing, with nutrition as a key factor in the most prevalent chronic diseases in the United States including heart disease, obesity, and diabetes. Food environments, the physical, economic, and socio-cultural settings that play a role in what people choose to eat, are associated with diet-related health outcomes. In the university setting, campus food environments are an important determinant of what students eat which influences their quality of diet and nutrition status. To examine the food environment at the University of Wisconsin-Eau Claire (UWEC), students enrolled in a course titled “Food Environments and Healthy Communities” measured the availability and accessibility of healthful food options on campus using University of Pennsylvania’s Nutrition Environment Measurement Surveys. In a student-led approach, sampling boundaries were determined to include food outlets on campus and in the surrounding community. Survey data was collected and scored to provide quantitative data regarding the affordability and nutritional value of food fromvending machines, cafeterias, grab-and-go shops, restaurants, and stores. The data gathered will enable researchers to provide evidence-based recommendations to student senate, university administration, and city council, with the overall goal of improving the campus food environment such that students have equitable access to affordable and healthy foods which is key to health, quality of life, and educational success.

Abstract Name: **Community Engaged Partnerships With Southeast Asian Community Health Liaisons, Leaders, and Health Care Professionals: A Pilot Project on Opiate Awareness, Overdose and Psychoeducation**

Opiate addiction and overdose is a major public health concern that disproportionately affects minority communities, yet little is known about the impact in Southeast Asian communities.1) Pilot a sustainable program of opiate awareness, pharmaceutical awareness, and education in Southeast Asian (SEA) communities. 2) Assess community needs around opiate education, prevention, and medical care for opiate addiction, and 3) Engage professionals (stakeholders) on SE Asian community needs.A three-part model included: 1) A train-the-trainer psychoeducational program delivered by community health liaisons (CHLs), 2) Stakeholder engagement around SEA opiate prevention, overdose prevention/reversal, and care (medical, mental health, pharmacy, and Narcan distribution professionals) and 3) Guided conversations with community leaders. Training sessions were delivered virtually, whereas community sessions varied in their delivery methods (verbally in a community's native language). Three community health liaison training sessions involved a train-the-trainer psychoeducational model on the nature of opiates, drug effects, pharmacist-patient communication, stigma, and community comfort in discussing opiates. A pharmacy professor delivered five two-hour training sessions for the CHLs. We held stakeholder conversations with pharmacy students, physicians, addiction counselors, and clinic supervisors. Common barriers identified were funding and availability of translators, stigma, transportation, and community awareness of resources available. Significant needs exist in SEA communities. First, we observed a lack of knowledge and awareness around opiates across communities. Program materials delivered in a narrative format were useful (per leader feedback). Several leaders and community members expressed concern about the community proliferation of online purchases of drugs marketed as painkillers. Third, community members may lack awareness of risks around opiates and addictive potential. Cultural factors and stigma prevent community members from seeking information and treatment, and there is a need for Narcan education and linguistically and culturally competent providers.

Abstract Name: **Burnout and Work-Family Conflict are Associated with Drowsy Driving Risk in Surgical Residents**

Driving while drowsy is associated with reduced driver's attention, reaction time, and decision making, ultimately costing the lives of hundreds of Americans in motor vehicle collisions annually. Burnout, or chronic workplace stress that has not been effectively managed, has been implicated as a factor associated with increased drowsy driving risk. A precursor to burnout may be work-family conflict. However, little research has been conducted on the risk factors for burnout and the subsequent association of burnout and drowsy driving among healthcare workers. This study examined the relationship of burnout and drowsy driving risk among surgical residents. Eleven surgical residents (Mage=28.9 years, 64% female), with 64% in their first two years of residency, completed the Epworth Sleepiness Scale as a measure of sleep propensity, or daytime sleepiness, where greater sleep propensity translates to a greater chance of drowsy driving. A single item quantified self-reported work-family conflict. Burnout was assessed using the well-validated Maslach Burnout Inventory that categorizes three dimensions of burnout: emotional exhaustion, depersonalization, and personal accomplishment. Residents also completed a 30-45 minute simulated night-time drive in a high-fidelity driving simulator and observational ratings of drowsiness (ORD) were conducted on video data from the drive. Job interference with residents' personal lives was positively correlated with depersonalization (r=0.80, 0.01) and increased sleep propensity (r=0.71, p=0.02). Both greater emotional exhaustion (r=0.63, p=0.04) and depersonalization (r=0.69, p=0.02) were also associated with increased sleep propensity. There was no association between burnout and ORD from the simulated drive. With an estimated prevalence of burnout at 50% among physicians, nearly twice that of the general working population in the United States, further investigation of this topic is required to improve mental health outcomes and driving safety of the American healthcare workforce.

Abstract Name: **Impact of Argon DBD Plasma With and Without Oxygen Addition on Bacteria Mitigation**

Plasma, the fourth state of matter, may be created by passing a high voltage through a gas medium at low or ambient temperatures. Dielectric Barrier Discharge (DBD) plasma is a non-thermal plasma with ions and neutrals remaining at low temperatures and electrons at high temperatures. This process to create plasma splits molecular bonds, which creates free radicals, including Reactive Atomic Oxygen (RAO). This RAO reacts with water in the blood to produce Hydrogen Peroxide, H2O2. The hydrogen peroxide forms growth factors in the body and can then be used to lower activation energies and accelerate chemical reactions. This, in turn, can be applied to the mitigation of bacteria, specifically Escherichia coli (E. coli), which is the bacteria of interest in this experiment [1]. A plasma sheet generator was specially designed at San Jose State University for bacteria mitigation. In this configuration, the plasma sheet will take less time to scan the bacterial surface, as compared to a traditional plasma jet. To observe the impact of Oxygen addition on DBD Plasma, experiments have been conducted to find the amount of bacteria sterilized under various operating conditions (0-5% Oxygen gas in up to 15 slpm Argon gas). The O I Line at 778.97 nm and the OH line at 315.52 nm are predicted to have the highest impact on the formation of RAO, and thus the generation in H2O2. Further investigations on bacteria mitigation will be conducted, and the relative changes will be presented in full.

Abstract Name: **Examining Use of a Standard Structured Meeting Agenda to Improve Learning Outcomes for Instructional Interns**

BackgroundThe Instructional Internship (II) program at a Midwestern University was developed in response to the American Speech-Language-Hearing Association initiative to increase student recruitment into Ph.D. programs (ASHA, 2002) and designed to provide undergraduates with a teaching experience. This experience provides a glimpse into the daily life of a faculty member, including opportunities for teaching and mentoring students (Hemmerich, Hoepner,; Samelson, 2015). II roles are similar to that of teaching assistants. Typically, one or two IIs are assigned to a given course. IIs are undergraduate students that have already taken the course, earning an A-or better. Roles include leading weekly meetings, reviewing course content, responding to emails, and answering students' questions. IIs approach course content from a student perspective, increasing accessibility and reducing any power disparity. The experience changes II's perspectives on teaching and learning, has future implications for teaching clients/families, and develops interpersonal skills (Hemmerich et al., 2015). While associated with positive outcomes, individual experiences vary across instructors. Increasing consistency among instructors may increase consistency across II outcomes. Therefore, a standard structured meeting agenda was developed to increase inter-instructor consistency. The aim of the current study was to evaluate implementation of the structured meeting agenda. MethodsSpring 2022 IIs were recruited to participate in an online survey about their experiences with the structured meeting agenda. Quantitative results were analyzed through descriptive statistics. Open-ended responses were analyzed through collaborative qualitative analysis.ResultsMean ratings were calculated for scaled survey questions regarding use of the structured agenda. While no significant changes in approach to meeting agendas were noted, most instructors were already using a similar structured agenda. Open-ended responses were analyzed qualitatively. Instructors acknowledged that the structured agenda helped strengthen and guide the flow of the meeting, making meetings more focused, more interactive and supportive, increasing flexibility, and clarifying expectations.

Abstract Name: **UAS Based Photogrammetric Analysis of a Rock Slope In Montana**

With UASs (Unmanned Aircraft Systems) becoming more and more integrated into the engineering toolbox, there are many different platforms and equipment to choose from to accomplish a given job. Many companies will claim their system for data capture and analysis is the best tool for the job. The focus of this research is to put some different UAS systems and data-capturing methods to the test from the standpoint of an engineer who may be analyzing these different methods to see what is most cost and time effective, what system is more accurate, as well as the learning curve. The research is focused on using two different aerial platforms (DJI Phantom 4 Pro, DJI Matrice 300) to capture data to then construct a point cloud of the research site. One platform (P4P) was fitted with a 4k camera to generate a point cloud using photogrammetry and the other (M300) used a Lidar scanner with an RGB camera for colorizing. The site was surveyed using a GNNS receiver and base station and was then flown on two different days in October 2022. The point clouds from each method will be processed with Pix4D photogrammetry software to do a geotechnical analysis of the research site. Point clouds from both Lidar and photogrammetry have been successfully generated and are accurate to within 3cm. The next step will be to process the point clouds for geotechnical analysis as well as go back to the site to take hand measurements for a traditional approach to Geotech analysis. All this will then be compared for accuracy within the models and field mapping approach while considering time and cost-effectiveness.

Abstract Name: **Deep learning Approach for Detection of Inferior Vena Cava Filters from CT Scans**

IVC filters (IVCF) perform the important function of breaking down blood clots. However, most IVCF are temporary, and delays in their removal can cause complications. Current tracking of temporary IVCF is performed manually,which can delay treatment if the patient transfers healthcare providers.This study proposes a pipeline to automate detection of IVCF. A patch-based 3D Convolutional Neural Network (CNN) is created using a database of patient's abdominal CT scans. The data is preprocessed using normalization techniques, along with a window/level to enhance the brightness of dense materials, which makes the metal IVC filter easier to detect. The database is split into training and testing, and patches are extracted from each. A postprocessing step is performed on the segmentation, where neighborhood connectivity is used to remove small objects. The scan is then classified as either IVC or non-IVC if the number of positive slices is greater than our selected threshold. The model's DICE score reached 0.93 for training and 0.81 for validation. The prediction pipeline was able to accurately detect scans with IVC filters 100% of the time. The false positive rate on scans from normal patients was also 0. The proposed IVCF filter prediction pipeline requires lesscomputing power while providing high accuracy, there by reducing the time needed to track IVCF in health records.

Abstract Name: **Mapping Food Insecurity in Minnesota**

This study evaluates predictors of food insecurity rates across counties in Minnesota. As economic uncertainty in the US rises, hunger is becoming a growing problem that affects thousands of families across the state. According to data from the US Census Bureau's 2020 Pulse survey, 37% of Minnesotans reported experiencing some level of food insecurity. While previous research has identified the presence of food deserts in Minnesota - areas where geographic access to a grocery store is limited - this study utilizes data on cost of living to identify potential food mirages. A food mirage is an area where grocery stores are present, but inaccessible due to prices being higher than the surrounding neighborhood can support. In order to identify these areas, an OLS regression was conducted. After comparing cost of living data, data on the availability of grocery stores per county, and several other factors, it was found that cost of living in a county has a stronger correlation with food insecurity rates than the number of grocery stores. In addition, multiple counties in Minnesota identified as outliers by this regression could potentially be suffering from the situation of a food mirage. These results have some implications on future research and economic policy. A more precise method of measuring the prices of food in a neighborhood - rather than a county - would better be able to recognize the relationship between prices and food insecurity, and may then identify other areas in Minnesota where a food mirage exists. Once these areas are found, economic policy could be able to reduce food insecurity by focusing on increasing the affordability of groceries in that neighborhood.

Abstract Name: **First report of the introduced isopod Ligia exotica Roux, 1828 in rocky intertidal habitats of Midway Atoll, Papah?naumoku?kea Marine National Monument as confirmed by morphological and molecular approaches**

The Papahānaumokuākea Marine National Monument (PMNM) is one of the world's largest marine protected areas and covers marine habitats as well as the islands and atolls of the Northwestern Hawaiian Islands. Despite its protected status, the biodiversity of the PMNM face several threats to its preservation, including the presence of introduced species. Given its history as a shipping and military outpost, Midway Atoll represents a potential entry point for introduced species to the PMNM. Thus, monitoring for new introduced species in Midway is of importance for the management and preservation of the PMNM. In this study, we use morphological and molecular approaches to confirm the presence of the coastal isopodLigia exotica, a species of Asian origin that has been introduced to coastlines around the world, in Midway Atoll and thus the PMNM. The presence ofL. exoticain Midway Atoll is of concern as islands of this marine monument harbor endemic species ofLigiaisopods.

Abstract Name: **Virtual Reality Exercise Effects on College Students with Anxiety and Depression**

Mental health has been an extensive concern across college campuses, especially coming out of the COVID-19 pandemic (Lipson, et al., 2022). Left untreated, anxiety and depression can have an impact on college students in all areas of life, not just in the classroom (Adams et al., 2016). Using virtual reality (VR) to provide an alternative exercise environment can alleviate additional stressors of beginning and adhering to an exercise regimen for those who struggle with mental health. The purpose of this study is to investigate the physiological and psychological effects of VR biking exercises on college students with anxiety and/or depression. Thirty participants (18-22 years of age) will be recruited via emails and flyers across the University of Minnesota Duluth campus. Participants will perform 20-minute biking sessions under each of the following conditions: (1) VirZoom immersive VR exercise bike; (2) NordicTrack Grand Tour non-immersive VR exercise bike; and (3) VirZoom bike without VR system (traditional condition). Participants' heart rate and rate of perceived exertion (RPE) will be measured every 4 minutes during each session, and their anxiety and mood will be measured before and after each of the three biking sessions. For statistical analysis, a repeated two-way ANOVA will be conducted. It is hypothesized that heart rate and RPE will be different between the VR exercise and traditional exercise sessions; and immersive VR exercise will result in a significantly greater improvement in psychological variables than both non-immersive VR and traditional exercise. The results of this study may lend themselves to improved long-term exercise adherence in individuals suffering from mental illness, as they can perform engaging workouts from the comfort of their home.

Abstract Name: **Ask the Parents! What Preservice Teachers Learned about an AAC User**

This mixed methods research study investigated how preservice teachers' perceptions of children with complex communication profiles (CCP) change when given parent-provided information. This important research highlights the value of parents' expert knowledge of unique communication modalities (e.g., technology and nonverbal) that support a team of educational professionals. Previous research shows teachers lack knowledge about their students' communication modalities and competencies, including AAC tools (Costigan; Light, 2010). Parents of children with CCP have vast amounts of insight into their child's personality and nature of communication (Cress, 2004; Marshall; Goldbart, 2008) which can shape teachers' capacity to communicate with their child. Data was collected from undergraduate education majors (n=86) enrolled at the University of Wisconsin-Eau Claire. Procedures included showing a video of a child with CCP, a pre-intervention survey, the Hear Me into Voice (Mayne; Rogers, 2020) protocol to showcase parent expertise, the same video, and a post-intervention survey. The following research questions were addressed: (a) How does pre-service general and special education teachers' efficacy for communicating with an individual with a complex communication profile change after reading a parent-reported narrative about their child? (b) Based on a video depicting an individual with a complex communication profile, how do pre-service general and special education teachers describe the individual before and after reading a parent-reported narrative about the child?Data analysis to date indicates statistically significant findings were yielded demonstrating improved efficacy for preservice teachers' communication with a person with a CCP. An example being the quality of conversational topics that preservice teachers increased after reading the parent reported narrative. Data analysis is still being completed. Further quantitative and qualitative analysis on other pe- and post- survey questions will be discussed at NCUR.

Abstract Name: Analysis of Gene Expression in Mutant Strain of Alga Chlamydomonas reinhardtii Under Low-Nitrogen Conditions

Nitrogen is an essential element for life, especially for photosynthetic organisms, such as plants and algae, that have nitrogen-rich chlorophyll. Nitrogen depravation leads to various physiological and metabolic changes; thus, its supplementation with fertilizer is necessary for proper growth, particularly for crop plants, which leadsto high financial and environmental costs. In 2020, we reported a mutant strain of the green alga Chlamydomonas reinhardtii that maintains high growth in low-nitrogen media. Genetic crossing and genomic sequencing have revealed that the tolerance-to-low-nitrogen phenotype (TLN) is a heritable trait due to a recessive mutation. Further, the possible genetic source of this mutation has been narrowed down to two candidate genes: the firstis predicted to encode a transcription factor, and the second, a predicted RNA-binding protein. The aim of this study is to further investigate the involvement of these genes in the TLN phenotype by evaluating their expression within the first two days following exposure to low nitrogen. Two cultures each of the mutant (TLN1) and wild-type (WT) strains were grown in both regular TAP media and 10% nitrogen media (N10). Cells were harvested at day 0, 0.5, 1, and 2, and total RNA was isolated and purified. RT-qPCR will be used to assess the RNA expression of each gene at the specified times. It is expected that the RNA levels of the candidate genes will differ significantly between the WT and TLN1 strains in N10 media, which would provide supporting evidence for their involvement in the TLN phenotype.

Abstract Name: "I get physically ill when I think about us?: Making sense of memorable breakup messages

All relationships have a beginning; some have an end. The experiences we have as we disengage from relationships influence our understanding of those relationships. To better understand the memorable messages that individuals received during romantic relationship breakups, we sought to answer the following questions: What is the significance of memorable breakups? Which words or phrases are consistently remembered during a breakup? Do memorable messages usually come from the person breaking up or the person being broken up with? To answer these questions, the research team conducted 16 semi-structured interviews; participants were recruited via convenience sampling. Thematic analysis techniques (Nowell, Norris, White; Moules, 2017) were used to identify the following themes: Many of the reasons for a breakup appealed to an individual's desire for independence as they looked toward the future. Many memorable breakups also had connections with an individual's family or friends' disapproval of the relationship. In general, negative or harmful relationships yielded negative breakup memories while healthy relationships usually yielded more positive or mutual disengagement conversations. As participants reflected on a memorable breakup and pondered future breakup communication they would execute, every individual mentioned something they learned from in their memorable breakup.

Abstract Name: Analysis of Stellar and Exoplanetary Attributes to Determine the Feasibility of Carbon Based Life in Exoplanets

Over the past few decades, the search for a counterpart to Earth has only increased in prominence, with reliable data from satellites such as Gaia and datasets like the NASA Exoplanet Archive providing more possibilities for habitability than ever before. Searching for habitable exoplanets is crucial because it gives us insight into the early history of our solar system and potential theories of primitive life formation on Earth. The main criterion for an exoplanet's habitability is its ability to host liquid water. This depends on many characteristics unique to each exoplanet and its host star, all of which must work together to create an environment capable of sustaining carbon-based life as we know it. Our research aimed to analyze the habitability of the exoplanets in the NASA Exoplanet Archive by determining if the exoplanets resided within their host stars' circumstellar habitable zone (CHZ). To accomplish this, we first removed entries considered controversial or redundant to ensure accuracy in our data. We then calculated each host star's bolometric luminosity to determine the inner and outer bounds of its CHZ and see if its exoplanet was within the region. We hypothesized that all of the exoplanets we found to be habitable would have eccentricities less than or equal to 0.4 and host stars with surface temperatures less than or equal to 7500 K. Based on our results, all of the exoplanets we deemed habitable had host stars with temperatures less than or equal to 7500 K; however, some had eccentricities greater than 0.4, thus disproving our hypothesis. We then compared our data with the NASA Planetary Habitability Laboratory (PHL) Dataset and found three exoplanets in common: Kepler-1649c, Kepler-174d, and Kepler-62f. Furthermore, our results yielded an extra 50 exoplanets as potential contenders for habitability in addition to NASA's findings.

Abstract Name: **Engaging Undergraduate Students with Animal Assisted Therapy Activities, Outreach, and Research**

Animal Assisted Therapy (AAT) is a recent phenomenon in the research literature with the first reports appearing just over 20 years ago. The current and popular trend of embedding certified animals into the higher education system is based on the overwhelming popularity of the practice and on the positive outcomes of research endeavors related to the activity. This presentation will be a discussion of how the AAT program at the University of Central Oklahoma Department of Nursing has been shown to be an effective strategy to improve the mental outlook and modify stress of students and faculty. Not only does AAT provide modify stress, it provides opportunities for students to engage in research, conduct independent research, and assist in the care and management of the dogs. This is hands-on approach is a very effective approach to teaching research methodologies, and helps students learn the importance of complementary and alternative health interventions. Topics to be addressed in this talk include barriers to animals on campus as well as the expense associated with such programs. Although the dogs initially arrived on campus Fall of 2019, the pandemic prohibited the practice of AAT for the next 18 months.Once restrictions were lifted, the program began to develop quickly, with undergraduate research students given an option to do AAT research.Acquisition of grant funding to add a dog to the team led to a group of students who participated in training and socialization of the new dog.This spring will be the second-year students will be presenting evidence-based practice and/or research findings that involves the AAT Dogs. Animal Assisted Therapy, Undergraduate Research, Nursing Students, Stress Modification, Complimentary Health Approach

Abstract Name: **UWEC Campus Environmental Monitoring of PM 2.5 using Purple Air Monitors during residence hall demolition**

During September and October 2022, construction crews conducted demolition projects on two residence halls (Putnam Hall and Katherine Thomas Hall) on the University of Wisconsin- Eau Claire campus.Elevated PM 2.5 levels on campus could present a risk of throat and lung irritation, decreased respiratory function, and long-term health impacts to students, faculty and the workers on this project. Two EPA- and Wisconsin Department of Natural Resources-testedPurple Air monitors provided real-time monitoring of PM 2.5 levels in two locations on campus within 50 meters of the worksites. Hourly PM 2.5 measurements from each Purple Air monitor were corrected using the EPA correction factors and graphed alongside PM 2.5 measurements recorded by the WDNR, which served as a control. Periods when demolition activity occurred were established and detailed in data. Environmental monitoring was conducted to determine if the demolition activity was a source of increased PM 2.5 pollution as a health risk to the general campus population of students, staff, and faculty. The hourly and average PM2.5 levels measured on the UWEC campus were typically higher than the WDNR monitor between September 5th and October 5th, 2022. However, increases during or immediately following demolition activities were not apparent.

Abstract Name: **Viability of Trypanosoma cruzi in RBCs at cold storage temperatures**

Chagas disease (American Trypanosomiasis) is caused by the protozoa Trypanosma cruzi. Chagas disease affects approximately 10 million people in Latin America, manifesting in pyrexia, malaise, splenomegaly, and cardiomyopathies. T. cruzi is commonly spread through the infected feces of the 'kissing' bug. After insect bites, blood transfusion is the second most frequent mode of transmission. The Center of Disease Control (CDC) estimates in the US, around 300,000 individuals are infected with T. cruzi, causing a considerable disease burden. The goal of this research will be to study the viability of T. cruzi in packed red cell aliquots stored at various cold temperatures to study parasitemia. If successful, storage of packed red cells in cold temperatures will show reduced viability of infectious T. cruzi; creating a simple adjustment to current prevention methodologies furthering the reduction of transfusion-transmitted American trypanosomiasis.Warming temperatures can shift the distribution of triatomine insects, allowing the spread of the disease to non-endemic areas such as the United States as climates become more favorable. Pollution, insecticide resistance, and tourism are additional factors that may contribute to this threat. Means to prevent trypanosomiasis from blood products will become pertinent with this change.Routine screening of blood-donors using a questionnaire has reduced the incidence of contracting trypanosomiasis in non-endemic areas. Serological testing is not mandatory outside endemic areas because it is suspected that the number of T. cruzi-infected donors is small, and screening each donor would not be cost-effective. Although the questionnaire has been effective, it fails to screen asymptomatic carriers resulting in transfusion-transmitted infections.To mimic organ-donor tissue, cultures stored at low temperatures have shown a reduction of trypanosomes. Past research has explored cold storage on the viability of Babesia in blood bags. Minimal research has been conducted on the viability of T. cruzi in blood stored at cold temperatures

Abstract Name: **COVID-19 Pandemic Data Analysis: Does Income Affect Mortality Rate?**

The ongoing COVID-19 pandemic is one of the deadliest disasters in United States history, ranking first with a death toll of over 1,000,000. While pandemics affect people regardless of wealth, they hit the poorest people the hardest. This one is no exception, as it has disrupted every area of the country's healthcare system and has had a devastating impact on poor and low-income communities. In an effort to better understand and support at-risk populations across America, we investigate how income has affected mortality rates during the pandemic at the county level. This study was conducted with the R language and its respective IDE, RStudio, which offer powerful, statistical tools to support data science. Data was used from two sources. The simplemaps US Counties Database contains comprehensive census data for 3,234 counties with up to 78 fields as of May 13, 2022. Our own COVID-19 database has been tracking cases and deaths for 3,223 counties since the start of the pandemic on Jan 21, 2020 until now.After establishing connections to the databases using a MySQL Connector/ODBC driver, each dataset was imported via SQL queries as Data Frame objects. Once in the R environment, they are filtered for noisy data, non-US counties and missing values. The two tables are joined according to their county FIPS codes. Deaths per 100,000 people as well as case-fatality ratio are calculated for each county. By analyzing and visualizing the data, we find a possible negative correlation between county median household income and COVID-19 deaths. However, other likely variables associated with lower socioeconomic status will be investigated, as they could place these populations at higher risk of dying to COVID-19. This includes pre-existing conditions (diabetes, heart disease, obesity, etc.) and lack of health insurance.

Abstract Name: **Using Facebook and Reddit to code support group member posts: What we can learn about the needs of patients with Postural Orthostatic Tachycardia Syndrome (POTS)**

Many patients with chronic illnesses feel that they lack resources when it comes to finding knowledgeable specialists, helpful consumer products, and support for loved ones. This research project aims to bridge the gaps of understanding between patients and their families and medical professionals by observing common patient complaints and requests for advice on social media platforms. By coding these responses and looking for commonalities, manufacturers may also benefit by learning to create better products that serve the needs of chronically ill patients. Similar studies have been performed for other areas of research. Sutter et al. (2021) used Facebook and Reddit to code for food parenting posts. They categorized food parenting styles that were coercive, structured, or autonomy supportive. They found a correlation between food parenting styles and children's unhealthy eating habits and adiposity (Sutter et al., 2021). A social media study was conducted in Canada to determine social levels of hesitancy toward COVID-19 vaccines (Rotolo et al., 2022). Most Canadian citizens have been vaccinated, and researchers believe that the results of this study can help guide educational attempts for unvaccinated citizens (Rotolo et al., 2022). Perry and Park (2021) performed a qualitative analysis of Twitter feeds to search for major themes of suicidality and found that while intrapersonal and interpersonal factors were amply expressed, about half of the tweets expressed suicidality when discussing social issues such as health and politics.This study will compare posts from Facebook and Reddit to search for commonly used keywords among patients in support groups for Postural Orthostatic Tachycardia Syndrome (POTS). After posts are qualitatively coded, a statistical analysis will be performed. By discovering the most discussed support group topics, doctors, manufacturers, and loved ones can better understand the needs of patients with POTS.

Abstract Name: **Flipped Medicine: A Guide to Deconstructing the Normative Patient Model**

Historically, medicine has centered on a singular model: that of the white, cisgender, heterosexual, young, abled, middle-class male. While it is well-documented that patients of diverse identities often present differently in clinical settings, medical education continues to use this dominant, normative model as the standard for all patients while ignoring marginalized groups in their curricular resources. Normative medical educational practices systematically reinforce bias at the institutional level, causing even well-intentioned providers to be ill-equipped to diagnose and treat diverse bodies. Rectifying our society's deeply ingrained healthcare disparities will require active acknowledgement of the medical field's role in reinforcing discrimination, starting with a diversity-centered reexamination of our medical education system.Flipped Medicine: A Guide to Deconstructing the Normative Patient Modelbegins this conversation by challenging the validity of the normative patient model and inviting providers to critically engage with bias in medical education. This resource "flips the script" on the normative patient model by reimagining basic lessons on heart attacks, CPR, cyanosis, and EKG lead placement as if a currently marginalized group were considered the norm. For instance, Flipped Medicinecenters its description of heart attacks on the "silent" symptoms typically experienced by female patients, such as indigestion and fatigue, instead of the predominantly male experience of chest pain. This reversal of hegemonic narratives draws attention to the fragility of the normative patient model, calling into question society's construction of "normal."Rather than simply call for change, I proposeFlipped Medicineas a tool for reflection, self-critique, and systemic challenge. By imploring medical professionals to reflect on hidden biases, this resource sparks recognition of normativity in medical education and imagines a future where medicine is inclusive and integrated.

Abstract Name: **Social Connectedness and its Association with Mood, Resilience, and Well-Being in College Students**

College students often experience adversity which can be difficult to overcome based on inherent mental and psychological traits. Students with elevated social connectedness appear to overcome adversity due to having higher levels of mood, well-being, and resilience.In previous studies, positive emotions and social belonging supported the health of the parasympathetic nervous system. These factors seemed to feed into the self-sustaining upward spiral of growth and overall physical health. Social connectedness was found to be a significant mental health factor with impacts across diverse areas of physical and mental health. One hundred and eighty-nine students between the ages of 18 - 34 at a private liberal arts university in the southeast participated in the current study. Data collection was based on face-to-face surveys from lower and upperclassmen from diverse majors. The Positive and Negative Affect Scale, Ego-Resilience Scale, Mental Health Continuum Short Form, and the Social Connectedness Scale Revised were the instruments administered. The purpose of this study was to explore the relationship between mood and social connectedness, resilience and social connectedness, and lastly, well-being and social connectedness. The first hypothesis predicted a positive correlation between mood scores and social-connectedness scores, the second hypothesis predicted a positive correlation between resilience scores and social connectedness scores, and the third hypothesis predicted a positive correlation between well-being scores and social connectedness scores. All three hypotheses were supported. It was found that mood and social connectedness scores were significantly positively correlated, resilience and social connectedness scores were also significantly positively correlated, and finally, well-being scores and social connectedness scores were significantly positively correlated. Results of the current study were consistent with existing literature. Recommendations, implications, and limitations are discussed.

Abstract Name: **Nuclear Fuel Remediation: A Computational Study**

Increased global attention on sustainable energy initiatives sparked renewed, global interest in nuclear energy. However, asignificant pitfall of nuclear energy is the production of high-level nuclear waste (HLW) with an extensive half-life. HLW waste storage poses a significant environmental and security risk. Remediating spent nuclear fuel (SNF) using nitrogen and sulfur-based chelation agents is a promising venture for recycling HLW into usable fuel or stable, nonradioactive compounds. This research paper aimed to perform computational studies on various nitrogen and sulfur chelation agents to determine if such agents are viable options for SNF remediation. The 6-31G(d) and MWB60 basis sets were used with Gaussian simulation software to perform computational simulations on viable chelation agents. Of the various agents studied dimercaperol, diethylenetriamene pentaacetate, and ethylenediaminetetraacetic acid appear to be the most promising in producing stable compounds from SNF byproduct. Thermodynamic and thermochemical properties of independent molecules were analyzed and documented to determine if stable compounds are possible. Lanthanide and actinide molecules were analyzed and documented for future research. Current simulations indicate promising results for dimercaperol in producing stable compounds for remediation; future research on this topicshould aim to understand if newly discovered compounds are applicable to industrial waste treatment processes.

Abstract Name: Influences on Farmer Perceptions of Specific Farming Practices

Previous research suggests that specific farming management practices can have a big impact on water quality and understanding what influences farmers to engage (or not) in these practices is important (Liu, Bruins,; Heberling, 2018). Hundreds of studies have been conducted showing the impact of social norms on a variety of environmental conservation behaviors (Passafaro, Livi,; Kosic, 2019). My research was looking to identify what management practices farmers are currently using and whether the use of these practices were related to their perceptions of what most other farmers are doing (descriptive social norm) and their perceptions of what most other farmers think about these practices (injunctive social norm). I created an online survey asking farmers to indicate what farming practices they use and to estimate how many of the farmers around the area they think also use the practices and whether other local farmers approve of the practices. Only 8 farmers responded to the survey. Results suggested that the sample was not representative and was using the best management practices at a considerably higher rate than the local community. Gathering responses from farmers was difficult but point to several recommendations for future researchers. Gathering data from farmers over longer periods of time and outside the summer months is important. Also developing a more comprehensive plan to connect with farmers by building relationships and holding events would be likely to increase farmer engagement with projects like these.

Abstract Name: Investigation of Photoproducts from the Reaction Between Deoxynucleotides in DNA and Excited-State Lumazine

Lumazine (2,4-(1H, 3H)pteridinedione) is a derivative of the family pterins, a group of compounds that are present in a variety of biological systems. Though not harmful in its ground state, lumazine was found to possess the ability to initiate selective cell death, making it incredibly attractive as a potential photodynamic therapy (PDT) agent. Unfortunately, the mechanism through which it causes apoptosis remains unknown. In other PDT therapies, two types of photosensitized oxidation reactions leading to degradation of biomolecules were identified: type I and type II. Type I involves an excited-state electron transfer between the sensitizer and a nearby biological molecule. If this pathway occurs between lumazine and a nucleotide, the resulting radical nucleotide is expected to undergo a series of reactions that result in cell death. The other proposed mechanism, type II cell death, involves an energy transfer between the excited sensitizer and oxygen, resulting in reactive singlet oxygen ($^1O_2$) that catalyzes reactions that can fragment proteins, nucleotides, and other molecules in the cell. Though type I is suspected to be dominant for lumazine, type II's competition and contribution are both possible and concerning. In this study, we aim to identify and quantify the products of the reaction between the excited state of lumazine and monomeric deoxyguanosine monophosphate (dGMP) and deoxyadenosine monophosphate (dAMP) using absorbance spectroscopy and high-performance liquid chromatography (HPLC) with and without oxygen and with varying exposure times to light excitation of lumazine. The study aims to deepen our understanding of the interaction between excited-state Lumazine and DNA molecules and provide valuable insights to improve the efficiency and mechanism of future PDT drugs.

Abstract Name: Wealth Begets Wealth: Intergenerational Correlations of Housing Wealth Inequality

This research will evaluate the effect of parents' housing wealth on their children's housing wealth in adulthood. Wealth is associated with a wide range of outcomes. Higher levels of wealth increases access to more favorable terms for credit, provides economic security to take risks, and shields against transitory fluctuations and shocks to the labor market. Given the importance of housing wealth for middle-income households in the United States, the persistence in housing wealth is likely a large factor in the intergenerational transmission of total household wealth. Previous research has examined the correlation of overall wealth across generations. However, few papers have studied the intergenerational relationship in housing wealth specifically. This paper contributes to the literature by using the Panel Study of Income Dynamics (PSID), a nationally representative panel dataset with information on parent and children's wealth, to estimate the relationship between parent and child housing wealth ranks. I expect that an increase in parents' housing wealth position is associated with an increase in their offspring's housing wealth position in adulthood. I will then document the extent to which channels of wealth transmission can explain the correlation in housing wealth across generations. These channels include earnings, asset ownership, marriage, bequests, and education. I expect that income and assets are central in this process, accounting for most of the parent-child housing wealth correlation. These results would suggest that parents' housing wealth becomes more important for predicting their children's housing wealth as overall U.S. wealth inequality increases.

Abstract Name: Improving the Classification Performance on Small-Sized and Imbalanced Datasets

Predicting rare but high-impact events is critical in many medical applications, such as health risk prediction and disease diagnosis. While sensor technology has improved rapidly in the last decade, machine learning (ML) techniques for the prediction of rare events lag behind general prediction models.Most optimization techniques used to train ML models implicitly assume a balanced distribution of events in training data. This research focuses on improving the performance of classifiers on imbalanced and small-sized individual asthma patient datasets using oversampling techniques, as these issues significantly affect medical datasets in healthcare applications.Imbalanced data causes the classifier to be biased toward the class with more data samples (the majority class), reducing its accuracy for minority class data. The class imbalance problem is particularly challenging in the medical domain because the goal is to predict whether a patient is at risk for a particular disease. However, these cases are often in the minority class. Moreover, machine learning-based classifiers require a large amount of data to be adequately trained. Therefore, having a small-sized training dataset is also an obstacle because it hinders the classifier's performance.To improve the performance of prediction models on imbalanced and small-sized asthma patient data, we first investigated existing synthetic minority oversampling technique (SMOTE) variants at the data level. SMOTE variants solve the class imbalance problem by generating synthetic data samples and adding them to the minority class data until the classes are balanced. We proposed three new minority oversampling techniques: Incremental K-Means Clustering (IKC), SMOTEBoost and SMOTEBoost with Control Coefficient (SMOTEBoost and SMOTEBoostCC), and Average Neighbor Vector Oversampling (ANVO). We evaluated the effectiveness of the proposed techniques compared to the existing SMOTE variants. The evaluation results show that the proposed methods are comparable with state-of-the-art oversampling methods.

Abstract Name: **Tectonic Setting in the 1.9 Ga Eau Claire Volcanic Complex, Eau Claire County, WI**

The Eau Claire Volcanic Complex is part of the 1.9 billion-year-old Penokean Volcanic Belt (PVB) which contains numerous base and precious metal deposits. The discovery of metallic deposits requires the evaluation of tectonic settings. For example, many other metallic deposits PVB are a part of an ancient submarine rift. This study focuses on the Eau Claire Volcanic Complex and seeks to determine its tectonic setting. This region has not been evaluated in depth since the 1980s, and its tectonic setting and potential for metallic deposits is poorly understood. This research involved mapping and sampling bedrock exposures of the Eau Claire Volcanic Complex along the North Fork region of the Eau Claire River. Twenty-four samples were collected from the North Fork region for petrographic and geochemical analyses. Mapping results describe metamorphosed supracrustal sediments, volcanic gneisses, and foliated granodiorite to tonalite intrusions. These outcrops were cross-cut by a series of post-orogenic pegmatite intrusions. Trace element geochemistry is used to interpret the composition of protoliths and mineralogy of heavily metamorphosed and deformed rocks, while primary rock fabrics seen in thin sections will aid in interpretations of protoliths. Results from geochemical data will aid in deciphering tectonic events. Preliminary data from other regions around Eau Claire County, such as Big Falls County Park, constructs a baseline for this project's geochemical interpretation.

Abstract Name: **Collaboration Between Protein Science and Artwork**

Proteins are a main player for biological functions. Understanding protein science is essential for students majoring in biological sciences. Currently more students are not pursing a STEM career due to lack of resources, opportunities, and general difficulty of STEM classes according to a survey by Pew Research Center. After the Covid Pandemic many students had less interest in science due to learning online. We have developed a protein expression and purification procedure to create a high visual method to draw in student interest via chromoproteins. The plasmids with purple, lime, or pink chromoprotein genes were transformed into E. coli. While the E. coli with the plasmid expressed chromoprotein, students observed the chromoprotein expression by the purple, lime, or pink color. After the chromoprotein expression in E. coli, the chromoproteins were purified using a his-tag affinity column chromatography. In the purification step, students could easily follow when the chromoproteins bound to the column and eluted from the column. Following the purification of the chromoproteins, students used paint brushes and paper to paint images. Once the dye had dried, the chemicals in the chromoprotein buffer crystalized and formed in the brushstrokes, making a unique style of art observed in this protein dye painting. This method facilities a visually pleasing and enjoyable experiences to encourage scientific learning. Furthermore, this procedure is a great introductory practice for protein science and is also a unique collaboration between art and science.

Abstract Name: **Political Divide**

The current climate in the US is more than contentious. The current state of the us verses them attitude divided along the political lines is ever worsening. What informaiton is fact and what is political rhetoric? How can the divide be bridged? What are the potential dangers of such a divide in a powerful country? This research is designed to study how the political attitudes across the US are shaped by unfriendly dialog and news media bias. The goal is to understand how the varying forces around the political disconnect predict the perspective of adults in the US. This research will focus on political knowledge, willingness to connect with people of differing views, commitment to current political views, and news seeking behaviors when identifying underlying reasons for the unwillingness to accept otherswith different viewpoints and what can be done to mediate the negative behaviors creating an even wider divide between the groups. How does having friends with widely different political views impact inter-political group discourse? What communication skill sets can be cultivated to foster necessary listening and dialogue techniques? Data analysis will be completed in the spring semester of 2023.

Abstract Name: **Investigation of Weathering on Automotive Clear-Coat Formulations Using Fourier Transformation Infrared Spectroscopy (FTIR) for Forensic Purposes**

Traces of automotive paint are often left behind at hit-and-run scenes. One of the most commonly employed techniques used to analyze paint chips is Fourier transform infrared spectroscopy (FTIR), in which the resulting spectrum acts as a fingerprint that can be compared to samples from suspect vehicles. The Paint Data Query (PDQ) database was created by the Royal Canadian Mounted Police in order to simplify the identification of unknown samples. A problem arises when using the database because it may include the spectra of non-weathered or less-weathered samples. Paint from vehicles that have been exposed to weathering conditions have shown significant changes to their spectra. Because of this, samples collected from crime scenes could be easily misidentified. Through the systematic comparison of weathered clear coats to unexposed clear coats, it is possible to determine specific weathering patterns for clearcoats of different chemical compositions. Once these patterns and the chemical links between them are determined, forensic scientists will be able to more accurately identify the source vehicle of the sample. The purpose of this research is to explore those weathering patterns by comparing the compromised outer layer of the clear coat to the nondegraded or less degraded portion of clearcoat underneath in order to understand the chemical changes that occur during the weathering process. Our current results show that the chemical changes of weathering are primarily due to the breakage of the crosslinkers of the polymers of clear coats and the formation of amines is evident in the comparisons of FTIR spectra. Currently, the chemical changes of different clearcoat formulations are being investigated using automotive paint samples collected at auto body shops' junk yards.

Abstract Name: **What Changes Voters' Perceptions of Inflation**

This paper examines the effect climate change narratives have on households' inflation expectations. Economic agents, especially households, exhibit substantial heterogeneity in their expectations about macroeconomic outcomes. Specifically, heterogeneity in inflation expectations has implications for consumer spending, the transmission of monetary and fiscal policy, and voting behavior. There are two prevailing arguments on what drives heterogeneity across individual-level expectations surrounding macroeconomic outcomes. The first suggests that the differences stem from information individuals perceive on the state of the economy, while the second focuses on heterogeneity based on subjective models of the economy. Specifically, we collect evidence on the second argument through our pre-post information provision experiment. The experiment is conducted with a representative US sample using Prolific. We elicit participants' inflation expectations and randomly assign them to one of three treatment arms: an economic narrative, a political narrative, and no narrative (pure control). Our economic and political narratives are crafted on the basis that climate change impacts inflation through the supply side. Participants in each treatment arm are provided with an identical narrative. The survey prompts respondents to provide their inflation expectations and the propagation channels (e.g., demand or supply side) they use to explain climate change's effect on inflation after being exposed to the narratives. The propagation channels used in their forecasts provide evidence of selective memory. We implement a political narrative to identify the effect one's political affiliation has on inflation expectations. Our work situates in the growing economic literature studying inflation expectations using information provision experiments. We provide evidence on whether climate change impacts inflation expectations and the heterogeneity of subjective models of the macroeconomy. Our potential findings offer policymakers evidence on how to use narratives to anchor macroeconomic expectations and influence voting behavior.

Abstract Name: **Modeling Allee Effect in an Aggregated Eco-epidemiological Model**

A continuous predator-prey model subject to the Allee effect, prey aggregation, and infectious disease in the prey population will be presented during this talk. We assume that the prey population grows logistically in the absence of predator species. We split the total prey population into two distinct classes: infected prey and susceptible prey. Mathematical preliminaries such as positivity and boundedness are investigated. The analysis of the dynamical behaviors of the proposed model centers on the numerical simulations in which the Allee threshold and disease transmission rate of the prey are the primary parameters. The biologically feasible equilibrium points are analyzed. We will discuss our findings with emphasis on the potential applications in conservation biology.

Abstract Name: **Development of Small Molecules which Inhibit the Activity of Interleukin-4**

Interleukin-4 is a pleiotropic cytokine. When dysregulated, interleukin-4 can be associated with asthma, allergies, and various forms of cancer. In asthma, IL-4 induces airway inflammation, obstruction, and hyper responsiveness, while in cancer IL-4 activity is linked to promoting tumor progression, immunosuppression, and increasing tumor resistance to apoptosis. Using small molecule microarray, 50,000 small molecule compounds were tested for binding to interleukin-4. A small molecule, Nico-52, is the first small molecule inhibitor found for interleukin-4. This compound shows binding affinity to IL-4 in the micromolar range. In this work, we tested homologs of this small molecule inhibitor for further enhancement of affinity and potency for IL-4 inhibition. By changing the structure and composition of one or more of the three rings of Nico-52 but keeping the nicotinonitrile scaffold, inhibition of the cytokine was tested. Multiple homologs of Nico-52 were successfully synthesized. Using high performance liquid chromatography, mass spectroscopy, and nuclear magnetic resonance, compounds were purified and confirmed. After these were synthesized, a cell-based assay was conducted to determine affinity and inhibition of the molecules. In this presentation, I will present the synthesized homologs and their respective activity for IL-4 affinity and my current work on structure based drug design to improve affinity.

Abstract Name: **Hmong in France: History and Identity in an Age of Globalization**

This study examines the experiences of Hmong refugees resettled to France after the end of the Vietnam War in 1975. The data in this study is drawn from twenty-six in-depth interviews conducted with Hmong in France in cities such as Paris, Lyon, Nimes, and Toulouse. Hmong refugees continue to experience various challenges nearly fifty years after their migration to France. This study undertakes a sustained examination of various themes, including the transformations of Hmong identity and religion, experiences of racism, their community building efforts, their histories of labor, and their hopes and dreams, all within the French national context. Since the French Republican model formally erases racial, ethnic, religious, and cultural differences among its citizens, Hmong in France have had to devise creative strategies to maintain a distinct sense of self apart from dominant French nationalism. Yet, the French Republican ideology of official colorblindness continues to inhibit the development of a strong Hmong identity and their community building efforts. Furthermore, actual racism and discrimination on the ground have profoundly shaped Hmong's exclusion from education, housing, and employment. This study attempts to provide a humane and ethical portrait of Hmong French experiences in the age of globalization, when ethnic and cultural identities, religious practices, and minoritized experiences of living are all constantly being transformed. Together, the study shows that while Hmong continue to face extreme challenges to community building in ways that demand their assimilation into a colorblind French society, they have nonetheless successfully maintained a unique sense of self in a French society by dreaming and hoping for alternative futures.

Abstract Name: **Fostering Creative Inquiry on the Two-Year Campuses: A Discussion at the Confluence of Humanities, Sciences, and Academic Support**

As undergraduate research is a high-impact pedagogical practice, offering our students opportunities for meaningful and creative inquiry and guiding them as they undertake that inquiry is especiallyimportant on the two-year campus. Some of our students will graduate with an associate degree, meaning that this is the only chance they will have to do this work. Others will transition to four-year institutions, where they will need to be prepared for higher-level research when they arrive. At the same time, two-year colleges present unique challenges in supporting undergraduate research and embedding it into the curriculum. This panel will share some of the challenges faced by students, faculty, and staff in our two-year colleges from three perspectives—the sciences, the humanities, and academic support—then guide a discussion about strategies for meeting those challenges to enrich undergraduate research and creative inquiry. By bringing together these perspectives, we will examine undergraduate research on the two-year campuses at the confluence of the humanities, the sciences, and academic support with the goal of fostering creative inquiry and preparing our students to succeed in the next stage of their intellectual growth.

Abstract Name: Religiosity, Perceptions of Mental Health Services, and Well-being among U.S. Adults

Mental health treatment remains stigmatized within many religious communities (McGowan, 2012). Previous literature indicates that as religiousness increases openness to psychotherapy decreases (Mayers et al., 2007). Though previous research has examined the relationship between religiosity and perceptions of mental health services, little is known about how this relationship manifests in diverse groups and may be impacted by different mental health outcomes (Crosby, 2012). The present study investigates the following three research questions among a group of U.S. adults diverse in religious ideology and identity: (1) What is the relationship between level of religiosity and perceptions of mental health services; (2) What are the relationships among level of religiosity, perceptions of mental health services and well-being?; (3) Does level of well-being moderate the relationship between level of religiosity and perceptions of mental health services? Participants for this study are U.S. adults that identify as religious. Participants will be solicited via recruitment emails. Study data will be collected via an anonymous online survey consisting of the following instruments: A) Demographic Questionnaire; B) Attitudes Toward Seeking Professional Psychological Help Scale; C) Centrality of Religion Scale; and D) The Mental Health Continuum Short Form. To test the research questions, regression analyses will be used. A simple regression analysis will be used to test the relationship between level of religiosity and perceptions of mental health treatment. A multiple regression analysis will be used to test the relationships between level of religiosity, perceptions of mental health treatment, and overall well-being. A moderated regression analysis will be used to determine if level of well-being moderates the relationship between level of religiosity and perceptions of mental health treatment. Results of this study may inform future mental health interventions targeted towards religious individuals and those focused on reducing the stigma of mental health services.

Abstract Name: Borodin String Quartet No. 2

Borodin's Second String Quartet in D Major is a piece that requires advanced ensemble techniques, fine intonation work, and balanced melodies. It is an essential quartet piece within the string repertoire, and one which our group has grown from immensely while preparing.
The passing of melodies from cello to first violin and viola to second violin requires eye contact, breathing, and togetherness as a group. Borodin includes immediate tempo changes marked at the two animatos, as well as poco a poco dim. e rit at the end of the piece.
Beginning in the deceptively easy key of D Major, intonation inaccuracies are not easily hidden in this piece. Several moments require the performers to play in unison or octaves, and every chord must be carefully tuned. Compounding this, the piece changes keys several times during its development. The F#s in these keys are naturally dissonant and difficult to tune, especially in a group setting. Our quartet has spent hours together refining our intonation.
Throughout the piece, the first violin and cello converse with each other by trading the main melody. Later in the development section, the melody is passed around to the rest of the quartet. At the recapitulation, the cello hands the melody to the viola, requiring a strong sense of balance among the group. Because of this, our quartet has been working on balancing the melody and the accompaniment. The passing melodies require each member to use the same bow techniques and distribution, keeping everything uniform and beautifully phrased.
An influential work for any group, Borodin's second string quartet blends beautiful melodies and textures with flawless technique to create a timeless masterpiece.

Abstract Name: **Electrochemical Characterization of Recast Nafion? Film Modified Electrodes in Nonaqueous Systems**

The behavior of recast Nafion® films on platinum working electrodes in nonaqueous solutions is characterized by cyclic voltammetry and rotating disk voltammetry. The behavior of recast Nafion® films in nonaqueous solutions has been observed to be different from the well-studied behavior in aqueous solutions. This work seeks to extensively study that behavior. The reversible redox couple tris(2,2′-bipyridine)ruthenium(II) hexafluorophosphate is studied in nonaqueous solvent acetonitrile with different electrolytes (tetrabutylammonium tetrafluoroborate, tetrabutylammonium trifluoromethanesulfonate, tetrabutylammonium hexafluorophosphate, and ammonium trifluoromethanesulfonate). The effects of the electrolytes will be compared against each other and controls (an unmodified platinum electrode and a recast Nafion® platinum electrode equilibrated in aqueous solutions of the redox couples). Electrolytes have been chosen for a variety of ion charges and ion sizes; in aqueous solutions, Nafion® is a cation exchange polymer and will exclude neutral and anionic redox molecules, however this does not necessarily occur in nonaqueous solutions. Additionally, there is some preliminary evidence that trifluoromethanesulfonate electrolyte may interact with the Nafion® sulfonate groups, so this will also be explored. Studies of each electrolyte variation will involve both transient cyclic voltammetry and rotating disk voltammetry; the relationship between scan rate and peak current will be explored for transient cyclic voltammograms and the relationship between rotation rate and limiting current will be explored for rotating disk voltammetry. The data from both techniques will be combined to identify the thickness of the in situ film and the diffusion coefficient for each variation.

Abstract Name: **Law Enforcement and Mental Health**

Law enforcement is a stressful career that can lead to or exacerbate mental health issues in officers. The objective of this project was to identify and analyze stressors and mental health needs of local law enforcement officers in the Chippewa Valley. The study location helps us learn more about unique stressors and mental health needs of officers in small and medium-sized departments. To do so, we surveyed officers from six law enforcement agencies and conducted follow-up interviews with those who wanted to provide more insight. We found that the stress of shift work, strained personal relationships, and negative public perceptions were foremost on officers' minds. Additionally, officers reported that mental health resources were provided through their department in various ways including debriefing, peer support, and professional counseling. However, officers suggest that resources could be improved or expanded. This poster will highlight these findings, and more, in depth and discuss the implications of the results.

Abstract Name: **Artificial Intelligence Enabled Heating, Ventilation, and Air Conditioning: Algorithm and Control Investigation**

Buildings account for a sizable portion of societal energy use, particularly in their heating, ventilation, and air conditioning (HVAC) systems. Incorporating artificial intelligence (AI) into commercial HVAC systems offers the potential for reducing this energy consumption while still being cost-effective in the long run. An individual investigation on AI and controls (algorithm and control investigation, “ACI”) for these HVAC systems was conducted within the context of a larger project known as the Wayne State University DTE E-Challenge on AI Powered HVAC Control, where a physical implementation is to be implemented. Within the ACI, Bayesian optimization (BO) and model-predictive control (MPC) were investigated, along with simulations primarily focusing on generic thermal modeling for context review of HVAC principles and dynamics. The ACI attempted to gather meaningful takeaways from its review, potentially to be applied in the DTE E-Challenge project, including principles, implementation-related recommendations, and algorithm abstractions to make implementation more practical and scalable. BO and MPC were both found to be effective in reducing energy consumption. Certain differences apply between the BO and MPC, and additional investigation is warranted to identify which may be better. AI can also improve overall occupant comfort. AI-enabled HVAC connects to sustainable manufacturing with the elements of sustainability, including environmental, social, and economic sustainability.

Abstract Name: **Determination of Nutrient and Anti-nutrient factors in cassava leaves of selected varieties in Kenya.**

Food security has significantly increased due to climate change. With corn being the staple food in Kenya, cassava (Manihot esculenta,family (Euphorbiaceae)), have the potential to provide an additional source of nutrition. Cassava leaves are good sources of vitamins, protein, iron, and other micronutrients. However, it is an underutilized in Kenya due to highly poisonous constituents found in the leaves. The objective of this study was therefore to analyze the nutritional and anti-nutritional content of cassava leaves from five varieties (AdhiamboLera, Wild cassava 3, Wild cassava 1,KME-4, andselele) in Kenya. We hypothesize that there is no significant difference in protein and fiber content, Cyanide and Phytate content from vegetable leaves of the 5 varieties of cassava. Fresh vegetable grade, 7 months old cassava leaves were collected from Migori County, Kenya. Protein content was determined using the Latimermethod andfiber content usingAOAC method.Anti-nutritive factors: cyanide content was determined using the alkaline titration method and phytate content using Makkar, method. Results indicated that fresh leaf protein content was high in all 5 varieties of cassava.Fiber content varied among the varieties withAdhiamboLeraposting the highest content at 22%. All the varieties results showed a high Cyanide level above WHO tolerable level (10 mg/100g), withWild cassava 1having the highest level at 31 mg/100g. Phytates content was generally low except in Wildcassava 1, which registered a high level at 1500 mg/100g. Future studies will focus on proper processing, detoxification of cyanide for safer vegetables.This research waas conducted at Egerton University, Njoro, Kenya. Under the supervion of PI Dr Anne Osano of Bowie State University and Richard Mulwa of Egerton University with assistance from Milcah Wambua.

Abstract Name: **Optimizing HPLC-UV Method for the Measurement of Monoamine Neurotransmitters in the Hub of the Central Auditory System**

Hearing loss and tinnitus are conditions that affect multiple groups of people including construction workers, military personnel, dentists, and those who frequently listen to loud music through headphones or car stereos. These conditions can be caused by prolonged exposure to loud noise above 85 dB. As there is no objective measure for a condition like tinnitus, its diagnosis is based solely on self-reporting. Presently, the monoamine neurotransmitter, dopamine has been implicated in these noise-induced hearing disorders. However, not much is known about how excessive noise modulates the monoamine neurotransmitter systems centrally. This project utilizes tissue content analysis with high-performance liquid chromatography (HPLC) to examine potential changes in synthesis and metabolism of key monoamines in the central auditory system. Herein, we explored varied HPLC-UV/Vis methods. The methods include both isocratic and gradient elution with 0.05% Formic Acid and Acetonitrile at different ratios and flow rates between 0.5 – 1 mL/min. These methods were optimized, validated, and used to analyze dopamine, norepinephrine, epinephrine, and serotonin in the inferior colliculus of rats exposed to deafening noise (10 kHz, 118 dB SPL, 1/3 octave band noise for four hours) and compared with their controls. The data obtained suggest neuroadaptations that could underline noise-induced hearing loss/tinnitus.

Abstract Name: **Racial-Ethnic Identity and Academic Success B**

There is immense discussion on what helps or hinders academic success. A person knowing who they are, no matter who, tends to know what they want and how to get it. This is not different in the academic setting. There are many different levels of understanding who we are within the culture from which we come. This study aims to connect several components of identity development with the resulting success in college. The aim is to see how the level of connection with one's racial-ethnic group, awareness of the perceptions by others and how one's racial-ethnic group is seen through the lens of academic achievement will impact the overall success in college. Other areas of interest in this study include college experience and how it impacts the motivation to attend classes and involvement in on campus activities connecting the student to the college leading to academic success. The final area that will be considered in this research is the level of college preparedness of the student and how the family or culture contributed to that preparedness. Correlational analysis will be completed through data collection in the spring semester of 2023.

Abstract Name: **Isolating beta-klotho receptors to define brain regions supporting alcohol intake**

Binge drinking is more prevalent in men than women. This sex difference is partly due to disinhibiting risk-taking and impulsive behavior. One hormone that may contribute to this behavior is fibroblast growth factor 21 (FGF21), which is secreted by the liver but acts in the brain to suppress alcohol consumption in mice. Interestingly, FGF21 actions are also known to be sexually dimorphic, so it is possible that FGF21 could mediate differential binge drinking behaviors observed in men and women. FGF21 requires a coreceptor, beta-klotho (Klb), to carry out its actions. Therefore, defining the precise spatial distribution of Klb mRNA in the brain will point to neural correlates that support FGF21 action on alcohol intake. We performed in situ hybridization to visualize Klb mRNA expression in the male and female mouse brain to account for possible sex differences. We focused our analyses on brain regions like the amygdala, hypothalamus, and subiculum that are involved in suppressing alcohol consumption. We generated brain maps of Klb mRNA cells, and we also identified whether they express low-, medium-, or high-levels of Klb mRNA. We found upwards of two-fold more Klb mRNA cells in the amygdala, hypothalamus, and subiculum of female brains. Specifically, the basolateral amygdala; the periventricular, arcuate and dorsomedial nuclei of the hypothalamus; and the ventral subiculum showed higher Klb mRNA expression in females, and these regions are implicated in alcohol intake. We are now pursuing in vivo studies in freely-behaving male and female mice to determine whether the activation or inhibition of Klb mRNA cells in the amygdala and/or subiculum would regulate alcohol intake in mice. As FGF21 action suppresses alcohol consumption, the elevated Klb mRNA expression in the female amygdala may inhibit impulsivity to curb binge drinking.

Abstract Name: **Titanium Orbital Debris Removal Via Laser Ablation**

Orbiting our planet is an ever-growing amount of debris. This orbital debris poses severe threats as the speeds at which debris travels means that even a speck of dust can do damage equivalent to that of a rifle bullet. This danger compounds with the potential triggering of Kessler Syndrome, which is an uncontrollable growth in the amount of debris. To remediate the possibilities of Kessler Syndrome, there must be found a way to remove or reduce the existing debris. Lasers and laser ablation may be able to do just that. For our experiment, we tested this potential on titanium, which is believed to be one of the significantly present metals within the orbital debris cloud.For our experiment, a 12 mm by 12 mm titanium target that had been polished to 1200 grit was placed in a vacuum chamber before facing a series of ablations from an Nd-YAG laser. The spherical vacuum chamber has a volume of0.05 m3and a pumped pressure of 10-2Pa. This is approximately the pressure at the Karman Line, or about 1000x the pressure at the typical altitudes of orbital debris. The Nd-YAG laser was operated at 1064 nm with a pulse duration of 90 μs and a pulse energy of 150 mJ. Each individual ablation focused on a previously unablated region of the target, based on a 20° rotation of the target. With each ablation, impulse, heat production, and UV-Vis spectra datum were collected. Additionally, a pre- and post-mass determined the overall mass removed after the series.The data on the titanium for impulse, heat production, UV-Vis spectra, and mass removal will be presented. Based already on these results, we were able to determine that yes, laser ablations would be a viable way to remove or reduce titanium debris from orbit.

Abstract Name: **Parental Involvement in Education B**

How relative is parental involvement in a child's education to the overall success of the child? Can parents be too involved in their child's education? In society today we are seeing an increased debate over the different types of parents and how good or bad they are to the overall growth and development of their children. Are helicopter parents harming their children's future? Are free range parents raising children with no rules or boundaries providing a need for society to deal with the evenual negative outcomes? The goal of this research is to study the different parental involvement levels in the education of their children and determine what positive and negative outcomes are present under each type of parental behavior. Some criteria that will be important in this study are the level of parental invovlement, to what age of the child does the involvement continue, academic performance and self-efficacy of the children. Other areas of interest in this study include whether gender and race/ethnicity are impacted differently under differing parenting styles. Correlational analysis will be completed through data collection in the spring semester of 2023.

Abstract Name: **Paleontology of Faunas from Initial Transgression to Deep Marine, Cretaceous (Albian) of Central Texas.**

The Early Cretaceous (Albian, 100-113 million years old) Walnut Formation crops out in the low valleys of the Lampasas Cut Plain in Central Texas. The Walnut records the transition from nonmarine into fully marine conditions with various lithologies of limestone, marls and shales, and is extremely fossiliferous, dominated by Bivalves, gastropods, Echinoids and Cephalopods. The succeeding stratigraphic Members of the formation contain distinct faunas: 1) the basal Bull Creek Member contains a low species richness, low evenness fauna dominated by the large gastropod, Peruviella dolium; 2) the Cedar Park Member contains an ichnofauna of arthropod burrows representing a tidal flat paleoenvironment; 3) the Keys Valley Marl Member contains both a high species richness fauna dominated by the ammonites Oxytropidoceras salasi and Engonoceras pierdenale and an oyster biostrome of Texigryphaea mucronata and 4; the Upper Marl Member is dominated by the bivalves Protocardia multistriata and Homomya bravoensis. Gastropods are abundant throughout all Members, and include several possible new species at the top of the formation. Overlying the Walnut, the wavy-bedded limestones of the Comanche Peak Formation contain a similar, open-marine fauna. Expected results will include multiple diversity indices and size-frequency histograms for dominant species at all fossiliferous horizons.

Abstract Name: **Topical Bacteriophage Treatment Against Common Epidermal Infections**

Bacteriophages have shown promise in killing resistant organisms and in controlling infections to antibiotic resistant organisms. Both S. aureus, specifically MRSA, and S. pyogenes are common in epidermal infections and their respective bacteriophages have proven effective in resolving epidermal infections. While broad spectrum bacteriophages targeting these bacteria have been assessed in topical administration, little research has been published on bivalent phage therapies. The aim of this study is to assess the efficacy of a mixture of S. aureus and S. pyogenes bacteriophages in treating common skin infections that may be resistant to topical antibiotic creams. Laboratory strains of S. aureus and S. pyogenes will be used in an in vitro model of skin infection, using epithelial cell monolayers, and will be treated with a combination of their phages. Effective phage dosing against combinations and concentrations of organisms will be determined through calibration curves. Calculations from these calibration curves will provide information about the optimal doses of the bivalent phage treatment and used to assess the ability of the phages to clear infection in the in-vitro skin model. The epithelial monolayers will have different groups assigned to them, namely: controls for both bacteria and bacteriophages, individual bacteriophages in a mixture of MRSA and S. pyogenes, and finally a mixture of both genera of bacteria and both groups of bacteriophages. Following treatment, supernatant and cell layers will be tested using a standard IL-36 ELISA and confocal microscopy to assess overall pathology and success of the phage treatment compared to that of the control epithelial monolayers. If successful, the bivalent phage therapy will show reduction of bacterial growth and tissue damage. This would provide insight into how bivalent phage therapies treat wound infections and how it may reduce future reliance on antibiotics.

Abstract Name: **A Pilot Study Exploring Veteran Identity Using Lyric Analysis in a Qualitative, Community-Based Participatory Action Research Framework**

Researchers attempt to define what it means to be a Veteran, but it is rare for that question to be directly asked of Veterans. Traditionally, experimenters define variables and ask the community of interest (CoI) to provide responses without the CoI being included in the research process or reaping any direct benefit from participation. There is a high degree of distrust and disenfranchisement reflected in Veterans towards the mental health care system and the scientific community. We aim to use the CbPAR model to amplify their voices and focus on what is important to them. We are seeking to allow Veterans to define their identity in their own words. Researchers serve as messengers to help amplify Veteran voices and disseminate their stories to the larger community. In the current study, we asked Veterans to identify songs that answered the question, “What does being a Veteran mean to you?” This study is part of a larger research project using both photovoice and lyric analysis to help define the “sights and sounds” of Veteran identity. Veterans worked individually with researchers through the process of lyric analysis, which is a music therapy intervention in which the client and therapist listen to a song together and discuss the connection the lyrics have to the client’s life experiences. Transcripts of interviews will be analyzed to uncover common themes and elements that help researchers understand how they conceptualize their community identity as Veterans. External validity is addressed through member checking, in which participants will review transcripts, discuss identified themes, and choose representative songs to present as a part of an immersive, interactive gallery experience for the community to allow for their stories to be told. We assert that more research should be done with the Veteran community, not to them.

Abstract Name: **Bumblebee Distribution on UW-Parkside's Campus**

Purpose: Bumblebees are known pollinators and contributors to healthy ecosystems. In Wisconsin, UW-Parkside is a known location for the federally endangered Rusty-patched-bumblebee (Bombus affinis) and other bumblebee species. The objective of this project was to locate and identify various members of Bombus in four distinct campus phases (phase 1 and 2: completed restoration, phase 3: current restoration, phase 4: pre-restoration). Artificial nests were deployed into phases to encourage nesting and assess feasibility of monitoring resident bumblebee populations.Methods and Materials: Weekly, one-hour, surveys were conducted under appropriate conditions from 11 May to 5 October, 2022. Sites of ~15m radius within each phase were surveyed for Bombus activity. Information regarding location, weather, and topography were recorded. During surveys, specimens were tallied and photographed for later identification. In each phase, six randomly placed artificial nests were either wood-covered or unsheltered to resemble natural nesting conditions. Early in the season nests were regularly inspected for activity.Results: During 50 surveys, 199 bumblebees were recorded on the UW-Parkside campus; no Rusty patched bumblebees were observed during the first year of this project. Bumblebees appeared to prefer phases based on habitat composition rather than levels of restoration. In spring, it appeared queens frequented wooded areas, presumably for nesting purposes. Artificial nests were unoccupied this season perhaps due to delayed placement and challenges from vegetation encroachment. This pilot project provides guidelines for future artificial nesting placement and construction. Overall, our first season of survey data provides needed information on the current state of bumblebee activity on campus which serves as a guide for further restoration.

Abstract Name: **Investigating the use of crayfish as environmental water quality sentinels for metal pollution in Indiana creeks**

Ephemeral creeks and streams can be difficult to monitor and assess for water quality. Unfortunately, these same water systems can play a significant role in the input of metals and other pollutants into major waterways. Metals are often the result of nonpoint source or historic point source pollution that is no longer active, making assessment and exposure prevention difficult. An economical and reliable approach to determine water quality in these areas would be the use of reliable sentinel species that are endemic, easily identified, and respond in a quantifiably way to metals in the environment. Macroinvertebrate assemblages have been historically used to create comprehensive biotic indexes, but these indices can be complicated, seasonal, and difficult to assess without identification bias. For this project, crayfish samples, water samples, and sediment samples were collected in several creeks in Indiana representing a variety of environmental exposures. We hypothesized that because are omnivores and biotic engineers, their environmental interactions place them in a unique niche making them a reliable sentinel species. By testing and comparing the bioaccumulation of metals in crayfish tissue, water, and sediments to dominant species, average crayfish size, and population density, we can reliably predict creek health for metals. Our results determined thatFaxonius rusticus(rusty crayfish) were found in creeks with higher environmental metals. Also, crayfish cephalothorax measurements were smaller in higher metal environments. This data, along with metal bioaccumulation and biomagnification make crayfish an excellent sentinel for water quality in creeks.

Abstract Name: Catharsis in Choreography

The following research examines the cathartic experiences of dancers by intentionally incorporating psychological principles into the choreographic process. These ideas were used to shape the dancers' perception of the movement and message of the dance work. Throughout this process "Flow state" and "mindfulness", were used as choreographic devices, in which two groups of dancers learning the same dance work based on Elizabeth Kebbler-Ross' five stages of grief, explored how the varied prompts influenced their feeling of connectedness to the piece. The basis of the movement stemmed from the physiological responses of the body in each stage of grief, and were adapted based on the psychological principles being used in coaching. Using surveys completed by the participants and coded to specification, correlation was then drawn about how the choreographic process influences the experience of the dancers, and how coaching choreography has a direct effect on the connection the dancers make with the message. Overall the dancers coached into a "flow state" reported a stronger bond with the dance, while the dancers coached in "mindfulness" reported that the process helped them grow as performers as opposed to those coached into a flow state. This project served as a representation of how dance and psychology are intrinsically linked and how understanding that relationship can be useful in fostering a cathartic experience, and increased connection between dancers and their movement.

Abstract Name: Grass Fed Beef Benefits and Water Eutrophication

Eutrophication of water bodies, resulting from high levels of nitrogen and phosphorus from various non-point sources, can be addressed through best management practices that aim to promote better soil health and keep soils and nutrients from running off the land. One excellent way to prevent run-off is to promote perennial grasslands. In order to understand more about the potential to encourage more farms to convert to grazing, I investigated the costs and benefits of grazed beef in comparison to the predominant corn silage feeding of cattle in Wisconsin, an area with many eutrophic lakes. Through independently reviewing publicly available information and policies, I synthesized financial and environmental data on the grass-fed beef industry in comparison to corn for silage in order to evaluate which of the two would be the most financially and environmentally beneficial option for small-scale farmers to pursue. I found an abundance of environmental and financial benefits that grass-fed beef farming has to offer to its practitioners and ecosystems. Grass-fed beef farming offers the most cost-effective system for farmers to reduce their labor time, production expenses, and greenhouse gas emissions. This is vital information for regional Wisconsin farmers and surrounding communities to know in order to make better-informed production decisions that can positively influence the health and stability of their own and their land's future.

Abstract Name: **Tactics to Prevent the Use of Blockchain Technology as a Facilitator for Laundering Money**

The nature of decentralized currencies has led to its use as a medium for laundering money by illicit businesses, perpetuating the detrimental effects of organized crime and terrorism. This not only endangers the safety of the general population but also disrupts the global economy. Scholars agree that there is an urgent need for the United States government to establish regulations that would apply anti-money laundering legislation to cryptocurrency. Scholars also agree that the nature of decentralized cryptocurrency makes it difficult to implement any preventive measures that would inhibit money laundering. This paper argues that the most viable method of regulating decentralized currency is through the framework proposed by the Financial Crimes Enforcement Network (FinCEN). This would include revising the Bank Secrecy Act (BSA) and implementing the FinCEN framework, allowing the federal government to enforce regulations over cryptocurrency exchange platforms and conduct direct investigations of transactions that occur over exchanges. To establish these regulations, it is crucial that state governments unify in order to enact legislation that would provide federal agencies with sufficient authority to develop and enforce the proposed framework. These actions would deter criminal organizations from conducting laundering operations through cryptocurrencies to preserve the United States financial system and promote other nations to enact similar anti-money laundering (AML) legislation. The finances of crime and terrorist organizations are one of the most vulnerable components of their organization and for that reason, restricting the capital of these illicit organizations is one of the most feasible methods of combating crime and terrorism both domestically and internationally.

Abstract Name: **Effects of Stereotype Threat on Executive Function**

Activating age-related stereotypes, known as stereotype threat, can lead to a decrease in executive functioning in older adults (Hess et al., 2003). However, there is limited research on the effects of aging stereotypes on middle aged adults. We examine the effects of stereotype threat on executive function across three age groups: young, middle-aged, and older adults. All participants are randomly assigned to either a stereotype threat condition or a control condition. We plan to investigate the role of stereotype threat on an executive function task using the “Age Identification Scale” (Garstka et al., 1997) and the “Attitudes Towards Own Aging” questionnaire (Lawton, 1975) to establish stereotype threat and using the Digit Span Task (Blackburn; Benton, 1957) and the Wisconsin Card Sorting Task (Heaton et al., 1993) to assess executive function. We have completed our data collection and are starting our data analysis. We hypothesize that (1) middle-aged and older adults will have lower performance under the stereotype threat condition compared to their counterparts in the non-stereotype threat condition and (2) middle-aged and older adults will have lower performance on the cognitive tasks than younger adults in both conditions. We will use a two-way independent factors ANOVA to examine the relationship between stereotype threat and performance, age and performance, and the interaction between age and stereotype threat. Findings from this research expands the literature surrounding stereotype threat and executive function in middle age, which has not been extensively studied. Further, we will examine the influence of people’s beliefs about their age and the impact of those beliefs on cognitive tasks that assess executive function. Findings from this research will have implications for how we understand executive function in the aging population.

Abstract Name: Flexible Finger Design for Robotic Gripper

In industry, the safety and productivity of collaborative robots make them a vital part of many pick and place applications in production. Collaborative robots offer many advantages including their flexibility. In keeping with the advantages of collaborative robots, this flexibility should be extended to the grippers and fingers to reflect human-like dexterity. Flexible fingers have several advantages over traditional, rigid grippers. Adaptive fingers can pick and place a much broader array of oddly shaped objects than traditional grippers. Flexible fingers are also advantageous when working with fragile objects, such as produce, as the gripping force can be distributed by the flexing of the finger.The purpose of this project was to design, optimize, build and evaluate flexible fingers which can be mounted to a Schunk gripper on the end of a Fanuc collaborative robotic arm. Flexible fingers were designed in SolidWorks to integrate with the robotic gripper assembly. By testing prototypes, aspects were identified to improve the flexibility and functionality of the gripper. Using DOE (Design of Experiment) as an optimization strategy, the effects of each variable such as material, wall thickness, infill, etc. was studied. Mechanical simulators were used to isolate and test these variables to see their effects on the system with realistic situational constraints.The manufacturing of the flexible fingers consisted of using SLA and FDM printing to test, compare, and combine the more promising features into a robust finished product, capable of gripping and lifting various objects.Using technologies such as CAD, additive manufacturing, and agile engineering methodologies; it was possible to accomplish the design process and optimize the finger design in a collaborative manner.

Abstract Name: Smartphone Use on Well Being

How has Smartphone use impacted the general well-being of people today? The Smartphone usage has certainly increased over the past generation. The use is so prevalent that nearly everyone from 9-99 has one. Questions regarding how this intense Smartphone use is impacting the overall health and well-being of society has been discussed across many different aspects of research. This research intends to study how Smartphone use impacts the physical, psychological, cognitive, and social well-being of individuals across the generations. Previous research tendedto focus on one aspect or another of well-being, for example sleep or academic performance (cognitive functioning) or anxiety (psychological functioning). The research is lacking when looking at the global health of an individual and its association with Smartphone use. Thisstudy will also examine the specific ways individuals are using the Smartphones as well as how much of their daily life is consumed by the use. A correlational analysis will be completed in the spring semester of 2023 to determine what factors are impacted by Smartphone use.

Abstract Name: Gender Differences in the Accuracy of Self-evaluations of Performance on Math and English Tests

Despite years of progress towards gender equity in society, stereotypes and discrimination against women persist (Moss-Racusin et al., 2019). Sexism may lead to serious consequences such as succumbing to stereotype threat, especially in occupations, social interactions, and academia. A common stereotype is that men are better than women in stereotypically masculine fields such as STEM, which have led men to develop a false sense of superiority in the field of mathematics and other STEM-related fields such as computer science (Beyer, 2002; 2019). Previous research by Beyer (2002) found that men tend to overestimate their abilities in mathematics, but that there are no gender differences in self-perceptions in stereotypically feminine fields such as English. She found that women struggle with self-doubt in mathematics but not in English (Beyer, 2002). 20 years after this study, it was our intention to revisit this study to explore whether gender differences in self-perceptions still exist in higher education. Using survey-based research with questions mimicking standardized testing, participants' expectations and self-evaluations of performance in English and math were measured before and after completing each test. Like the research done in the early 2000s, we hypothesize that men will overestimate their mathematical abilities but that there will be no significant gender differences in expectations and self-evaluations for English. This study will reveal whether expectations and self-evaluations are still affected by stereotypes about women's and men's abilities. We are still collecting data from our university-level participants this fall semester; however, data collection will be completed by December and we will be conducting statistical analyses using ANOVAs in January of 2023.

Abstract Name: An Analysis of the Representation of Gender within Children's Books at a University CSD Clinic

Speech-language pathologists are increasingly called to provide culturally and linguistically responsive services (ASHA, n.d.). As a part of meeting this call, SLPs are tasked with using culturally responsive materials, including the use of books that are representative of a wide variety of identities across race, ethnicity, gender, religion and ability (Harris; Owen Van Horn, 2020). Research investigating gender representation within children's books has overwhelmingly found the presence of underrepresentation of women along with pervasive gender stereotypes. The purpose of this research is to analyze the quality of gender representation within children's literature at a university clinic. The research question the study aimed to answer was, "what roles do female and male characters assume in books found within the children's literature at a Midwestern University SLP Clinic, and how do these roles relate to traditional gender stereotypes?"To complete this research project, an annotated bibliography was completed to gain adequate background knowledge. Next, a checklist for analyzing gender representation was formed to code books and pilot data was collected. A random sample of 262 books within the library have been analyzed. It was found that the presence of male main characters was higher than female main characters within narrative and expository books. Another finding was that nonhuman characters are more common in children's books and have male overrepresentation at a much greater rate than books with human characters. As a next step in this study, the authors of this study will further review the 262 books that have been analyzed thus far and conduct a qualitative analysis of the stereotypes and gender roles. Findings will inform practices for evaluating clinical materials to ensure quality representation of gender within materials used for assessment and intervention services.

Abstract Name: **Subscription Models Taking on the World**

For a little over a decade the rise of subscriptions-based models has seemed inevitable. This has become even more so with the Covid-19 pandemic. When faced with uncertain territory of fighting a global pandemic, the world locked down to help curb covid-19 transmissions. This lockdown led many to evaluate the way they were using their discretionary income when it came down to day to day purchases. This prompted both businesses and customers to attempt to squeeze more value, in part by offering subscription-based payments instead of one-time purchases in uncertain times. The purpose of my study is to see the people's preferences between subscription-based models and one-time purchases. To do so, I conducted a 12-question survey and collected data using Amazon M Turk, which compiled over 195 responses. The results show that there is a statistically significant difference between age and the usage of subscription-based models. In addition, I found there is a difference between gender and subscription-based models. These results are important because they highlight the strict breakdown of who has been most effected by the switch in spending patterns.

Abstract Name: **Sex Differences in the Neuroplasticity of Trigeminal Ganglion Neurons Projecting to the Rat Vibrissal Pad During a Stress-Exacerbated Orofacial Pain State**

Psychological stress contributes to orofacial pain, which is 3-4x more prevalent in women. Our previous studies indicate that stress exacerbates orofacial pain to a greater degree in female rats. Some of the mechanisms associated with stress and orofacial pain include changes in the plasticity of the trigeminal ganglion (TG) cells and glial cell density. The phosphorylated extracellular regulated kinase (pERK; plasticity marker) is present in the TGs of male animals exposed to masseter muscle inflammation. Further, Glial Fibrillary Acid Protein (GFAP; glial cell marker) increases in TGs in males after inflammatory pain. However, the mechanisms underlying stress-exacerbated orofacial pain are not very well understood in female rodents. Here we hypothesized that exposure to orofacial pain and stress increases neuroplasticity and glial density in TGs of female rats. Male and female Sprague-Dawley rats received one injection of complete Freund's adjuvant (CFA) into the right vibrissal pad (RVP). Animals were subjected to three consecutive days of either forced swim test (FST; sub-chronic stress model) or sham conditions. Eight days post-FST, all rats received an injection of the trans-synaptic tracer wheat germ agglutinin conjugated to the Alexa Fluor 488 (WGA-488; Fisher-Scientific) into the RVP. Eleven days post-FST, all animals were perfused. The TG was extracted and processed for immunohistochemistry using antibodies against GFAP protein (rabbit anti-GFAP; Abcam) and pERK (rabbit anti-pERK; Cell Signaling). The pERK+ cells were similar across sexes during stress-exacerbated orofacial pain. However, WGA-488 colocalization with pERK was greater in males, indicating increased neuroplasticity in males. While glial density did not change across sexes, GFAP and pERK were colocalized, indicating that glia are implicated during stress-exacerbated orofacial pain. Overall, our data indicates that TG-VP projections undergo neuroplasticity, are sexually dimorphic, and may play a protective or antinociceptive role in reducing the amplifying effects of stress on orofacial pain in males.

Abstract Name: Effect of shortenings on the physicochemical, textural and sensory properties of gluten free cupcakes

The objective of the study was to determine the effect of shortenings (butter, margarine, and vegetable shortening) for optimizing the cupcake formulations on the physicochemical, textural, and sensory properties of gluten-free cupcakes. The demand for gluten-free baked products is increasing gradually because a large number of populations are affected by gluten intolerance. Also, the right butter replaces and different gluten-free flour ingredients in cupcakes open a healthier cupcake option for the consumers. In this study, three cupcake doughs with oat milk and gluten-free flour were prepared using three dairy-free shortenings (butter, margarine, and vegetable shortening). The cupcake doughs were baked at 350°F for 20 min to develop the gluten-free cupcakes. The physicochemical, textural, and sensory properties of the cupcakes were determined. The statistical analysis ANOVA indicated that those three shortenings affected the physicochemical and textural properties significantly (0.05). However, the sensory panelists were not able to determine the difference among the cupcake samples (p>0.05). The sensory analysis for the overall acceptability results indicated that the vegetable shortening cupcake was the most preferred cupcake formulation having a score of 6.39 and the butter cupcake formulation was the least preferred one having a score of 6.11. The variation of water activity (0.72-0.76), L-value (57.28-65.09), and total color difference (34.12-78.61) wasfound among the cupcake samples. Relatively moderate textural properties such as hardness (15.70 N), cohesiveness (2.00), springiness (0.16), gumminess (26.14), and chewiness (26.57) were achieved by the vegetable shortening cupcakes. The findings of this study will be beneficial for the commercial development of gluten-free cupcakes with healthier ingredients.

Abstract Name: Viscosity and Viscoelastic Behavior of Stimuli-responsive Copolymers for Use as Dispersants in Architectural Coatings

Viscosity and viscoelastic properties are important for the application of stimuli-responsive polymers as dispersants in architectural coatings such as paints. Viscosity is a fluid's resistance to flow under stress, while viscoelastic materials exhibit solid-like elastic or liquid-like viscous behavior depending on experimental conditions. New stimuli-responsive polymers, which change their properties in response to changes in temperature, pH, and mechanical environments, could affect the dispersion of opacifying particles such as titanium dioxide in the coating. By adding stimuli-responsive polymers, the properties of architectural coatings can be controlled to produce a more opaque coating with controlled viscosity. This decreases costs and reduces environmental impact. A rheometer is used to test a polymer's viscoelastic properties under different pH, temperature, shear rate, and frequency conditions. Understanding how viscoelastic properties change in response to external conditions is necessary for matching these polymer properties to properties needed for architectural coatings. Viscosity testing is used to determine how well the polymer will mix with titanium dioxide particles. Ideally the coating will have the lowest polymer concentration and lowest viscosity possible to meet performance needs. Viscosity tests help determine where this minimum occurs for different copolymers. This can help determine which polymer is most suitable for dispersing titanium dioxide particles. Viscosity and viscoelastic testing can allow for determination of how changes in polymer structure result in changes in stimuli-responsive properties. The copolymer structures can be tuned, and the properties can be predicted in order to optimize properties for architectural coatings. This results in new materials to meet performance requirements to compete with traditional, commercially available dispersants.

Abstract Name: **Student Perceptions of Mask Wearing in Classes**

For the last two years, mask-wearing has been commonly required by colleges and universities. Mask wearing has the potential to influence the ways faculty teach and how students learn in the classroom. The purpose of this study was to examine students' perceptions of how mask wearing affects them in the classroom. This research also examined whether cognitive and personality variables are related to students' responses to mask wearing. Students completed a survey containing the Adaptability Scale, the Student Learning Experiences Scale, and two other scales to measure students' reaction to Face-to-face learning versus remote learning. In addition, I examined de-identified grade data comparing student grades prior to the COVID pandemic, during the first year of the pandemic, and during the second year of the pandemic. I hypothesized that students would report a decreased learning experience due to mask wearing. I also expected that grades during the first year of the pandemic would be lower than prior to the pandemic and in the second year of the pandemic. Understanding student response to mask wearing in learning environments can inform methods to limit negative effects that mask wearing might have on learning.

Abstract Name: **Testing a Theory of Population Neural Coding in the Visual Cortex Using Motion Adaptation**

Direction repulsion refers to the illusory visual perception that the angular separation (AS) between the motion directions of two overlapping random-dot stimuli is wider than they actually are. The human visual system's ability to adapt to the sensory environment, specifically through motion adaptation, or adaptation to a moving stimulus, can have a profound effect on visual perception. Adaptation has served as a powerful tool to investigate the neural mechanisms underlying visual perception. However, the impact of motion adaptation on the illusion of direction repulsion is unknown. To address this question, we performed a psychophysics experiment using a two-alternative forced choice task and a staircase procedure to measure the perceived AS between two motion directions, with and without motion adaptation. Visual stimuli were overlapping random-dot patches moving in two different directions separated by 30°, 45°, 60°, and 90°. Two human subjects fixed their eyes at the center of the visual stimuli and compared the AS of the random-dot stimulus with the angle of two stationary lines to determine which stimulus had a wider angle. The adaptation stimulus was a random dot patch moving in the vector-averaged (VA) direction of the bi-directional stimulus for 3 seconds immediately before the motion of the bi-directional stimulus. In comparison to no adaptation, motion adaptation significantly increased the ratio of the overestimated AS versus AS, i.e. (perceived AS – AS)/AS, from 0.31, 0.19, and 0.11 to 0.39, 0.24, and 0.15, respectively, for AS of 30°, 45°, and 60° ($p \leq 0.01$), but had little effect on 90° AS, where direction repulsion was minimal without adaptation. Our study showed that adaptation to the VA direction of a bi-direction stimulus significantly enhanced the illusion of direction repulsion. These findings have important implications for how the brain represents multiple visual stimuli in the activity of neuronal populations.

Abstract Name: **Determination of arsenic at (ultra-) trace levels using spectrometric methods**

Arsenic (As) and other heavy metals are present at trace levels in the environment but are still highly toxic. Increased industrial activity has led to their pollution in water and soil, where they are highly soluble and able to form complexes with biological molecules. Arsenic in particular is a by-product of power plant emissions and mining waste and has been shown to accumulate in plants from soil contamination. Flame-atomic absorption spectroscopy (F-AAS) and inductively coupled plasma-mass spectrometry (ICP-MS) were used for the determination of As and other metals in this study. Methods for both spectrometric techniques were designed and optimized, and ICP-MS was used to quantify As in different biological samples. Tree leaf samples collected around the Czech Republic, as well as animal tissue samples, were prepared by microwave digestion. The leaf samples collected in Praha (Kobylisy), Praha (Petřín), and Desná (Riedlova hrobka) were found to have the greatest concentrations of As. As, nickel (Ni), cadmium (Cd), and lead (Pb) content was also determined in several pharmacy-grade and grocery store tea samples. Both tea infusions and tea leaves decomposed by microwave digestion were analyzed. Additionally, the dependence on time and temperature of the tea infusion was studied. Tea infusion samples prepared with higher temperatures of water were found to have greater As levels.

Abstract Name: **Can firefighters wipe away dermal toxins? Evaluating removal efficiency from synthetic skin**

In June of 2022, the International Agency for Research on Cancer (IARC) finalized their evaluation that occupational exposure of firefighters should be classified as “carcinogenic to humans”. Many articles have identified health risks of various substances that firefighters are exposed to via inhalation, ingestion, and dermal exposure. In response to this, companies have introduced several products to reduce toxic chemical exposure for firefighters. In our research, we evaluated a commercial product, microdot® AfterFire™ Wipes, intended for use by firefighters to remove chemicals from their skin after exposure during firefighting operations. We evaluated several target compounds of interest, including benzo[a]pyrene (B[a]P), tris(2-carboxyethyl)phosphine (TCEP), perfluorooctanoic acid (PFOA), lead(II)oxide, and soot. They represent several common categories of chemicals that firefighters encounter, including polycyclic aromatic hydrocarbons (PAH) resulting from incomplete combustion, phosphate ester fire retardants, per- and polyfluoroalkyl substances (PFAS) found in firefighting foam, and hazardous building materials, respectively. Experiments were conducted on a synthetic skin surrogate (VITRO-SKIN®) that has topography, pH, critical surface tension, chemical reactivity and ionic strength similar to human skin. Known amounts of target compounds were deposited on controls and samples, which were wiped with the AfterFireproduct. The quantity of target compounds remaining on the VITRO-SKINwere analyzed usingmethods such as solvent extraction and gas chromatography-mass spectrometry (GC-MS) for B[a]P, PFOA, and TCEP, ignition, acid digestion and microwave plasma-atomic emission spectroscopy (MP-AES) for lead(II)oxide, and suspension and optical extinction by UV-Vis spectrophotometry for soot. Preliminary results suggest that the percent removal of these chemicals each approximates 50% with a 95% confidence interval. This study is supported by Cambridge Sensors, USA, developer and producer of AfterFireWipes.

Abstract Name: **Education By Omission: Racial Threat and White Support for Public School Curriculum Restrictions**

Recently, the United States has seen a significant uptake in state laws seeking to ban so-called "critical race theory" (CRT) from public school curricula. U.S. Census data predict that by approximately 2042, racial and ethnic minorities will make up the majority of the U.S. population. Using the framework of "group threat theory," (Blumer 2016) this project explores how exposure to the threat of changing racial demographics in the United States affects the likelihood of support for banning CRT in school curricula. Based on the work of Craig et al. (2018) we conducted a survey experiment to prime White respondents with racial threat. While our initial analyses did not indicate a primary effect of our experimental threat treatment, findings suggest that, net of socio-demographic controls, White respondents higher in racial resentment were more likely to oppose the teaching of CRT. Respondents high in racial resentment were also more likely to support a CRT ban. Further, our analyses indicated that those who live in counties in which the white population has declined are more likely to support a CRT ban than those in which the white population has increased the most, although this effect was just below the threshold for statistical significance. Past works illustrate how group threat theory and changing racial demographics influence political beliefs, but none have yet to explore it in the context of schooling. This study provides further evidence of the racialization of attitudes about school curriculum policy.

Abstract Name: **Inducible depletion of Atg3 specifically in endothelial cells worsens outcomes of acute ischemic stroke.**

Treatments for acute ischemic stroke (AIS) include thrombolysis (clot dissolution) and thrombectomy (clot removal). Most patients are ineligible for these procedures because they must be initiated within 4.5h (thrombolysis) or 24h (thrombectomy) of AIS onset. New targets for intervention are needed. Here we evaluate the contribution from endothelial cell (EC) autophagy to outcomes of AIS. AIS creates nutrient stress and activates EC autophagy. Heightened EC autophagy in response to AIS helps to : (i) identify, and shuttle damaged proteins to the lysosome for degradation and recycling; (ii) generate ATP from recycled macromolecules; and (iii) preserve arterial function by enabling EC nitric oxide production. First, we hypothesized that depleting EC autophagy worsens outcomes of AIS. Adult mice with intact autophagy (ATG3 WT) or depletion of autophagy-regulated gene 3 (Atg3) in ECs (ATG3 EC-/-) were challenged with an induced stroke, followed by 23 h reperfusion. By design, AIS increased (0.05) EC autophagy in brains from ATG3 WT but not ATG3 EC-/- mice. Infarct volume was larger, and neurobehavioral/physical deficits were worsened (all 0.05), in ATG3 EC-/- vs. ATG3 WT mice (n=7 per group). Second, we hypothesized that amplifying autophagy improves outcomes of AIS. For 3-weeks adult mice consumed standard chow that was (rapa) or was not (control) supplemented with the mammalian target of rapamycin complex 1 (mTORC1) inhibitor rapamycin, a potent activator of autophagy. As evidence of mTORC1 inhibition, fasting-induced p-s6K : s6 was greater (0.05) in liver segments from rapa vs. control mice (n=4 per group). AIS–induced outcomes concerning infarct volume, and neurobehavioral/physical performance, were superior in rapa vs. control mice (n=8 per group). These results indicate EC autophagy depletion worsens, whereas EC autophagy activation mitigates, outcomes of AIS. Our ongoing studies are targeting EC metabolism to improve outcomes of AIS.

Abstract Name: **The Effect of Dietary Amino Acids Glycine and Serine on Body Composition**

Advancing age is associated with deterioration of the skeletal muscle (SkM)—a commonly reported aging phenotype. Although SkM deterioration is multifactorial, it has been linked to heightened inflammation, mitochondrial dysfunction, and dysregulated proteostasis. A notable previous research utilized aSkM regenerative model todemonstrateGly/Ser as essential nutrients for maintaining and regaining SkM homeostasis andhow levels of the nutritionally non-essential amino acids glycine (Gly) and serine (Ser) decline with advancing age. The therapeutic potential of Gly/Ser for age-related SkM deterioration will be explored by measuring the effect of dietary Gly/Ser on body composition as well as markers of inflammation, mitochondrial function, and proteostatsis. In this experiment, both old (20-22 months) and young mice (4-6 months) were randomized to a control, supplemented, and deficient diet (isonitrogenous, isoenergetic). After 28 days of the diet, the weight of the mice was measured, the tibialis anterior (TA) muscle and liver samples were taken, and RNA was isolated, quantified, and quality checked. GDF15, which is thought to be involved in protein catabolism and inflammation, is being measured along with inflammatory cytokines (IL-6, Tweak). After 28 days of the diet, mice on the supplemented diet had a greater body masswhile mice on the depleted diet had the least body weight, but whether differences in body mass were due to changes in lean and fat masses is yet to be determined. Gly and Ser are a likely therapy for improving age-related SkM deterioration. Experiments are ongoing to elucidate the effects Gly/Ser for SkM health.

Abstract Name: **Creating Music That "Causes a Scene"**

Everyone has heard the expression "a picture is worth a thousand words," and perhaps "music is worth a thousand pictures," but what exactly does it entail to create music that describes motion pictures such as film and television? As a fan of film and television music, I've spent a lot of time listening to scores, noting how certain moments are highlighted, and pondering how composers make audiences feel the scenes they're watching. Eventually, I was given the opportunity to score music for a short animated film, which was then performed by the WVU Film Scoring Ensemble in 2021. The film's title "Jinxy Jenkins and Lucky Lou" was inspired by the two main characters, Jinxy Jenkins, who was a gloomy, human-shaped bad luck magnet, and Lucky Lou, who was a sunshine-and-rainbows type who was as lucky as her name suggests. The idea was simple: "to try to tell the story of two contrasting characters," but actually creating the music was no easy task for an aspiring composer like myself. A tight deadline, fixed instrumentations, traditional orchestration, and additional music considerations such as choosing hit points, style, and thematic material, as well as all the technical aspects of syncing music to picture, made the project an exciting challenge. For the purposes of this conference, I will examine the function that my original music serves in the animation from both the composer's and the listener's perspectives, and I will attempt to analyze how that function is carried out. The presentation of this work will either be through a video recording or a live performance. <u>Jinxy Jenkins; Lucky Lou</u> Duration: ca 2:00 Instrumentation: Flute, Bb Clarinet, Alto Saxophone, 2 Horns in F, Bass Trombone, Tuba, Violin, 2 pianos, synthesizer, glockenspiel, snare drum, bass drum.

Abstract Name: Visualizing Utah Lake Nutrient Concentration using GIS-Remote Sensing Analyses

Utah Lake, one of the largest freshwater lakes west of the Mississippi River, has been experiencing harmful algal blooms (HABs) in recent years. These blooms produce a cyanotoxin that poses a health risk to the ecosystems and people living near the lake. HABs have been linked to excessive nutrient loading in lakes and reservoirs. There are various nutrient sources in Utah Lake, including nutrients from tributaries, surface runoff, effluents, stormwater, groundwater, and atmospheric deposition. The objective of this study is to use nutrient measurements and remote sensing imagery to examine any potential correlations between nutrient concentration and HABs distribution in the lake and to visualize how the HABs vary spatiotemporally. Measurements of ammonia, nitrate, nitrite, and phosphate were conducted over the course of a 5-week period in the summer of 2022 as well as 1 week of on-lake sampling. The measurements were used to interpolate the nutrient concentration in the entire lake. The interpolation maps were then compared against a band ratio from Landsat satellite imagery which is a good indicator of levels of chlorophyll a, a pigment-protein within algal blooms. These interpolation maps were also compared against an interpolation map made of phycocyanin concentrations, another pigment-protein within algal blooms, measured at each sampling site. The preliminary results have shown the highest correlation between phosphate and nitrite concentrations to the algal blooms in Utah Lake. The highest concentration measured was 2.96 mg/L of phosphate at the Hobble Creek downstream sampling site, the next two highest at 2.29 and 2.17 mg/L were also phosphate measurements taken at downstream sites. The nutrient with the highest average concentration was nitrate with an average of 0.46 mg/L. Observations from this study could be beneficial for decision-makers to prioritize the areas for HABs management and establish in-lake nutrient standards to minimize HABs occurrence and frequency.

Abstract Name: Targeting Malic Enzyme 1 Dependence in Pancreatic Cancer

With a 5-year survival rate of only 11%, pancreatic ductal adenocarcinoma (PDA) is projected to become the second leading cause of cancer-related death in the U.S. by 2023. While the outlook for other cancers has significantly improved in recent years, the survival rate for PDA remains stagnant. This is largely due to the fact that effective treatments for PDA do not exist. Thus, there is a pressing need to explore new therapeutic approaches and drug targets. Metabolism in PDA is unique in that the tumors are often accompanied by extreme inflammatory responses and subsequently, elevated intratumoral pressure and limited access to nutrients by PDA cells. Normally, such harsh, nutrient-deprived conditions would cause a significant increase in oxidative stress and eventually, programmed cell death. However, PDA cells are able to survive and thrive in these conditions. It is predicted that pancreatic tumors must've altered their metabolism to facilitate survival and proliferation, and thus presents potential exploitable therapeutic vulnerabilities. Previously, the Lyssiotis team reported that PDA cells utilize a metabolic pathway to manage oxidative stress through the maintenance of NADPH and glutathione (GSH). Recently, our result suggests that inhibition of the final enzyme in this pathway, malic enzyme 1 (ME1), profoundly inhibits growth across a large panel of PDA cell lines and PDX-derived primary PDA cells generated with doxycycline-inducible short hairpin RNAs that target ME1. In addition, we also developed a germline Me1 knockout mouse strain that is not embryonic lethal, and these mice matured to adulthood without observable phenotype. While PDA cells are dependent on ME1 activity for survival, normal cells are able to tolerate ME1 inhibition. Altogether, these results highlight the importance of understanding the role of ME1 in PDA tumor metabolism and present ME1 as a potential target for therapeutic vulnerability in PDA.

Abstract Name: Using Survey Data to Report on Low-Income Household Experiences Shopping at the Eau Claire Downtown Farmers? Market

Food insecurity is a significant issue facing many American households. The Supplemental Nutrition Assistance Program (SNAP) provides increased access to food for families in need. Additionally, fruit and vegetable (FV) consumption has been shown to improve health and reduce the risk of a variety of chronic diseases. However, poor nutrition among children and adults, including low FV intake have contributed to rising rates of obesity among US children which have been shown to persist into adulthood. It is particularly challenging for low-income households to purchase/eat the recommended amount of FV. Farmers' markets offer a wide variety of fresh, local and healthy foods, especially FV, but data show that low-income households are much less likely to shop at farmers' markets. The Eau Claire Downtown Farmers' Market (ECDFM) sponsors a Market Match Program (MMP) incentivizing SNAP households to shop at the market. Administrative data on program utilization suggests that most SNAP households shop at the ECDFM using the MMP relatively infrequently. This poster presents data from surveys of SNAP shoppers at the ECDFM in 2022 (N=349) to learn more about their experiences using the program including what limits their shopping at the market and what might increase their ability to shop at the market. Our results indicate that the most significant limitations to shopping at the ECDFM were the market location/hours, SNAP benefits running out and just not remembering. Correspondingly, the most mentioned things that would encourage more frequent shopping at the ECDFM were expanded market locations/hours, a larger match amount and also being reminded. Among our other key findings are that the ECDFM MMP provides many benefits including reducing food insecurity among EC SNAP households. This poster is connected to another submitted poster analyzing a variety of administrative data from recorded transactions of SNAP shoppers using the ECDFM MMP.

Abstract Name: Blockbusting and Racial Transition in Washington, D.C.

Blockbusting is the intentional action of one or more real estate agents to provoke white flight and fear in a previously racially homogeneous area, in order to sell properties for high profit to racialized minority groups. There is limited research on the causation of blockbusting, its distinguishing factors, and the living conditions in these neighborhoods. Our research aims to address these through a case study of Petworth, Washington, D.C., a neighborhood which underwent significant racial transition between 1950 and 1970, showcasing examples of possible instances of blockbusting and its mechanisms and key actors. Based on previous indications of blockbusting researched in the same area, our analyses explore the mechanisms of racial transition and possible blockbusting in Washington, D.C. and its impact on neighborhood disparities. While previous literature has often reinforced a dichotomous argument of either a structural model of racial transition (for example, invasion and succession) or an agent-based narrative (focusing on the influence of both white and Black individuals involved in blockbusting), this case study explores the circumstances which directly affected the racial transition and subsequent disinvestment of Petworth while bridging previous methodologies to provide a greater understanding of blockbusting as a practice. This is accomplished through a mixed analysis of both quantitative profit and loss statistics in home sales as well as individual narratives from oral histories. Oral histories from Washington D.C. residents are analyzed to examine blockbusting on a more personal level rather than at a group level. The sources come from three different oral history archives alongside property records from the Office of Tax and Revenue's (OTR) real property tax database. Preliminary results find repeating instances of likely motives for blockbusting as well as a complex story of profit and loss by potential blockbusters.

Abstract Name: Using SEAL and HARPOON to Find Potential Water-Splitting Oxide Semiconductor Electrodes

Photoelectrochemical water splitting is a potential way to lower our consumption of fossil fuels. There are numerous potential elements to be used in electrodes. While III-V semiconductors exhibit superior light gathering properties, metal oxide semiconductors generally cost less and are more robust. The Solar Energy Activity Laboratory (SEAL) 1 and the eterogeneous verpotential eutralization (HARPOON)2 are simple experiments that can quickly scan for suitable oxide semiconductors. The SEAL experiment measures photocurrent, and the HARPOON experiment measures oxygen production efficiency. An evaporative spotting procedure is used to apply the metal oxide to FTO plates. The FTO plates are then tested using the SEAL and HARPOON systems. Electrodes made of oxides of Pd, Ru, Fe, In, and Ni were produced in our laboratory and evaluated using the SEAL and HARPOON experiments. This presentation will communicate the preliminary results.

Abstract Name: Evaluating Internal Phosphorus Loading and Zooplankton in Mediating Algal Blooms in Loon Lake, Wayland, NY

Loon Lake, Wayland, NY, has been monitored by volunteers since 1994 via New York's Citizens Statewide Lake Assessment Program (CSLAP). This mesotrophic lake is characterized by seasonal shoreline algal blooms that are sometimes dominated by cyanobacteria. Recent monitoring has detected elevated deep-water concentrations of dissolved nitrogen and dissolved phosphorus during the summer months. Therefore, I focused on the dynamics of these major nutrients, commonly linked to harmful algal blooms (HABs), throughout the water column. I also collected associated in situ water chemistry data using a YSI multiparameter sonde (e.g., water temperature, dissolved oxygen, oxidative-reductive potential, pH, and in vivo chlorophyll/phycocyanin). In the summer, it is common for lakes to stratify which is when the water column separates into different layers depending on the temperature. When stratification happens, there is little oxygen at the bottom of the lake which causes the sediments to release phosphorus. In 2022, Loon Lake thermally stratified and dissolved oxygen in the bottom layer was depleted two months earlier than in previous monitoring years. As a result, we observed significant accumulations of phosphorus released from lake sediments in early summer and mid-summer concentrations were more typical of September in previous years. This led to a mid-summer cyanobacterial bloom in the northern portion of the lake that subsequently accumulated on the shoreline. Additional monitoring data are necessary to determine if 2022 was an anomalous year or indicative of a trend of earlier summer stratification and increased internal loading of phosphorus, leading to a heightened risk of cyanobacterial blooms. A trend like that could have detrimental effects on the lake and those who live around it.

Abstract Name: Equilibrium Quartet presents Keen by Roshanne Etezady

Equilibrium is a saxophone quartet at the University of Wisconsin-Eau Claire. The quartet was formed in Sepember of 2021 and is composed of undergraduates students, all with different majors: music education, applied instrumental music, integrated strategic communication-advertising, and biology. In our time as a quartet, we have performed in masterclassses, auditioned for competitions, and prepared multiple recitals.As an ensemble, we are interested in exploring timbre, balance, and color within the constraints of saxophone quartet. The saxophone is an incredibly flecible instrument capable of producing a wider range of wounds and colors. Roshanne Etezady's piece,Keenutilizes the saxophone quartet's unique ability to blend into one homogenous sound by leaning on droning characteristics to drive the piece. Etezady also highlights the individual instrument's timbral qualities in solo passages. We chose this piece because it explores a wide range of colors and challenges musicians to maintain consistent blend and balance in the extreme registers and dynamics of the saxophone.We are excited to share the music of Roshanne Etezady, a contemporary classical composer who uses timbre and balance to capture intense emotions in the pieceKeen. To keen means to express grief with a loud and sustained cry of sorrow. Etezady uses the concept of keening to stucture the piece and model the emotional affect of the title. However she goes beyond imitating this human response to grief. The unison drones are contrasted by shifting melodic lines andintense dissonances that further evoke a distressing affect. In our performance, we hope to convey this intense feeling of sorrow and highlight the work of composer,Roshanne Etezady.

Abstract Name: The Life and Music of Florence Price

Born in Little Rock, Arkansas, Florence Beatrice Smith Price (1887-1953) was America's first significant African American woman composer. The purpose of this lecture-recital is to uncover how Price's compositions are a historic symbol for traditional black composers today, revisit her significance in music history, and provide a biographical overview of her life through the exploration of her piano compositions and experiences composing as a Black woman. Graduating with a double degree in solo organ and piano teaching from the New England Conservatory of Music in 1906, Price was deeply influenced by mentors who helped reinforce an African American identity in her music. While living through the Great Migration and the Great Depression, Price slowly gained recognition throughout her lifetime as a prominent figure in the black community by writing piano compositions that included the "juba dance" and other Afro-American characteristics. Linda Rae Brown's findings in The Heart of a Woman: The Life and Music of Florence B. Price, reveal Price faced issues with conflicting roles both as a woman and a composer. With increasing racial tensions in the late 1920s, Price was denied access to professional music organizations such as the Arkansas Music Teachers Association. Although she lived a moderately private life, analyzing gender and race-based marginalization through the lens of Black feminism illustrates how Price challenged prejudicial social structures and contexts. Price challenges these notions by advocating for herself as a Black woman composer, eventually paving the way by fusing Euro-American structures with elements of her own American cultural heritage by emulating plantation melodies and African American folk melodies in her music. This lecture-recital is part of a growing momentum to give further attention to Price's piano compositions and life, which deserve continued further attention from scholars, teachers, and pianists.

Abstract Name: Development of a Selective Fluorescent Probe for H2S

Hydrogen sulfide (H2S) is gaseous signaling molecule that regulates vasodilation, cardiac function, inflammation, and serves as a cytoprotectant. Endogenous concentrations are in the micromolar range, with abnormal concentrations liked to Parkinson's and Alzheimer's diseases, chronic inflammation, and cardiovascular diseases. The goal of this project is to develop a selective fluorescent probe for the detection of H2S that can locate and quantify this gasotransmitter in living cells. Such an imaging tool will enable the biological roles of H2S to be determined in more detail. The probe features the fluorescent molecule coumarin shielded by a H2S sensitive group, capable of undergoing two subsequent nucleophilic reactions with H2S. Reaction with H2S removes the shielding group, generating an increase in fluorescence. The development of a synthetic pathway for the shielding group and probe will be presented, in addition to any sensitivity and selectivity tests that have been conducted. Details on the methods and completed synthetic steps along with characterization via 1H NMR will be the focus.

Abstract Name: The Effect of Co-Culturing H9c2 Cardiomyocytes with Mesenchymal Stem Cells on the Expression of Cardiac Troponin-T

Previous research has shown that mesenchymal stem cells (MSC) have the ability to improve heart function after myocardial infarction in mice, but the specific mechanism that mediates this therapeutic effect is unknown. It is possible that MSC are able to improve the ability of cardiomyocytes to contract. Cardiac troponin T is a regulatory protein that aids in muscle contraction of the heart. Levels of cTnT can be correlated to cardiomyocyte differentiation. In order to determine the effect of MSC on cardiomyocyte (rat H9c2 cells) gene expression of cTnT, mouse MSC were co-cultured with rat H9c2 cells in DMEM and 10% FBS; control H9c2 cells were cultured without MSC. After 2 days, the media was changed to DMEM + 1% heat-inactivated horse serum for 1, 3, 5, or 7 days to stimulate differentiation of H9c2 cells. RNA was extracted (RNA-4-PCR; Ambion), treated with DNAse to remove genomic DNA, and reverse transcribed to create cDNA (iScript; BioRad). Previously, rat-specific primers were identified to allow the quantification of rat cTnT in H9c2 cells during co-culture with mouse MSC. Gene expression was monitored with qPCR using SYBR-Green (BioRad) with GAPDH as the reference gene. Water and no-RT controls were included. Preliminary results demonstrated a transient increase in cTnT expression in H9c2 cells after 3-5 days in co-culture. Additional studies will confirm and extend this data. These results aspire to describe the mechanism by which MSC work to prevent the functional loss of cardiac function after myocardial infarction.

Abstract Name: Yearly Survival and Growth Rates of Propagated Fatmuckets (Lampsilis siliquoidea) in Central Wisconsin

Freshwater mussels are key members of riverine ecosystems and are crucial for improving water quality. Mussels serve as valuable indicator species and suffer from many environmental disturbances, but despite their importance, large gaps remain in knowledge of freshwater mussels in Wisconsin. We measured the survival and growth of mussels exposed to ambient conditions in two streams in Central Wisconsin. Both selected streams included those that support diverse mussel assemblies. On October 29th, 2021, we received 120 Fat Muckets (Lampsilis siliquoidea) from the Genoa Fish Hatchery, measured, then released them into suitable areas on the Mill Creek; the Plover River Near Stevens Point, WI. Before release, mussels at the Mill Creek site averaged 1.853 cm in length, 1.03 cm in width, and 0.52 cm in thickness. At the Plover River site, mussels averaged 1.859 cm in length, 1.068 cm in width, and 0.546 cm in thickness. We utilized silos to encompass the 1.5-year-old mussels. Each site has 1 silo, containing 15 individuals per silo. Our objective is to determine seasonal survivorship and growth rates throughout our year-long study. Experimentation at these sites will provide an indication to determine which areas are suitable for future reintroductions. We expect 1) Mussel growth and survival will be significantly reduced in the winter months, compared to the summer months. 2) Mussel growth and survival will be significantly different between the two sites. These sites were measured monthly beginning April 21st and lastly October 21st, 2022. This is part of an ongoing study through the University of Wisconsin – Stevens Point's student chapter of The Wildlife Society.

Abstract Name: The Galveston, Houston and Henderson Railroad: The Old Reliable Shortline, the Longest Little Railway in Texas

This paper tells the story of the Galveston, Houston and Henderson Railroad, the railway that operated longer under its original charter than any other railway in the United States. Running from the Port of Galveston to the city of Houston, it played an integral part in Texas importing and exporting as well as human travel. The railway included the first causeway and bridge connecting Galveston Island and the mainland. The railway even played an important role in the recapture of Galveston from Federal forces during the Civil War—the only port recaptured by the South during the war. The railroad also turned Houston into a primary hub for trade and travel, accounting for its growth as a major city. Throughout its history it often became embroiled in legal actions especially during Jay Gould's ownership and leasing of the Galveston, Houston and Henderson Railroad. Today the railroad has been absorbed by the Southern Pacific and no longer operates independently. What remains are some of the tracks and a museum in Dickinson.Based on primary sources, such as local newspapers, as well as appropriate secondary sources, this paper tells the unusual story of the 136-year-old, fifty-mile trunk line that originally connected Houston with the world through Galveston's port. Thus the shortest railway in Texas has the longest history.

Abstract Name: **Evaluation of a Pilot Program for Improving Mentored Undergraduate Research Experiences in STEM**

The Entering Research and Entering Mentoring training curricula have been established to promote positive outcomes for undergraduate and graduate researchers and improve relationships with faculty mentors. However, evidence related to the impact of mentorship training for graduate students who are mentoring undergraduate researchers is limited. Furthermore, the effect of implementing both frameworks in a single context is unclear. A pilot program guided by both curricula was designed to connect underrepresented undergraduate students to high-quality mentored research experiences in STEM at Purdue University. This program offered mentor training to graduate students using the Entering Mentoring framework, as well as practical mentoring experience by matching mentors with students from the Honors College. This study assessed and evaluated the pilot program after one semester. Data was collected from 27 graduate student research mentors who completed a credit-bearing mentor training course and their undergraduate mentees. By incorporating certain elements of the Entering Research curriculum into their mentor-mentee compacts/syllabi, mentors were equipped with student-centered and evidence-based tools to foster their trainee's development as researchers. Other activities from the Entering Research curriculum were implemented through a community of practice for undergraduate researchers. Results indicate that the program was effective in helping graduate student mentors gain in their mentoring skills of undergraduate researchers and mentors were satisfied with the training and practicum experience of the course. Undergraduate mentees reported significant gains in knowledge, skills, and researcher identity. Furthermore, 90% of mentees reported their intention to remain in the same lab during the following semester.

Abstract Name: **Multicultural Perspectives in Aphasia**

Language is the production of our thoughts, cultures, and lives. It converts our minds into a more concrete form that allows people to understand each other. It also associates closely with our habits and mentality. The speech-language-hearing sciences field is one of the whitest fields in the U.S. and most research is biased toward the white-dominant population while some racial and ethnic minorities are more likely to suffer severe strokes and disparities in long term outcomes. Whereas there is almost forty percent of non-white in the United States of America, signaling the existence of diverse mindsets in which the disorders and treatments cannot be concluded only from the existing data. The mental health, the related cultural background, and the customs of different ethnicities may broadly impact the therapy and the results. In the current speech-language-hearing science field, we barely examine clients through the lens of mental health and multiculturalism. This single subject design study is to explore diverse perspectives about aphasia reported by marginalized clients with aphasia. Two participants were interviewed about their views about aphasia. The interview questions were modified from an explanatory model approach proposed by Kleinman and Beeson (2006) to explore the participants' understanding of the meaning of illness. Thematic analysis will be conducted. The results of this study will help further understand and help meet the needs of individuals who belong to an ethnic minority group and are affected by aphasia.

Abstract Name: The Determinants of Income Inequality in Rural Wisconsin and Policy Implications

Rural communities in Wisconsin are currently facing many economic challenges, namely high levels of poverty, declining population, lack of high-quality services, and poor infrastructure. These are issues that call for innovative and creative approaches and require prompt attention. This project is a collaboration of three faculty members at the Department of Economics at our institution. Our project has three main goals. First, we propose to measure regional, particularly rural, income disparities while identifying the main explanatory factors with American Community Survey data and quantile regression analysis. Second, we will examine and quantify the impact of entrepreneurship, growth of immigrant populations and access to broadband on rural incomes in Wisconsin. Third, we will offer insights and recommendations to Wisconsin policy makers. Our research findings will help assess economic needs and resources and provide policy options to address challenges facing rural communities.

Abstract Name: Fostering the Implementation of Industry 4.0 in SMEs: A Life Cycle Cost Analysis

Many different worldwide initiatives are promoting the transformation from machine dominant manufacturing to digital manufacturing. The implementation of Industry 4.0 in manufacturing industry is continuing to grow, as shown by the extensive research, development, and standardization regarding Industry 4.0. However, Small and Medium Manufacturing Enterprises (SMEs) encounter many barriers and difficulties (economical, technical, cultural, etc.) in the implementation of Industry 4.0. A deficiency of Industry 4.0-related knowledge and experience is still a serious barrier to decision-making in Industry 4.0 implementation. Operations and management education should prepare students for the future by equipping them with new technology and problem-solving skills through research experience. Examples from the field of Industry 4.0 include system life cycle cost analysis, data analytics, cloud computing and simulation, which will be fast growing Industry 4.0 within the next decade. The implementation of Industry 4.0 comprises decision making, cost and benefit analysis, leadership, machine learning and data analysis—all the elements potentially present in an operation and management research. This can be an effective and versatile tool for advancing high-quality undergraduate research in operation and management. This study develops a methodology to evaluate the impact of Industry 4.0 implementation on life cycle costs to support decision-making of Industry 4.0 implementation in SMEs based on the factors involved in LCC, causal relationships, ROI (Return on Investment). Students' efforts are made in the disciplines of management, supply chain, financial management, simulation, data analytics and manufacturing engineering. Students participate in original research activities designed to empower and prepare students for advanced degrees and careers in operations and management, and train students in interdisciplinary and collaborative thinking necessary to solve real-world problems. Our efforts in this study are separated as a few different research projects and these projects can be applied to interdisciplinary undergraduate teaching and improve our effectiveness in collaborative problem-solving.

Abstract Name: Role of Motivation on Academic Success

The collegiate world is constantly discussing how student motivation is related to student success. How true is this correlation? Does the motivation importance change with the specific course or the format the course is taught in? Can the institution or instructor impact the student motivation level by understanding intrinsic and extrinsic factors that motivate students? The aim of this study is to determine what motivation in education is and how it impacts the academic success of college students. Factors that will be studied include intrinsic and extrinsic motivation factors, academic performance, familial college experience (1st generation students vs non 1st generation students), and the role of the institution and faculty. The study will be completed through a survey with a battery of questions adressing all the key areas mentioned above. Demographics will also be collected to compare possible inter-group differences. Correlational analysis will be completed through data collection in the spring semester of 2023.

Abstract Name: The Cancer Health Equity Collaborative: Does it effectively support cancer related stakeholders in the San Diego region?

The Cancer Health Equity Collaborative (CHEC), supported by the UC San Diego Moores Cancer Center, seeks to foster networking and improve access to cancer prevention, detection, treatment information and resources among underserved communities. From July 7th to July 29th, 2022 we queried CHEC members using a brief on-line survey created using Qualtrics, followed by a virtual interview that was scheduled with 10 participating organizations over a 2-week period. The purpose of our assessment was to understand and evaluate the effectiveness of CHEC among participating stakeholders. The collaborative consists of 39 organizations. Among these, 24 participated in the online survey (62% response rate). Ninety five percent (95%) of respondents agreed that CHEC's mission aligned with their own organization's goals and CHEC supports important community needs related to cancer. Eighty three percent (83%) of participants strongly agreed that CHEC meets the objective of sharing cancer-related resources and tools to better inform stakeholders and the community. Sixty six percent (66%) of respondents stated that they share CHEC resources with others. One organization reported sharing information with as many as 1,000 individuals. Among those that participated in the on-line survey, 10 participated in the virtual interviews. One hundred percent (100%) of those interviewed reported that CHEC has in some way positively supported their organization by providing resources, networking opportunities, and necessary cancer information. Overall, our assessment concluded that CHEC is effective in providing access to information for cancer stakeholders in San Diego and has benefited organizations through facilitating networking, sharing resources, and educational presentations. Results highlight the importance of participating in CHEC in order to gain a comprehensive and an all-encompassing perspective on cancer.

Abstract Name: **Stereoselective Synthesis of ?-Quaternary ?-Hydroxyketones**

In medicinal chemistry and drug discovery, quaternary centers, which are three-dimensionally complex chemical systems consisting of a carbon atom bound to four distinct carbon substituents, are a vastly important synthetic target for the development of new drugs and therapeutic agents. Quaternary centers have been shown to confer drug molecules enhanced binding selectivity to target proteins associated with human diseases, and molecules decorated with high percentages of quaternary centers are highly coveted as drug candidates. Despite the importance of quaternary centers, exploration of organic molecules with quaternary centers in drug discovery remains limited due to the considerable difficulties associated with the synthesis of these sterically congested systems. To combat this synthetic deficiency, we have developed a selective and efficient synthetic reaction for the installation of quaternary centers at the alpha position of cyclic carbonyl compounds. The hypothesis for the mechanism of the reaction is as follows. The starting material is subjected to an organomagnesium reagent and undergoes a reaction known as a Grignard addition. The two proximal oxygen atoms are chelated to a magnesium ion, and this chelation promotes the Claisen rearrangement of the neighboring triple bond, thereby generating the product. Amazingly, this reaction sequence produces the desired structural motif with excellent diastereoselectivity and high yields. For these reasons, this project has potential to be highly impactful in synthetic biomedical research endeavors. This reaction has been extended to many electronically diverse chemical environments, and these exciting results are promising for the continued expansion of the substrate range.

Abstract Name: Mapping America?s Native Food Trail

The purpose of this project is to create a new digital asset to help reawaken our Indigenous people and the public to Indigenous culinary traditions and sustainable practices by American Indians in the United States. This project maps out those contributing to our awareness of Indigenous pre-contact diets, America's Native chefs, Native food authors and Native food films to bring them together into America's NativeFoodTrail.org.Is it possible to reconnect our Native people to our Native foodways and can this reconnection help heal? Could promoting traditional Native diets help turn Americans' declining health around? Contemporary health issues facing American Indians include higher rates of drug abuse, alcoholism, obesity, diabetes, cancer, poverty and malnutrition that compound post-traumatic stress disorder, depression, historical trauma, suicide and genocide. I believe food is medicine and I believe one way to help decrease health disparities is by reconnecting to our Native "First Foods". This new website could help chefs like Sean Sherman, founder of The Sioux Chef draw attention to a "long-forgotten Native culinary tradition". Native restaurants could include: cafegozhoo.com; owamni.com; makamham.com/cafeohlone; and wahpepahskitchen.com. NativeFoodTrail.org could highlight award-winning documentaries like "Return: Native American Women Reclaim Foodways for Health and Spirit". In this film, filmmaker Karen Cantor draws attention to the fact that American Indians have trouble tolerating most foods sold in commercial grocery stores, that "Over 15% of Indigenous Americans have type-2 diabetes"; and Native Americans' lives are cut short due to declining health and a lack of access to their own foods. Mapping America's Native Food Trail is also a decolonizing way to create new possibilities to help reverse American Indians' health conditions by empowering Native Peoples as they struggle to survive assimilation and reclaim their ancestral foodways. A bonus is to encourage education, healing, forgiveness, reconciliation, and unification around food. Let's reclaim our wellness.

Abstract Name: The Korean War: China's New Precedent

The Korean War from 1950 to 1953 was the first international conflict that the new government of mainland China, the Chinese Communist Party or CCP, would be involved in after the end of the Chinese Civil war in 1949. The deployment of the United States Navy to the Taiwanese straits forced Mao Zedong and the CCP leadership to stop their preparations to invade Taiwan and instead shift focus to supporting the Democratic People's Republic of Korea's invasion of the Republic of Korea. While originally calling for the complete unification of Korea under the DPRK, as the war progressed the goal of the CCP in the war evolved to match the challenge that the United States and NATO posed. The relative success of the Chinese forces upon their intervention in the war saw a shift from the previous centuries of China being routinely beaten by imperial powers such as the Japanese and British Empires.Using evidence from letters, translated from Chinese to English, written by Mao Zedong as well as accounts of decision-making at the highest levels of CCP leadership, this paper shows the shaping of China's goals for the Korean War, their involvement in the war, and how the war impacted the development of their foreign policy going into the Cold War Era and today. China has gone from being subject to the demands of other powers to being a strong and independent nation. While the end of the Korean War was a stalemate, it set a new precedent for the Chinese people to be able to compete on the world stage with other world powers such as the United States.

Abstract Name: **Investigating Biofilm-producing Phenotypes in Clinical Staphylococcus aureus Isolates: Implications for Infection Persistence in Cystic Fibrosis Patients**

Pseudomonas aeruginosa and Staphylococcus aureus dominate infections in cystic fibrosis (CF) patients, and coinfection with these two bacteria leads to poor outcomes and a rapid decline in prognosis. The mechanism for these worse outcomes as a result of coinfection is poorly understood, though the biofilm-producing ability of S. aureus is thought to play a role. Therefore, the aim of this research is to determine the biofilm-producing ability of clinical S. aureus isolates from CF patients in order to understand the role that biofilms may have during infection by these isolates. Biofilms are a build-up of bacteria on a surface covered in a sticky substance made of polysaccharide. This polysaccharide can lead to immune evasion and infection persistence in CF patients by creating a physical barrier that prevents antibiotics from working properly. In order to evaluate the presence of biofilms, we grew each isolate on Congo red agar, a differential media, and observed the appearance of colonies. Smooth, red colonies reflect normal producers of biofilm, while maroon, rough-textured colonies indicate overproducers of biofilm. Results indicate that many of the clinical isolates examined are overproducers of biofilm and thus likely contribute to the chronic nature of infection in the CF patients they originated from. In the future, this data will be combined with information we have obtained about how these same S. aureus clinical isolates interact with P. aeruginosa. Overall, this work will add to our understanding of how biofilm production and potential persistence of S. aureus relates to its ability to coinfect with P. aeruginosa, and may provide valuable information to help us better treat these chronic infections.

Abstract Name: **No One Will Talk: The Horrors of Sexual Trauma in the Holocaust**

An anonymous rape victim once said, “Not enough people understand what rape is, and, until they do..., not enough will be done to stop it.” Jewish women posed a unique threat to the Nazi ideal of a “perfect” Aryan race, with their identities being both Jewish and female. Every victim of the Holocaust has valuable experiences to share, yet little attention has been devoted the multitude of women who suffered from sexual trauma. Arguments against the study of violence towards women in the Holocaust exist; however, it is important to note this violence independently because of the targeted sexual connotations that were simultaneously inflicted. Sexual violence is usually expressed in the form of rape, forced abortions, and sex work; Nazi practices went further. They attacked women’s femininity by shaving their heads, beating them, stripping them naked and mocking them. Such acts of violence were traumatizing to these women. Victims stated that this trauma was so normalized and ingrained that they would become numb to the concept of assault. While many would simply await their time of death or assault, others would take power over their situation and sexually barter themselves for potential survival. The Nazis goal was to eradicate specific people group to create the perfect race without impurities. They would humiliate and degrade people before killing them, forcing their last moments on this earth to be excruciatingly painful and utterly humiliating. Following liberation, the trauma these women endured was ignored, and they were left to heal and morn in silence.

Abstract Name: **Quantifying organic phases in coral skeletons at the nanoscale**

Nanoscale mineral structures of coral are not well understood. When corals build their skeletons, they are composed of nanoscale crystalline structures. It is known that coral skeletons are affected by ocean acidification and climate change at the macroscale. However, understanding how the coral skeleton-building process functions at the nanoscale would allow for better modeling and prediction of how coral might fare under varying ocean conditions and climate changes. Specific isotopes in coral skeletons can mark the organic or mineral parts of the skeletons, and thus can be used as indicators of different phases in the coral skeletons. Our goal is to statistically investigate quantitative relationships that exist between different organic and mineral associated isotopes in coral skeletons. Multiple corals were lab-grown under various controlled conditions at St. Olaf College, and they were analyzed at the nanoscale by a mass spectrometer to extract concentration data for specific isotopes present throughout the skeletons. We use Pearson correlation to measure the strength of the relationship across coral isotopes and Mander's coefficient to measure co-occurrence. Co-ocurrence looks at the high concentration clusters of isotopes across isotope pairs. Knowing the quantitative co-occurrence of isotope pairs in the coral skeletons helps in understanding the spatial distribution of organic molecules within the coral skeleton, which in turn can help us better understand the growth process of the coral skeleton itself.

Abstract Name: **Virus infection of the brain induces neural stem cell loss in juvenile mice**

Virus infections in the central nervous system (CNS) can lead to devastating neurological outcomes, including cognitive dysfunction, seizures, and death, especially in newborns and young children. Therapies for CNS infections are limited, and little is known about how the brain responds to the inflammatory environment created by the virus.In order to examine the effects of a viral infection in a younger host, we used the CD46+ mouse model, where the human receptor (CD46) for measles virus (MV) is expressed only on neurons in the brain. In the CD46+ model, juvenile mice (10 days postnatal) develop signs of illness (e.g. tremors, weight loss) during infection, but ~80% ofmice will survive into adulthood. Here, we analyzed the fate of neural stem cells (NSCs) in juvenile CD46+ mice. NSCs are key to brain development and repair, giving rise to new neurons in the growing brain. In the CD46+ model, NSCs are not infected directly by MV, but are bystanders to the immune response. Using flow cytometry to count NSC numbers, we found a striking loss of NSCs early in infection. We hypothesized that the loss of NSCs was due to apoptosis, which is a form of cell death.Thus, we quantified the levels of proteins that are activated during apoptosis (PARP and Caspase-3) using western blot analysis. Tissue samples from the hippocampus and subventricular zone were examined, as these brain regions are rich in NSCs. We found significantly higher levels of both activated PARP and Caspase-3 in MV-infected mice (n=6 mice/condition), suggesting that apoptosis occurs during infection. Current studies aim to quantify the numbers of apoptotic cells in each brain region, and to identify the type of cell undergoing apoptosis. Together, our studies suggest that viral infections in the brain can dramatically reduce NSCs, even when the host survives infection.

Abstract Name: **Effects of Injection Characteristics on the Particle Deposition within Human Airways**

Aerosolized drug delivery through the human airways is an effective strategy for treating pulmonary diseases such as asthma, cystic fibrosis, chronic obstructive pulmonary disease, and pulmonary infection. Targeted regional deposition of the drug in the diseased pulmonary regions is key to effective treatment with minimal side effects. While recent advancements in radiological imaging techniques have allowed for detailed anatomical information to guide treatment procedures, such information still tends to be limited leading to an inefficient treatment. Thus, computational tools can provide further insight to guide and enhance the efficiency of the treatment procedure. In this study, we employ large-eddy simulation (LES) as a computational tool to investigate the airflow and particle deposition characteristics within the upper human airway. LES of one-way coupled particle-laden flow within the human airways is carried out by employing the widely popular Eulerian-Lagrangian strategy, where the airflow is simulated using Eulerian formulation and the particles are tracked using a Lagrangian approach. We examine the effects of injection characteristics of the particles on their regional and global deposition within the human airways. The airway model considered in this study is adopted from the well-established SimInhale benchmark case where we consider a truncated portion focusing on extrathoracic and part of intrathoracic airways. First, the airflow features within the airways will be discussed in terms of the instantaneous and time-averaged behavior of the flow field. Afterward, the results from polydisperse injection of particles for regional and global deposition will be discussed and the global deposition fractions of three models of particle distribution will be compared.

Loock, Lauren

Lauren Loock

Abstract Name: **Mindfulness and Memory**

Purpose: Mindfulness may improve memory through promoting awareness of, attention to, and openness to information presented. The positive effects of mindfulness on memory may be seen even after brief, one-time interventions. However, mindfulness may only affect memory performance if the intervention is administered directly before retrieval rather than at encoding. Additionally, mindfulness might selectively affect some types of memory tasks and not others. Procedure: Participants will be randomly assigned to a mindfulness condition (a ten-minute mindfulness meditation) or a control condition (a ten-minute podcast about the history of mindfulness). All participants will study a list of words, either presented individually or as word pairs, and asked to memorize them for a later memory test. Participants will then take a memory test,item recognition for those who studied individual words or associative recognition for those who studied pairs. Some participants will listen to the podcast (mindfulness or control) before encoding the study list while others will listen to the podcast before retrieving the words at testing.Expected results: We will compare memory recognition performance, specifically false alarms, of participants in the mindfulness condition to those in the control condition. We expect that mindfulness should reduce false alarms only if the intervention is given directly before retrieval. However, we might find that mindfulness facilitates familiarity as a cue when making memory judgments. We expect larger differences in false alarms between the mindfulness and control groups for the item recognition task compared to the associative recognition task. Data collection is currently underway. Conclusions: Advancing or amending theories of mindfulness and memory could improve our understanding of human memory and also aid potential translations of research findings to practical applications. For example, would a brief mindfulness intervention presented before administering a classroom exam improve student performance?

Abstract Name: **The Influence of Prior Exposure to Weapons on the Weapon Focus Effect**

The proposed study aims to further investigate if ownership of firearms decreases the weapon focus effect (WFE). When a weapon is present during the commission of a crime a witness is less likely to accurately remember details, specifically peripheral details, about the perpetrator's appearance compared to when no weapon is present. It is hypothesized that having prior experience with weapons, through ownership, decreases the WFE compared to no prior experience with weapons.The proposed study will be a 2(Gun Familiarity: gun ownership vs. no ownership) x 2(Weapon Presence: present vs. absent) between subject's design. Participants will come to a lab in groups of 1-10. After receiving and signing an informed consent, participants will watch one of the two mock crime videos that are approximately 42 seconds in length. Both videos depict a mock robbery in the woods where a young woman carrying a backpack is approached by a man who robs her. The robber either only uses his words while holding a backpack to demand her belongings (weapon absent condition) or holds a rifle to demand her belongings (weapon present condition). After watching the mock crime, participants complete filler activities for 20 minutes. Then, participants complete a survey about what they remember about the perpetrators' appearance, select from a 6-person target-present line-up, rate their confidence for the selection, and complete demographic information. Students will be thanked for participating and community members will receive $10.00.The accuracy of participants descriptions will be calculated (total correct details/(total correct + incorrect details)).A series of 2X2 factorial ANOVAs will be used to see if Weapon Presence and Gun Familiarity affected the accuracy, the number of correct details, and the number of incorrect details reported. We expect that those who own firearms will have higher accuracy compared to those who do not own

Lopez, Christina

Abstract Name: **Biodegradation of Oily Sludge Via the Use of Impellers and a Chemical Dispersant**

The presence of oily sludge from factories and wastewater treatment are a detriment to the state of the environment, as it contains many harmful and toxic substances, including polycyclic aromatic hydrocarbons (PAH), cycloalkanes, benzene, and similar compounds; benzene alone is a group 1A carcinogen, putting those in contact with it at risk for developing cancer. Though this is not a new issue, there has been an increased need for the treatment of oily sludge as its production only increases as time goes on. Numerous methods are used for the treatment of oily sludge and are continuously being modified and improving. The use of two-phase composting and the use of chemical hydrocarbon dispersants have both been proven effective in achieving significant removal of total petroleum hydrocarbons (TPH) present in sludge samples. Another method that this research in particular focuses on is the method of chemical dispersants and extended periods of agitation to achieve TPH removal. This research was an attempt to analyze the effectiveness of oily sludge dispersion and biodegradation in a controlled setting. A dispersant effectiveness test (DE) and biodegradation test were done using paddle and helical impellers, samples of West Texas Crude Oil (WTCO), Petroclean dispersant, and bacteria that was cultured in a bioreactor. The DE lasted 4 hours and the biodegradation took place over the course of 28 days. The results show the overall DE of each impeller, as well as the results of the biodegradation-- which had the most consistent success with the helical samples, particularly the sample inoculated with bacteria.

Lopez, Edson

Institution: ***IA - Iowa State University***

Discipline: Earth & Environmental Sciences

Abstract Name: Impact of wastewater treatment plants' processes and operations on per- and poly-fluoroalkyl substances (PFAS) removal

Per- and poly-fluoroalkyl substances (PFAS) are contaminants of emerging concern. Due to their unique properties, they are used in everyday items such as cookware coatings, food packaging, and foams. However, PFAS are linked to harmful health and environmental effects, and are broadly distributed. The fate and transport of PFAS in wastewater treatment processes is poorly understood. Many perfluoroalkyl acid (PFAA) concentrations in treated wastewater effluent are higher during warmer seasons. This increase may be due to biological or physical effects on treatment systems and their microbial communities. Measuring carbon, nitrogen, and phosphorus is critical to quantify the microbial activity in wastewater treatment facilities (WWTFs) and understanding its impact on PFAS transformation. I quantified microbial nitrification, phosphorus absorption, and carbon respiration as indicators of microbial activity inside WWTFs. My results will indicate how temperature influences microbial activity , and resulting transformation of precursors PFAS to PFAAs throughout the wastewater treatment process. Microbial parameters are compared at the same WWTFs at different operational temperatures to see if there is any correlation between microbial activity and the transformation from precursor PFAS to PFAAs based on the change in temperature.

Abstract Name: American Media: Vice Grip on the influence and perspectives of Undocumented Immigrants of Latino Background in the United States

The growing racial tensions in the United States have reached a fever pitch, especially in educational settings. Little research has been conducted on how college students' views on undocumented immigrants in the United States is influenced by the media. Therefore, I propose to investigate the views and perspectives about undocumented immigrants in the United States at Northeastern Illinois University. I will investigate the correlation between media, specifically looking at news organizations, and how the views towards immigrants presented by the news anchors affect an individual's opinion about undocumented immigrants in the United States. My research employs a mixed method, using both qualitative and quantitative research, with a survey and an optional interview. I would use the findings from the survey to be able to ask relevant questions to the subjects doing the optional survey. This research will provide valuable insights into how students view undocumented immigrants in the United States and the role that media played in developing these opinions.

Abstract Name: **Terrestrial friction-reducing properties of mucus and scale anisotropy in northern snakehead (Channa argus)**

The mucus coating around a fish's body is essential to its survival. It contains antimicrobial properties, aids in drag reduction, and protects against physical damage. It provides a lot of versatility for aquatic fishes in certain environments and is a key adaptation among amphibious fish. The Northern Snakehead (Channa argus) are a species of amphibious fish that is not only invasive to the Chesapeake Bay but is renowned for its unique ability to crawl on land. However, the role of their slippery mucus in terrestrial behaviors is currently unknown. This project aims to investigate how snakehead mucus affects friction during terrestrial locomotion, assess if their mucus evolved to facilitate such movements compared to the mucus of fully-aquatic fish (i.e., Common Carp), and determine how their scales influence friction anisotropy using scale-less fish (i.e., Blue Catfish). This will be tested by pulling on freshly euthanized fish along two types of surfaces in the forward and backward directions using a force meter. Each fish will be tested using the above with its mucus coat intact and then again with it wiped off, allowing for paired comparisons. This will illustrate how mucus and the anisotropic properties of fish scales influence terrestrial friction. The snakehead mucus significantly reduced friction, and did so proportionally more than carp mucus. Additionally, fish scales exhibited frictional anisotropic properties, with less friction in the forward direction and more in the backward direction, similar to how snake scale anisotropy promotes forward movement. Amphibious fishes like snakeheads may have evolved particularly slippery mucus to aid in terrestrial locomotion by reducing friction and energy required to move overland, potentially between bodies of water. This study may also provide insight to the biomechanics of snakeheads, which could inform as well as improve the development of bio-inspired robotics and bio-materials.

Abstract Name: **Divisions of Aspect and Mood in Mixtec Spoken in Central Wisconsin**

The purpose of this research project is to identify temporal, aspectual and modal markings in a variety of Mixteco, an indigenous language of Oaxaca, Mexico, whose speakers migrated from Oaxaca to Veracruz and subsequently to Central Wisconsin. The result of this study will contribute to ongoing research on aspect, tense and mood (e.g. Timberlake 2007) and to research on the expression of these three categories in other varieties of Mixteco (Bickford; Marlett 1988). I am conducting this project through interviews with relatives who are native speakers of Mixtepec Mixteco, with a focus on eliciting verb paradigms. Following Bickford; Marlett, I expect to discover a primary division of mood into irrealis and realis, and within realis mood, a secondary distinction between perfective and imperfective aspect. Confirming these distinctions, or finding data that challenges Bickford; Marlett's research, will add to our understanding of the tense, aspect and mood system of Mixteco languages. Perhaps, more importantly, though, this research adds to our understanding of the complex and poorly documented relations among varieties of Mixteco. With roughly 530,000 speakers, Mixteco constitutes a dialect continuum in which local varieties are not mutually intelligible with one another. Many speakers of Mixteco live in the mountainous regions of Oaxaca, an underdeveloped area whose poverty has driven significant migration to the United States. Poor documentation of these varieties has made it challenging to identifymigrants' home language andpresents an obstacle to individuals and institutions whose aim is to support new arrivals in the US. Documenting and describing the structure of Mixteco varieties thus lays important groundwork for humanitarian efforts.

Abstract Name: **The Impact of Surgical Masks on Emotion Perception and Gender Classification**

Mask-wearing has become a common practice due to COVID-19, affecting numerous aspects of social interaction and perhaps affecting children's social development (Chester et al., 2022). Mask-wearing may impact children's perceptions of emotion and their ability to classify another's sex due to the occlusion of faces (Mollahosseini et al., 2016).Before COVID-19, studies demonstrated that children attend to others' eyes and mouths to differentiate between emotions (Mollahosseini et al., 2016). Few studies examine children's ability to differentiate emotions when the lower half of the face is covered; those studies have found conflicting results. In some, masks did not significantly impair children's ability to infer and respond to others' emotions (Ruba; Pollack, 2020; Schneider et al., 2021), whereas others found that toddlers are more greatly affected by masks than adults, and that masks led to a drop in children's performance on emotion perception tasks (Gori et al., 2021; Kim et al., 2022).Wild et al. (2000) studied sex categorization and found that 7-year-olds, for the most part, correctly classify the sex of adults using facial structure alone. Fagot and Leinbach (1993) found that infants as young as 9 months of age can correctly categorize males and females from pictures of their face. We extend this work to mask-wearing contexts, exploring 3- to 6-year-old's ability to classify the sex of masked and unmasked faces.We aim to understand how young children detect masked and unmasked individuals' emotions and sex. Additionally, we will explore which parts of the face facilitate children's emotion and sex categorization. This will be explored by presenting children with images of uncovered faces, faces with sunglasses on (i.e., upper-face occluded), and faces with a surgical mask on (i.e., lower-face occluded). We hypothesize that mask-wearing will significantly affect children's emotion perception and sex classification.

Abstract Name: **The Associations between Belongingness, Trust, and the Willingness to Donate to One?s Alma Mater**

Donations are a vital part of keeping universities up and running across the globe. Thus, it makes sense that universities have a vested interest in fostering relationships with students that will generate future donations. This study examines the degree to which feelings of belongingness, trust, and engagement in campus activities affect an individual's willingness to donate to their alma mater. The 72 participants in this study represent a diverse group of students at the University of Wisconsin-Eau Claire. The findings indicate that feelings of belongingness with the university and the belief that one can trust the university are more strongly associated with a willingness to donate. Engagement in campus activities was not significantly associated with a willingness to donate. Thus, we learned that while it is important for a university to provide opportunities for students to engage in campus life, the university should spend equal time fostering a sense of belongingness and trust with their students.

Abstract Name: **Cleavage of Classical Complement Pathway Components by Tissue Kallikrein**

The complement system, a part of the innate immune system, serves as a first-line defense against foreign pathogens in the body, but can lead to disease if overactivated. The complement system is composed of a series of proteins within a cascade that cleave and activate each other, ultimately leading to the lysis of the foreign pathogen. The complement system consists of three different pathways—classical (CP), alternative (AP), and lectin. Previous research by Sartain et al. found a serine protease outside of the complement system, known as tissue kallikrein (KLK1), cleaved components within the AP. KLK1 plays a role in regulating blood pressure and blood flow, and can produce inflammatory effects similar to C3a, a protein found in the complement system. Since KLK1 was able to cleave AP components, this study aimed to determine if KLK1 was capable of cleaving CP components—C2, C4, C1r proenzyme, and C1s proenzyme. CP components—C2, C4, C1r, and C1s—were incubated with KLK1, and analyzed by SDS-PAGE under non-reducing and reducing conditions and western blotted. We found KLK1 cleaved C2, but not C4; and KLK1 cleaved C1s, but in a different location than its native cleavage enzyme (C1r). KLK1 also demonstrated to cleave C1r in a location other than its known cleavage site. Future experiments will examine if KLK1-activated C1s can cleave downstream CP component C4. Taken together, these results provide new insight as to how KLK1, a protease outside of the complement system, is capable of activating the CP, contributing to complement system overactivity often associated with disease.

Abstract Name: **Investigating the Role of Increased Germline Apoptosis at High Temperature in Caenorhabditis elegans**

Exposure to environmental stress can decrease an organism's ability to reproduce successfully, especially elevated temperature. What mechanisms organisms use to maintain fertility when under stressful temperatures is not well known. Here we explore the role of apoptosis, programed cell death, in regulating the fertility of the nematode Caenorhabditis elegans at high temperatures. In wild type C. elegans, about 50% of germline cells undergo apoptosis under normal environmental conditions, and under high temperature stressed conditions apoptosis increases. We used a series of mutants that have changes in the level of apoptosis: ced-3 and ced-4 mutants that have no apoptosis in the germline, a ced-1 mutant that has no engulfment of cells undergoing apoptosis, and gla-3 and cpb-3 mutants that have increased apoptosis in the germline, to determine how changing the level of apoptosis affects the quality of embryos made. We measured the number of embryos laid and the embryonic lethality at 20°C, the ideal temperature, and the high stress temperatures of 26°C and 27°C. We found that both mutants that decreased and increased apoptosis resulted in decreased embryo number and higher embryonic lethality. This suggests that the balance of apoptosis levels in the germline of C. elegans is important for maintaining embryo quality at stressful temperatures. Additionally, we investigated the mechanisms that may lead to increased apoptosis at high temperature, using the loss of function mutants that interrupt the synapsis checkpoint or the DNA damage checkpoint. We measured the number of apoptotic nucleic at normal and increased temperature in these mutants and found that the synapsis checkpoint but not the DNA damage checkpoint plays a significant role in the increase in germline apoptosis at elevated temperatures. This data together suggests that increased apoptosis occurs in response to increased asynapsis, which ensures resources are not wasted on unfit embryos.

Abstract Name: **The Role of Ideology, Culture, and Identity During the Anglo-Irish Conflict**

On December 6th, 1921, the Anglo-Irish Treaty was signed, thus culminating a centuries-long battle for Irish independence. This treaty was the product of a long road of discourse, debate, and disagreement amongst both English and Irish alike. The corresponding question is: how did identity, ideology, and culture influence all sides of the Irish Question, on both the macro, and micro levels, as it applied to Home Rule, independence, and the establishment of the Act of Union in 1800? The goal is to analyze the ideologies of unionism and pro-independence movements in Ireland and England, including an examination of religious and national identity. This research utilizes primary sources such as the writings and words of prominent figures in support and in contention with Empire.Examples include debates from Hansard's report on Parliamentary debates as it relates to home rule, such as the speeches of Edward Carson, a prominent Irish pro-empire activist. Another example involves the rhetoric and actions of former Prime Minister William Ewart Gladstone, as well as the writings of John Stuart Mill. These sources will allow me to interpret the shifts over time in ideological thought from the late eighteenth century to the early twentieth century as it relates to culture, identity, and empire by examining perspectives revealed in electoral results, letters, oral histories, and in other discourses.In tracing the evolution of fruitful rhetoric over the course of the Home Rule movement, and taking careful consideration of nuanced public opinion, this presentation will offer a considerable contribution to the history of the Anglo-Irish conflict. By better understanding the proposed outcomes from all sides of the conflict, we can learn to approach history in a more humanistic context.

Abstract Name: **Low Cost Filter Media for the Removal of Phosphorus in Agricultural Runoff Treatment Systems (ARTS)**

Seasonal hypoxia of lakes in the Midwest, Gulf of Mexico, and surface waters around the world as a result of excessive algal production, has a detrimental effect on the local aquatic species, environment, and recreation. Despite investments in point source reductions, seasonal hypoxia is persistent, in part due to non-point agricultural sources of phosphorus (P) (35% of total P load to Lake Michigan). Agricultural runoff treatment systems (ARTS), consisting of sedimentation basins and phosphorus removal structures, are an effective field treatment to reduce nutrient pollution .pollution. Numerous media (>80) for phosphorus removal structures have been investigated for their P removal potential and the hydraulic conductivity; Ca, Fe, Mg and Al content of media are important factors. Reactive media derived from waste products would create a product from waste, extending time prior to disposal, supporting a circular economy. Waste residuals (e.g. drinking water treatment residuals, wood waste, vegetative waste) will be modified (through metal additions, heat treatment, pelletizing, and binder addition) for and evaluated for dissolved P removal from agricultural runoff.. Treatment potential of modified waste media will be measured using flow through lab scale reactors constructed out of 0.75-inch diameter PVC pipe. Columns will be completed in triplicate for each media. Influent and effluent samples will be collected every 5 to 10 hours until effluent P is >50% of influent P. Ortho-phosphorus will be measured in collected samples using a discrete analyzer (Seal AQ300) at UWGB. Media will be designed to maximize P sorption capacity, hydraulic conductivity, mechanical strength, efficacy in high flow systems (< 10 min retention times), and reuse potential; minimize toxic side effects, energy consumption, and cost, critical to adoption. Results from flow through analysis will guide selection of reactive media deployed for field evaluation.

Abstract Name: The Influence of Prior Exposure to Weapons on the Weapon Focus Effect

The proposed study aims to further investigate if ownership of firearms decreases the weapon focus effect (WFE). When a weapon is present during the commission of a crime a witness is less likely to accurately remember details, specifically peripheral details, about the perpetrator's appearance compared to when no weapon is present. It is hypothesized that having prior experience with weapons, through ownership, decreases the WFE compared to no prior experience with weapons.The proposed study will be a 2(Gun Familiarity: gun ownership vs. no ownership) x 2(Weapon Presence: present vs. absent) between subject's design. Participants will come to a lab in groups of 1-10. After receiving and signing an informed consent, participants will watch one of the two mock crime videos that are approximately 42 seconds in length. Both videos depict a mock robbery in the woods where a young woman carrying a backpack is approached by a man who robs her. The robber either only uses his words while holding a backpack to demand her belongings (weapon absent condition) or holds a rifle to demand her belongings (weapon present condition). After watching the mock crime, participants complete filler activities for 20 minutes. Then, participants complete a survey about what they remember about the perpetrators' appearance, select from a 6-person target-present line-up, rate their confidence for the selection, and complete demographic information. Students will be thanked for participating and community members will receive $10.00.The accuracy of participants descriptions will be calculated (total correct details/(total correct + incorrect details)).A series of 2X2 factorial ANOVAs will be used to see if Weapon Presence and Gun Familiarity affected the accuracy, the number of correct details, and the number of incorrect details reported. We expect that those who own firearms will have higher accuracy compared to those who do not own

Abstract Name: The Mesoscale Conditions that Contributed to the development of the Morton, Texas Tornado on 23 May 2022

On 23 May 2022, the participants of UW-Whitewater's Field Course on the Forecasting and Verification of Extreme Weather witnessed a tornado in west Texas. The official tornado report had tornadogenesis occurring at approximately 0007 UTC 24 May 2022 (7:07 pm CST 23 May 2022). Based on synoptic-scale (i.e., large scale) conditions most of west Texas from the US-Mexico border into the Texas panhandle were under the threat of severe weather on this day. While in the field and in the post-mortem analysis of this day it was determined the mesoscale conditions were the main factor as to why a significant tornado occurred in the west Texas region near Morton. Mesoscale conditions were evident during the course's morning weather briefing using various mesoscale forecast models. As the day progressed and conditions changed slightly, adjustments were made by the course participants that allowed them to witness the development of the thunderstorm that would end up producing a dust storm (with straight-line wind gust up to 80 mph) and large hail (1.5 – 2.5 inches in diameter). In the post-mortem analysis, a detailed analysis of the mesoscale conditions was performed with additional data from mesoscale networks around the west Texas region. This post-event analysis did find that a localized area of enhanced shear formed near the Morton area due to a surge of dry air out of eastern New Mexico. Preliminary results show that this surge of dry air interacted with an outflow boundary from the earlier developing thunderstorms. The interaction of these differing boundaries created a small area of enhanced lift and wind shear that allowed one of the on-going thunderstorms to intensify and produce an EF2 tornado that occurred 7 miles north of Morton, which the course participants witnessed.

Abstract Name: **Mapping Historic Properties and Landmarks in Eau Claire with ArcGIS StoryMaps**

Through this project, we aim to work closely with the City of Eau Claire to create enhanced and interactive GIS maps of local and national landmark designations in the City. Currently, there is a lack of digitally available resources on the City's historic preservation efforts. Creating these enhanced maps will now provide more access to individuals that has not been executed yet. These maps would help property owners understand the history and value of their property. Many of these property owners do not have important documentation on the history of their property that could be useful to them for future decision-making and/or overall knowledge of their property. Being well informed reduces the pitfalls that owners may face when making improvements without first contacting the City to see what is allowed.

Abstract Name: **Floating Wetlands Garden for Bioretention Basin**

This research aims to enhance water quality in a bioretention basin by adding an additional layer of aquatic plants in the form of artificial floating wetlands. The water basin mimics natural aquatic systems that provide a variety of ecological services including flood abatement, nutrient uptake, and sediment removal in retained waters. This mitigates pollutant entry into adjacent aquatic systems. An additional ecological service this project explores is the ability to plant species that can produce edible vegetation, in contrast to current research that focuses on nonedible wetland plants. A set of 5 different cool weather and warm weather tolerant plant species suitable to North Carolina climate will be analyzed for germination, growth rates, and metal uptake. Plants will be grown in an indoor hydroponics system to mimic the outdoor bioretention basin growing conditions before being tested outdoors. It is essential to examine the growth of vegetation in polluted wetlands to determine which species will grow the best in excessive levels of nitrogen and phosphorous. Growth will be determined by recording root length and overall plant height, as well as the quality of the produce. Further chemical analysis of metal uptake will provide information on the safety of plant consumption. This would take the impact of the hydroponic system from simply runoff nutrient removal from the environment to the addition production of produce.

Abstract Name: **The Effect of School Funding Disparities on Economic Inequality**

Since the 1980s, the United States has experienced increased income inequality, which has fueled a variety of social, economic, and political concerns regarding the state of the American Dream and the true nature of opportunities available throughout the country. One major contributor to the ability of impoverished peoples to climb up the socioeconomic ladder has been the attainability of education; however, common barriers to quality education exist in our society that have prevented the classroom from reaching its full potential as an enabler of equity. These barriers to quality education are the focus of this research project, which aims to study the effect of disparities in school district funding on economic inequality.In order to study this, an instrumental variable method approach is used (to allow for causal inference in non-controlled experiments) with a variety of data sources from federal agencies like the U.S. Departments of Commerce and Education and research labs such as Opportunity Insights at Harvard University, and other data sources in order to provide an empirical analysis component to the project. This is combined with models in machine learning to model the aforementioned relationship in a more accurate fashion than the linear regressions that are typically utilized with instrumental variables.From an initial analysis, we expect a statistically significant relationship between certain school funding policies (and the corrosponding funding disparities) and the rates of economic mobility in their corresponding communities. While preliminary, these observations will provide groundwork for further study in this burgeoning area, and will allow for us to make detailed policy recommendations in the future in order to help remedy this source of inequality.

Abstract Name: **How can ponderosa pine seedlings be propagated to improve drought resistance in the field?**

Ponderosa pine, a widespread species in the western US, is a valuable species economically and environmentally. The preservation of this species is important for the ecological health of many forests due to increased temperatures, drought, and frequency of forest fires. Reforestation efforts following fire and timber removal often fail because seedlings propagated in greenhouses are not resilient to stressful field conditions. To increase seedling field survivorship, drought resistance, and to decrease mortality rates, we implemented a number of treatments in the greenhouse during the initial propagation. The treatments were a manipulation of water supply and different types of fertilizer, tested with seeds collected from varied elevations. After threemonths of growth in the greenhouse under these treatments, we measured height and both shoot and root biomass of the seedlings. We also measured days to mortality on a subset of the seedlings. Seedlings subjected to drought treatment and amino fertilizer grew shorter but survived longer. These seedlings allocated more biomass below ground, which likely contributed to their longer survivorship in the days to mortality test. However, despite the potential benefits these treatments conferred to seedlings in the greenhouse, all seedlings experienced nearly 99% mortality after they were outplanted to a nearby field site. We suspect that most of this mortality was due to frost-heaving, a process whereby seedlings can be pushed out of the ground during frost-thaw cycles that occur in soils in the winter, and is exacerbated by the creation of bare patches of soil around the seedling during planting.

Abstract Name: Pride Versus Prejudice: A study on the approach to race and sexuality by faith affiliated counselors and counselors in training

Despite training inmulticultural counseling, counselors demonstrate a gap in integrating what they have learned into clinical practice (Owen et al., 2011; Rutherford et al., 2012). The purpose of this mixed methods study is to examine the responses of religiously affiliated counselors torace and sexuality. Thirty-five participants completed the following scales measuring religious affiliation and multicultural competency: Quest scale (Baston; Schoenrade, 1991), I/E-R Scale (Gorsuch; McPherson, 1989), Revised Religious Orientation Scale (Gorsuch; McPherson, 1989), Multidimensional Cultural Humility Scale (Gonzalez et al., 2021) and The Lesbian, Gay, Bisexual, and Transgender Developemnt of Clinical Skills Scale (Bidell, 2017). Participants answered open ended questions addressing theirbeliefs and clinical training. Themes emerged wherein participants described issues of race and sexuality within their training; some demonstrated prejudice while others demonstrated open-mindedness, both groups used faith to justify their ideas. We found significant positive correlations between counselors' self-assessed competency in their LGBTQ+ clinical skills and quest orientation (N=35, r=0.348, 0.05), self-awareness and fundamentalism (N=29, r=0.416 0.05), as well as significant negative correlations between extrinsic religiosity and supportive interactions (N=35, r=-0.336, 0.05), and intrinsic religiosity and LGBTQ+ clinical skills (N=35, r=-0.418, 0.05). This suggests that quest oriented participants, who allow themselves to wrestle with their religion,had higher self-assessed competencein providing care to the LGBTQ+ community as opposed to those who are more traditionally religious.Dataalso suggests that those who have rigid religious beliefs had more self-awareness. Overall the data suggest that a counselor's faith influences their ability to work with issues of race and sexuality. By having a clearer understanding of the relationship between religiosity and multicultural competency, counselor training can foster integration of multicultural principles in counselor practice.

Abstract Name: Enhancing Healthcare with Real-Time Body Gesture Recognition: The DroneX Solution

Due to the increasing popularity of drones in mainstream entertainment and business sectors and the limitation of controllers, we realized the need for hands-free control and expansion of user-defined commands that hardwired controllers cannot support for drones. This project uses the DJI Tello drone to recognize different commands through body gestures. The DroneX should distinguish between a series of body gestures and return the desired commands to the Drone. We have implemented the MediaPipe tool by using its APIs to currently recognize eight gestures; stop, take/up, land, forward, backward, left, right, and flip. We also used OpenCV and its APIs to display the image on a separate device. The DJI Tello drone is used as the environment for deploying the DroneX software. The Tello is connected to a separate device via Wi-Fi limited to 100 meters. It has a camera that is 5 megapixels (2592 x 1936), has an 82.6-degree field of view, and is HD 720 p. We are aware that DJI RyzeTM has a drone called the DJI Spark that uses hand gestures to issue commands. We are using body gestures to have a better range than hand recognition. Social media platform Snapchat also had a drone called Pixy that would take a selfie of the user, but Snapchat discontinued the efforts to develop it in August 2022. Pixy would just take a picture and return it to the user's hand. Currently, the DroneX project has some limitations, such as working in low-light flight conditions, harsh environment flight, and in an area of multiple detected objects. In future work, we plan to overcome the mentioned limitations, detect gestures at big distances, and include larger body gestures in our dataset.

Abstract Name: **Oxidative Reactivity of Biomimetic Nonheme Diiron(III)-Peroxide Compounds**

Diiron(II) compounds of the anion of the dinucleating ligand N-EtHPTB (N, N, N′, N′-tetrakis(2-benzimidazolylmethyl)-2-hydroxy-1,3-diaminopropane) and the bridging anion (O2X) of either HO2PPh2, HO2PMe2, or HO2AsMe2 were synthesized. Upon reaction with O2 in MeCN at -40° C, these compounds form metastable O2 adducts previously described as (mu-eta1:eta1-peroxo)diiron(III) complexes with 1,3-O2X bridges. When warmed to -30° C, the O2PPh2-bridged peroxo complex irreversibly converts to a peroxo complex with the O2PPh2 moiety in a terminal position on one iron. The same effect can be produced by adding OPPh3 to the O2PMe2-bridged complex. The oxidative capabilities of these different peroxo species are compared with each other by reaction with various substrates. The effects of bridging O2X versus non-bridging O2X ligands are discussed, as well as the effects of electronic differences in the O2X ligands and the effects of coordinated OPPh3.

Abstract Name: **Development of a Cable Checkout Board for the SuperCDMS Experiment**

Dark matter is an invisible form of matter that is inferred from its gravitational effects on visible objects to account for 85% of the matter in the universe. One of the leading hypotheses of the nature of dark matter is that it is composed of weakly interacting massive particles (WIMPs). The Super Cryogenic Dark Matter Search (SuperCDMS) experiment is designed to search for WIMPs that elastically scatter off of nuclei. We present the results of a research and development project to check SuperCDMS readout cables for possible defects before deployment.Readout cables enable communication between the cryogenic detectors and the warm electronic system that controls, monitors and processes signals. SuperCDMS utilizes approximately 30 pairs of readout cables connected together, each of which consists of 100 wires. A specialized cable checkout device will identify circuit shorts and breaks in a time-efficient manner before their deployment in a cryostat where a defect could impact the acquired data. This presentation describes the different stages of the research and development process, including background research of electronics used in the experiment, printed circuit board design and manufacturing, hardware testing and software development.

Abstract Name: **Synthesis and miscibility characterization of stimuli-responsive polymers for applications in architectural coatings**

Polymers are long repeating chains of atoms or molecules with applications as additives in a wide variety of products. Stimuli-responsive polymers change their properties when exposed to different environmental conditions such as temperature, pH level, and salt concentration. Controlling polymer structure through precise synthesis techniques directly determines the stimuli-responsive properties of these polymers. Stimuli-responsive polymers can be used as dispersants for titanium dioxide particles (TiO2) within architectural coatings, such as paints, primers, and stains. Titanium dioxide is an opacifier in architectural coatings, blocking light from passing through. By controlling the polymer environment, the stimuli-responsive polymers can improve the dispersion of titanium dioxide, lowering the amount of titanium dioxide needed in the coating while increasing the opacity of the coating. Lower amounts of TiO2 lowers cost for consumers as well as environmental impact from titanium mining and processing. Synthesis of diblock and triblock copolymers with controlled copolymer composition and stimuli-responsive properties using activators regenerated by electron transfer atom transfer radical polymerization has yielded smart polymers with observable switchable miscibility properties. Characterization methods of the properties of these polymers includes nuclear magnetic resonance spectroscopy, gel permeation chromatography, and pendant drop tensiometry. Nuclear magnetic resonance spectroscopy provides evidence of synthesis success and yield proportions by indicating which functional groups are present and whether stimuli-responsive structures have been synthesized. Gel permeation chromatography allows us to identify the polymer molecular weight and weight distribution, in order to predict the smart properties of each polymer. Pendant drop tensiometry provides data on interfacial tension at several temperatures, pH levels, and concentrations, to predict how the polymer will behave as dispersants for TiO2 in different architectural coating environments. Determining how stimuli-responsive structures and properties are related by polymer synthesis is essential to optimize materials for the dispersion of titanium dioxide in architectural coatings.

Abstract Name: **MenomiNet: A Prototype Network for Real-Time Public Lake Data**

Currently, there is a high cost and low frequency of data collection on the Red Cedar watershed in the Midwestern United States. The existing processes involved with eutrophic lake monitoring put volunteer health at risk. Nevertheless, the regular collection of eutrophic lake data is important because it can identify which rural, suburban, and urban areas are at risk of having excess levels of nitrogen and phosphorus in their water supply. Moreover, in the Red Cedar watershed, there is a severe backlog in data collection of multiple ecological metrics. We developed the research question, what is an efficient and cost-effective way to gather lake health data in real-time? Using a submersible sensor suite, our team gathered four different kinds of lake health metrics: temperature, dissolved oxygen, turbidity, and pH. This data was broadcast through a LoRA (long-range) transmitter network at distances of approximately 500 feet between transmitter and receiver. After obtaining a running log under several physical and weather conditions, including during interactions with waterfowl, as well as under multiple time frames, ranging from multi-hour stretches in the day to overnight/multi-day readings, we stored the data into log files that capture the limnological data over time. We also began developing a web dashboard to publish this data in a readable format. Our low-cost LoRA approach uses components that cost less than $1000 per node and drastically reducethe cost of lake health monitoring relative to current state-of-the-art approaches. This may empower not only academics or students but also groups of citizens, lake associations, and lake districts throughout the Red Cedar watershed to allocate funds and resources towards local monitoring projects. This level of coordinated effort would provide continuous, distributed lake health data for the first time in the watershed's history.

Abstract Name: Engagement and Retention of Volunteers

Volunteers are an integral part of any nonprofit organization. It is essential to have volunteers engaged and committed to their work at an organization because this will increase volunteer retention (Faletehan et al., 2021). Engaging and retaining volunteers can be challenging in an environment where volunteers change every few months, and each nonprofit presents unique site-specific challenges. When people feel connected to an organization and community, their engagement with service increases (Hellman et al., 2006). The process used to onboard volunteers is integral to creating healthy, sustainable relationships (Rafe, 2013; Faletehan et al., 2021).The purpose of this research is to examine strategies for engaging and retaining volunteers in Nonprofit businesses in general, explore the specific roles, goals, and sense of purpose of the volunteers at a youth-based community center in the New York Capital Region, and create a targeted center-specific training for their volunteers and administrators. The study sample consists of college student volunteers for the after-school program at the center. The questions were created from the literature on engagement and retention to investigate the volunteer mindset (Burns et al., 2006; Rafe, 2013).The focus groups will provide insight into specific volunteer experiences, knowledge, and effective volunteer strategies. It will allow us to learn what volunteers want to accomplish while volunteering and discover what would encourage them to continue. Utilizing the focus group data combined with a review of the current research in the field, I will provide the center with strategies for engagement and retention, a training for the volunteers, and a structure for the volunteers that will facilitate retention. Gaining a greater understanding of how to effectively engage and retain volunteers is essential, and learning from the volunteers themselves will help prepare future volunteers and retain current volunteers (Hellman et al., 2006).

Abstract Name: A Comprehensive Survey to Address the Implementation of a Campus Wide Composting Program

University Composting plans have been shown to bevery beneficial for the local environment and help to lower waste and conserve water usage for community gardens on campus. The implementation of a campus composting program can help to lower greenhouse gas emissions as well as provide local gardens with nutritious compost for their soils and an educational medium for individuals to learn sustainable practices. The intention of this research was to identify the best strategies to use to implement a successful and effective campus wide composting program for the University of West Florida's Pensacola campus. In order to determine the most appropriate way to build a comprehensive and efficient composting program, a survey was used to assess the understanding, preferences and intentions of individuals on campus related to composting. Students, faculty, and staff were evaluated on their overall understanding of composting in general, awareness of the positive impacts of community composting, their willingness to participate in the program and educational workshops, and their overall motivation for a campus composting program. The survey was also used to determine whether a quick composting tutorial would influence participants willingness to participate in the campus wide program. The survey results were used to create a detailed plan of implementation, along with a proposal of funding for specific equipment and maintenance needed to run the program. This research aims to raise interest and involvement in sustainable practices on campus, to provide students with future opportunities for research and sustainable action locally and to help launch the campus composting program.

Abstract Name: **Using Gene Knock-Outs to Study WXG/LXG Operon Expression**

Every bacterial cell contains protein secretion systems which are essential to their propagation and survival. The Type VII secretion system (T7SS) is required for virulence in some Gram-positive bacteria. Proteins secreted by the T7SS include the WXG100 family of proteins and the deadly LXG toxins that will terminate nonkin cells without the cognate anti-toxin. Bacillus subtilis encodes its T7SS and primary substrate on a single operon, the yuk operon. Additional substrates are encoded on other WXG/LXG operons. Recently, competition assays demonstrated that using attacker strains with the T7SS knocked-out allowed the prey to survive. This showed that the LXG toxins are substrates of the T7SS. Little is known about these proteins; one outstanding question is about when the bacterium is using these toxins to enact their effect. To answer this, we will directly test the expression of WXG/LXG operons in various environmental and cellular conditions using transcriptional fusions of each WXG/LXG operon promoter with a GFP reporter. Further, we will combine these reporters with knock-outs of key regulators, such as degU or spo0A, which have shown positive or negative regulation on the yuk operon. Expression of the reporters will be determined by measuring the GFP emissions from cell culture in a plate reader and by fluorescence microscopy. Results from these expression studies will reveal regulation profiles of each of the WXG/LXG operons. This data will directly inform on the conditions in which the bacteria may be using these LXG toxins.

Abstract Name: **Enabling a clean-energy economy from U.S. rare earth resources: characterization of low-grade allanite-based ore from Halleck Creek, Wyoming**

Rare earth elements (REEs) have significant value to technologies critical for energy infrastructure and independence, decarbonization efforts, and defense applications. REE supply is heavily constrained to deposits outside of the U.S., making economic and sustainable REE and other critical material recovery from low-grade source materialsparamount to U.S. national security.The goal of this research is tocollect, pulverize, and analytically characterize unutilized REE-containing allanite ores from primary deposits in Halleck Creek, Wyoming to define major mineralogical and elemental compositions.Halleck Creek core (130-kg) and surface (33-kg) samples were crushed to a top size of 4-mm through primary and secondary reduction processes. Mineralogical and total metal analyses were performed on screened size fractions and representative core and surface samples via X-ray diffraction spectroscopy (XRD), X-ray fluorescence spectroscopy (XRF), and inductively coupled plasma optical emission spectrometry (ICP-OES). A mineral liberation study was conducted via scanning electron microscopy with energy dispersive X-ray analysis (SEM-EDAX) to identify allanite and other REE-containing particles in the host rock. Grindability was investigated through standard rod mill laboratory tests to determine optimal conditions to generate 150- and 500-µm 80% passing size (P80) sample lots. The results of this research will identify what and where the value (i.e., REEs, critical materials) is in this uncharacterized allanite ore along with any intrinsic processing constraints.This comprehensive ore analysis will inform activities related to: REE beneficiation from the allanite-ore feedstock and outlining a REE biomining and purification workflow. Ultimately, this research will enable the development and demonstration of a modular, biobased REE biohydrometallurgy process through theDefense Advanced Research Projects Agency (DARPA) funded project titled Synthetic Biology for Biomining of Rare Earth Elements (SynBREE).

Abstract Name: **The Effect of Gerrymandering in the State of Wisconsin as it Pertains to Voter Turnout, the Number of Candidates Running for Office, Contested Districts, and Margin of Victory in Elections**

In 2011 leaders from the Republican party in Wisconsin redrew the voting maps for the state. Their efforts resulted in a heavily gerrymandered map favoring the Republican party, which virtually assured Republican control of state level legislative politics for the foreseeable future. The issue of gerrymandered maps has been litigated at several levels including a hearing by the United States Supreme Court which issued a ruling in June 2019. The Court asserted that drawing voting maps lies within the realm of the state legislatures, and it is not the role of the federal courts to dictate rules and regulation pertaining to state voting maps. This ruling effectively quashed the most likely avenue for voters in Wisconsin to have fair voting maps.The question this correlational research seeks to answer is whether gerrymandering has had a significant cooling effect on voter turnout, the number of candidates running for state senate and assembly and the number of contested districts in the state. Additionally, researchers are interested in whether gerrymandering has resulted in a significant change in the margin of victory for either political party in gerrymandered districts. These variables will be examined by comparing pre and post gerrymandered elections in the state of Wisconsin.Researchers hypothesize gerrymandering has resulted in a significant decrease of voter turnout by district, a decrease in the number of candidates running for state legislative offices, a decrease in the number of contested districts in the state and an increase in the margin of victory in the districts that have been most heavily gerrymandered.

Abstract Name: **Classically Blue: Jazz Music Manifest in Classical Pieces for the Piano**

The goal of this project was to analyze jazz-influenced classical pieces for the piano to gain inspiration for an original composition. To begin, I conducted a survey of academic writing to define the intersection between jazz and classical music and listened to many composers and pieces to pick repertoire to study. Through this process, I honed in on three composers that fit my style and criteria: Nikolai Kapustin, George Gershwin, and Maurice Ravel. In the following weeks, I practiced and analyzed their pieces such as Kapustin's Eight Concert Etudes, Op.40 and Variations, Op.41,Gershwin'sThree Preludes,and Ravel'sLe tombeau de Couperin, M.68. I noted in their works the integrationof jazz harmony into classical forms using techniques such as extended chords, rootless voicings, and blue notes, the use of jazz rhythms such as successive syncopations and swing sections, and a variety of pianistic textures and counterpoint. Then, I began my composition using what I learned. The piece is named Blueberry Islandand is thematically set on Lake Pemigewasset in New Hampshire during the Fourth of July. The opening theme is written using the classical technique, canon, meant to literally portray the children on the lake shore chasing after one another in the summer sun. On the second occurance of the theme, the left hand responds with a countermelody which symbolizesthe White Mountains watching over the lake. A quick three measure transition is very Gershwin-esque, transitioning the story to nighttime. The middle section is in a slower triple meter as the chords become a little bigger, incorporating jazzy extensions, telling the love story on the lake. At last, the A theme returns harmonized with left-hand syncopation inspired by Kapustin's etudes as friends and familydance under the fireworks.

Abstract Name: **Serotonin N-acetyltransferase Inhibitors for Treating Circadian Rhythm Disorders**

Circadian rhythm (CR) dysregulation contributes to mental health disorders, including major depressive disorder (MDD), bipolar disorder (BD), and seasonal affective disorder (SAD). Melatonin has been strongly associated with CR, but despite years of research, many questions remain regarding its role and how it influences mood. The rate-limiting step in melatonin synthesis involves the enzyme serotonin-N-acetyltransferase (SNAT, AANAT). Inhibition of SNAT would be a valuable approach for studying the physiology of melatonin and could be used to treat disorders such as SAD that involve abnormally high melatonin. Published inhibitors have problems with cell permeability, selectivity, and/or potency, which have prevented advancement to testing in humans. We have applied X-ray crystal-based models to modify a previously described indolinone scaffold with polar substituents as well as aromatic rings for conformational restriction to improve interactions with the Coenzyme A (CoA) binding site of SNAT. The synthesis and structure-activity relationship (SAR) from an enzymatic assay of these new indolinone-containing inhibitors will be presented. Our results could lead to a better understanding of SNAT's function and provide an approach to regulating melatonin.

Abstract Name: **Community Engaged Partnerships With Southeast Asian Community Health Liaisons, Leaders, and Health Care Professionals: A Pilot Project on Opiate Awareness, Overdose and Psychoeducation**

Opiate addiction and overdose is a major public health concern that disproportionately affects minority communities, yet little is known about the impact in Southeast Asian communities.1) Pilot a sustainable program of opiate awareness, pharmaceutical awareness, and education in Southeast Asian (SEA) communities. 2) Assess community needs around opiate education, prevention, and medical care for opiate addiction, and 3) Engage professionals (stakeholders) on SE Asian community needs.A three-part model included: 1) A train-the-trainer psychoeducational program delivered by community health liaisons (CHLs), 2) Stakeholder engagement around SEA opiate prevention, overdose prevention/reversal, and care (medical, mental health, pharmacy, and Narcan distribution professionals) and 3) Guided conversations with community leaders. Training sessions were delivered virtually, whereas community sessions varied in their delivery methods (verbally in a community's native language). Three community health liaison training sessions involved a train-the-trainer psychoeducational model on the nature of opiates, drug effects, pharmacist-patient communication, stigma, and community comfort in discussing opiates. A pharmacy professor delivered five two-hour training sessions for the CHLs. We held stakeholder conversations with pharmacy students, physicians, addiction counselors, and clinic supervisors. Common barriers identified were funding and availability of translators, stigma, transportation, and community awareness of resources available. Significant needs exist in SEA communities. First, we observed a lack of knowledge and awareness around opiates across communities. Program materials delivered in a narrative format were useful (per leader feedback). Several leaders and community members expressed concern about the community proliferation of online purchases of drugs marketed as painkillers. Third, community members may lack awareness of risks around opiates and addictive potential. Cultural factors and stigma prevent community members from seeking information and treatment, and there is a need for Narcan education and linguistically and culturally competent providers.

Abstract Name: **MENtal Suppression: Toxic Masculinity's Impact on Men's Mental Health and Trauma from a Woman's Perspective**

According to Tina Maschi, “Male youths are overwhelmingly the victims of nonsexual crimes, such as homicide, aggravated assault, simple assault, robbery, larceny, and vandalism,” (Maschi, 2006). Many of these young boys are also victims of toxic masculinity, the “harmful social norms about how men should behave that lead to misogyny, homophobia, violence, and mental health issues” (Fisher, 2019). These norms have become ingrained into the traditional male psyche. A common societal expectation for men is for them to hide their emotions and “be a man”; however, this only pushes this large demographic of individuals away from forms of therapy, such as poetry therapy, proven to help “enable the person to facilitate his or her own understanding of feelings and lifestyle” (Lerner, 1991).There is much scholarship on the subjects of men’s health, the impacts of toxic masculinity, and poetry therapy individually. However, the connection between the categories has been significantly overlooked in academia. The goal of “MENtal Suppression,” my slam poem used as a call-to-action regarding men’s mental health, is to acknowledge these concepts in a cohesive setting to ultimately show how toxic masculinity restricts their freedom to write creatively without judgment. This restriction ultimately prevents men who have suffered trauma from utilizing poetry therapy in their healing process.“MENtal Suppression” uses the ethos methodology presented within Tupac’s “Keep Ya Head Up” (1992), reversing the original message of encouragement and solidary from a man towards women to a woman’s support for men regarding their mental health. In doing so, the poem presents the urgent need to reform the view and expectations of men within society.

Abstract Name: **Development of nerve replacement method using a gelatin scaffold platform for the three-dimensional culture of neural stem cells.**

Three-dimensional (3D) biopolymer scaffolds, such as those made of gelatin, offer a culture system that could create a better environment for stem cell proliferation and growth by providing a more physiologically relevant microenvironment. 3D biopolymer scaffolds also offer the potential for cells to be initially cultured in vitro and then placed within the human body, creating a platform for new tissue to grow. Adult rat hippocampal progenitor cells (AHPCs) can differentiate into neurons, glial cells, and astrocytes in vitro. When paired, AHPCs and 3D gelatin scaffolds could offer a potential therapy to replace lost nerve tissue by creating a bridge between severed nerves. Initial experiments developed cell culture protocols for AHPCs within several different configurations of 3D porous gelatin scaffolds. We demonstrated the growth and viability of AHPCs utilizing fluorescent microscopy and propidium iodide assays. We have also demonstrated that these scaffolds support cell proliferation and differentiation through immunocytochemistry. We have also identified occurrences of colocalized staining of RIP (oligodendrocyte marker) and Ki67 (proliferation marker) which implies the presence of oligodendrocyte precursor cells. Further characterization of AHPCs into neurons, glial cells, and oligodendrocytes is currently being conducted to understand differentiation. This work has the potential to advance peripheral nerve tissue engineering.

Abstract Name: The Crime of Rebuilding Babylon

The land of Babylon lies upon the ruling of the most notorious and brutal dictators of all time. Since committed as the ruler of the Republic of Iraq, Saddam has made his mission to hoard every means necessary to secure his position as leader. One of the things that he utterly destroyed was his land. He poisoned the soil that stood beneath the hanging gardens of Babylon. All of that rich history was fractured by the touch of Saddam Hussein. The rich history of Babylon was tarnished by a narcissistic dictator that lay upon Babylon's soil for 30 years. That dictator is known as Saddam Hussein. Iraq is currently known as the poisonous field of broken buildings due to war. The authentic Iraqi tradition is wealthy with the architecture and history of Babylonian, Sumerian, and Assyrian remains. Sadly most of what Iraq is known for now is 30 years of poverty led by Saddam Hussein. Saddam Hussein Abd al-Majid al-Tikriti was a brilliant and educated politician who exceeded in diplomacy and authenticity to people. Hussein demanded that most of his palaces mimic artificial royalty by demolishing the grounds of Babylon and rebuilding a palace that suited his position. The rebuilding of Babylon by Saddam Hussein is a naturalistic, narcissistic, and a crime to all historical architecture. The 30-year dictator fulfilled his infatuation with other ancient civilizations by walking through a time capsule of cultures that dominated power and architectural impact. His fixation with other ancient civilizations fulfilled his need for power. Without Hussein's desperate need to fulfill his ego, there wouldn't be a narcissistic design in architecture.

Abstract Name: Associations of Obstructive Sleep Apnea (OSA) Severity and Excessive Daytime Sleepiness, Insomnia, and Fatigue in Women

Introduction/Background: The apnea-hypopnea index (AHI) is the measure of OSA severity. Categories of OSA severity, established primarily in men with OSA, are Mild: 5<=AHI<15; Moderate: 15<=AHI<30; and Severe: AHI ≥ 30. It is well established that excessive daytime sleepiness (EDS) often gets worse in men with moderate-severe OSA. It is unknown if insomnia and fatigue, symptoms more common in women with OSA, and if EDS in women, also worsen in moderate-severe OSA. The purpose of this study is to determine if insomnia, fatigue, and EDS worsen with increased OSA severity in women.
Methods: In an ongoing study of continuous positive airway pressure adherence in women, the baseline sample of women with complete data before treatment (N=43) were middle aged [Mean = 49 years (SD 14)] years), primarily white (76.4%), and not partnered (52.0%). Common symptoms found in women with OSA were measured using the Insomnia Severity Index (≥15 = moderate-severe insomnia), Promis Fatigue Scale (t-scores ≥ 50 = worse fatigue), as well as Epworth Sleepiness Scale (≥13= moderate-severe EDS). One-way ANOVA determined if there were statistically significant differences in means on the measured symptoms amongst the categories of OSA severity.
Results: EDS did not worsen: Mild [Mean=14.0 (SD=5.9)], Moderate [Mean=11.2 (SD=6.1)], Severe [Mean=14.7 (SD=4.4). Insomnia showed a tendency to worsen with increased OSA severity: Mild [Mean=16.2 (SD= 5.8)]; Moderate [Mean=16.6 (SD= 4.8)], Severe [Mean=19.2 (SD=6.1)]. Fatigue showed little association with increased OSA severity: Mild [t-score= 58 .8 (SD= 2.3)], Moderate [t-score=58.8 (SD= 2.3)], Severe [t-score= 57 (SD= 2.3)]. None of these means showed statistically significant differences (p>.05).
Conclusion: Women reported a high burden of EDS, fatigue, and insomnia at all categories of OSA severity. Clinicians should not expect that women with mild OSA will experience a lower symptom burden than those with moderate or severe OSA.

Yingzi Ma *Chenfeng Ke*

Abstract Name: **Digital light processing enabled 3D-printing of thermo-responsive polyrotaxane hydrogels**

Rapid advancement in 3D printing technology has drawn research attention to developing 3D-printable functional materials includingbiocompatible hydrogels. In particular, thermo-responsive hydrogels–capable of undergoing reversible phase transition at specific temperatures–find a wide range of biomedical applications such as drug delivery, cell encapsulation, and tissue repair. In this work, I would like to present our recent design of 3D-printed thermo-responsive polyrotaxane hydrogels using Digital Light Processing (DLP). DLP uses photopolymerization to print three-dimensional objects layer-by-layer with high resolution. Polyrotaxane-based hydrogels, specifically,exhibit temperature-dependent size switching due to the controllable sliding motions of cyclodextrins macrocycles on the polymer axles. The UV curable resin is composed of methacrylate-functionalized Pluronic P123 (PEO20-PPO70-PEO20-MA2)–an amphiphilic, triblock copolymer comprising poly(ethylene oxide) (PEO) and poly(propylene oxide) (PPO)–and methylated-β-cyclodextrin(Me-β-CD). In water, β-CD forms inclusion complexes with P123 selectively on the PPO block because of favorable hydrophobic interactions. To prevent the formation of β-CD aggregates which leads to high viscosity, Me-β-CD was employed to reduce the hydrogen bonding interactions between neighboring CDs. Well-tailored UV curable resin possesses low viscosity and fast-curing kinetics suitable for DLP printing. Upon UV activation, P123-MA2 threaded with Me-β-CD undergoes free radical polymerization with acrylamide co-monomers to form covalently crosslinked hydrogels. Me-β-CD/P123 polyrotaxane hydrogels exhibit phase transition above the lower critical solution temperature (LCST) around physiological temperature due to the hydrophobic aggregation of the polyrotaxanes. Our 3D-printed polyrotaxane hydrogels are expected to exhibit temperature-dependent swelling behavior which can be further tailored toward various biomaterial applications.

Abstract Name: **A Life of Invisibility of the LGBTQIA+ community within The Republic of Trinidad and Tobago**

The Republic of Trinidad and Tobago had, up until 2018, criminalized homosexuality among male citizens only. Even though homosexuality has been de-criminalized, there are currently no protected rights in the Constitution for the LGBTQIA+ community. There are no rights regarding gender identity, sexual identity, same-sex marriage, civil unions, or adoption. LGBTQIA+ people do not have equal access to health services, nor protection from discrimination in employment and education. School systems do not offer sex education, no discussions in the legislature about issues such as gender-neutral restrooms. The purpose of my research is to amplify the voices of the LGBTQIA+ community in Trinidad and Tobago and bring to light the experiences of people living without basic protected rights. My IRB-approved research involves face-to-face and video interviews with12 LGBTQIA+ peopleand NGO allies. Through the interviews, which will be completed by January 14, 2023, I am discovering (a) how participants' live realities affect their mental health, the ability to gainful employment, and safely live their true selves. Reasons, why the Queer community has been left out of legislation aimed at Equity and Inclusion, have been morecultural in nature, creating societal problems within the diverse gay community in Trinidad and Tobago. The existence of harsh discriminatory lawshas forced many difficult choices resulting in living in fear, discrimination, violence, and in some cases death. The government has stagnated interest in generating legislation that protects LGBTQIA+ groups. These interviews are audio- or video-recorded, and excerpts will be used in a documentary video telling their stories, forced to be 'invisible'because of their sexual preference, and highlighting legal realities for LGBTQIA+ citizenry in the Republic of Trinidad and Tobago.My poster presentation will include de-identified information about participants, key opinions, quotations from the interviews, interview themes, and a QR code for the video.

Abstract Name: Nanoporous Bi-layer Structures for the Electrochemical Conversion of Carbon Dioxide to value-added chemicals

Prior research has shown that alloys of copper (Cu) with metals such as silver (Ag) or tin (Sn) have the ability to catalytically convert Carbon Dioxide (CO2) into economically useful products such as ethylene, methane or formate. Varying the particle size, surface morphology, texture, porosity and composition of these catalysts have been shown to dramatically change its electrocatalytic properties. However, these studies have been limited to the use of conventional liquid-phase reactors, which severely limits the rate of conversion, as determined by current densities of ~10 mA/cm2. Furthermore, translation of this catalytic performance to industrially relevant scales is not trivial, and is known to be highly sensitive to the local reaction environment, which in turn changes as a function of reaction rate.In this current work, we utilize dc/rf magnetron sputtering to deposit thin layers of copper, silver and specific combinations of the same on both stainless steel and gas-diffusion layer (GDL) substrates. Detailed characterization of these bi-layer thin films has been done through X-ray diffraction, Scanning electron Microscopy (SEM) as well as Energy-dispersive X-ray (EDX) analysis to determine relative ratios of the metals present, as well as changes in texture and porosity. Herein, we present on preliminary results showing the electrocatalytic performance of these thin films for the conversion of CO2 inside both liquid-fed conventional H-Cell reactors, as well as gas-fed flow reactors.

Abstract Name: The effects of Time Poverty on Stress and Life Satisfaction in university students and workforce participants

In an increasingly connected world, where work and school are just a click away, work-life has integrated more and more into personal-life taking more of one's personal time. Advancements in telecommunication, telecommuting to work, has contributed to an 'always on' culture that values productivity and always being available. In light of this, there is limited research on perceived time poverty. This study examines perceived time poverty in conjunction with environmental demands and their effects on stress and life satisfaction in the context of university students and workforce participants. A survey using scales on time poverty, irritation, and environmental demands were used in a quantitative analysis to measure their effects on stress and life satisfaction.

Abstract Name: **Development of an Internet Connected Remote Solar Module Current-Voltage Characterization System**

In recent years solar power has emerged as a promising sustainable energy solution within the renewable energy sector. The photovoltaic performance of solar panels degrade over time causing shift of its electrical characteristics. In addition, if major defects are generated, the current-voltage (I-V) characteristics change drastically. Therefore, by periodically acquiring and analyzing I-V characteristics of field deployed solar modules, we can monitor the health of the modules and also predict their power output under different environmental conditions. In this work, we have built an internet-connected remote experimental setup to measure the current-voltage (I-V) and power-voltage (P-V) characteristics of a solar module (or an array) of up to 300 Watts. The system consists of a DC electronic load, electronically controllable relays, and a Raspberry Pi single board computer (SBC) with integrated wi-fi capability. We have developed a python program which is deployed on the SBC. The python program communicates to the electronic load through USB serial interface. In a typical experiment, the electronic load is first set in constant voltage mode and then the voltage value is increased in small steps until it reaches the open-circuit voltage of the solar module. In each step, the current, voltage, and power values are measured and acquired by the SBC which are then used to trace the I-V and P-V curves. The Raspberry Pi transmits the data to the cloud which allows the I-V and P-V data to be accessed and viewed remotely. To enable full remote operation, we have created a Windows compatible graphical user interface (GUI) program using Microsoft Visual C#. The GUI allows running an experiment on-demand, logging continuous data throughout a day or multiple days, and analyzing the data to extract important electrical parameters of the module. Details of the system design, programming, and sample data will be presented.

Abstract Name: **Identifying the Impact of Geographic Disparities in Adult Smokers**

The purpose of this project is to identify geographic disparities inadult smokers within Tulsa County and Osage County. Our community campus is located near the boundary of these two counties. A statistical comparison will be made to both state and national data. Smoking-Attributable Mortality data for the state of Oklahoma will be compared to survey data (BRFSS)for the purpose of recognizing the implications of smoking as an identified cause of death. Public Health initiatives regarding tobacco use are relevant and significant.Cigarette smoking is the leading cause of preventable death in the United States, causing approximately 480,000 deaths each year. Smoking has impacts on the smoker, as well as those individuals exposed to secondhand smoke. About 2.5 million people have died from medical problems caused by second-handsmoke since 1964. In addition, thirdhand smoke is persistent contamination by gases and particles from smoke that become embedded in surrounding household materials. These substances can be measured and do contain carcinogens. Cigarette butts contribute approximately 300,000 tons of potential microplastic fibers to the aquatic environment annually. The scope of this project includes comparison of CDCall-cause tobacco mortality data(SAM)and BRFSS data. Accessible data sources managed bythe US Office on Smoking and Health (OSH)can provide insight into public health disparities to describe impacts that are primary, secondary, tertiary and environmental.

Abstract Name: **Gender Effects and Peer Influences on Risky Driving**

Background: Distracted driving contributes to over half of all motor vehicle collisions (MVCs) involving teenagers. Driving with other teenagers is a risk factor for MVCs. Male teen drivers may be more influenced than female teen drivers. Teen male drivers also report driving more recklessly and with more distractions than teen female drivers, despite their perception that they are safe drivers.Method: Male (n=35) and female (n=45) newly licensed drivers reported the number of days they engage in distracted driving behaviors. They also reported their own driving habits and those of their closest friends on the Driving Behavior Questionnaire.Results: Compared to female drivers, male drivers reported a higher frequency of texting while driving, t(78)=2.41, p=.02, and committing driving violations, t(78)=2.32, p=.01. Self-report and report of friends on risky driving were correlated (driving errors, r=.65, p=.01; driving violations, r=.52, .01). Both males and females rated themselves as committing significantly fewer violations than friends, t(78)=2.84, p=.01, and t(78)=4.20, .01, respectively. Females' self-reports of driving errors were significantly lower than reports of friends' driving errors, t(78)=2.01, p=.04. Males' self-reports did not significantly differ from reports about their friends, t(78)=.96, p=.34.Discussion: Findings support a need for gender-specific teen driver injury prevention and education initiatives. Although teen males overestimate their driving safety, when directly compared to peers, female teens may similarly underestimate errors. Teenagers' opinions of their driving behaviors and risky driving practices might be the focus of prevention initiatives. Future interventions targeted at peer influences on teen driving safety should be created.

Abstract Name: **Implementation of Vertically Integrated Projects (VIP) Program to Expand the Participation of Underrepresented Groups**

Research shows the underrepresented groups participate in undergraduate research at lower rates than their peers, and undergraduate research is difficult to scale-up to serve all students. The Vertically Integrated Projects (VIP) Program is a transformative approach to enhancing higher education by engaging undergraduate students in ambitious, long-term, large-scale, multidisciplinary project teams that are led by faculty. VIP model is designed to serve all students and has proven to be adaptable to varied institutions. Process of developing a VIP Program that successfully integrates research experiences into curriculum at a liberal arts college and its impact on students, faculty and staff will be presented. The challenges, possible remedies, and the educational benefits gained from this model will also be discussed using examples from several US and international institutions.

Abstract Name: Bioreactor for Corneal Tissue Engineering

Millions worldwide are negatively affected by a shortage in transplants used to treat patients with visual impairment caused by corneal damage[1]. Developments in tissue engineering of human corneas can increase the supply of corneal transplants to resolve the donor shortage. A bioreactor and a pressure control system to impart mechanical strain to growing tissue was developed and optimized to mimic the in-vivo corneal environment. Understanding how mechanical signals affect the protein expression of growing corneal cells can lead to more effective methods of engineering accurate corneal transplants. Previous studies have shown that corneal fibroblasts grown under physiological levels of mechanical strain differentiated into quiescent keratocytes, which have lower α-SMA protein levels compared to myofibroblasts, and are more representative of normal corneal tissue [2]. Corneal fibroblasts were isolated from the stromal layer of harvested New Zealand white rabbit eyes, and successfully seeded in our bioreactor system. Our bioreactor system allows us to study the effects of different levels of mechanical strain as well as electromagnetic stimuli on α-SMA protein levels in growing corneal tissue. These studies will help to produce more efficient methods of engineering new corneal tissue for transplants.

Abstract Name: Dishing up Feminine Icons: The Business of Communicating Roles in The Post-War Kitchen

The invention of Betty Crocker exemplifies the tactics used by the food industry in their conversation with women in defining women's role in the post-war kitchen. A major contributor to the historical conversation around these convenience foods has been Laura Shapiro. Shapiro's work spanning multiple books highlights the methods and evolution of the methods used by the food industry to cultivate acceptance of convenience foods from consumers. The marketing lens is focused on by Katherine J. Parkin in her book Food is Love: Advertising and Gender Roles in Modern America. Parkin specifically explored the stubborn nature of food advertisers and their insistence on advertising to upper class white women, despite the profitability in targeting other demographics. Susan Marks' book, Finding Betty Crocker, provides a history of Betty Crocker and acknowledges her role as a powerful symbol. Communication scholar John R. Thompson explores the temporal aspects of industrial society and the place of convenience foods as 'genre benders' with unique market advantages. My work will contribute to this conversation by focusing on feminine icons, most notably Betty Crocker, but also less successful attempts in the genre. My work will focus on these icons as tools and rhetorical devices used by the food industry in an ultimately successful attempt to shape taste in favor of convenience foods. Using primary sources including advertising, letters, and branded cookbooks, I will trace the negotiation between the food industry and post-war women. It is important to trace how food has historically divided society and also created roles. In the post-war kitchen I argue that there exists a back and forth negotiation. Women's desires caused food advertising to mask themselves as a friendly companion through the creation of these feminine icons and their adjustments in the ways that convenience foods were used in the post-war kitchen.

Abstract Name: **Foucault's Ideas Of Power And The Consequential Implications On Academic Bullshitting**

Foucault says that power moves all around. People claim that academic 'bullshitting' is the fault of students, yet the power in this relationship between student and academic bullshitting is multi-faceted and relies on the student, the teacher, the tested content, and outside circumstances. Dr. Frankfurt, a professor of philosophy at Princeton, studied bullshit extensively and defined it as "short of lying and those who choose to perpetrate it misrepresent themselves". Viewing this in an academic context, researchers see academic bullshitting as the idea of misrepresenting oneself for academic gain. Yet, the misrepresentation is not at the full fault of the student. In world-wide tragedies such as Covid-19, students lean on academic bullshitting, or cheating. This has been proven consistently, yet, what many have failed to consider is the lack of responsibility for this action that should fall onto the students. Power in academic bullshitting in this case is derived from the world-wide pandemic, not the individual choices of the students. Foucault often looks to the ruled rather than the rulers in relationships of power. When applying this train of thought to academic bullshitting one must look to the power that the ruled, or in this case, the students, hold. Being told what to learn and when leaves them with little power in their academic choices, leaving power to teachers, administrators, and educational content. It has been proven that "Cheating is more likely among lower achieving students" (Finn and Frone) which reveals that the power from outside sources causing students to cheat leads to lower academic success. In a similar sense, students who feel powerless due to their low academic achievement may feel more drawn to academic bullshitting. Academic bullshit is an issue that plagues students, however, the power in this choice to cheat lies far beyond the student themselves.

Abstract Name: **Solar Cycle Variability and its effect of Geomagnetic Activity**

Variation of Sun's magnetic field and its activities are governed by an 11-year cycle, called the solar cycle. Solar cycle influences the activity on the surface of the Sun, resulting in sunspots which are caused by the Sun's magnetic fields stretching and becoming intertwined.The highly active Sun during solar maxima emits higher volume of radiation, higher energetic charge particles with magnetic flux and thus create hazardous space weather and can affect Earth's atmosphere too.In this research, we are presenting the variability of solar activity in solar cycles 23,24 and its influence on geomagnetic activities. We have studied sunspot numbers, F10.7 flux, solar wind speed, and Coronal Mass Ejection (CME).For solar activity, we are using GOES, ACE satellite data. For geomagnetic activities we are usingKp,DsTindex data. We are categorizing the geomagnetic activity data for low latitude (0-250), mid latitude (250-500), and high latitude (>500).Understandingsolar activity and its effects onspace weather and Earth's atmosphere is highly important. This work will be helpful in building a framework for an empirical model for future solar activity prediction.

Abstract Name: Positive Reward Conditioning 13-Lined Ground Squirrels

The 13-Lined Ground Squirrel (13-LGS) visual system is remarkably similar to that of humans, making it a useful animal model for blinding diseases and prompting research to create 13-LGS mutants with human hereditary retinal degenerations. While humans can report visual function by using an eye chart, rodents must be tested by using the Optomotor Reflex (OMR) Device. The OMR is a head movement tracking device equipped with moving stripes and a camera. The user controls the size and speed of the stripes: thick-slow moving stripes are like the large letters on the human eye chart, whereas thin-fast moving stripes are like the smaller letters. When the animal can see the stripes move, its head will move reflexively to track them. When the animal can no longer see the stripe movement, the corresponding head movements cease. The OMR requires the unrestrained animal subject to always voluntarily remain on the platform in camera focus. The OMR has never been attempted with 13-LGS, so this project addressed the species' response to the device and how positive reward conditioning might facilitate its successful use. The training scheme used and the time frame over which it occurred gave only one clear positive (a male) among the 8 juvenile littermate subjects, although a female also showed intermittent improvement to a lesser extent. These data suggest that, under the conditions employed, we expect significant inter-individual variation in how well positive reward conditioning works for the task of remaining on the raised platform of an OMR device.

Abstract Name: False Memories: the Fear Factor

Purpose: How does mood affect susceptibility to false memories? People are less likely to form false memories when sad, ostensibly because sadness encourages memory encoding of item-level information, while neutral moods encourage holistic processing, in favor of the gist (Storbeck, 2013). Though the protective benefit of sadness in avoiding false memories has been demonstrated, we investigate how both sadnessand fear–another important negative emotion– affect susceptibility to false memories. This is significant to investigate because when a negative event is experienced, people often remember vivid and specific details of the incident. In these traumatic scenarios, fear is likely the strongest emotion. From our work, we will be able to demonstrate whether fear, like sadness, protects against false memories.ProcedureParticipants view movie clips validated to reliably elicit the desired emotions: neutral, sadness, fear (Gross; Levenson, 1995; Hewig et al., 2005) and rate their mood using the positive and negative affective schedule (PANAS). False memory susceptibility is evaluated with the Deese–Roediger–McDermott (DRM) paradigm in which participants study lists of words that are each related to a critical, unpresented lure, then take memory tests on the words. If a participant misremembers a critical lure as being presented, a false memory has occurred (Roediger; McDermott, 1995). The mean number of falsely recognized critical lures across the three mood conditions will be analyzed using ANOVA. This project has received IRB approval and data collection has begun.Expected Results and ImplicationsIf fear, like sadness, confers a protective benefit against forming false memories as we hypothesize, participants in neutral moods will have significantly more false memories than sad or fearful participants. Of theoretical significance, we will determine if fear, like sadness, encourages detail over gist processing. Of applied significance, this study may add to our understanding of memory formation in traumatic situations.

Abstract Name: **Detecting Bias in Intelligent Autonomous Hiring Systems**

This project analyzed if artificial intelligence (AI) hiring systems demonstrate prestige bias, and how that bias may be mitigated. We chose to look at prestige bias since the quality of a candidate's education will naturally be reflected in their skills and experience; a school's reputation should not additionally be factored into a hiring decision. Of note, this project analyzed prestige bias against Historically Black Colleges and Universities (HBCUs). The majority of students attending HBCUs are people of color who are already marginalized members of society. We examined how hiring site Indeed utilizes AI to list candidate resumes by relevance and measured the relationship between a candidate's resume ranking and the university they attended. We expect to find a negative association between HBCU status and ranking, which is stronger than the association between ranking and other confounding variables such as experience type, degree level, field of study, etc. Subsequently, we will develop our own AI system, utilizing hiring decision data that we collected from Indeed, to observe if it will present a similar bias. If so, then we will apply debiasing techniques to our model to create a new AI hiring system that is not biased against HBCU applicants. With businesses considering AI as a tool for hiring, companies must understand that AI hiring systems can perpetuate the same biases found in human hiring on a larger scale.

Abstract Name: **Characterization of Prox1a Expression and Function During Retinal Development in Zebrafish**

Prospero (Pros)/Prox1 is a highly conserved transcription factor that was originally identified and characterized in the fruit fly (Drosophila melanogaster). These studies showed that Pros functions in neural stem cell proliferation and neuronal-glial fate decisions. Additionally, in vertebrate models, Prox1 was shown to function in the development of the pancreas, liver, and lymphatic systems. Finally, variations in human PROX1 expression have been linked to multiple human cancers, obesity, and diabetes. The current project sought to explore the expression and function of Prox1 in zebrafish retinal development. Prox1 expression was revealed using a recently generated antisera specific to zebrafish prox1a, and Prox1 function was determined by characterizing retinal development in the prox1a mutant line. Immunohistochemistry revealed that Prox1a was expressed in newly formed neurons exiting the stem cell niche in the marginal zones of the retina. This expression profile was not present in the prox1a mutant retinas, suggesting specificity of the antisera. Functionally, we observed that prox1a mutant embryos were micro-ophthalmic, but correctly formed all three laminar nuclear layers of the retina and an optic nerve. Furthermore, rods and cone photoreceptors were both present in prox1a mutant retinas and appeared morphologically normal. Given these findings, we hypothesize that Prox1 expression in the developing zebrafish retina plays a conserved role in stem cell proliferation/neuronal-glial cell specification, and when disrupted leads to the micro-ophthalmic state we observed in the prox1a mutant embryos. Future directions will explore a potential role for Prox1 during other aspects of cell proliferation and specification in the central nervous system, including during adult retinal regeneration in zebrafish.

Abstract Name: **Caught on camera: Are humans a safety cue for mammalian vertebrates?**

Anthropogenic pressures are imposing environmental modifications at unprecedented spatial and temporal scales to drive ecological change. One provocative notion is that fear of humans (so called “super-predators”) in human-altered landscapes may substitute for predation pressures that were historically imposed by large mammalian carnivores. This project addresses the question of whether free-living mammals actively avoid or are attracted to human presence over space and time. We examined the impact of human activities on the assemblages of free-living mammals as part of a long-term behavioral ecology study at Briones Regional Park in California. Specifically, we characterized the presence of humans, their dogs, and native vertebrates by analyzing thousands of photos from automated-camera traps (e.g., trail cams deployed over the past several years). We tagged photos of coyotes, bobcats, deer, skunks, and ground squirrels using the image software organizer “digiKam” and analyzed the data using the R statistical package “camtrapR.” We report on variation in the visitation rates by mammals across space and time to uncover the interrelationships among multiple species within the park. Our data set documents the crepuscular activities of carnivorans (e.g., bobcats, coyotes, skunks) and offers insights into the potential effects of visitation by humans (and dogs) on the lives of these elusive mammals. This information about the activity schedule of these animals offers key insights into the behavioral ecology of these animals as well as useful information for wildlife managers as burgeoning human populations visit natural areas.

Abstract Name: **Deepfake Detection Using Support Vector Machine and Convolution Neural Network**

Social media is currently being used by many individuals online as a major source of information. However, not all information shared online is true, even photos and videos can be doctored. Deepfakes have recently risen with the rise of technological advancement and have allowed nefarious online users to replace one’s face with a computer-generated face of anyone they would like, including important political and cultural figures. Deepfakes are now a tool with the potential to spread mass misinformation. There is now an immense need to create models that are able to detect deepfakes and keep them from being spread as seemingly real images or videos. In this paper, we propose a new deepfake detection schema using two popular machine learning algorithms; support vector machine and convolutional neural network, along with a publicly available deepfake dataset retrieved from Kaggle combined with real faces from the Flickr-Faces-HQ (FFHQ) datasetto accurately detect deepfakes in images with accuracy rates reaching as high as 88.33%.

Abstract Name: **People with Antisocial Personality Disorder and Psychopathic Traits and their Self-Talk**

Introduction: The purpose of this research is to find out the frequency and kind of self-talk individuals with Antisocial Personality Disorder (ASPD) and psychopathic traits experience. ASPD is a debilitating mental illness that interrupts how the individuals relate with others and view themselves. This disorder typically causes a lack of empathy and a lack of remorse for damaging actions. This study analyzes the inner experiences of those with traits of ASPD and psychopathy. We expected that those with more ASPD characteristics would report more frequent self-talk overall as well as higher levels of several kinds of self-talk, compared to those with fewer ASPD characteristics. Method: Surveys were given via Qualtrics to college student research participants (N = 134, 72% female). The survey consisted of measures of automatic positive and negative thoughts, general self-talk, ASPD, and psychopathic traits, as well as demographic items. The order of presentation of the main measures was counterbalanced across participants. Results: We found that social-assessing self-talk was negatively correlated with antisocial self-control ($p = 0.038$) and positively correlated with antisocial self-esteem ($p = 0.019$). We found that antisocial deviance was positively correlated with self-critical self-talk ($p = 0.015$) and antisocial extraversion was negatively correlated with self-critical self-talk ($p = 0.015$). Psychopathic callousness was negatively correlated with self-managing self-talk ($p = 0.022$). Antisocial psychopathy was positively correlated with self-critical self-talk ($p = 0.004$) and social-assessing self-talk ($p = 0.016$). In addition, negative automatic thoughts were significantly associated with a wide range of ASPD characteristics. Discussion: As we predicted, individuals with traits of ASPD and psychopathy show patterns of self-talk and automatic thoughts that are theoretically meaningful. We will discuss the implications of these results for personality and clinical psychology

Abstract Name: **Analyzing limited reform efforts through the dynamics of curriculum**

This analysis of education-centered articles from a Foundations of Education course will bring insight into how educational theorist's critique the exclusive focus on mainstream curriculum by persons of privilege, and how it creates a lack of acknowledgment for the influences null and hidden curriculum have on students as they pursue their education. Themes of the origins of American education, struggle towards meaningful reform, the integration of assimilation and separatism into curriculum and school infrastructure, as well as the current struggles such unavailability of equal and equitable education for all students pervading into education supports the notion that an elite minority continuously perpetuate ideologies of inequality into their false movement towards accessible and inclusive education by making infrequent and minute changes to the mainstream curriculum to subdue the demand for school reform. This elite minority embodies a false subscription to progressive values, which is weaponized through tacit acknowledgment of issues within the structure of mainstream curriculum and repudiating the influence that null and hidden curriculums have on a student's ability to learn and find community. The intentional disregard for reform within the null and hidden curriculum creates an environment that assimilates students into perpetuating harmful social behaviors, unjust and heavily influenced political beliefs, as well as negates the already limited government efforts to create equal opportunities for and equitable education for students. In order to create a more effective and equitable learning environment, educational reform needs to move out of the hands of the elite minority and into the hands of the affected student body. By creating a more dynamic and open narrative to share experiences from the system shaped by null and hidden curriculum, reform can take placeKeywords: education, ideologies, null and hidden curriculum

Abstract Name: Phagocytosis by RAW Macrophage Cells

Macrophages are a type of white blood cell and are an important part of the innate immune system. Macrophages have a role in removing dead cells, stimulating other parts of the immune system, and disposing of invading organisms. Macrophage function in part by using phagocytosis to engulf foreign bodies (e.g. bacteria). During phagocytosis, cells engulf microorganisms by encircling their plasma membrane around the target and endocytosing it into their cytoplasm. Phagocytosis gives them the capability to immobilize potentially harmful pathogens and allows them to safely remove them from the organism. The RAW 264.7 cell line is a transformed macrophage cell line derived from mice. It is a popular cell line for testing because it continuously proliferates and is hardy for in vitro work. This research project is aimed at demonstrating and imaging the process of phagocytosis by RAW macrophage cells. Microbeads coated with fluorescein conjugated to rabbit-IgG antibodies are used to observe the engulfing process as the cells slowly bring their “prey” into their cytoplasm. This process is captured using a fluorescence microscope. Observing how macrophage cells perform in cell culture provides insight into the roles they play in their original organism.

Abstract Name: Traumatization During the Argentine Dirty War

From 1976 to 1983, four military juntas, each led by a different commander, assumed power in a period known as the Argentine Dirty War. The first junta was established from 1976 to 1981 under the leadership of General Rafael Videla, Admiral Emilio Massera, and Brigadier General Orlando Agosti. Together the leaders of Argentina’s 1976 junta began the Process of National Reorganization, which allowed for the reduction of the power of government institutions and the persecution of subversives. People categorized this way by the Argentine junta were taken without warning from their homes, jobs, and off the streets and were transported to secret detention centers and concentration camps where they were tortured for information and murdered. The junta’s actions have left an imprint on Argentina not only on an individual level but on a societal one. The topic of this paper addresses one of the most horrific human rights violations in Argentina’s history. The paper views the origins and course of the Dirty War, the individuals involved, explains the Process of National Reorganization in a step-by-step manner, and looks at what human rights abuses occurred and where they were committed. Ultimately, arguing that the victims of the terror and systematic process of torture that began with the passing of the Process of National Reorganization during the leadership of Rafael Videla resulted in the traumatization of its victims, and said trauma changed Argentina’s society. The societal shift caused by this period can be viewed through the changes to Argentina’s lexicon, the significance of specific symbols due to the Dirty War, and the collective remembrance of the events. This study examines a journal article, textbooks, interviews and personal recollections of victims, and confessions of torturers to reveal the impact of the Dirty War on individuals and Argentine society from 1976 to 1981.

Abstract Name: **Establishing Behavioral and Neurobiological Markers Associated with Ethanol Vulnerable Phenotype**

Alcohol use disorder (AUD) is a chronic and relapsing brain disease. It is characterized by excessive consumption of alcohol, using alcohol in the face of negative consequences, and the experience of withdrawal symptoms. In 2019, it was reported that 14.1 million Americans over the age of 18 had been diagnosed with AUD. With excessive alcohol use causing 140,000 deaths a year in the U.S., treatment of AUD is an important social issue. While there are treatments available, such as mutual help groups, cognitive behavioral therapy, and medication, there are still challenges posed by the chronic relapsing characteristic of the disease. Further research still needs to be done into the behavioral aspect of alcohol consumption and the neural activity that is involved in a relapse event. In this study, we used a preclinical rodent model of ethanol self-administration to attempt to establish a vulnerable to ethanol-use phenotype. To accomplish this, we utilized behavioral economics to determine which rats have a high and low demand for ethanol. We hypothesized that rats with high demand for ethanol would show persistent responding in the face of negative consequences (the electric shock) and would have a distinct neural profile during the relapse compared to rats with low demand. Our findings show that some rats work harder for ethanol than others based on the assessment of their economic demand for ethanol. We also show that rats with higher economic demand for ethanol continue perusing ethanol in the face of negative consequences and have higher cue-induced reinstatement than rats who had lower demand for ethanol. Therefore, for the first time, we are showing the approach to identify a vulnerable to ethanol use phenotype on the individual level encompassing a constellation of behaviors spanning from using phase to the relapse phase.

Abstract Name: Investigating Whether Dietary Nutrition Can Impact Sex Ratios in Drosophila melanogaster

In organisms with genetic sex determination, the number of males and the number of females is generally expected to be equal at birth. Sex ratios have long been researched, but many questions are still left unanswered. The Trivers-Willard hypothesis states that sex ratios could be altered due to the relative stress that a mating pair may face while reproducing. This hypothesis has been supported by several scientific studies in mammals, but it could benefit from more research in a wider variety of organisms. I raised fruit flies (Drosophila melanogaster) in various media to determine whether nutrition has an effect on the produced sex ratio. There were six experimental conditions where the amount of lipids, carbohydrates, or proteins was increased or decreased by 30%, and one control group with standard nutritional media. Here we ask, does a scarcity of nutrition cause a skewed sex ratio; if so, what change in nutrient causes it? Studies have shown that males are selected more often when females are exposed to a high nutrient food supply. I hypothesized that the group exposed to a low fat diet will be significantly skewed towards the females, as they would not be ingesting the needed fat content, resulting in body distress. The results of this test will expand the understanding of factors that affect sex ratios.

Abstract Name: Humanity, from Life to Death

Inspired by an interdisciplinary seminar on sustainability, this triptych comments on human identity and its sustainability. "Flower Constellation" conveys the full bloom of human life and nature. Imagery of constellations and religion reveals human invention and beauty. Stars exist independently of humanity, but constellations are a human creation and add to the beauty of stars. The painting also depicts the famous Hindu image of Brahma the creator sitting on a lotus sprouting from Vishnu the preserver. “Dewdrop” acknowledges the toll of creativity on artists, such as Mary Wollstonecraft, Emily Dickinson, Antoine de Saint-Exupéry, and Vincent Van Gogh, whose words form the arch above the wildflowers. Art can be unsustainable to the individual; people with difficult lives often have artistic talent. The flower image itself alludes to the poem “On a Drop of Dew” by Andrew Marvell, which portrays humanity straining to return to heaven in the same way that a dew drop strains to return to the atmosphere. Since the shape of the arch resembles a bell jar over a rose and a door to heaven, the painting simultaneously symbolizes preservation and death. Finally, given that the Voyager Golden Records aim to preserve the essence of humanity, “Golden Record” asks how an individual would choose to represent their own identity for eternity. The artist includes several of her personal choices slipping away from the Golden Record and disappearing into space while Earth, the pale blue dot, is far in the distance. On the Golden Record itself is written the name of a song actually selected, “Jaat Kahan Ho”, which means “where are you going”. The Golden Record, the memory of all humanity, drifts into unknown territory, distant and alone in space.

Abstract Name: **Mechanotherapy Attenuates Collagen Accumulation, but Not Muscle Atrophy in Female Rats**

Background: Mechanotherapy in the form of cyclic-compressive loading (massage) induces an anabolic response during recovery from atrophy in male rats, but does not attenuate atrophy when applied during disuse. Preliminary data show females respond differently to mechanotherapy than males during recovery from atrophy. However, the response to mechanotherapy during disuse has not been evaluated. Objective: To determine the response to mechanotherapy during atrophy. Hypothesis: Mechanotherapy during disuse will reduce muscle atrophy in female rats. Methods:10-month-old female BN/F344 rats were randomly assigned to three groups: weight-bearing (WB; n=6), hindlimb suspension to induce atrophy (HS; n=7), and HS with massage (HSM; n=7). HS and HSM were suspended for 7 days during which HSM received 30 minutes of mechanotherapy every other day on the right gastrocnemius muscle beginning the first day of suspension (total 4 bouts). Mean fiber cross-sectional area (CSA) and fiber type distribution (MyHC), satellite cell number (Pax7+ cells), collagen percentage (picrosirius red), and myonuclear number (dystrophin-DAPI+) were analyzed on the right gastrocnemius muscle. One-way ANOVA was preformed, and statistical significance was assumed at 0.05. Results: Bodyweights of HS and HSM were significantly lower than WB. CSA was lower in HS (2096 ± 127.4; p=0.0011) and HSM (2228 ± 130.7; p=0.0050) compared to WB (2892 ± 68.26), with no significant difference between HS and HSM. Fiber type distribution and satellite cell number were not significantly different between groups (p 0.05). Collagen percentage was significantly higher in HS (10.4 ± 0.3) than in WB (8.0 ± 0.2; 0.0001) and HSM (9.0 ± 0.3; p=0.0040), while HSM was not different from WB (p.0.05). Conclusion:Mechanotherapy did not attenuate atrophy but is beneficial in preventing buildup of collagen in the extracellular matrix, thereby potentially reducing fibrosis due to atrophy. Work supported by NIH grant AT009268.

Abstract Name: **Isolation of M. smegmatis bacteriophage lysin B and characterization of its potential as an antimicrobial agent for M. tuberculosis**

Phages are viruses that infect bacterial cells. The recent surge in antibacterial-resistant bacteria has brought attention to bacteriophages as an alternative treatment for pathogenic bacterial infectious diseases such astuberculosis, leprosy, and wound infections. Recently, scientists have demonstrated that bacteriophages can be used to reduce Salmonella species in meat and poultry products, a discovery that reignited interest in phage therapy as a means of controlling pathogenic bacteria.Toexplore the potential for phage therapy as a means of fighting pathogenic bacteria, we isolated phage LestyG from Mycobacterium smegmatis, arelative of the bacterium responsible for tuberculosis.Further analyses were made on the annotated genes by comparing the genome of LestyG to that of DS6A, the only bacteriophage discovered from Mycobacterium tuberculosis. It was discovered that LestyG has one gene in close homology with DS6A: gene 48 in LestyG and gene 72 in DS6A. Gene 48 codes for lysin B, a mycolylarabinogalactan esterase that cleaves the ester bond between arabinogalactan and mycolic acid and, thus, compromises the link between the mycobacteria cell wall and the outer membrane to completes cell lysis. Because of the potential in lysin B for disrupting the cell wall structure of pathogenic bacteria, it became the focus of our research.We have successfully cloned the LestyG Lysin B gene into a protein expression vector for the purposes of characterizing the ability of this protein to influence Mycobacterium pathogenesis. We intend to extend this investigation into the effects of Lysin B on an attenuated strain of M. tuberculosis to determine whether lysin B compromises the integrity of the cell wall of M. tuberculosis, thereby weakening its resistance to antibiotics. This experiment is ultimately aimed to be the foundational model of the use of lysin B in conjunction withantibiotics to effectively treat tuberculosis.

Abstract Name: **The Staying Power of the Klan: An Investigation of Groton, Massachusetts**

American inquiries into white supremacy often center around the South and the legacy of slavery. While more Americans are beginning to confront the fact that white supremacy's roots reach beyond the historic slave-holding states, there are many places where the legacy of white supremacy remains hidden, particularly in currently politically liberal North Eastern states. The Town of Groton's proximity to the educated liberal Northern elite then makes itshistory of Klan activity a question of interest. As a small town with a strong archival tradition, Groton's rich collection of primary sources from local historical societies andmunicipal orprivate collections enabled the effective study of the effects and legacy of the Klan. The town's intimaterelations, careful census and notarial records, and active local press make it possible to trace the impact of individuals associated with the Klan, organizations affected by the Klan, and the public boards that elected Klan-endorsed candidates to municipal office. I was able to reconstruct a complex set of social dynamics that, taken in totality, force us to question our preconceived notions of white supremacy in US politics.The empirical questions that this study addresses include: How did the Klan arrive in Groton, and what was the extent of its support? How did resistance to and support for the Klan shape the town, particularly along gendered lines? How did the Klan seek to redefine what it meant to be a citizen of Groton? These empirically-based questions allow me to reflect on the followingissues: What does Groton's experience with the Klan in the first three decades of the twentieth century tell us about our national histories of the second wave of Klan activities, which until now have focused on other regions? How might Groton's experience with theKlan inform our understanding of right-wing social movements today?

Abstract Name: **Antimicrobial Activity of Earthworm and Raw Honey Bacteria Against Human & Fish Pathogenic Bacteria**

Many medical treatments rely on antibiotics to treat infections. Due to repeated and improper use of antibiotics some bacteria have developed antibiotic resistance making them unaffected by antibiotics that were originally designed to kill them or inhibit their growth. The purpose of this study is to find bacterial isolates that have antimicrobial activity against human and fish pathogens, providing us with a possible alternative source for new antibiotics. Secondary metabolites derived from bacteria found in earthworms and raw honey offer a wide range of health benefits including anti-inflammatory, antioxidants and antidepressant properties and are reasonable candidates to test for antimicrobial activity against pathogenic bacteria. In this experiment bacteria from earthworms and raw honey were isolated and tested against fish/human pathogenic bacteria. Locally collected earthworms were euthanized with 70% alcohol and crushed into a paste. Sterile distilled water was used to make 10-fold serial dilutions of up to 106. Raw honey obtained from a local honey farm was melted and diluted with sterile distilled water in a 1:1 ratio. Both sample dilutions were plated onto nutrient agar medium and incubated at 30°C for 24 hours. Colonies were counted to calculate the cfu/g and also patched onto Brain Heart Infusion (BHI) agar and incubated overnight at 30°C. Bacterial isolates were tested for antimicrobial activity against a variety of pathogenic bacteria. In total, 24 isolates showed antimicrobial activity against the pathogens (23 from earthworms, one from raw honey). Future research will consist of testing antimicrobial activity of the isolates on different media, identification by DNA sequencing, characterization of metabolic profiles, and isolating bacteria from other organisms.

Abstract Name: **Analyzing the impact of bottleneck size on the recovery of influenza A replication capacity**

Influenza viruses cause annual epidemics and occasional pandemics throughout the world. About 11% of the U.S. population contracts the flu every year, resulting in hospitalizations and death. The influenza virus is a segmented negative-sense RNA virus. It contains eight RNA strands that each code for one or more viral proteins needed for attachment and proliferation in a host. One of these proteins is RNA-dependent RNA polymerase (RdRp) and it is needed to copy the RNA genome of the influenza virus. During transcription, RdRp has shown a high error rate due to a lack of proofreading ability. This results in the generation of mutations, creating a genetically related but distinct population of influenza viruses with a relatively high level of genetic diversity. Analyzing the causes and implications of this genetic diversity helps understand the ubiquity of influenza epidemics. A dilapidated virus generated as a product of prior research will be used to analyze two bottleneck conditions. The dilapidated virus was sequentially passaged in MDCK cells under two bottleneck sizes. The resulting viruses were used to compare replicative capacity following the bottleneck. Each virus is sequenced and after receiving the genome, we will look for inconsistencies that could correlate with varying degrees of fitness. Based on current data, new primers are being designed to account for currently unsuccessful sequencing. Once sequencing is complete, mutations will be evaluated.

Abstract Name: **A comparison of geologic influence on phosphorus loading through lacustrine groundwater discharge in three lakes in western Wisconsin**

Lake eutrophication in Wisconsin and throughout the upper Midwest has resulted in severe environmental and economic impacts across the region. Most lake eutrophication events are attributed to excess phosphorus loading. Historically it has been assumed that phosphorus is primarily contributed from agricultural sources and migrates through sediment runoff. Recent investigations have demonstrated that phosphorus is elevated in both surface water and groundwater in western Wisconsin, and that lower Cambrian bedrock may be a significant contributor of phosphorus to the hydrologic system. Case studies were conducted in lakes positioned in three different geologic settings common to western Wisconsin. This includes settings of thick sand and gravel overlying Cambrian Mt. Simon sandstone (Mud Lake, Barron County), thin sand and gravel overlying shallow Cambrian Mt. Simon sandstone (Lake Altoona, Eau Claire County), and glacial deposits overlying Ordovician Prairie du Chien Group (Bass Lake, St. Croix County). The average concentration of phosphorous in surface water of Mud Lake is around 43.6 ppb and the groundwater average is around 283 ppb. Average concentration of phosphorous in surface water of Lake Altoona is around 71 ppb and the groundwater is around 184 ppb. In Bass Lake the average phosphorous concentration is around 4.1 ppb for surface water and 82 ppb for groundwater. Overall, the data demonstrated high phosphorous levels consistent with interaction in the Lower Cambrian units (Mt Simon). This study provides a preliminary understanding of how geologic setting may influence groundwater phosphorous loading in the investigated lake systems.

Abstract Name: **Investigating Interactions Between Bacteria Infecting Patients with Cystic Fibrosis**

Lung infections in cystic fibrosis (CF) patients are the main cause of morbidity and mortality, and most are caused by either Staphylococcus aureus (SA) or Pseudomonas aeruginosa (PA). SA infections are mostly present in younger CF patients, but as they age, there are fewer SA infections and more PA infections. CF patients coinfected with SA and PA have worse outcomes than those infected with only one type of bacteria. PA is known to kill SA in coculture, so the mechanisms of how they coexist are unknown. Therefore, this project aims to investigate the interactions between two PA laboratory strains and various clinical isolates of SA. The two PA strains used are PAO1, a wild-type PA strain known to kill SA, and PDO300, a strain of PA known as mucoid, which produces an abundance of polysaccharides and coexists with SA. The SA clinical isolates are each grown separately and then mixed with the two PA strains separately and also with JE2, a reference SA strain that is known to be killed by PAO1 and coexist with PDO300. We observed three different outcomes for the clinical SA isolates: the wild-type PA strain only killed the SA, the wild-type and mucoid strain killed the SA, or the SA survived coculture with both PA strains. Most isolates were killed by PAO1 and fewer isolates were killed by PDO300. This data will help us determine the variety of interactions between SA and PA and how prevalent these interactions are among these clinical isolates. Further data needs to be collected to determine the correlation between the interaction of SA and PA and other noteworthy clinical phenotypes. This work will help us identify the prevalence of coexistence between these two clinically important bacteria and potentially identify ways to prevent coinfection and the accompanying decline in patient health.

Abstract Name: **College Students' Perception of School-Based Mental Health Services: A Scoping Review**

The global prevalence and severity of mental illnesses are increasing among late adolescents and college students. One model to address these issues is school-based mental health services (SBMHS) which provide mental health (MH) services and resources on an individual or classroom-wide basis. SBMHS have the advantage of making treatment more accessible compared to community-based external MH services. Research efforts are starting to examine the short-term outcomes of SBMHS, as well as college students' view of MH treatment. To date, undergraduates' satisfaction with previous use of SBMHS remains largely unknown. Thus, a scoping review of the literature was conducted to assess this knowledge gap. Five databases (PubMED, Web of Science, PsycINFO, ERIC, and Cochrane Library) were searched to identify 361 English language papers published between January 2000 and June 2022. Search terms were related to undergraduates, SBMHS, perception, and satisfaction with SBMHS. After screening titles and abstracts, assessing full texts for eligibility, and searching within relevant reference lists, the search yielded zero publications addressing college students' perceptions of high school SBMHS. With the absence of eligible articles indicating a significant gap in the literature, the focus of the review shifted to examine the need for further research in this area. Research on MH services received by high school students should expand to cover perceptions of service effectiveness on MH challenges faced as a college student. As MH research advances, further understanding of the long-lasting impacts of SBMHS is needed to guide service improvements and intervene early to address mental health problems.

Abstract Name: **Novel Monoclonal Antibodies Against Influenza N2 Neuraminidase**

Influenza poses a very large problem to public health. The disease spreads quickly and in the most severe cases, can be lethal. Additionally, vaccinations against influenza must be updated yearly and tend to have notoriously low efficacies among vaccines, owing to the virus's tendency to mutate very rapidly to the point that its surface antigens no longer closely resemble those used in previous vaccinations, a process known as antigenic drift. Furthermore, like almost all vaccines, vaccination against influenza is a prophylactic measure and will not help against preexisting infections as therapeutics would. One therapeutic currently being explored for its use against influenza, monoclonal antibodies (mAbs) are antibodies derived from a single clonal B cell lineage that are all reactive against the same epitope. Currently, most mAbs being developed against influenza are reactive toward hemagglutinin (HA), the predominant glycoprotein on the virus that's responsible for binding and allowing the virus to enter the host cell. However, because HA is so common, it is most often targeted by the immune system and therefore, is subject to the most selection pressure. As such, these mAbs may suffer the same pitfalls as vaccines and could require frequent updates. Alternatively, targeting a mAb against neuraminidase (NA), another surface glycoprotein that functions in viral budding and cell-to-cell spread, could yield similar efficacy without the pitfalls of binding such variable antigens. This goal is exactly what our project aims to accomplish. In particular, we would like to target N2 due to the exceptional prevalence and variability of the H3N2 influenza virus subtype. We aim to generate N2 reactive mAbs and characterize their binding and inhibition profiles. We have already completed preliminary experiments, and our results are promising, as we have thus far successfully generated and characterized the binding profile of a single N2 specific mAb.

Abstract Name: **US GAAP versus IFRS: the Impact of Research and Development on Reported Income and Capital Infusions**

The current accounting system used in the US is known as the Generally Accepted Accounting Principles (GAAP), while the vast majority of the remaining countries use the International Financial Reporting Standards (IFRS). One distinguishing factor between the two is the regulations on accounting for research and development (R&D). GAAP states that all R&D expenditures must be expensed, thus decreasing income, while IFRS expenses research but capitalizes development. Capitalization is the process of turning an expense into an asset which decreases over time. This difference causes companies using GAAP to have large immediate increases in expenses, compared to companies using IFRS, which exhibit an increase in assets which decreases over time by turning into expenses. Prior literature has found that capitalization of development found in IFRS is more informative to investors for showing property value. This paper will contribute to literature by exploring the hypothesis that accounting for R&D using GAAP puts US companies at a competitive disadvantage versus international companies using IFRS, pertaining to capital infusions in the forms of stocks, bonds, and loans. In order to test the hypothesis, a panel regression analysis will be conducted on a sample size of 30 companies from 2015-2019 in high R&D focus sectors: automotive, pharmaceutical, and technology hardware. I expect to find a statistically significant causal relationship between GAAP and a decrease in capital infusions in the form of stocks sold. If I am successful in finding this, I will discuss how IFRS system of capitalizing development shows investors a more nuanced presentation of R& D, which also makes R&D more attractive to investors. If such a relationship is not found, I will discuss potential reasons for this, including issues with the statistical test and the efficient market hypothesis.

Abstract Name: **The Characterization of Unknown Black Yeasts**

Multiple unidentified black yeasts were investigated with the use of using molecular and culture-based approaches in an effort to determine the identity of the fungi as well as their potential applications. Using PCR, extracted DNA from the fungi was amplified and ITS sequence regions were sequenced. The preliminary results show that the closest matches for these fungi are Exophiala sideris and Exophiala viscosa. Gel electrophoresis was performed in order to confirm that there was no contamination in the samples before sequencing. The broader clade that these species belong to produces melanin. Melanin is a costly molecule to produce artificially. There has been an industrial application for extracting the melanin from similar fungi, which could also be a potential application for the fungi under investigation. For industrial applications, it is important to determine how the fungi will be grown which is why phenotyping and carbon source utilization was performed. Phenotyping was done by testing whether the fungi would grow on a variety of media types to see broadly what nutrients, as well as the amount of nutrients, the fungi were capable of utilizing. To determine specific compounds that the fungi are able to utilize, c-strips were used to determine the usable specific carbon sources for these fungi. Both of these methods for determining how to grow these fungi also allowed for potential changes in growth time, melanin production, appearance, and other factors to be observed with differing carbon containing molecules.

Abstract Name: **Cybersecurity Network Analysis for Spacefaring Nations**

Analyzing relational patterns between spacefaring nations provides insight into how individual countries can improve their security and how the international system can increase in stability. Fifteen of eighty satellite-owning countries currently possess capabilities to launch satellites into orbit. This results in bilateral country relationships between owner and launcher as satellites are transferred from one country to another country. In this paper I use network analysis to map how bilateral owner-launcher relationships and the cybersecurity scores of those actors coalesce to influence international system dynamics, such as dependency. Other core concepts used to analyze the network include centrality, density, and structural equivalence. The network analysis methodology emphasizes how material and social relationships relate to each other - as satellite transfers and cybersecurity scores are the evaluated materials, the links drawn between state-nodes reveal the social relationships at play. The International Telecommunication Union's Global Cybersecurity Index measures state cybersecurity commitments across five pillars: legal measures, technical measures, organizational measures, capacity development measures, and cooperation measures. As country-nodes are clustered into groups with cybersecurity scores of 0-5, 5-10, 10-15, and 15-20, I find that organizational, cooperation, and capacity factors help explain dependencies within the model. Where densely connected subnetworks have low flexibility and low dependency, sparsely connected subnetworks have high flexibility and high dependency. The network analysis presented in this paper offers a means of addressing current interdependence and flows of influence among states with satellites in orbit. For future analyses of structural holes, an international framework is proposed.

Abstract Name: Race Based Memory Errors in the Cross Race Effect When Remembering a Narrative

Two experiments analyze how a narrative and its protagonist are remembered depending on the participants' race. The cross-race effect (CRE), a phenomenon where individuals have poorer memory for faces outside of ones' race compared to faces within their race, was examined. It was hypothesized that White participants would experience more race-based errors when the protagonist was a Black male in comparison to a White male. Also, White participants would be more likely to confuse the Black protagonist with other Black characters. Black participants (experiment 1 only) and White participants were given a short narrative about a male protagonist, Jackie. Four faces would appear: Jackie and the loiter, who alternated being Black and White, and the cashier and server, who were both White females in experiment 1, but Black or White females in experiment 2. After reading the narrative, the participants responded to a series of questions to test their memory of events and character faces. In both experiments, findings suggest that White participants had a higher rate of race-based memory error when presented with Black Jackie than White Jackie. The results suggest that patterns are used to aid in filling in memory gaps and those patterns can be related to racial expectations. Additionally, White participants, in experiment 1 and 2, misidentified Jackie the most when he and the loiter were both Black. In contrast, Black participants misidentified Jackie the most when both he and the loiter were White. In short, the CRE was supported in both experiments and in Black and White participants. Implications are that race and culture may influence the way we remember and misremember details of an event.

Abstract Name: Patriarchal Beliefs Influence on Christian Women's Pursuit of Career Leadership and Education

One major variable Christian women are influenced by is patriarchal beliefs, and these can have an impact on her educational and career leadership opportunities. Although both variables seem to be related, there is not a lot of research about the correlation between the two. Through previous research, we know that many societal, religious, and environmental pressures surround the belief system that many Christian women seek to uphold. This paper investigates whether there is a significant relationship between a Christian woman's patriarchal beliefs and her pursuit of career leadership and educational opportunities. To understand whether there is a significant relationship between these variables, I surveyed Christian women using the Attitudes Toward Christian Women Scale (ACWS) and the Leadership And Achievement Scale (LAAS). My survey results demonstrate a significant relationship between patriarchal beliefs and Christian women's leadership in career aspirations, as well as a significant relationship between patriarchal beliefs and education aspirations. The results of each survey also reflected a major negative correlation with each other, therefore proving that my hypothesis was correct. This study shows how important it is for family scientists, family life educators, family therapists, and policy makers to understand the mindset that many Christian women have, so that they can better help them within their respective careers. Additionally, the result of this study validates Christian women who possess both patriarchal beliefs and desire to hold a leadership position in their careers or pursue higher education and feel that they struggle to bridge the gap between these two factors. Furthermore, this study informs Christian institutions and organizations that desire to develop career leadership or education programs specifically for women. Understanding why many Christian women may struggle to make decisions in favor of their career or their education will help these organizations and institutions develop more effective programs.

Abstract Name: **Diversity of Endophytes in Sunn Hemp (Crotalaria junicea)**

DIVERSITY OF ENDOPHYTES IN SUNN HEMP (Crotalaria junicea)Sunn hemp commonly known as Mito,is a very important indigenous vegetable in Kenya. It also fixes nitrogen, good green manure, reduces soil erosion, conserve soil moisture, suppress weeds and nematodes, and recycle plant nutrients. It grows at fast rate in sub-tropical and tropical climates and its stem is used in industrial production of fiber. The crop is plagued with numerous biotic and abiotic stresses that can be solved by inoculation of endophytes. The objective of this study was to identify endophytes associated with sunn hemp and profile their functions.The healthy vegetables were randomly collected from vegetable farmers in Vihiga count, Kenya. Bacterial and fungal endophytes were isolated on nutrient agar (NA), and Potato Dextrose Agar (PDA) media supplemented with antibiotic, respectively. Pikovskayas media was used to test for phosphorous solubilization efficiency (PSE) while Jensen's media was used to test nitrogen fixation. Total of 31 bacteria and 22 fungal endophytes were isolated from the plant.Aspergillus sppwas the most dominant fungal endophyte isolated with the highest PSE of 11.84%. 58.83% of the bacterial endophytes fixed nitrogen while 1.87% fungal endophytes were able to solubilize phosphates. The endophytes found to enhance plant growth promoting traits will be recommended for inoculation on seed or incorporated in soil to improve crop productivity. More research will be done on the other endophytes to establish their role in terms of pest, disease or drought resistance. The research was completed over the summer at Egerton University in Njoro, Kenya under the supervision of Dr. Anne Osano of Bowie State Universityand Joseph Mafurahof Egerton, with assistance from Mary Simiyu.

Abstract Name: **Gun Violence in Schools**

Gun violence has become a huge problem, especially when it comes to our schools. Just this year, as of October 31, 2022, there have been forty school shootings, twenty-eight of the victims were students and the other six were staff members. According to SIERP (Stanford Institute for economic policy Research) more than a hundred thousand students between 2018-2019 were involved in school shootings. School shootings have a major effect on students' mental health, academic performance, and enrollment ((Dodson, 2021,). School should be a place where children want to go to learn, make new friends, and a place where they can feel safe and secure. Sensible Gun laws need to be implemented in addition to school based interventions that address problems before shootings occur. One solution that has been tossed around and will not help this situation is arming teachers with guns. This literature review looks at the effects and impact of gun violence on students and offers some research-based approaches for creating safer schools and communities (McMillan, Jordan; Bernstein, 2022),

Abstract Name: **Adjusting the mathematical model of harmonic motion to variable mass**

Simple harmonic motion is a particular sort of periodic motion that describes a sinusoidalcurve that deviates from a horizontal line which is the equilibrium position of the motion. In this research we focus on the simple harmonic motion generated by a mass on a vertical spring, which can be described, by virtue of Hooke's law, by means of a second-order differential equation whose unknown function is the elongation x=x(t) considered as a function of time: mx''+ kx = 0, where kis theelasticity constant of the spring. The specific problem that we address in our study is that of adjusting the mathematical model when the mass m is considered to change with time,i.e., m=m(t). This simple consideration significantly complicates the problem from both the theoreticaland practical points of views. Thus, we focus on computing and analyzingthe behavior of the exact solution to the differential equation above for several elementary paradigms of the mass function. Other examples of mass function are constructed by observing the change of mass of a perforated container of sand or water. For the latter, we rely on numerical methods such as Finite Difference and Runge Kutta to compute an approximate solution to the problem. In all cases, we consider that the mass decreases with time, and we observe that the equilibrium position is described by a nonlinear curve that also decreases with time, while the elongation is the sum of two functions where at least one of them is proportional to a wave.

Abstract Name: **Male Participation in Parent Education**

The student researchers seek to create an environment that motivates fathersto attendparent education courses by exploring the factors involved in the participation of males in parent education. The student researchers targeted a sample size of 78 fathers while utilizing a mixed methodology survey with an emphasis on quantitative. The students distributed this survey through online platforms and local grocery stores. The student researchers collected data during a three-week-long period. The survey contained five demographic questions regarding age, race/ethnicity, marital status, number of female children, and number of male children. The majority of respondents were ages 41 to 50, (28.2%; n=22), 20.5% (n=16) were ages 31 to 40, 16.7% (n=13) were ages 20 to 30, 12.8% (n=10) were ages 51 to 60, 10.3% (n=8) were ages 61 to 70, 7.7% (n=6) were ages 71 to 80, and 2.6% (n=2) were 81 to 90 years of age. Regarding race/ethnicity 85.4% (n=51) of respondents were White/Caucasian, 28.2% (n=22) were Hispanic, 2.6% (n=2) were American Indian/Alaskan Native, 2.6% (n=2) were Black/African American, and 1.3% (n=1) were Asian/Pacific Islander.The student researchers created a code sheet using Google sheets, which consisted of converting the survey questions into a code. The student researchers used the Statistical Package for Social Sciences (SPSS) to analyze data collected. The student researchers utilized the Hahn's Coding Process to analyze the qualitative data. The themes: Work, Family, Time, and Disability consist of responses that reveal obstacles within the father'slives that would interfere with their attendance toparent education classes. Conducting this research provides information to include programs specifically for males to become more involved in parent education.By gaining insight from fathers in the community, the researchers will brainstorm ideas on how to make it easier for fathers to be able to attend parent education classes.

Abstract Name: **The Gender Gap in Refugee Education: Analyzing the Existing Research on the Shortage of Women Teachers in Refugee Classrooms**

As of 2019, the United Nations High Commissioner for Refugees (UNHCR)identified only 27% of all refugee children enrolled in school as female due to several barriers they face, including social and cultural limitations such as unwilling parents, unsafe journeys to the classroom, and a lack of girl-friendly facilities. One major barrier suggests that a shortage of female teachers could be a larger factor affecting the gender gap in education. If more female teachers were present in the classroom, they would serve as a role model, help girls to feel safer inside the classroom, and help break down social-cultural barriers for all women and girls. Much of the existing literature is limited and heavily anecdotal-based meaning that there is a need for more research both quantitatively and qualitatively that addresses specific characteristics of refugee teachers. This project consisted of a literature study of 48 sources beginning in 2005 through 2022 which identified a direct relationship between the presence of a female teacher and higher test scores, subject appreciation, and motivation of female students in refugee classrooms. The findings of this study also identify four main areas of future research to help close the gender gap in refugee education:allow female refugees to finish their education before becoming teachers, revise teacher training programs to be more tailored to women's needs, create a strategy to diversify the employment of women across urban and rural camps, and redesign learning materials to be inclusive of both female teachers and students.

Abstract Name: **Numerical Study of the Effect of Rainfall on Partly Saturated Compacted Clay Slopes**

Global warming has increased the total annual precipitation received in a single day globally. Heavy rainfall and earthquakes have been found to be one of the major factors causing 'mass wasting'. The most recent case of rainfall induced landslides, in the US, is the Yellowstone National Park that was closed due to flooding and landslides caused by incessant rainfall. These events have been known to contribute to major loss of life and property. In this research, the effect of rainfall on partially saturated compacted clay slopes is studied numerically. Matric suction in the soil contributes to shear strength of unsaturated soil. Rainwater infiltration into the soil reduces the matric suction and develops positive pore pressure in the soil decreasingthe shear strength of the soil causing slope instability. In this study, numerical analyses of three small-scale experimental models of slopes studied experimentally previously at California State University, Fullerton were conducted. Coupled pore pressure and stress analysis of slope models at void ratios of 0.89, 1.0, and 1.2 with slope inclination at 40 degrees, subjected to a rainfall intensity of 1.68 cm/hour is studied. The study focusses on understanding the relation between rainfall duration and intensity on the seepage velocity, time taken by the slope to completely saturate, and the deformations occurring in the slope during the process of saturation for varying void ratios. In this study it was found that the seepage velocity increased with an increase in the void ratio of the soil while the time taken by the slope to saturate and the swell in the crown of the slope was found to decrease. The finite element model results were found to be in good accordance with experimental results. In the future we plan to conduct slope stability analysis on these numerical models to accurately predict slope failures.

Abstract Name: **Spirituality as a Buffer Between Traumatic Experience and Posttraumatic Stress**

According to the American Psychiatric Association, trauma can be defined as exposure to actual or threatened death, serious injury, or sexual violence, involving direct exposure, etc. As a result of experiencing trauma or a traumatic event, it can lead to symptoms consistent with a formal diagnosis of PTSD. PTSD can then arise from stressful events or situations “of exceptionally threatening or catastrophic nature, which is likely to cause pervasive distress in almost anyone” (WHO, 2016). Anxiety buffer disruption theory (ABDT) suggests that posttraumatic stress disorder (PTSD) is a result of the disruption of one’s anxiety-buffering mechanisms. This disruption can lead to overwhelming emotions, hyperawareness of one’s mortality, and wide-ranging reactions to traumatic events. However, the anxiety-buffer system mitigates the effects of potential terror, promotes posttraumatic growth (PTG), and is comprised of three components: cultural worldviews (e.g., spirituality), self-esteem, and social support. In some cases, depending upon the threshold of the PTSD, traumatic experiences can lead to one experiencing a spiritual awakening. A spiritual awakening is a term given to describe a subjective experience in which an individual’s ego transcends their ordinary, finite sense of self to encompass a wider, infinite sense of truth or reality (James, 1902/1985). Moreso, it has been seen recently within research that although trauma has been experienced there is still a relatively low prevalence of PTSD in some due to “natural resilience”, often related to a survivor’s spiritual resources (Feurerstein, 1989; McClintock et al., 2016). A sample of N=300 individuals with above-threshold PTSD symptomology (PCL-5 scores > 34) will be recruited via a research panel to examine the relationship between spirituality, PTSD symptoms, and posttraumatic growth. Thus, we expect that individuals who have experienced a traumatic event and who report higher spirituality will report lower PTSD symptoms and exhibit higher posttraumatic growth.

Abstract Name: **Titan Providence: Autonomous Drone System utilizing AI and GPS for Navigation**

Data and analysis of information have become a crucial aspect of society’s current development, allowing accurate awareness of our environments, and benefitting maintenance, safety, and overall innovation. At the same time, the big data trend has grown in popularity, and the use of drones has also taken off to be considered valuable data collection devices. However, the control of the drone always lies with the pilot who uses visual tracking to determine its position and orientation. To overcome these issues, we propose an advanced technology that allows a drone to autonomously fly with little to no input from a human pilot. Differing from common Unmanned Aerial Vehicle (UAV) systems, Titan Providence implements AI vision with a GPS system, allowing for fully autonomous completion of a given “mission”. Our objectives for this project include the construction and design of the drone framework, adaptive pathfinding, and awareness, in addition to task assignments.To achieve our goals, we integrated a Raspberry Pi with a compatible flight control module with additional telemetry and peripherals docked on a custom quadcopter chassis that allows modularity and expansions in accordance with a task’s outline and requirements. By using these two systems in conjunction, we passively maintain the stability of the system through its inertial measurement unit (IMU) and individual multirotor electronic speed controllers (ESC), allowing further independence of the system’s microcomputer. Regarding autonomy, the Raspberry Pi hosts the machine learning platform known as Tensorflow lite which would allow the drone to recognize obstacles and relay this information to the flight computer to avoid them. We also plan to utilize OSMNx which would allow the drone to create routes through urban environments where extra care and consideration for the law, powerlines, and private property is needed.

Abstract Name: **Does the CIO's Gender matter more than her Expertise and Leadership Style in affecting IT security policy compliance?**

Information security threats have become a major concern for organizational leadership. Research suggests that IT leadership is vital in influencing employees' IT security compliance with security policy; however, there is little research measuring the role of the CIO's gender in influencing employees toward IT security compliance. The IT field has progressed, and there are more women CIOs now, but women leaders are still a minority in IT. According to a Pew Research report published in 2018, societal role expectations and barriers have discouraged women from going into the IT domain. Barriers to learning and advancing in IT careers have also hampered women's self-confidence to pursue careers in this industry. Thus, perceived credibility or IT expertise becomes another serious challenge women IT leaders face.While it is known that women leaders are more transformational than transactional, men, in contrast, are known to follow a transactional leadership style in general. Prior studies provide overwhelming evidence that the transformational leadership style is more effective in influencing behavior change and positively related to team and organization performance.Thus, this paper seeks to understand the role of CIO gender, perceived IT expertise, and leadership style in influencing employees' behavior change and intention to comply with cyber-security recommendations. The 2x2x2 controlled experiment uses various vignettes in Qualtrics to manipulate gender, IT expertise (low/ high), and leadership style (transactional/ transformational). Data will be collected from all over the US using MTurk during December 2022 and analyzed during January 2023. The findings of the study will have theoretical and practical implications. It will help inform IT literature on the role of the security message sender's characteristics and the contextual outcomes; on the other hand, they will guide CIOs, particularly women, on how they can tailor their leadership style and security recommendations to achieve greater behavior change.

Abstract Name: **Comparing Trajectories Toward Activism Amongst Asian American and Latinx Young Adults**

Following the murder of George Floyd, the Black Lives Matter movement inspired an increased awareness of social injustices and racism in America. In this research, we examine how the anti-racism movement that followed this historical event impacted Latinx and Asian American young adults and their social activism. We conducted in-depth interviews with Asian American (n=12) and Latinx (n=12) emerging adults who identified as activists. Utilizing Interpretive Phenomenological Analysis we examined recurring themes in participants' life stories that explained their involvement in activism. We found that both Asian and Latinx participants were motivated to join political-cultural heritage organizations to bridge and integrate their American and ethnic cultural identities. Prejudice against the Latinx community motivated Latinx participants to become involved in cultural-political organizations in comparison to Asian American involvement in organizations alike, which led to an increased awareness of anti-Asian racism. The rise of the Black Lives Matter movement motivated Asian American activists to advocate against Asian discrimination. In contrast, the Latinx participants were more motivated towards coalitional activism for people of color, specifically Black and Brown. This research illuminates the similarities and differences in trajectories toward activism for Latinx and Asian American young adults.

Abstract Name: **Lina Sandell and the Hymnody of the Evangelical Covenant Church**

The hymnody of Protestant Christian traditions in America has long been researched, reflected on, and loved by those who are a part of those traditions. Hymnody encompasses hymn writing, hymn singing, and the specific hymns of a time, place, or church. The hymnody of the Evangelical Covenant Churchis no exception to research interest.The Evangelical Covenant Church is a prominent example of a Protestant denomination in America whose hymns merit renewed research interest. The purpose of this project is to provide a history of the theology of the Covenant Church, and of the Church itself, through the lens of hymnody. The focus of this project is especially on the hymns of Lina Sandell (1832-1903), a prominent Swedish hymn writer. Sandell here acts as an access point to Covenant theology as well as Church history. The hymnals of the Evangelical Covenant Church, especially those of 1950, 1973, and 1996, will be central to a study of the relation between Sandell's hymns and the Church over time. A study of Sandell's hymnody tells the story of the theological and historical evolution of the Covenant Church, as well as of Protestant Christianity in America more generally. The consistent inclusion – and exclusion – of Sandell hymns across editions of the Evangelical Covenant Church hymnal, spanning nearly 100 years, provides insight about the theological concepts most valued throughout the Church's history. Thus, one woman's personal theology gives invaluable insight into the Covenant as a whole both at its beginning and in its current state. The position taken by this thesis is that Sandell hymns, since they are widely recognized as central to Covenant hymnody, have provided a kind of theological snapshot of what the Church has valued the most - or differently - at various points throughout its history.

Abstract Name: **Enlarged Perivascular Spaces in Patients with Mild Traumatic Brain Injury: Characterization with 7T MRI and Relationship with Neurobehavioral Outcome**

Mild traumatic brain injury (mTBI) is a growing epidemic caused by blunt force trauma or sudden acceleration and deceleration to the head. This sudden impact of trauma has been found to create implications for the waste-removing function of the glymphatic system. In this study, we examined the development of enlarged perivascular spaces (ePVS), a biomarker of glymphatic function, during the acute, 30-day, and 90-day post-injury periods using 7T MRI. Imaging sequences included T2*, MP2RAGE, T2 FLAIR, SWI, and SPACE. mTBI participants at each of the post-injury time periods completed the Neurobehavioral Symptom Inventory (NSI) and the Pittsburgh Sleep Quality Index (PSQI) assessments to identify their neurobehavioral symptoms and sleeping patterns during the post-injury period. The ePVS were identified and the burden severity was rated for each hemisphere. When scored, 83% of the healthy individuals were rated as being "none" or "mild" while 78% of mTBI participants were rated as being "moderate", "frequent", or "severe". There was a significant difference in ePVS burden in mTBI participants when compared to the healthy controls at the acute time point. Both the total number of ePVS ($t(13) = 2.19$, $p = 0.02$) and the number of linear ePVS ($t(13) = 2.4$, $p = 0.01$) were significantly higher in the mTBI group. Preliminary analysis revealed that mTBI participants had significantly higher NSI scores for cognitive, somatosensory, and affective domains following the post-injury time periods (0.02). There was found to be no significant difference in the number of ePVS between the mTBI participants who were identified as being good or bad quality sleepers under the PSQI ($t(15) = 1.22$, $p = 0.27$). Overall, the greater ePVS burden observed in mTBI participants suggests acute disruption to the brain's waste clearance system following a mTBI.

Abstract Name: **Synthesis of mesalamine and curcumin capped silver nanoparticles for the treatment of Irritable Bowel Disease (IBD)**

Silver nanoparticles are innovative materials which have found uses in the field of antiseptics and drug delivery systems as of late. The term IBD (Inflammatory Bowel Disease) is used to describe the series of chronic illnesses that are characterized by inflammation of the intestinal track lining. The two main diseases are Ulcerative Colitis (UC) and Crohns' disease (CD). One (UC) affects mainly the entirety of the colon while the other (CD) affects the entirety of the digestive system (from mouth to anus). To aid in the remission of an inflamed bowel, 5-ASAs (Mesalamine, balzalaside etc.) and curcumin are beneficial, alongside corticosteroids (prednisone) and biologics (Adalimumab and Infliximab). 5-ASAs (Mesalamine) are used to halt and avert flare-ups within the digestive tract while steroids and natural supplements such as curcumin, assist in the management of inflammatory and oxidative conditions. An effective synthesis of silver nanoparticles involves the use of silver nitrate, a capping agent (such as mercaptosuccinic acid) and a strong reducer (such as sodium borohydride). The two experiments were conducted while studying pH changes at each step. Then, UV-Vis was applied to verify the appearance of the nanoparticles. Signals around the 350-400 nm area confirmed the presence of silver nanoparticles in the two experiments. This work explores conditions that are used to synthesize these nanoparticles, that could be beneficial someday, in the delivery of therapeutic agents straight to intestinal lesions in the colon or digestive track.

Abstract Name: **Multihost pathogen creates ecological links between its hosts and thus influence host population dynamics.**

Pathogens that infect multiple species are crucial because they create ecological links between species, even if those species do not directly interact. To understand how multihost-pathogens influence disease transmission dynamics in a multi-host system, we mathematically and computationally model this system, with one common pathogen (Saprolegnia) and multiple hosts, including hosts that are saprobic and tolerant to the shared pathogen. Saprolegnia is an aquatic microbe that can live outside of its hosts; thus, we consider an environmental pool can infect multiple host species living in the same body of water. Host species can indirectly have negative effects on each other by amplifying the number of pathogen infective propagules. Our focal host is the American Bullfrog (Lithobates catesbeianus). Saprolegnia infects the eggs of the frogs and also infects pathogenically and saprophytically other hosts in the same pond. We have completed a mathematical model for the system using a four differential equations system of the Susceptible, Infected, Dead, and Pathogen populations.

Abstract Name: **Optimization of Scheduling Problems on Runways**

Purpose Currently, aircraft delays at airports are eliminated primarily through management by the control tower. Moreover, the Fukuoka Airport is designated as a congested airportwhere air demand greatly exceeds the airport facility capacity.In this paper, we express the creation of the take-off and landing schedules for multiple aircraft at the Fukuoka Airport using mathematical formulas. We developed an algorithm that mechanically resolves delays that occur owing to various reasons, such as weather conditions or delays in the arrival of the next aircraft to be used. In addition, a systematic aircraft arrival order is considered to reduce airline and passenger frustrations (We call this condition (1)). We plan to allow the two aircraft of All Nippon Airways Co., Ltd. and Japan Airlines Co., Ltd. to alternately use the runway as much as possible.Method First, we investigated the current usage of each aircraft and usage conditions at the Fukuoka Airport. Based on this information, the problem of minimizing the scheduled flight time delays of each aircraft, when delays occur, was expressed in mathematical formulas using a method called mixed integer programming, while considering various physical constraints. Furthermore, we expressed the equality in aircraft order using a mathematical formula. The formulas created were calculated numerically using the program. Based on the output results, the timetable was corrected to manage delays.Results By taking the above constraints into account, we were able to calculate a new timetable that improved upon the existing timetable at Fukuoka Airport. When focusing on the 30 minute timetable, the order of the aircraft, without the constraint condition (1), there was an inequity of about 10 minutes. However, with the new timetable with the constraint condition (1) added, the unfairness of the order of aircraft was eliminated.

Abstract Name: **Validation Study of Finite Element Analysis in Aerospace Applications**

Computer-aided design, also known as CAD, has been used to make and design many everyday items used in society, from laundry detergent bottles to heart valves. Finite Element Analysis, known as FEA, is a specific kind of CAD that focuses on simulating how stress and strain can affect the observed part. FEA is valuable when creating simulations, testing materials, looking at constraints and loads, and interpreting the results being simulated. An FEA study can perform different kinds of simulations such as static stress, model frequency, thermal stress, structural buckling, and event simulations just to name a few. This is a validation study with thepurpose of demonstrating the ease of use of FEA software and the repeatability of results. Researchsuggests that FEA is still valid in modernsociety. In this document, we revisit a previous publication onFEA applications in aerospace. Modern tools are used to perform analysis of fasteners and materials common in airframe construction. The previous publication used the ANSYS FE package. Our validation study uses Fusion 360 by Autodesk, which has interoperability with ANSYS.Our data suggest that modern software provides similar results to the previously published work. Unlike previous studies published by doctorial researchers, this publication suggeststhat FEA for aerospace applications can be performed by an undergraduate student. Our research providesnew data about the personnel hours requiredto set up the simulations, the equipment used to run the simulations, as well as how long the simulations took to complete. To show the modern applicability and ease of use of FEA we show the results from a similar analysis run in support of the SWOSU NASA Rover Dawgs competition rover.

Abstract Name: **#FakeBody: Studying How Different TikTok Categories Affect Viewers' Body Image**

Issues with body image are not a new phenomenon in the United States, nor are the media reflecting them. However, what is new is the way that social media platforms change one's perception of themselves, and therefore their body acceptance and disturbance levels. Social comparison theory argues that media can impact one's body perception since the person compares themselves to the people in the media. With different forms of social media there are different effects on a person's body perception. This research is an experiment to determine how TikTok impacts a person's body image. Participants are adolescents aged 18-25 who identify as "female aligned." Participants are found on the Juniata College campus and reached out via personal connections and online postings. In this experiment, there are three different groupings of participants. Each group receives a survey at the beginning and ending of the experiment and then shown different categories of TikTok videos (fitness, body positive, and non-body related). By doing this, the data is run to see the changes in body image perception after watching the different content. Social media is nuanced, and it would be incorrect to say that all social media has a negative effect. Instead, we must investigate where we spend our time online and how that impacts us personally. In media platforms like TikTok, the For You algorithm is set to show videos of content they have previously liked, but the algorithm is imperfect. My research sets a precedent of what types of TikTok videos affect body image and can be used to further research on what specific media have a greater impact on body image.

Abstract Name: **Development of a Graphene-Based Microelectronic Device**

In recent years, advancements in nanoscale carbon have led to an explosion of research and development on possible applications of graphene. Specifically, the electrical properties of graphene make it desirable for flexible devices, energy storage, and general computing applications. One of the most common ways to acquire graphene is through chemical vapor deposition (CVD), where a metal substrate is exposed to methane gas at high temperatures leaving a layer of carbon (graphene) behind. This project's goal is to use CVD graphene in combination with a silicon and gold substrate to create a microelectronic device that functions as a rudimentary transistor. So far, CVD graphene has been retrieved from the copper foil substrate using an Fe3Cl bath and channels have been etched into a SiO2 wafer using photoresist pattern transfer and NH4F etchant. Both the graphene and the channels in the SiO2 wafer have been characterized by white light and atomic force microscopy. The goal is to deposit gold within the etched channels, lay the graphene across them, and test for conductivity from one channel, through the graphene, and into another channel. To achieve this, chromium (for adherence) then gold will be applied to the SiO2 wafer through physical vapor deposition. The deposited metal will be polished until it only remains within the channels. Finally, the graphene will be laid across the channels and the assembled component will be tested for continuity between channels connected by the graphene sheet. Contingent on size optimization, it may be possible to create a transistor using graphene which performs the same functions as traditional semiconductors but with more desirable efficiency and thermal performance. This would allow for smaller, more energy efficient computing devices in a world where efficient, clean production and use of energy is a top priority.

Abstract Name: **Effects of Substrate Stiffness on Bacterial Biofilm Growth**

When bacteria settle onsurfaces, they can build up and form biofilms, which are groups of bacterial cells that are irreversibly attached to the surface. Biofilms have the potential to form on indwelling medical devices such as catheters and may eventually lead to bloodstream infections. In the United States, an estimated 250,000-400,000 catheter-related bloodstream infections (CLABSIs) occur every year. Researchers are exploring how surface characteristics such as stiffness, physical features, and chemical treatments can affect biofilm growth. We are investigating how varying the stiffness of polydimethylsiloxane (PDMS) substrates affects biofilm growth on the surface, specifically biofilm growth of bacteria such as S. epidermidis and S. aureus, which are commonly found on central venous catheters (CVCs). PDMS is a polymer that crosslinks into a soft solid upon heating, and results will be presented for biofilm growth on three different PDMS elastomers. Studying how different substrate stiffness affects the growth of bacterial biofilms may help provide a cost-effective and simple way to reduce bacterial adhesion on catheters, thereby improving the health of patients.

Abstract Name: **Teaching The California Genocide**

This presentation covers a nine-day Project-Based Learning unit plan for twelfth graders on the California Native American Genocide of 1846 to 1873. The unit plan sequentially scaffolds the students' learning, allowing them to construct meaning as they interact with content in various learning tasks requiring critical High Order Thinking (Jigsaw activity, research, public presentations, etc.). Along with inculcating virtue to prevent future genocides, the desired outcome of the unit is for students to extrapolate what they know about the California Genocide into the modern day to take a stand as informed citizens on the current Native American reparations debate.

Abstract Name: **Detecting Bias in Intelligent Autonomous Hiring Systems**

This project analyzed if artificial intelligence (AI) hiring systems demonstrate prestige bias, and how that bias may be mitigated. We chose to look at prestige bias since the quality of a candidate's education will naturally be reflected in their skills and experience; a school's reputation should not additionally be factored into a hiring decision. Of note, this project analyzed prestige bias against Historically Black Colleges and Universities (HBCUs). The majority of students attending HBCUs are people of color who are already marginalized members of society. We examined how hiring site Indeed utilizes AI to list candidate resumes by relevance and measured the relationship between a candidate's resume ranking and the university they attended. We expect to find a negative association between HBCU status and ranking, which is stronger than the association between ranking and other confounding variables such as experience type, degree level, field of study, etc. Subsequently, we will develop our own AI system, utilizing hiring decision data that we collected from Indeed, to observe if it will present a similar bias. If so, then we will apply debiasing techniques to our model to create a new AI hiring system that is not biased against HBCU applicants. With businesses considering AI as a tool for hiring, companies must understand that AI hiring systems can perpetuate the same biases found in human hiring on a larger scale.

Abstract Name: **Improving diagnosis of kidney cancer using Infrared Spectroscopic Imaging**

Infrared Spectroscopic Imaging has been shown to be a powerful approach to rapidly image human tissue biopsies to identify biochemical signatures associated with disease outcome. In this study we have applied two types of IR imaging to distinguish between two types of kidney cancer, chromophobe and oncocytoma. These two cancers represent a very difficult problem for the medical community to diagnose as the clinical symptoms are similar and they look almost identical to the experience pathologist. Definitive diagnosis between the two types is critical as the treatment options and prognosis for these two kidney cancers are very different. In this study we demonstrated that tradition IR imaging using a Fourier Transform based approach could allow for excellent objective diagnosis of these cancers. A newer faster laser-based approach which has potentially better applicability for clinical practice also demonstrated classification between the two groups. A comparison of the results between the two imaging tools will be compared and contrasted. Furthermore, we will present some new results about how kidney cancer can be effected by the diabetic status of the patient.

Abstract Name: Detecting Deception Through Facial Expressions: Using Facial Feature Extraction Methods to Identify Deception Through Video

There is a widely held belief that nonverbal forms of communication serve as reliable cues for detecting deception. Deception is often accompanied by hiding one's true internal states from others. Individuals under stressful circumstances may fail to inhibit their own feelings, causing an involuntary "leakage" of their emotional state through changes in body language or facial expressions. This leads us to believe that two distinct areas of the brain are responsible for voluntary and involuntary movements of the face. A "tug of war" between both systems would allow for quick leakage of facial expressions when an individual engages in deception to conceal emotional states. This study examines whether facial micro-expressions are a reliable means to detect deception with machine learning and feature extraction methods. To date, few studies have examined the accuracy of machine learning when exposed to specific sets of facial expressions, particularly those under involuntary control. Our first goal was to create a new data set of recorded videos to be used with a machine learning model. This data set includes video of participants playing a social deduction video game,Among Us, where participants must convincingly lie to their opponents to win the game. Videos of participants under these conditions were preprocessed with a feature selection method,OpenFace, to extract facial expression data from images and video collected from the study. We then extracted data to classify facial expressions as deceptive or non-deceptive. The results indicate that machine learning, paired with feature extraction methods, can provide additional insights for determining facial expressions involved in deception.

Abstract Name: Analysis and Optimization of Polycaprolactone Flow Diverting Stents for Treatment of Brain Aneurysms

Bioresorbable, flow-diverting stents (FDS) have great potential to reduce the risk associated with non-degradable metallic FDS such as late thrombosis and re-stenosis in the endovascular treatment of intracranial aneurysms. Recently, we developed a polycaprolactone (PCL) bioresorbable, non-braided FDS using a noble, in-house fabrication unit. Due to inconsistencies in temperature from available machines, a kiln was designed and made from a vacuum-sealed tumbler. The tumbler is exceptional in retaining heat within due to its vacuum layer. Heat is supplied inside the tumbler through a ceramic heater that is wired to a power supply. The ceramic heater is attached to a heatsink via thermal adhesive and a fan is placed below to allow for convection. A thermistor located inside the tumbler reads the temperature and sends the information to an Arduino. The Arduino controls a relay that turns the ceramic heater on and off in order to regulate the temperature to the set threshold of 55°C. Heat treatment of the PCL involves a temperature of 55°C ±1.5°C for a period of four hours. The surface and structural quality of the FDS was evaluated using a scanning electron microscope (SEM) and a 3D profilometer. A UniVert mechanical testing machine (UTM) is used post-treatment to determine differences in material elasticity via longitudinal tensile and perpendicular compression testing. FDS properties and structural integrity were also evaluated and compared post-ejection from the 4 Fr delivery catheter. The biocompatibility of the heat-treated FDS was evaluated through proliferation and adhesion of HUVECs, and lactate dehydrogenase (LDH) cytotoxicity assay with HUVECs. The results showed that heat treatment facilitates an increase in fusion between the layers and surface area of bonding between layers. Upon ejection from the 4 Fr catheter, the FDS better maintains the previous diameter before the FDS was inserted into the catheter, which was previously an issue.

Abstract Name: Behind the ?Runner?s High?: Effects of Acute Exercise and Meditation on Anxiety and Endocannabinoid Levels in Youth

Background: The beneficial effects of exercise and meditation on mental health are well established. Data in adults and animal models suggest that circulating endocannabinoids (eCBs) are elevated following acute exercise, which may explain beneficial mental health effects (e.g., lowered anxiety). However, no studies to-date have examined the impact of acute exercise or meditation on eCBs in youth. This is important because anxiety and other mental health problems typically begin during childhood and adolescence, which coincides with developmental changes in eCB signaling. This randomized controlled trial study compared effects of a 30-min (1) moderate-intensity treadmill, (2) light-intensity stretching, or (3) seated meditation session on state anxiety and circulating eCB concentrations in youth. Methods: Data were collected from 25 youth in an ongoing study (52% female, M=12.92±2.18 years). State anxiety and eCB concentrations were measured before and after randomization into one of the three conditions: treadmill exercise (N=12), stretching (N=9) or meditation (N=4). Results: There was a significant decrease in anxiety scores from before to after the 30-minute session (0.001, d=0.79), regardless of condition. There were no significant main effects of condition, nor significant time by intervention interaction on anxiety scores (p>0.05). Participants exhibited higher pre-to-post concentrations of the eCB anandamide following the treadmill condition; however, these effects did not reach statistical significance (p>0.05).Discussion:Our results demonstrate that acute exercise of both light and moderate intensity, as well as meditation, are associated with reductions in state anxiety in youth. Although not significant, preliminary analyses suggest that moderate-intensity exercise is associated with elevations in circulating eCBs.

Abstract Name: Food As Medicine Program Analysis

The relationship one has with food is directly correlated with one's health. Our current health system has a severe issue with individuals with chronic illnesses who face issues of affordability and accessibility to food. This has led food pantries across the country to develop food as medicine programs which can consist of medically tailored meals, medically tailored packages, and nutritious food referrals. Ultimately, the goal of these food intervention programs is to help create a better lifestyle and improve the health of individuals with food insecurity and chronic illnesses. This presentation will focus on an analysis of the Food as Medicine program at the Food Pantries for the Capital District. Our hypothesis is that Food as Medicine intervention programs improve the health of individuals with chronic illnesses which is evident through the changes in their A1C levels, BMI, number of hospitalizations, and blood pressure.

Abstract Name: A Computer-Based Model to Capture Gastric Electrophysiology Through Bio-Impedance Analysis

The ability to monitor the bioelectrical activity of the gastrointestinal tract, in a non-invasive manner is essential for the diagnosis and management of functional gastrointestinal disorders. Electrical bio-impedance (Bio-Z) analysis is a promising method to acquire a wide range of human electrophysiological activities, through wearable electrodes. The Bio-Z sensing system consists of a four-electrode configuration on the body surface in which the two outer electrodes deliver a sinusoidal excitation signal transcutaneously, and the two inner electrodes acquire a differential potential which will be conditioned, processed, and mapped to the electrophysiology of interest.To this end, we developed a computer-based model of the human gastric system in COMSOL Multiphysics, a simulation platform based on the finite element method. Through the model, we simulated the Bio-Z analysis to capture the gastric electrophysiology, through the body surface. The objective of the project is to simulate the penetration depth of the Bio-Z analysis as a function of frequency and find the optimum frequency for the clinical data collection on human subjects. We developed the model of the abdomen through four layers of skin, fat, muscle, and peritoneum. Besides, we developed the model of the gastrointestinal tract through four layers of serosa, muscularis, submucosa, and mucosa. The model of four AgCl electrodes was added to the model of biological layers, too. The frequency-dependent permittivity and conductivity parameters were assigned to each biological layer for the simulation at each Bio-Z frequency. In COMSOL, we generated the electric fields resulting from the applied sinusoidal excitation signals at various frequencies in the range of 10 kHz to 250 kHz to the stomach, transcutaneously. Then, we plotted the power spectrums of the electric fields and compared them at the penetration level of the gastric tract.

Abstract Name: Oxygen-glucose Deprivation Models Ischemic Cell Death in CA1 Hippocampus

In the United States, every 40 seconds someone suffers from stroke, and every 3.5 minutes someone dies from stroke. It has been shown that CA1 neurons specifically are imperative for retrieval of episodic memory as well as autonoetic consciousness. Areas important for learning and memory are nearly destroyed following ischemia (stroke) over time regain some but not all functionality. Calcium regulation is important for normal functioning of neuronal signaling cascades, but during ischemia too much calcium influx can trigger excitotoxic cell death. Therefore, regulation of intracellular Ca2+ is important for protection against ischemia, and may be useful in developing treatments that reduce ischemic brain damage and preserve cognitive functioning. In order to study the neuroprotective effects of treatment, baseline counts of cell death must be made for comparison. The present study used an in vitro rat brain slice model from 5 adult F344 rats to validate the hypothesis that cells that undergo oxygen-glucose deprivation (OGD) exhibit significantly more cell death than cells that did not undergo OGD. Dorsal hippocampal slices were prepared and subjected to 5 minutes of OGD, and cell death was assayed using the Trypan blue exclusion method. Dead and dying cells take up the Trypan blue while healthy neurons exclude the dye and are left unstained. The number of Trypan blue labeled neurons were then counted using the program ImageJ. The present study shows that just 5-min of OGD models an ischemic attack, resulting in a baseline control that can be used comparatively to examine effects of treatment on cell death. The general aim of this research is to produce a control value of cell death to demonstrate the effectiveness of this model for future neuroprotective research.

Abstract Name: Carbonyl Allylation by Allylic Acetates

Carbonyls are important centers of reactivity in Organic Chemistry. They react readily with electron-rich compounds to make carbon-carbon bonds. One common reaction is allylation, in which a carbon next to an alkene is added to the carbonyl. While many allyl groups can be used, allylic halides are the most common. Unfortunately, they are not very stable and, in most cases, must be synthesized immediately before use. Allylic acetates are much more stable and can be easily prepared and stored from highly stable allylic alcohols, but their use in allylation chemistry has not been well studied. My work explores their use in a nickel-catalyzed reaction. In the presenceof a nickel bidentate complex, heat, zinc, DMF,and a weak acid, allylic acetates react with carbonyl compounds.The carbonyls explored demonstrateseveral types of functionalitiesacceptable for this reaction from electronically rich aromatic aldehydes to non-aromatic cyclized ketones. Like the carbonyls, allylic acetates also can have varying functionalities. Non-symmetric allylic acetateshave been studiedfor their conversion efficiencies and regioselectivity. These properties include coordination, steric hinderance, and isomeric arrangement (geraniol and linalool).The goal of this work is to find a simple set of allylation conditions using stable allylic acetates that can be of use to other chemists.

Abstract Name: The Dutch Stranger?s Library: An Examination of Donations to the Library of the Dutch Church in London and What it can Teach Us About Modern Library Collection Development

My research focuses on the Dutch Stranger's Church in London, more specifically on their library, and how it grew and developed through periods of political and social strife, upheaval, and change in the seventeenth century. More specifically, I wish to research the two decades between 1640 and 1660, during the English Civil War and the Republic. During this time, England was in a tumultuous state for both Englishmen and foreigners, when considering the English Civil War, the short-lived Republic, and the restoration of the monarchy, as well as the Anglo-Dutch wars, all happened at this time. This was a difficult time for the Dutch community in London, and the library provides a lens through which to view how the foreign community navigated the political turmoil. Little scholarly attention has been paid to this historic library, but I am drawing on the data collected by the Dutch Church Book Provenance Project, a research effort in which I have participated and which seeks to create a census of the library's contents. I have created my own dataset of book donors that I am comparing to the libraries acquisitions to identify changes in the collection between the years of 1640 and 1660. The library's contents demonstrate ways the foreign community reacted to rapidly changing political realities. This research challenges the prevailing notion that libraries should remain neutral repositories. The research also affords an examination of the history of the Dutch Church Library, and how collections could serve as an expression of identity for foreign communities.

Abstract Name: **Are We Achieving Unity? Comparing Current Initiatives Addressing Political Polarization with Community Experience**

The United States has experienced increasing political polarization in the last 30 years, particularly since 2012. Many Americans have faced the division of political polarization within their communities, making not only straining daily relationships but slowly the democratic process.To better understand sources of and solutions to increasing political polarization in the US, this project utilizes two studies to examine how American civil society actors, specifically America-based religious and non-governmental organizations (NGOs), address this pressing challenge. Study 1 features a mixed-method analysis of mission statements and project descriptions of American NGOs (N=100) addressing domestic political polarization nationally and in three different case study states, Arizona, Louisiana, and Virginia. Preliminary results indicate a wide range of approaches and possible redundancies of projects being done by multiple organizations in one community. Specific data from Arizona, Louisiana, and Virginia offer interesting divergences and similarities in initiatives among different voting histories and policy priorities. To complement this national data and offer insight into Louisiana's NGOs' strategies, Study 2 centers on a series of semi-structured interviews (N=9) with religious leaders and congregants of two churches in Lake Charles, Louisiana, on topics related to (1) participants' conceptions of political polarization, (2) experiences of polarization in their communities, and (3) recommendations to address polarization. Taken together, results from both studies suggest civil society actors, specifically American NGOs and religious institutions, can play significant roles in addressing political polarization throughout the United States.This data offers a foundation for future interventions to be implemented in polarized communities across the country, especially those heavily religious. In comparing all NGO interventions with those of specifically religious institutions, possible advantages and disadvantages may be discovered, and best practices for addressing political polarization in religious communities may be uncovered.

Abstract Name: **Functional Genomics Tool for Calcium Signaling in Schrenkiella parvula.**

Combating environmental stressors such as salinity presents a major challenge to agriculture. Salinity in soil and water reduces crop yield, with the majority of plant species being adversely affected by salty environment. With higher concentrations of sodium, changes in hydrostatic pressure and ion transport cause physical changes in the plasma membrane and cell wall of a plant leading to dehydration and eventually cellular death. Exploring plant mechanisms for surviving such stressors are necessary as fresh water sources are limited and arable land are slowly being depleted. Salinity stress can also be observed to have consequence in hormonal imbalances particularly in the regulation of other ions. In salt tolerant plants calcium sensors play a key role in supporting plants in salt environments. Calcium signaling is a central aspect to both developmental and adaptive processes in plants being an essential macronutrient as well as a second messenger in biological processes. When sodium levels increase, signals for protein are activated throughout the cell by calcium there-for inhibiting excessive ion accumulation. This shows that intracellular calcium signaling lessens the effect of sodium levels in salt tolerant plants. Schrenkiella parvula in addition, shows significant growth capacity during salt stress when compared to its popular stress sensitive relative: Arabidopsis thaliana. Schrenkiella parvula being an extremophyte is a plant that can be characterized by its ability to withstand environments with extreme heat, cold, salt, acid and alkaline traits. Their ability to handle intense environments can be attributed to the high activity of its calcium sensors. The goal is to make transgenic plants expressing fluorescent calcium sensors proteins to study calcium signaling in S.parvula in response to salt and then compare this to the responses in the salt sensitive relative Arabidopsis thaliana.

Abstract Name: **Discovery of a programmed frameshift in the tail assembly chaperone genes of the novel bacteriophage SeaWolves**

Bacteriophages are viral particles that specifically infect bacterial cells and have a potential use in the treatment of antibiotic resistant bacterial infections. The goal of this study was to characterize and annotate the genome of the novel bacteriophage SeaWolves that belongs to the EE bacteriophage cluster. Previously, we had discovered and annotated two other novel Actinobacteriophages of the EE cluster, Vanisius and Jannah, which we used for comparison in this study. EE cluster bacteriophages generally utilize the virulent lytic cycle and their genomes are relatively small in size with approximately 17,383 base pairs. The novel phages were isolated from soil samples using a known host, the soil-dwelling bacterium Microbacterium foliorum. Genome characterization and annotation were performed using PECAAN, Aragorn v1.2.38, tRNAscan-SE and DNAMaster annotation software tools. Our comparative genomic analysis demonstrated that SeaWolves and other EE cluster phages have a programmed translational frameshift in the tail assembly chaperone gene family. We identified and mapped the highly conserved slippery nucleotide sequence GGGAAAA within the tail assembly chaperone genes #10 and #11 by specifically searching for a slippery sequence motif across the 89 phage members of the EE cluster. The overlapping two open reading frames of these genes, resulting in production of two proteins, are flanked by the genes encoding the major structural components of the phage tail architecture. Further bioinformatics analysis showed the absence of the tRNA genes in the SeaWolves genome but generated strong evidence for strong conservation in the (-1) frameshifting site GGGAAAA. We conclude that such a consistent similarity in the EE cluster phages gene organization is not accidental, and that the programmed frameshift plays an important biological role, which has been conserved during phage evolution.

Abstract Name: **Length Variation at a Microsatellite in the Human Relaxin (RLN2) Promoter Affects Transcription Levels in Vitro**

Complications with preterm birth are the leading cause of infant mortality and morbidity worldwide. Several factors contribute to susceptibility, but previous studies identified an association with the promoter region of the relaxin gene (RLN2) and levels of relaxin during pregnancy. RLN2 codes for human relaxin hormone, which is involved in preparation of membranes and cervical tissue at the onset of labor. We hypothesize that different compositions of a $(CT)_n(GT)_m$ microsatellite within the relaxin promoter will produce different levels of relaxin. To test our hypothesis, we amplified the ~1kb upstream promoter region from four different previously genotyped human DNA samples, ligated the products into a pNL1.1 luciferase reporter vector, and transfected into a human placental cell line to quantify transcription in vitro using a luciferase assay. DNA sequencing confirmed these promoter alleles contained 23, 28, 33, and 38 microsatellite repeat units. Differences in transcription levels among alleles were evaluated with a one-way ANOVA test. These results will be discussed in light of human genetic variation at RLN2 and susceptibility to preterm birth.

Abstract Name: **A New Method for Counting and Identifying Water Molds in Field Samples**

Water molds (Oomycota) are aquatic multi-host pathogens that infect many species of amphibians and aquatic invertebrates. We developed a modified method for the quantification of reproductive propagules (zoospores) responsible for water mold transmission between hosts in aquatic habitats using Microwell Plates (MWP). We added 100 µL of potato dextrose agar to each well of a 96 microwell plate. We then added 100 µL of water from a serial dilution of water mold zoospores with known concentrations based on hemocytometer counts. We found that there was a close relationship between hemocytometer counts and microwell plate counts. When we tested water samples from a local wetland, the MWP method proved to be precise and repeatable when water samples from four field locations were assessed. To confirm that the quantified growths on MWP are the target species of water mold, Saprolegnia Sp. 2, molecular methods of identification such as using specific probes and primers in a quantitative polymerase chain reaction (qPCR), and restriction fragment length polymorphism (RFLP) in a restriction enzyme digest were tested. A DNA extraction method using squishing buffer and proteinase K was successful in reliably extracting water mold DNA for use in qPCR. Moving forward, the specific primers and probes that were created for the target species of water mold for use in the qPCR and the restriction enzymes that were selected for use in a digest will be tested on extracted water mold DNA to identify the growths counted.

Abstract Name: **Measuring the validity of the Laboratory Perspectives Instrument and exploring the laboratory perspectives of undergraduate chemistry students.**

Students' perspectives of the chemistry laboratory may influence their motivation or performance. In a prior phenomenographical qualitative study, eight laboratory perspectives were identified. A survey instrument was developed using the wording provided by undergraduates in this qualitative study about their experiences in the chemistry laboratory. These perspectives – Explorer, Independent Researcher, Socialite, Mastery, Skill Developer, Time Saver, Detail Oriented, and Apathetic – are common in gateway chemistry courses which are crucial for developing medical, industrial, and academic minds. Using these laboratory perspectives, we seek to answer the following questions: (RQ1) Is the laboratory perspectives instrument valid and reliable? (RQ2) What perspectives are prevalent in general and organic chemistry labs? In the fall 2022 semester, students in general and organic chemistry participated in the survey and cognitive interviews. By incorporating cognitive interviews and quantitative survey data, the researchers take a mixed-method approach to answer the research questions. Through cognitive interviews item wording, comprehension, and the reasoning behind decisions on the survey will be assessed, and changes will be made to the instrument when applicable. The validity of the instrument will be investigated using exploratory factor analysis and scree plots. Statistical correlations will be determined to provide information about relationships that may exist between course levels, laboratory perspectives, goal orientations, and demographics. Through these analyses, we expect to provide additional evidence for the eight laboratory perspectives uncovered in the previous study and for the validity and reliability of the survey instrument.

Abstract Name: **The Prevalence of Urinary Incontinence in Female Collegiate Athletes**

The unintentional loss of urine, or urinary incontinence (UI), can have a negative impact on quality of life, including low self-esteem, depression, and reduced participation in social activities. UI has been studied in post-partum and older women; however, there is little research on female collegiate athletes, likely due to the fact that most collegiate athletes are young, relatively healthy, and have not given birth. The purpose of this study is to identify the prevalence of UI among National Collegiate Athletic Association (NCAA) Division-III female athletes at a Midwestern university. Emails and fliers were used to recruit all 159 eligible student-athletes; potential participants were asked to complete a voluntary, anonymous, online survey regarding their experience with UI during sport. Questions included information about unintentional leakage of urine during sport participation (practice, training, competition), as well as everyday life. The response rate was 80.5%. In everyday life, 59.4% of participants experienced UI, while 43.0% experienced UI related to sport. Based on prior literature, the eleven sports were divided into three impact groups: high, moderate and low. According to a chi-square analysis, there was no statistically significant difference in prevalence of UI between impact groups. Based on the high prevalence of UI in this study population, it is recommended to screen for UI in the female athletic population, beginning in adolescence, to treat the condition in its early stages. It is important to encourage screening to allow women to continue to be physically active and improve their overall quality of life. Further research should include how education for healthcare providers, athletes, and athletic staff can impact the prevention of UI and assist in promoting early interventions to keep athletes in sport and mitigate future issues.

Abstract Name: **Understanding the minimal requirements for selective ribose binding using de novo protein design**

Adenine triphosphate, ATP, is the main energy source in nature, but how it interacts with proteins, specifically their binding sites, is not fully known. There are two main reasons for this. First, ATP has three distant chemical parts: adenine, triphosphate, and ribofuranose. While some proteins bind ATP the contribution from each part is unknown. Secondly, natural protein is complex due to millions of years of evolution. By building a de novo protein that can bind each individual component and then retroactively recapitulate the active site, the fundamental biophysical forces for binding the entire ATP molecule can be found. These principles can then be transferred to other proteins for a variety of different uses such as understanding the metabolic pathway through ATP kinase activation and inhibition. My project specifically looks at generating a protein that binds ribose, the 5-carbon sugar in ATP. We used computational tools to design and analyze our initial protein designs. We used computational tools to design and characterize our initial protein designs. The gene was ordered with a histidine tag and purified using standard Ni-Column denaturing protocols. The predicted secondary structure, both with and without ribose present, was confirmed using circular dichroism. Currently, the dissociation constant and thermodynamic properties are being found by utilizing isothermal titration calorimetry. Simultaneously, we are looking at using alternative computational methods, Rosetta, to build different protein variants to test if different computational approaches will design a protein with an equivalent or better affinity for sugar. Currently, no Rosetta protein is better than the previous hand-designed protein, however, flexible docking is being implemented to test for secondary structure change.

Abstract Name: An Interregional Analysis of Scandinavian Pre-Roman to Roman Iron Age Ceramics

During the peak of the Roman Iron Age, the site of Sorte Muld in Bornholm, Denmark was a thriving settlement that flourished on agriculture, livestock, and oceanic trade with the Roman Empire and Gothic groups in Germany. These trade connections highly influenced the customs and material culture of the occupants of Sorte Muld. What remains of Sorte Muld is buried below a wheat field with the looming threat of agricultural activity disturbing the cultural context of this spectacular site. While Sorte Muld is famous for itsgulgubbes(hammered gold foil images depicting men, women, animals, and other unidentifiable figures), the ceramics at the site are much more abundant and can tell us about the daily life and true purpose of the settlement. After analyzing and determining the typology of 64 ceramic sherds, it can be determined thus far that the site can be placed between the Pre-Roman to Roman Iron Age. However, I will be taking a step further in comparing my finds to a dataset from Sorte Muld's sister-site, Uppäkra, to determine if the area of excavation was domestic or ceremonial. Evidence suggests that Sorte Muld is primarily a domestic site, but the area of excavation, where I worked last summer, may have been ceremonial. During that research, the postholes of a large domestic structure were uncovered along with agulgubbeand other special metal items. My ceramics analysis sheds light on what activities may have gone on within this building at Sorte Muld and whether its primary function was ceremonial or domestic.

Abstract Name: Intentional Paleoart: Creating Accessible and Engaging Resources for Children using Fossils from the Arlington Archosaur Site

Aside from the representation of dinosaurs in media and pop culture, scientific concepts in paleontology are often inaccessible to and misunderstood by many. Media often misrepresents paleontology, and many outside the sciences misunderstand even accepted theories, such as evolution. Challenging concepts, unfamiliar vocabulary, and difficult-to-pronounce names can be intimidating and diminish interest in the field. For most children, exposure to paleontology will be mediated through adult caregivers, and the level of exposure, will be relative to the adult's relationship with and understanding of science. Since a child's encounter with paleontology may be brief, it is critical to remove barriers and capitalize on these moments by introducing paleontological materials which are both engaging and scientifically accurate. With a goal of making paleontology accessible, informative, and appealing to children, we have developed intentional line illustrations to be utilized as coloring page activities. The drawings represent real species discovered at the Arlington Archosaur Site (AAS) near Dallas, Texas. Each species image is created with a targeted age group in mind with respect to cognitive abilities and attention skill levels of a developmental stage. Features we have fossil evidence for, such as teeth or toe bones, are highlighted to explain how paleontologists make inferences about a species' diet, behavior, and environment. Through intentional paleoart, we can connect a fossil to a species' ecology, allowing for analogies to be made between extinct animals and living counterparts. In creating paleoart which is accessible and relatable, we can support child caregivers in relaying scientific information which leads to learning gains, and in turn, better represent paleontology as a discipline.

Abstract Name: Development of a Socio-Scientific Air Quality Data Interface: A Study of Loyola University Chicago?s Inter-Campus Shuttle System

In 2010, the Loyola University Chicago (LUC) Biodiesel Program became the first school program in the U.S. licensed to sell biodiesel, a renewable liquid fuel produced from used cooking oil. When used as a blend in existing diesel engines, there is a 50% reduction in particulate matter (PM) emissions from biodiesel engines compared to conventional diesel engines and 70% reduction in hydrocarbon emissions. The LUC Biodiesel Program has begun fueling two of the six shuttle buses utilized by LUC on 100% biodiesel (B100). This project aimed to study the socio-scientific impact of bus emissions on air pollution by compiling a community-science air quality dataset through a comparative study of LUCs shuttle bus system. Seventeen air quality sensors were strategically placed throughout the shuttle bus route system for B100 and petroleum diesel buses, including on five student passengers. These sensors recorded GPS coordinates, PM2.5 and volatile organic compound concentrations by minute. Data was stored in a relational database and used alongside GIS software to generate a heatmap of air quality across LUCs campuses and transportation systems. We hypothesize that B100 buses will emit less PM and VOCs than petroleum diesel buses. We anticipate that analysis and modeling in early 2023 will correspond with our hypothesis.

Abstract Name: ParaView-ing Data at NERSC using Jupyter Notebook

ParaView is an open source data visualization and analysis program that is used by researchers around the world to analyze complex scientific datasets, containing things like a mixture of particles and fluids. Due to their size and complexity, these datasets cannot be effectively analyzed with general-purpose tools like Microsoft Excel. Prior to this project, ParaView data at Lawrence Berkeley National Laboratory was exclusively analyzed using the ParaView graphic user interface (GUI) client. However, Jupyter is an increasingly popular web-based application that allows users to create and share documents containing code. This project is investigating ways to expand ParaView support in Jupyter. Kitware, the creators of ParaView, have developed a kernel for Jupyter that allows a python representation of the ParaView scene in Jupyter to be rendered by ParaView and displayed in the same notebook. In previous work we have shown that Jupyter notebooks running the ParaView Kernel can be set up on a personal computer and connected to a ParaView server that is running on a supercomputer. This project aims to fully implement this kernel on the supercomputers at the National Energy Research Scientific Computing Center (NERSC) through a Kubernetes cluster on the NERSC network.

Abstract Name: **Oak Osmolyte Concentrations in Response to Drought**

Water represents an essential environmental factor, as it impacts plant growth, development, and structure. Drought stress induces plant acclimation to avoid tissue loss or death. Plants must adjust their physiology in response to low water concentrations. One way plants acclimate to drought is by accumulating more osmolytes (e.g., sugars, sugar-alcohols, proline). Osmolytes are known to increase drought tolerance in plants by increasing the uptake of water by plant tissues. Oak species are widespread and adapted to a wide range of mesic, and xeric conditions. Mesic environments have an abundance of water, but xeric, or drought environments lack water. The objective of our research is to investigate the amount of osmolytes, specifically proline, produced by various oak species using a common garden. Eleven oak species were grown under two water conditions: well-watered and drought. Leaf tissue extracts were analyzed for proline through a colorimetric assay. Currently, results indicate that oaks from well-watered treatments and that originate from high organic carbon soils have higher concentrations of proline. Oaks from drought treatments increased overall osmolyte concentration and did not increase proline concentrations. This may result from limited nutrient uptake under drought treatments. More research should be done to elucidate how access to soil nutrients impacts drought tolerance. Data from this research could spring new directions for higher crop yield in drought conditions. Furthermore, results from this research may provide insights as to how plants acclimate to drought in a changing global climate.

Abstract Name: **Examining Short-Term and Long-Term Stress Impact on Cognitive Health in College Students**

Stress can impact psychological health, and for college students, the short-term (ST) stressors involved in school have been correlated with higher psychiatric problems such as depression, anxiety, and substance abuse (Pedrelli et al., 2014). Chronic stress has been linked to lower cognitive functioning, but studies have mainly focused on older populations (Marin et al., 2011). Much of this work has pointed to the impact of long-term (LT) stressors, such as the link between PTSD and cognitive impairment, especially in veterans (Vasterling et al., 1998) and the effects of childhood trauma on adults (Majer et al., 2010). Most of the cognitive research done on stress has been focused on memory and does not adequately compare ST to LT stress. In our study, we want to examine whether the relation between stress and cognitive deficits seen in older populations also applies to college students. We will examine attention in addition to memory, meanwhile comparing ST and LT stress in hopes to fill these gaps. Participants will complete two surveys, one for LT stress (Strain and Adversity Inventory for Adults; Slavich, 2018), and one for ST stress (Student Stress Scale; Firn, 2017). To test cognitive functioning, students will also complete measures of spatial working memory (Corsi Block Task), and attention (Flanker Task). Regression analyses will be used to identify any effects of ST and LT stress on these cognitive tasks. Data collection is ongoing, but we predict that students who score higher on both the ST and LT stress surveys will score poorer on both the memory and attention tasks. Memory and attention are cognitive skills that are necessary for successful learning, and studying the implications stress can have on these skills is essential to coming up with solutions on how to prevent cognitive impairment during such a pivotal time in life.

Abstract Name: **Simulated Rooftop Prairie Plant Community Comparison to a Prairie Remnant Plant Community**

In 2008, in downtown Kansas City Missouri, a 14,000-square-foot rooftop prairie garden was established in a 4-inch coarse substrate. 15 years later, the garden consists of a self-organized community of native prairie plant species. In novel anthropogenic conditions, we compared this simulated plant community and its comparable ecosystem. A restored prairie remnant, Jerry Smith Park, served as a comparative community to the rooftop. We observed species richness and abundance via the Daubenmire Quadrat Method over three sampling plots: the rooftop garden, an unmanaged field in Jerry Smith, and a recently burned hillside in Jerry Smith. In a three-month sampling period, 77 plant species were observed. The three plots were compared using functional group percentages, Conservatism Coefficient (CC) means, and Floristic Quality Index (FQI) scores. The rooftop prairie Conservatism Coefficient means were similar to both prairie remnant sites. The rooftop prairie had lower FQI scores than the managed site, but similar scores to the old field site. The rooftop had higher abundance of native forbs compared to both Jerry Smith sites. While both remnant sites had higher abundances of grasses, sedges, and rushes, the managed plot had a significantly higher abundance of native graminoids. Within Jerry Smith, we observed higher abundance of native species overall. However, they varied throughout the sampling season. These differences are reflective of the abiotic and aesthetic pressures on the rooftop garden. Contrasts between the remnant plots are representative of the management they have received.Similarities found between the rooftop and remnant sites offer insight into the bridge between anthropogenic environments and reference sites. Further research comparing the biotic and abiotic structure and function of different prairie remnants to anthropogenic prairie communities is warranted.

Abstract Name: **Identifying the Presence of Semen Through the Detection of Fructose**

Seminal fluid is among the most valuable sources of biological evidence which can be recovered from a crime scene. Current tests such as the prostate-specific antigen (PSA) test and microscopic examination for spermatozoa are non-comprehensive and have high potential for false positive or false negative results. Fructose is a naturally occurring sugar which serves as the main energy source for sperm in semen. We hypothesize that quantification of fructose in semen under different conditions, and compared to other bodily fluids, may aid in identification of crime scene samples. A colorimetric fructose assay kit was used to quantify fructose levels in semen samples, as well as other common biological fluids such as blood, saliva, urine, and vaginal fluid. Additionally, we aim to compare semen samples from vasectomized and non-vasectomized men, under the hypothesis that the presence of sperm will decrease fructose levels over time as this sugar is metabolized. The differences in fructose concentrations observed, as well as potential implications for the discriminatory power of fructose-based identification of body fluids, will be discussed.

Abstract Name: Quantifying the Effects of Tissue Biomechanical Properties Using Fluid-Structure Interaction Analysis

Developing computational models and predictive frameworks for biomedical systems is crucial to advancing research on pathological conditions, considering that certain in vivo studies are particularly challenging due to invasive procedures, and in some cases, improper diagnostic and treatment tools. One type of computational mode of analysis is known as a fluid-structure interaction (FSI) which is the Multiphysics interaction of a fluid flow with a deformable structure. In FSI both fluid and mechanical properties of the tissue are important factors and contribute significantly to the model predictions. Young's modulus and Poisson's ratio are two essential mechanical properties that are necessary to describe the elastic behavior of the tissue, however,wide range of elastic modulus values have been reported in the literature. This study aims to provide a better understanding of biomechanical properties that can be used to build computational simulations. We investigate the influence of tissue elasticity on the structural and fluid dynamic response of models, with application to human cardiovascular and phonation systems. Specifically, the interaction between turbulent glottal airflow in the larynx and vibrating vocal fold during phonation is simulated using a fully coupled FSI approach. We have also explored the interaction between the blood flow and arterial wall deformation in patient-specific abdominal aortic aneurysm models. The fluid flow is described by the unsteady, viscous, incompressible Navier–Stokes equation, and the dynamics of tissue is modeled by the Navier equation. Tissue is considered as a transversely isotropic material for which the stiffness parameters include the transverse elastic modulus and longitudinal elastic modulus. Parametric simulations are performed by systematically varying the transverse and longitudinal stiffness parameters. Important model predictions including flow rate, fluid pressure, maximum tissue displacement and spatiotemporal stress metrics, as well as the effect of the stiffness parameters on these output parameters are analyzed.

Abstract Name: Addressing Money Laundering in the United States Real Estate Sector

The United States faces threats to economic stability and legal integrity from money laundering practices in the real estate market. Legislative loopholes, complicit enablers, and aging technological systems used by government agencies allow individuals to flow ill-gotten wealth into the United States with little effort. As a result of these factors, local economies suffer job loss, once-inhabited properties lie empty in decay, and trust in government weakens. Illegal wealth is transformed into protected assets in the form of property and can be stored to later fund terrorist organizations or influence the American people. Approximately $2.3 billion was laundered through real estate in the last five years alone.To address this issue, I identified policy alternatives using criteria of security, technological capability, and lasting effectiveness. I also prioritize solutions that are more likely to produce long-lasting results over temporary fixes.

Abstract Name: **Preparing Communication Disorders and Sciences Students to Collaborate with Interpreters: The Power of Interdisciplinary Experiences**

Nearly 25% of children in the United States currently speak a language other than English at home (Ann Casey Foundation, 2022). Despite the clear and compelling need for competent and linguistically responsive assessment and intervention practices, practicing speech language pathologists (SLPs) frequently report feeling underprepared to accurately work with interpreters when serving dual language learners (DLLs) (Guiberson; Atkins, 2012; Santhanam; Parveen, 2018). However, collaborative training experiences can provide SLPs and interpreters with the opportunity to converse about their roles, discuss ethical problems with interpretation, and merge their shared thoughts to ensure best practices for clients (Zhang, 2020). The purpose of this research project was to understand the ways in which an interdisciplinary simulated training experience and interdisciplinary immersion screening experience compare and contrast in relation to communication sciences and disorders (CSD) and interpreter students' feelings of preparedness for working collaboratively within their future professions.Researchers gathered data through reading, analyzing, and then qualitatively coding CSD and interpreter student summaries written post- simulated experience and post-screening. Student reflections included overall perceptions of the experience as well as perceptions regarding the ways in which the experiences influenced their feelings of preparedness. Student reflections and interviews were analyzed using inductive coding procedures as described by Merriam and Tisdell (2016). Codes, categories, and subcategories were revised and operationally defined during the coding process, until a final set of codes, categories, and subcategories was developed. Findings highlight the similarities and differences in CSD and interpreter perceptions, as well as the similarities and differences in student perceptions of an interdisciplinary simulated experience as compared to an interdisciplinary immersion screening experience. Findings will inform future pre professional and professional training experiences designed to increase SLP confidence and competence for working with interpreters and to increase the quality of interpreter and SLP practices for DLLs.

Abstract Name: **The Continual Analysis of the Effects of Poor Infrastructure and Environmental Justice on Hydrologic Systems of the Walnut Creek**

This project focuses on the Walnut Creek area where environmental justice, poor infrastructure, and faulty floodplain management have been prevalent issues since the 1990s. This research aims to determine how past inequalities in the Walnut Creek Wetland area have influenced land-use decisions today and analyze how poor infrastructure has caused an increase in bacteria found in our creeks. Our study area consists of weekly visits to four different sites to determine the effects of local development on the creek. We currently measure chemical and physical parameters at all four sites. Measurements of pH, specific conductivity, dissolved oxygen, and temperature are done using a YSI device. Along with these variables, we also utilize nitrite/nitrate strips to quantify their respective levels. In addition, a sewage pipe located near our testing sites has begun to show signs of deterioration. This leads us to hypothesize whether this pipe has caused waste leakage in Wetland Creek. Due to this concern, we test the biological aspect of the water quality via E. Coli testing once a month at two of the four sites. We will test these parameters before, during, and after replacement to determine whether there has been a significant increase or decrease in levels of bacteria. The findings of this research will be hugely beneficial to the community surrounding Walnut Creek and the world as a whole. Throughout this project, scientists and everyday individuals will be able to identify certain environmental stressors and possibly link them to inequalities occurring in similar communities.

Abstract Name: **Examining Low-Income Household Shopping with Supplemental Nutrition Assistance Program Benefits at the Eau Claire Downtown Farmers? Market Using the Market Match Incentive Program From 2018-2022**

Food insecurity is a significant issue facing many American households. The Supplemental Nutrition Assistance Program (SNAP) provides increased access to food for families in need. Additionally, fruit and vegetable (FV) consumption has been shown to improve health and reduce the risk of a variety of chronic diseases. However, poor nutrition among children and adults, including low FV intake have contributed to rising rates of obesity among US children which have been shown to persist into adulthood. It is particularly challenging for low-income households to purchase/eat the recommended amount of FV. Farmers' markets offer a wide variety of fresh, local and healthy foods, especially FV, but data show that low-income households are much less likely to shop at farmers' markets. The Eau Claire Downtown Farmers' Market (ECDFM) sponsors a Market Match Program (MMP) incentivizing SNAP households to shop at the market. In 2020, COVID-19 increased the number of families facing food insecurity while the ECFM also faced challenges regarding how to operate safely. This poster uses administrative data to analyze shopping by SNAP households at the ECDFM using the MMP between 2018-2022. The number of SNAP households shopping at the ECDFM increased in 2020 and 2021 while the associated spending also increased in both years as the SNAP caseload was rising due to the pandemic. As the SNAP caseload declined to about the same level as in 2020, the number of SNAP households shopping at the ECDFM using the MMP and the corresponding spending declined in 2022. The remainder of this study provides more detailed results regarding the patterns in SNAP household shopping at the ECDFM using the MMP over this period. This poster is connected to a another submitted poster analyzing a variety of data from surveys of SNAP households shopping at the ECDFM using the MMP during these years.

Abstract Name: **Evaluating the Effect of Planting Time on Nitrogen Fixation in Winter Legume Cover Crops in High Tunnels**

Cover crops are non-harvested plants grown to improve soil health in agricultural systems.Legume cover crops associate with beneficial soil bacteria that form root nodules and fix atmospheric nitrogen into a plant-available form via a process known as biological nitrogen fixation (BNF). Plastic covered greenhouse structures, called high tunnels, are a valuable season extension tool in cool regions of the United States, however, the resulting intensified vegetable production can negatively impact soils. Planting legume cover crops in rotation with summer vegetable crops is an emerging strategy to mitigate these negative effects, yet knowledge about specific planting times and their effects on BNF is limited. This research evaluates the degree to which planting time of two winter cover crops, hairy vetch (Vicia villosa Roth) and Austrian winter pea (Pisum sativum L.), affects: 1) plant biomass and productivity, 2) legume cover crop nodulation, and 3) BNF. I hypothesize that cover crops planted earlier in the fall will have greater biomass contributions and increased BNF, as there is a longer growth period and more time for beneficial associations with soil rhizobia to develop. Biomass was collected in December 2021 and 2022 using 0.1M quadrat frames, dried, and weighed. Nodule mass will be collected in December 2022 by collecting, drying and weighing root nodules from two plants per treatment plot. Biological nitrogen fixation will be measured using 15N natural abundance. In 2021, planting time and species type affected biomass production, with biomass highest in early planted vetch, and lowest in late planted vetch. Across species, both early planted pea and early planted vetch produced more biomass than their late planted counterparts. Nodulation, BNF, and year two biomass data will be collected and analyzed in winter 2022.

Abstract Name: **Optimizing Structure and Fabrication Process of Thin Film Solid-State Lithium Ion Batteries**

Although lithium ion batteries (LIBs) have been utilized in a broad range of technical applications such as: electric vehicles, laptops, cell phones, and other electronics, few studies have been conducted in utilizing thin film lithium ion batteries for low power electronics. In this study, thin film layering of aluminum, nickel, lithium cobalt oxide, lithium phosphate, silicon, pyrolytic carbon/graphite, titanium, and copper were constructed through thermal vapor deposition and magnetron sputtering deposition equipped within a high power vacuum chamber. Various parameters (e.g., deposition time, deposition power, hot-pressing time and temperature, anode electrode materials) were tested to optimize the structure and electrical properties of LIBs. Through the process of product experimentation over 200 batteries have been fabricated, tested, and thoroughly analyzed to determine the overall efficiencies of our selected parameter combinations. Testing results demonstrate copper as a necessary addition to titanium serving as a negative current collector. Active testing of the implementation of various graphites and layering thickness have demonstrated positive contributions to increase successful charging cycles. Many parameters are still available for tests and analysis to further advance our research. Result analysis indicates promising directions to improve solid-state thin film LIBs while increasing battery performance through continuous optimizations of various structural and procedural parameters.

Abstract Name: **Peaceful Planet: The Relationship between the Environment, Conflict, and Peace**

Since the end of the Cold War, intrastate conflict has become the most predominant type of armed warfare in the world. There are a multitude of factors that lead to and affect the continuance of this type of violence, including natural resources and environmental issues. This has led to increased interest and research in environmental peacebuilding, a process comprising the multiple management pathways that integrate environmental issues to support conflict prevention, mitigation, resolution and recovery. Peace building in this form allows both local and international actors the ability to not only target the root issues of conflict and gain mutual trust, but also to utilize an important sector to push for peace and rehabilitate society, thus resulting in longer-term peace. In order to study this phenomenon, I used case studies of Liberia and the Central African Republic, with Liberia as my success case and the CAR, in which war resumed, reflecting failed peacebuilding. I hypothesized that environmental peacebuilding would lead to a longer period of peace if it used a combination of top-down and bottom-up movements and included communication of opposing groups. Through the analysis of the movements, actors, and violence, it became clear that my hypothesis could not be supported, and instead that environmental peacebuilding largely works as a proxy for a more inclusive peacebuilding process that targets root causes of conflict.

Abstract Name: **The Impacts of Access to Food, Healthcare, and Recreation as Barriers to Licensure in Adolescents**

Mobility is essential for daily tasks, such as receiving healthcare, obtaining food, and engaging in leisure activities. Adequate access to food and healthcare is an essential component for leading healthy, productive lives, while leisure or recreational opportunities benefit autonomy development and well-being. This project examined if food, healthcare, and recreation access were contributing factors in the decision to obtain a driver's license in adolescents. Drawn from a larger, longitudinal study, 16- to 18-year-old adolescents with and without a driver's license (Mage=17.11 years, SD=1.08, nLicensed=77; 53% female; 73% Black) provided sociodemographic information, home addresses, and family affluency. Geospatial software mapped participants' addresses and assessed the density of food, healthcare, and recreational services within a 1-mile radius. Logistic regressions indicated increased recreational service density and black race were associated with decreased odds of licensure (OR=0.75, 95% CI=0.58-0.95 and OR=0.14, 95% CI=0.2-0.90, respectively). Higher family affluency was associated with increased licensure odds (OR=2.32, 95% CI=1.69-3.18). Access to food or healthcare had no influence on licensure status. These findings may help target areas with low access to recreational activities for expansion of recreational options or alternative transportation options. Additionally, areas with lower recreational service density may require focus for driver training programs due to increased licensure in those areas. Those with lower accessibility to recreational activities may be at a greater risk for poor health outcomes, due to both the need to drive for recreational activities (i.e., injury risk) and lack ofphysical activity. Future research should identify other geospatial factors affecting mobility and subsequent health outcomes, as well as examine additional sociodemographic factors affecting licensure and mobility.

Abstract Name: **Measuring Physiological Synchronicity in "Story Troves", a novel treatment tool for those with Aphasia**

Group activities seem like an obvious tool when promoting social connection, but it is not sufficient to place people within the same context. Those who could benefit most from social connection are limited by the biological, psychological, and social processes creating their need. Individuals with Aphasia have a significant reduction in verbal communication following stroke or injury and are at risk of social isolation and the associated neurological impact. My Independent study involved developing an experimental design to assess a novel treatment tool for those with Aphasia. "Story Troves" are a creative strategy meant to improve social connection. Using a psychophysiological framework, my design measures and models autonomic nervous system activation between group members while assessing their perceived frustration. These two variables address two of the main reported communication obstacles reported bythose with Aphasia. They also assess the impact of increased group synchrony on perceived psychological state. We will compare a group of individuals in a classic conversation group to a group using the "Story Trove" condition. Our hypothesis is that increased group synchrony will lower frustration. Should this be the case, we will have generated empirical support for a tool that could be incorporated in Aphasia treatment. We hope to extend the findings on this study to other scenarios where the risk of social isolation is present, which we may argue is far reaching given the state of the world today.

Abstract Name: Homeless Shelter Design in America

There are 11,118 homeless shelters in America with an estimated 420,000 homeless families, consisting of 920,000 children. Homeless shelter design in America lacks elements that contribute to the mental and physical wellbeing of occupants and rehabilitation back into their communities, which can be harmful long-term. Largely, the issues plaguing these spaces the most are crowding and a lack of privacy, which is detrimental to the family units that have been making up a growing percentage of the homeless population since the 2007 economic crisis. Additionally, many individuals, largely single mothers, are dealing with PTSD, which is not taken into consideration into the larger designs. If this is allowed to continue, there will be increases in the degradation of these family units and increased stress and defensive actions. This presentation of this research is to denote harmful practices in homeless shelter design, but also elements that are beneficial for human health. Research found that while many of the homeless population are struggling with PTSD, the implementation of Trauma-Informed Design can be beneficial in combating the symptoms and aiding in taking these individuals out of fight or flight. When an individual is taken out of fight or flight, they are able to think clearly and able to better solve their problems. Additionally, positive design elements such as biophilia, natural light, and accessibility create improvements in human health and wellbeing by lowering health risks and increasing performance, general health, and healing. Allowing those who make up the homeless population to be in a space that decreases stress and improves physical health is the first step to rehabilitation.

Abstract Name: How Gender Influences Gym Comfort Level in UCO Students, Staff and Faculty

Background. Physical activity and its positive effect on overall health has been studied for decades. The goal of this research is to understand if there are observable differences in gym comfort level between self-identified genders. Methodology. Researchers curated an online questionnaire to measure one's comfort level in the gym. Data collection spanned over 6 weeks during the summer of 2022. The participants (N = 290) were 24.83% cis men, 65.52% cis women, and 9.66% transgender/gender-non-conforming (GNC). Results included students, staff and faculty with several cross-tabulations functions performed through SPSS 28.0 to examine differences between self-identified genders. Results. Notable results indicated that on a scale of 1-10 (lower scores indicating less comfort) the average result for cis men being 7.90, cis women at 5.21, and GNC individuals at 6.14. Percentages listed indicate a "yes" to if participants are comfortable in certain settings. 83.33% of cis men were comfortable participating in weight training activities in contrast to 35.79% of cis women and 53.57% for GNC individuals. When asked about cardiovascular training, 100.00% of cis men were comfortable as opposed to 76.32% cis women and 75.00% of GNC individuals. Those who were comfortable in the gym in terms of social setting were: 80.56% cis men, 37.37% cis women and 46.43% GNC. Discussion. Through data collected, researchers have been able to support the hypothesis that there are differences in gym comfort levels between gender identities. One limitation was confronting how to protect transgender or non-cis individuals because the response was very low. To do this, all non-cis people were grouped into one category (though researchers acknowledge that there are differences between trans/gender fluid/non-binary individuals). Possible outcomes to this result could be future improvement on making public and private gyms feel more open and comfortable to all genders.

Abstract Name: **Outdoor Electric Field Measurements for Physics Students**

Electric field meters (EFMs)have been designed and constructed by Langmuir Laboratory, New Mexico Institute of Mining and Technology, for educational use at the University of New Mexico-Valencia Campus. In recent physics labs, students have used these meters to detect electric fields indoors, produced by charged combs, pom-poms, and Van de Graaf generators.A more practical application of EFMs is to measure the atmospheric electric field at ground level, to warn of potential cloud-to-ground lightning—at, for example, golf courses and testing grounds for explosives. Our current goal is to, with an EFM located outside on campus, measure the outdoor ground-level electric field for not only physics classes, but also for any campus faculty and staff who might be interested. This will require (1) achieving wireless transmission of the data to the UNM-Valencia Intranet and (2) designing software that will present the data in an understandable form, e.g. a plot of the electric field versus time. Such a presentation will be especially interesting during thunderstorms, when ground-level fields can become very strong and, in the event of lightning, suddenly and dramatically change.

Abstract Name: **Smartphone Use and Well-being**

How has Smartphone use impacted the general well-being of people today? The Smartphone usage has certainly increased over the past generation. The use is so prevalent that nearly everyone from 9-99 has one. Questions regarding how this intense Smartphonne use is impacting the overall health and well-being of society has been discussed across many different aspects of research. This research intends to study how Smartphone use impacts the physical, psychological, cognitve and social well-being of individuals across the generations. Previous research tends to focus on one aspect or another of well-being, for exmaple sleep or academic performance (cognitive functioning) or anxiety (psychological functioning). The research is lacking when looking at the global health of an individual and its association with Smartphone use. Thisstudy will also examine the specific ways individuals are using the Smartphones as well as how much of their daily life is consumed by the use. A correlational analysis will be completed in the spring semester of 2023 to determine what factors are most impacted by Smartphone use.

Abstract Name: Analyzing College Students' Mental Health Effects of Social Isolation During the COVID-19 Pandemic

In 2020, a global pandemic began due to COVID-19. This led to social restrictions potentially affecting emotional intelligence, rates of depression and anxiety, and stress. College students are a particularly vulnerable group given their reliance on social relationships and the stress of academic pursuits. The population of university/ college students may be strong and healthy medically, but this population is at elevated risk of psychosocial disruptions. Assessing the health of college/ university students depends on the lifestyle of the individual. A sense of belonging acts as a predictor of mental health. This study reviewed the literature to understand the mental health and social isolation among college students during the COVID-19 pandemic. A review of seventeen articles were reviewed. Through various perspectives, the mental health and social health of university students are examined. Various sources concluded that associated findings can direct this population to various health interventions that emphasize lifestyle behavior, social connection, and overall well-being while refining the mental and social health of university students. Inclusion criteria included articles that were published within the last three years. Results showed that the research suggests during the pandemic, loneliness, emotional suffering, and social isolation. COVID-19 acted as a snowball effect by establishing essential differences in cognitive functions, academic settings, clinical practices, professional environments, and much more. These findings are essential for evaluating potential long-term consequences on the social dimension and mental dimension of wellness. Bringing awareness to college students' health challenges amid a pandemic is essential for evaluating potential long-term consequences on the social dimension and mental dimensions of wellness.

Abstract Name: The Year of the Lustful Lesbian: an Exploration into the Creation of the Attractive Lesbian Archetype in Pornographic Media

Pornographic media isan industry worth upwards of 1 billion dollars, showing how ingrained pornography is in American culture today. In addition, the "Lesbian" category of porn has appeared in the top five searches on Pornhub since 2007, underscoring how influential the sexualization of lesbianism is within American society. However, the sexual image of lesbians did not always exist, with lesbians being historically pathologized, instead of being seen as sexual objects. This paper examines how the establishment and rise of second-wave feminism, the gay liberation movement, and the accelerated expansion of media technology led to the rapid development of lesbians being represented in pornographic media. By looking at lesbian-produced pornographic media, such as what was seen in the lesbian magazine On Our Backs, we can see how these three movements and developments created an outlet and audience for queer pornographic media. In addition, by looking at male pornographic and lifestyle magazines such as Playboy and Hustler, we see how this dynamic shift towards sexualization not only impacted queer culture, but also straight culture. Through this examination, we see that these three cultural movements intersected to form a time where lesbian sexuality became not only tolerable- but also marketable.

Abstract Name: **Producing Datasets: Creating Mock Crime Scene Footwear Impressions Dataset**

One of the fundamental problems in forensic science is a lack of data. Creating datasets representative of casework is a challenge, because it can be difficult to obtain large quantities of images collected under the same protocol and with the same shoes. Though, the data collected in this way can be of significant use for researchers and training within forensic science disciplines.This project's main objective is to create an open-source database containing a sizeable number of high-quality images of shoe impressions. The team at the Center for Statistics and Applications in Forensic Evidence (CSAFE) worked to collect images that could be representative of those found at crime scenes and made publicly available to the broader forensic and research communities. With mixed impression types, flooring, lift techniques, and digital file types, the complete dataset will include nearly 800 shoeprint images contained in more than 1,700 digital files. Our presentation will focus on the best practices for developing a data collection process, writing protocols and publishing open-source datasets, with the intention of reproducibility and details on how/why the project is important, as well as the process we went through while working on it. Attendees will walk away (pun intended) knowing: The significance of larger data sets for researchers and training; Actionable solutions to various obstacles associated with large dataset collection;Essential considerations for writing data collection protocols; and The importance of open-source data.

McHugh, Nell

Abstract Name: **Food is Function: How Nutritional and Culinary Literacy Can Aid in Repairing our Fundamental Relationship to Food**

Problematic relationships with foodare prevalent inmodern society due to a fundamental disconnect between mental health and eating. Many individuals rely on their emotional state to determine meals and mealtimes rather than listening to their bodies. This research includes consultation with licensed therapist Karen Koenig, an expert on eating disorder recovery, and a review of relevant literature. The study's primary data collection tool is a questionnaire on eating behaviors administered via social media. Participants (N=104) shared opinions on how their emotions affect their eating habits, their general level of happiness, the factors that inform meal selections, and the emotions they experience around and during mealtimes. The survey highlighted the prevalence of disordered eating among respondents, as most participants experience complicated emotions surrounding food, which negatively affects their life and health. Additionally, the survey uncovered that many participants were eager for more culinary and nutritional education. Thus, these research findings provide rationale for the design of a community-based expressive therapy program that will develop individuals' culinary and nutritional literacy to repair their fundamental relationship to food and improve their overall mental health.

Abstract Name: **Loneliness in the Sea of Stars: Team Building and the Possibility of Mars**

This study investigates composing an effective team for long-term spaceflight to Mars, with an aim to identify the optimal team traits for an isolated, confined, and extreme (ICE) environment. Through a review of team research with multiple Arctic and Submariner missions, this investigation builds upon analog ICE environment simulations (HI-SEAS and Mars-500) by evaluating effective team composition and establishing the essential traits for reducing human error through their frequency in appearance in successful simulations. These findings demonstrate communication is essential for resolving interpersonal issues and emotional expressivity acts as a catalyst to facilitate stronger communication. A stable sense of autonomy contributes to team cohesion in high-stress ICE situations when direct communication with Mission Control is unreliable. The analysis uncovered a number of potential weaknesses in the design of previous studies such as all male participant groups, dependency on analog missions, and small sample sizes. Based on this research, future studies should prioritize a more autonomous environment with Mission Control and the inclusion of specialists to support and reinforce team cohesion and productivity. Furthermore, this research suggests the need to reevaluate the perception of space as a masculine environment through additional team studies with female participants.

Abstract Name: **The Sublime in Art**

There is no denying that art has changed drastically since its first conception, from cave drawings to light installations, but throughout the different periods and styles, art has also retained many of the same elements and themes. In this presentation, I explore this connection across time and space through the works “Dovedale by Moonlight”, painted in 1785 by Joseph Wright of Derby, and “Odyssey”, done in 2010 by Cai Guo-Qiang. They’re created hundreds of years apart, coming from different cultures and done in different mediums, but both are elegant landscapes that explore the sense of the sublime – emotion experienced to its fullest potential, that which is both beautiful and horrible. Their works display the continuity of human thought and experience, connecting us to our ancestors. From these works we learn a vital part of what it means to be human, and it is imperative that we use this knowledge to further explore the idea of the collective unconscious – the idea that all of humankind shares a pool of information and memory. The fact that we as humans have the same experience, as displayed in these pieces, no matter the time or place lends itself to this idea of a collective unconscious, which in turn brings us comfort. The universality of human experience and the idea of the collective unconscious is one of the least explored topics in philosophy and art, and my research intends to expound upon the concept by using the shared theme of the sublime to connect the art of present day to the art of the past.

Abstract Name: **Development of Squeaky DC, a modular and affordable 3D-printed educational quadruped**

Squeaky DCis an updated and more powerful version of TREC Lab's Servo Squeaky, a modular and affordable 3D-printed quadruped robot. Quadrupeds have diverseapplications as research and educational tools, but the higher cost of similar quadrupeds prohibits their widespread use. Squeaky DC has been manufactured using 3D printing technology and materialsto reduce the overall cost as well asmanufacturing time. Due to theuse of 3D printing, Squeaky DC provides design flexibility and can be easily modified without restructuring the whole design. The objective for constructing Squeaky DC is to enhancethe usefulness of the earlier versionfor research and education by implementing the ability to perform more complex tasks such as running and jumping. In this work, the existing servo motors in Servo Squeakyare replaced with more powerful brushless DC motors in Squeaky DC, and Siemens NX CAD software isused to redesign the parts for overall improvement in the design of the quadruped. The new limb design isinfluenced by the anatomical structures of canine and primate limbs. This bioinspired design results in a greater range of motion and improved aesthetics. Several design iterations have been investigatedto finalize the overall geometry and dynamics of the design of Squeaky DC. To ensure the reliability and functionality of the design, the final design of the prototypeissubsequently manufactured through 3D printing with PLA+ material. Further, this quadruped robot will be programmed and extensively tested to prepare it for release as an open-source educational tool. In the future, Squeaky DC has great potential to beuseful for the exploration of fields such associal robotics and swarm/collaborative robotics.

Abstract Name: **?Childish Platform? or Universal Medium: Making sense of Gen Z?s SnapChat Attitudes and Usage**

In 2022, 44.5% of young people between the ages of 8 and 23 are Snapchat users. Snapchat usage for this generation is higher than all other platforms according to Statistica.While the majority of Gen Z uses Snapchat daily, there is a lack of extant research concerning how Gen Z uses and is affected by their Snapchat usage. Most research into social media use focuses on Facebook and Instagram given they have been the most used platforms until present times (Auxier; Anderson, 2021). As digital natives, Gen Z is used to building and maintaining relationships online. To better understand how Gen Z uses the Snapchat app to build and maintain relationships, this study sought to answer the question, " Why do people use Snapchat." To answer this question, we conducted a series of semi-structured interviews with 14 members of Generation Z. We utilized thematic analysis techniques (Nowell, Norris, White; Moules, 2017)to analyze the interview transcripts. The findings indicate that individuals continue to use Snapchat because it has been gamified (e.g., snap streaks, snap scores, story views, and emojis to indicate friendship closeness). That gamification has worked in conjunction with a fear of missing out to keep users interacting daily. Additionally, the analysis revealed that Snapchat users express a desire to move on from the app as they age, but continue to use it daily as it's the easiest way to maintain connections.

Abstract Name: **The effects of the herbicide glufosinate ammonium on chemically-mediated predator-prey interactions between two wolf spider species**

The herbicide glufosinate ammonium is increasingly used in agricultural systems due to the evolution of glyphosate-resistant weeds. The wolf spider,Pardosa milvina,lives year-round within crop systems in the Eastern United States.Pardosauses silk and excreta cues from the larger co-occurring predatory wolf spider,Tigrosa helluoto avoid being eaten. Upon detection of these cues fromTigrosa,Pardosashows increased freeze responses (tonic immobility) and vertical climbing. Both behaviors increase survival in the presence of a liveTigrosa. This chemically-mediated predator detection and avoidance system ofPardosamay be compromised by spraying herbicides on the soil surface. We tested the effects of glufosinate on chemically-mediated predator-prey interactions among these two spider species. Over three-hour trial periods, we measuredPardosasurvival, activity level, and wall-climbing behavior in the presence of adult male or femaleTigrosa across six treatments where we systematically varied the presence or absence of glufosinate,Tigrosa chemical cues and/or water. We found significant differences in wall-climbing behavior, activity, and survival across treatments. Pardosa survival was lowest on dry substrates lacking glufosinate or predator cues and was highest on substrates with predator cues without glufosinate. Adding glufosinate to predator-cued substrates significantly reduced vertical climbing, increased activity level, and resulted in shorter predation times than substrates without glufosinate. Glufosinate disrupts wolf spider predator-prey interactions by disrupting predator detection and avoidance systems of the prey.

Abstract Name: **Self-Esteem Stability's Impact as an Anxiety Buffer on Post Traumatic Stress Disorder**

Anxiety Buffer Disruption Theory (ABDT) explains maladaptive responses to traumatic events. Anxiety buffers such as our self-esteem help keep anxiety at bay when our mortality becomes salient. However, when traumatized individuals do not respond to mortality reminders in a psychologically healthy way (i.e., deploying their anxiety buffers in response) symptoms associated with post-traumatic stress disorder (PTSD) can develop.Self-esteem stability has repeatedly been shown to be a vital variable in psychological wellbeing especially for esteem related disorders such as MDD and BPD. However, there is little research on the influence of an individual's self-esteem stability on PTSD. The relationship between anxiety, trauma, and self-esteem stability as part of ABDT was examined.Adult participants (N = 303) completed a Qualtrics survey designed to assess anxiety buffers, PTSD symptomology, and stability of self-esteem. Germane to this study, the Rosenberg's Self-esteem Scale, which measured the participants attitude toward themselves, and the Self-Esteem Stability Scale, a cross-sectional direct self-assessment, were deployed.Regression coefficients reveal a negative linear relationship between Self Esteem and PTSD symptom severity, and Stability and PTSD symptom severity. The analysis showed that both Self Esteem(B = -.497) and stability (B = -.271) significantly predicted PTSD. However, general self-esteem had a greater impact on the overall model.The data supports ABDT as traumatized individuals showed lower self-esteem indicating the self-esteem buffer may be disrupted. Stability doesn't make self-esteem a more effective anxiety buffer.A second study will be conducted with a comparative sample of individuals with above threshold PTSD symptoms. Participants will complete a similar questionnaire and be screened for probable PTSD (PCL scores < 31). We expect to see self-esteem as a better predictor than stability in the above threshold population for PTSD but not depression. This would support the idea of a unique feature of PTSD among other psychiatric disorders.

Abstract Name: **Implementing Transformative Justice Into Our Neighborhoods: A Collaborative Model**

As the prison system in The United States serves to punish rather than rehabilitate criminals, victim-offender mediation provides inmates with an opportunity to both repair the community and educate the offender. This paper calls for the expansion of transformative justice services, a subcategory of victim-offender mediation, to identify the systemic issues that lead offenders to commit a crime. By analyzing the works of scholars Howard Zehr and Mark Umbreit, among others, this paper examines how to identify the social issues that create criminals as well as how to heal those impacted. Transformative justice guides the community to combat inequity to supplement the lack of rehabilitation within the criminal justice system. By the community taking accountability, there will be a method of identifying common factors that increase crime and recidivism. Therefore, resources can be funneled to marginalized groups and be accessible to convicts to eventually decrease incarceration rates. This service research paper proposes a collaborative model between The Missouri State University Center of Dispute and Resolution and the Mayor's Commission on Human Rights to expand mediation services in Springfield, Missouri. This expansion will amplify victim-offender mediation services as well as ease the introduction of transformative justice services into their resources offered.

Abstract Name: **World Bank: Villain or Facilitator of Human Development?**

Since its founding, the World Bank has adapted its policies to reflect changing ideas about economic development and poverty alleviation within the international community. Although established to finance long-term development and help stabilize global markets, the World Bank has shifted its focus from strictly macroeconomic analysis to pursuing social development projects in various sectors like education, infrastructure, and healthcare to encourage sustainable economic prosperity. With the overall purpose of poverty eradication around the world as a means to build peace and protect human rights, the World Bank's increased attention to the development of social sectors through conditional lending allows the organization to influence the economic policies within borrowing states as a way to achieve its global economic development goals. However, the debate remains on whether the World Bank's shift from macroeconomic issues to social development has affected the organization's success in alleviating extreme poverty and changed its role in the international community to include developmental policy and norm enforcement.This project seeks to weigh in on this debate by utilizing cases of World Bank development projects prior to and after the change in the organization's internal policies regarding social development issues to exemplify the necessity of the shift and its global implications. Evidence gathered to provide support for my hypothesis includes World Bank, United Nations, and national government documents and statistics and secondary sources such as scholarly evaluations of the World Bank's work and its impacts. Examining the World Bank's work is significant because effective and sustainable development is vital to national and international security and prosperity and the achievement of human rights for all.

Abstract Name: **Deep Learning and Feature Selection for Classification of Kidney Tissue Microarrays**

Renal function is an essential marker in the classification of renal disease and clinical symptoms of renal failure develop when there is 15% renal function. In this study, we used infrared spectroscopic (IR) imaging to investigate biomolecular markers from renal transplant biopsies. These images are used for the classification of regions of fibrosis from biopsies containing renal cell carcinoma (chromophobe and oncocytoma) and the prediction of fibrotic proliferation using biochemical signatures. IR spectroscopy is a diagnostic approach utilizing human tissue to label biochemical signatures. Images are captured in several hundred wavelengths in the infrared region of the electromagnetic giving researchers access to more information than traditional RGB images captured by a microscope. While images captured in several bands are great for disease diagnosis, it poses significant challenges for manual cell review by a pathologist. To address this issue, a fully automated pipeline for image processing is being explored. Preliminary research involves identifying feature importance using various algorithms, each of which returns the significant spectral bands necessary for detecting regions of fibrosis. The outputs are ranked and compared to find the first 150 most important features. After feature selection, a deep learning model called UNet will be applied for the classification and identification of fibrosis. Our results will then be compared to the discriminate analysis of the Bayesian classification used in clinical applications.

Abstract Name: **Impact of Title IV-E Education on Perceptions of Preparedness in Child Welfare Workers**

The present study considers the impact of a specialized child welfare training program, known as Title IV-E, on the preparation and retention of public child welfare workers. Participants (n=6) were graduates of UW-Eau Claire's Title IV-E Child Welfare Training program and at the time of the study were employed in public child welfare between 8-24 months. A mixed methods approach, consisting of an online survey based on the Comprehensive Organizational Health Assessment (COHA) and a semi-structured interview administered by student researchers, examined participants' opinions on peer support, supervision, job satisfaction, intent to stay, self-care, and impact of COVID-19 on their child welfare work. Participants' were also asked about the degree to which they were prepared for different facets of child welfare work including working within a bureaucracy, engaging in macro-level work, interfacing with the juvenile justice system, and participating in permanency planning.Analysis of the findings indicate that the majority of participants linked experiential learning opportunities and exposure to child welfare-specific course content as undergraduate students to their level of preparedness for work in child welfare. Participants varied in their responses to questions related to the degree to which they were able to manage their current workload, the level of support peer and/or supervisory supports present at their place of employment, and degree to which they implemented self-care strategies to cope with work-related stressors. The information garnered from this study seeks to evaluate UW-Eau Claire's Title IV-E program in order to enhance graduate preparation for work within child welfare.

Abstract Name: **Reimagining College Support: A Critical Exploration of the Impact of Grief and Loss on the Experiences of First-Year College Students**

Student attrition is a rising concern in higher education given the various challenges that have arisen over the past couple of years. The offset of the COVID-19 pandemic, the racial justice movements, and the current social-political climate have significantly impacted our college students like never before. Of growing concern is the rising mental health crisis that is sweeping through higher education which warrants an immediate and intentional response. Further, students are currently facing dire financial constraints, food and housing insecurities, and many other challenges that complicate their college experiences. As freshman students are now experiencing college for the first time, their experiences may vary drastically from their predecessors. Specifically, current first-year students' college transitions are muddied from their various high school experiences that may have been a remote, hybrid, or in-person with some variation of security measures. Further, the grief, loss, and trauma first-year college students have experienced during the pandemic warrant special attention as we are contending with the types of resources and support, they need to matriculate and complete their degrees. The remnants of grief and trauma from the pandemic still linger and are impacting the college experiences of first-year students and their abilities to navigate their academic and professional goals. Hence, through a qualitative research design, our research explores the lived experiences of first-year college students. Specifically, the research question explored in our study is: How or to what extent has grief and trauma from COVID impacted the educational journeys of first-year students? The aim of this research is to provide an important opportunity to investigate how to better support college students as they move through collegiate experiences.

Abstract Name: **Ceramide as a novel biomarker in Acute Respiratory Distress Syndrome?**

Acute respiratory distress syndrome (ARDS) describes a syndrome of acute onset, bilateral, inflammatory pulmonary infiltrates and impaired oxygenation. ARDS results in a life threatening, rapidly progressive illness and occurs in critically ill patients.Imaging shows bilateral opacities, showing the extent of physiological damage. Severity can be quantified by the ratio of the partial pressure of oxygen to the fraction of inspired oxygen, or PaO2/FiO2. A ratio of 200 mmHg to 300 mmHg is considered mild, a ratio of 100 mmHg to 200mmHg is moderate, and a ratio of below 100 mmHg is severe. ARDS can be caused by several diseases, including but not limited to infection or injury. Despite increased understanding of ARDS, we still lack good biomarkers for diagnosis and treatment. Our lab is examining the role of ceramide in lung disease. Ceramide serves a pivotal role in regulating cell structure and cellular mechanical properties which are especially important in the lung. Our hypothesis is than an increase in ceramide concentration levels in ARDS patients would be a predictor of disease severity and/or mortality. In a small cohort of patients, we examined levels of sphingolipid species in the bronchoalveolar lavage fluid (BALF) by liquid chromatography electrospray ionization-tandem mass spectrometry (LC-ESI-MS/MS). We compared these levels to clinical variables such as severity of illness, ICU length of stay, mortality, etc. We show a statistically significant correlation toAcute Physiology and Chronic Health Evaluation (APACHE) scores thus highlighting a potential novel role for ceramide in ARDS.

Abstract Name: **You?re Reading What, Now? The History of Book Banning in the U.S. and Its Societal Consequences**

Book banning is on the rise in the United States, with bands of parents and political groups protesting the exclusion of titles in classrooms. Parents are concerned about what their children are reading in school, at what age, and in what way—School Board meetings, as a result, have become literary bloodbaths. Our purpose is to understand what has brought on this latest surge of challenges; what the societal consequences of banning books in the U.S. may be; and, to create an applicable curriculum on Book Banning for classrooms. To gain a better understanding, we went to the texts themselves: By reading under-fire titles, we learned the arguments against them and discussed their controversies with students through our Subversive Book Club. Through our research and discussions, we found that books detailing the experiences of POC and LGBTQIA+ individuals, social issues, and historical events have been targeted most in recent years; however, the claims against them focus on explicit content and strong language. We believe this to be a way for parents and organized political groups to remove books that do not align with their ideological ideals or make them feel uncomfortable. But, this raises the questions of censorship and what we are “allowed” to teach students. Should we take additional measures to ensure their comfort at the expense of accuracy and truth? In the curriculum we are designing, we broach these questions as well as provide thorough background information on a number of banned and challenged books, along with companion discussion questions created to get students thinking more proactively about what they are reading. This work is significant because words have power, as do the stories we tell—to censor and remove them and their lessons are to withhold the most authentic education we can offer.

Abstract Name: **Using Survey Data to Report on Low-Income Household Experiences Shopping at the Eau Claire Downtown Farmers? Market**

Food insecurity is a significant issue facing many American households. The Supplemental Nutrition Assistance Program (SNAP) provides increased access to food for families in need. Additionally, fruit and vegetable (FV) consumption has been shown to improve health and reduce the risk of a variety of chronic diseases. However, poor nutrition among children and adults, including low FV intake have contributed to rising rates of obesity among US children which have been shown to persist into adulthood. It is particularly challenging for low-income households to purchase/eat the recommended amount of FV. Farmers’ markets offer a wide variety of fresh, local and healthy foods, especially FV, but data show that low-income households are much less likely to shop at farmers’ markets. The Eau Claire Downtown Farmers’ Market (ECDFM) sponsors a Market Match Program (MMP) incentivizing SNAP households to shop at the market. Administrative data on program utilization suggests that most SNAP households shop at the ECDFM using the MMP relatively infrequently. This poster presents data from surveys of SNAP shoppers at the ECDFM in 2022 (N=349) to learn more about their experiences using the program including what limits their shopping at the market and what might increase their ability to shop at the market. Our results indicate that the most significant limitations to shopping at the ECDFM were the market location/hours, SNAP benefits running out and just not remembering. Correspondingly, the most mentioned things that would encourage more frequent shopping at the ECDFM were expanded market locations/hours, a larger match amount and also being reminded. Among our other key findings are that the ECDFM MMP provides many benefits including reducing food insecurity among EC SNAP households. This poster is connected to another submitted poster analyzing a variety of administrative data from recorded transactions of SNAP shoppers using the ECDFM MMP.

Abstract Name: **Filling the Gap: The Correlation Between Particle Verbs and Transitivity in German and English**

Within linguistic inquiry, grammaticalized phrases are frequent phenomena that present unintuitive challenges for acquisition and translation. Currently, there is limited literature on the syntax of particle verbs; most extant research instead centers around acquisitional corpus study. In order to fill this gap and investigate the patterns underlying such phrases, this paper analyzes the correlation between particle verbs and their transitivity patterns in German and English, as sampled in two corpora, the enTenTen20 (Jakubíček et al., 2013) and the deTenTen20 (Jakubíček et al., 2013).Particle verbs are ubiquitous verb + prepositional adverbial constructions (e.g., take up) that output emergent semantic properties distinct from their constituents (Biber et al. 1999, qtd. in Liu 2011). German exhibits this construction in separable verbs ("trennbare Verben"), where the preposition prefixes to the main verb when not in clause second position. Transitivity identifies the specific number and type of objects that a verb takes, as in pick (it) up, where it undergoes the verb.In order to investigate any statistical connections between the grammaticalization of phrasal verbs and transitivity patterns, a list of particle verbs in each language was collected, with the transitivity of their non-particalized lemmas labeled with one of five categories: monotransitivity, ditransitivity, ambitransitivity, pseudotransitivity, and intransitivity. Using the SketchEngine corpus, the frequencies of each verb were gathered and normalized per million. Then an ANOVA test was run, resulting (F5 = 0.376, 0.861) in no significant relationship between the verb and transitivity type across both the English and German data; however, an ANOVA test on the English data alone approached significance (F4 = 2.796, 0.0749). This suggests that the particalization mechanisms could differ cross-linguistically, such that English transitive verbs are more likely to generate particle verbs where German verbs are not. Additional research is needed to confirm this tentative conclusion.

Abstract Name: **The Effect of Gaming on Novice Pilots**

Global aviation is a pilot shortage, and by 2032, it is expected that international aviation will be 80,000 pilots short. Hence, there is an immediate need to identify ways to expedite pilot training. Researchers have found that gaming positively impacts cognition and hand coordination. Specifically, the abilities of people with expertise levels in video gaming have significantly improved performance scores in many flight simulators. However, these studies lack generalization due to the small sample size. This study investigates whether prior gaming experience impacts the flight performance of novice pilots using a large sample size, flight simulator, and eye-tracking metrics. We recruited two student groups based on their gaming experience: students with little or no prior gaming experience and students with significant gaming experience. Both groups received initial training on basic operations and controls of an aircraft by watching a video and using a flight simulator. After the initial training, students were asked to fly a straight and level mission on the simulator, during which participants wore eye-tracking glasses to record their visual attention. Moreover, we used a five-scale rubric to evaluate their flight performance. The eye tracking data were analyzed using iMotions software in addition, we measured inter-rater reliability for data generated from four coders who assessed the flight performance of the participants using the rubric. Initial findings show that experienced gamers accomplish the mission with higher flight performance levels than novice gamers and had significantly lower dwell times on areas of interest and saccade counts. Results may assist in identifying good candidates to become pilots in addition to creating a fast-track pilot program for experienced gamers.

Abstract Name: **Limited Access to Rural Community Schools**

Sensitive topic agencies have limited access into the education system and are unable to inform school aged children on sensitive topics. Due to the limited ability agencies who facilitate sensitive topic programs contain in the rural community school systems, student researchers introduced a question pertaining to the issue. How do educators in rural communities perceive agencies who facilitate sensitive topic programs? This study aims to understand factors related to sensitive topic agencies. Through a survey, the student researchers collected mixed-methodological data with a concentration on quantitative data. The overall targeted sample size was 75 educators who have worked in rural community school systems. After speaking with individuals, researchers can reach out to schools as a whole. They can practice at a mezzo level by contacting the school about what individuals inside their facility believe is appropriate to be taught to the students. Reaching out to the school can allow researchers to obtain an approved number of topics that are allowed to be presented to the age group indicated. This will then allow agencies to provide some information regarding sensitive topics to schools. In terms of the macro level, agencies often branch out into counties. The student researchers found that a majority of female participants did report a positive perception of sensitive topic agencies, and male participants reported limited knowledge. They also found that age did not matter when looking at the perceptions the educators have on sensitive topic agencies.

Abstract Name: **Analysis of petroleum pollution along the Virginia shorline**

Industrialization is one of the major global contributors of petroleum pollution. Petroleum pollution along the Virginia coastline has caused many environmental issues in marine ecosystems, including toxicity to marine organisms and damage to the complex food web in the Chesapeake Bay. The goal for this research project is to study and develop methods using a variety of analytical instrumentation, including fourier-transform infrared spectroscopy (FTIR), gas chromatography-mass spectrometry (GC-MS), and high-performance liquid chromatography (HPLC) for the analysis of offshore pollution in natural waters, including the Bay and upstream rivers. Additionally, synthetic biology techniques will be used to investigate the possibility of bioremediation as a clean-up technique. The state of Virginia has largest naval station in the world, Naval Air Station Norfolk, as well as an economy that thrives off of marine ecosystems. Therefore, it is crucial for chemists to fully understand the environmental impact of petroleum pollution on the Chesapeake Bay.

Abstract Name: **STD-NMR Analysis of Xanthine Oxidase Binding to Small Molecules**

Analysis of saturation transfer difference (STD) from nuclear magnetic resonance (NMR) spectroscopy is a popular and powerful method for determining ligand interactions with proteins. Xanthine Oxidase (XOD) is an enzyme involved in the metabolism of purine to uric acid, with two intermediates in the pathway. High levels of uric acid (hyperuricemia) are considered harmful and can lead to gout, renal damage, and other diseases. Inhibitors like allopurinol are used as a drug to reduce or prevent uric acid by binding to XOD thus preventing the catalysis. This study analyzed the interactions between different small molecules with the enzyme XOD, with the goal of finding a potential inhibitor. The STD NMR technique is used to study the binding of XOD to two compounds (4-aminopyrazolo[3,4-d] pyrimidine (APPy) and 4-amino-1H-pyrazolo[3,4-d] pyrimidin-6-ol (APPO)). The STD NMR spectra showed that both compounds have interactions with XOD. Computational docking of these compounds to XOD showed that they have binding modes similar to uric acid and allopurinol. Both of the results will be presented at the conference.

Abstract Name: **Reversible Intracellular Gelation Reduces MCF10A Spheroid Growth**

Intracellular gelation achieved with bio-orthogonal strain-promoted alkyne-azide cycloaddition (SPAAC) click reactions can induce a quiescence state in mammalian cells.Intracellular gelation is achieved through a lipofectamine-transfection of SPAAC functionalized poly(ethylene glycol) (PEG) macromers, which are able to spontaneously crosslink in the cytosol. The intracellular crosslinked network increases the viscosity of the cell, resulting in reduced cellular activity. Here, the complexity of the biological model has been increased to explore the effect of intracellular gelation on the formation of 3D spheroid model. When transfected MCF10A cells were encapsulated in a synthetic MMP degradable thiol-ene PEG hydrogel, a reduction in spheroid growth (47%) was observed. This observation was replicated in a proteinaceous hydrogel, Matrigel,where the spheroid growth decreased after transfection with SPAAC macromers. In addition, when cultured in Matrigel, spheroids could be transfected after formation. The resulting intracellular network suppressed spheroid growth with a similar reduction exhibited in the synthetic thiol-ene matrix. To test for reversibility in the system, a photodegradable nitrobenzyl azide was incorporated into the SPAAC macromers, and degraded after formation of the intracellular network by exposure to UV light. Once degraded, proliferation and a return to normal spheroid growth resulted. With the reversible nitrobenzyl component incorporated into the intracellular network, a decrease in spheroid growth (30%) and a size reduction (20%) was measured. Upon exposure to light to induce degradation, spheroid growth returned to a rate level comparable to controls, while the spheroids not exposed to light (e.g. intracellular gelation remaining intact) remained smaller (50%). Intracellular crosslinking and its reversibility have applications in biostasis, and here, used a 3D tumor cell model and novel materials to induce quiescence and its reversal, all while maintaining cellular viability

Abstract Name: An Analysis of the Representation of Gender within Children's Books at a University CSD Clinic

Speech-language pathologists are increasingly called to provide culturally and linguistically responsive services (ASHA, n.d.). As a part of meeting this call, SLPs are tasked with using culturally responsive materials, including the use of books that are representative of a wide variety of identities across race, ethnicity, gender, religion and ability (Harris; Owen Van Horn, 2020). Research investigating gender representation within children's books has overwhelmingly found the presence of underrepresentation of women along with pervasive gender stereotypes. The purpose of this research is to analyze the quality of gender representation within children's literature at a university clinic. The research question the study aimed to answer was, "what roles do female and male characters assume in books found within the children's literature at a Midwestern University SLP Clinic, and how do these roles relate to traditional gender stereotypes?"To complete this research project, an annotated bibliography was completed to gain adequate background knowledge. Next, a checklist for analyzing gender representation was formed to code books and pilot data was collected. A random sample of 262 books within the library have been analyzed. It was found that the presence of male main characters was higher than female main characters within narrative and expository books. Another finding was that nonhuman characters are more common in children's books and have male overrepresentation at a much greater rate than books with human characters. As a next step in this study, the authors of this study will further review the 262 books that have been analyzed thus far and conduct a qualitative analysis of the stereotypes and gender roles. Findings will inform practices for evaluating clinical materials to ensure quality representation of gender within materials used for assessment and intervention services.

Abstract Name: Language Matters! What Newspapers Get Wrong in Wrongful Conviction Reporting.

According to The Innocence Project, Black people comprise 40% of the 2.3 million incarcerated people in the U.S. and 58% of wrongful convictions, despite comprising only 13% of the U.S. population. One can ask why these imbalances exist amongst the imprisoned and wrongfully convicted population and whether racial biases are the sources of a disproportionate amount of imprisonments and wrongful convictions of Black people. If so, then one must ask what is causing, perpetuating, or contributing to racial biases in criminal justice, especially wrongful convictions which rob innocent people of their freedom. A potential cause of racial biases and subsequent racial injustice through wrongful convictions is the media's portrayal of Black people as criminals, leading the public to associate Black individuals with guilt. To reveal any causal or correlating factors, this study first aims to detect whether there are differences in how the alleged crimes and exonerations between Black and White individuals were covered by journalists. To answer this question, I studied 100 exonerations via an analysis of newspaper articles from the 1960s-present. These articles were examined to determine if there are statistically significant differences in the frequency of race, employment, and prior convictions mentioned between Black and White exonerees. In this follow-up project, an online survey including visuals and text reporting will examine how readers perceive initial reports of crimes (allegedly) committed by eventually exonerated individuals. Hoping to include at least 75 surveyed people in Fall 2022, this project aims to explore how differences in information, especially regarding race, included within media crime reports influence readers' perceptions of whether an individual is guilty of a crime across races.

Abstract Name: **Mid-Infrared Variability of Galaxies Surveyed for Water Megamaser Emissions**

Astrophysical masers occur by the stimulated emission of molecules ininterstellar objects. When detected in galactic centers, they prove crucial to our understanding of how the universe formed and continues to evolve. Water masers found in the centers of disk-like galaxies are a unique tool for probing the properties of supermassive black holes and providing direct distance measurements to extragalactic astrophysical sources. Unfortunately, luminous water masers are extremely rare, inciting the push to find more. Considering this, it is crucial to further our understanding of which galaxies this variety of maser emission can occur in and investigate the conditions in the centers of these host galaxies. Currently, there is tentative evidence that suggests a connection between the maser pumping mechanism with the accretion of matter onto supermassive black holes in galactic centers, the region known as the active galactic nucleus(AGN). Herein, we investigate the degree to which AGN activity, as probed by mid-infrared variability, correlates with maser emission and its properties in galactic centers. Employing the mid-infrared and its properties offers the advantage of being less sensitive to cosmic obscuration, therefore revealing AGN signatures that are missed in other wavelengths. We work here with the Megamaser Cosmological Project (MCP), which offers an up-to-date list of galaxies that have been surveyed for water maser emission, as well as multi-epoch mid-infrared data from Wide-field Infrared Survey Explorer (WISE), and present comprehensive comparative analysis of variability in maser host galaxies as and non-hosts. These results constrain the possibility that AGN activity may provide the necessary seed radiation for central maser emission in galaxies and offer new opportunities to guide future surveys.

Abstract Name: **Acute Fluid Intake and its Effects on College Students' Body Mass Index**

Background. Body Mass Index (BMI) is a value derived from height (m) and mass (kg) measurements. BMI is broadly used to categorize individuals based on their tissue mass and height for purposes of medical screening, health information, and policy-making. A multitude of variables (e.g., race, gender, muscle mass, exercise, nutrient intake) can affect an individual's mass which alters their BMI. Individuals preparing for body fat screenings, including BMI measurements, are typically advised to abstain from drinking fluids four hours prior to testing to avoid inaccurate measurements. Few studies look at the effects of acute intakes of different types of beverages on BMI during a testing period. Statement of Purpose. The purpose of this study is to 1) examine the effects of acute fluid intake on college students' body mass index, and 2) investigate the relationship between beverage type and body mass index. Methods. Participants will be instructed to fluid-fast for twelve hours prior to testing. Participants will be randomly assigned into three groups: Water Intake (WI), Gatorade Intake (GI), or Control (C). Height will be measured prior to the ingestion of fluids. Participants will then consume their assigned beverage every thirty minutes for a total of three times. The amount of liquid ingested will be determined by their assigned sex at birth (Female: 75 mL/round; Male: 100 mL/round). The BMI formula, kg/m^2 = BMI, will be used. Data Analysis. Statistical analyses will be performed with SPSS Statistics 27.0.1.0. Descriptive statistics will capture critical patient characteristics. The BMI values will be compared using an ANOVA. Discussion. The researchers anticipate the GI will have significantly larger changes in BMI throughout the study compared to the WI and C groups.

Abstract Name: Nano-indentation Based Analysis of Healing Murine Callus

During the reparative phase of bone healing, a thick mass of callus forms around the bone ends, stemming from the fractured hematoma. The callus begins soft, composed of fibrous tissue and cartilage, and develops over time to become a hard callus. We have developed a novel method to differentiate the mechanical properties of soft tissue (including cartilage) and bone at different points during the healing cascade in the tibia of mice. The fractured tibia was attached to discs through bone cement. The fractured tibia is adjusted till the flattest part of the healing callus is at the highest point. Next, the sample is placed in the Agilent Nano Indenter G200, and the focus is adjusted to the flattest part of the callus. The Nano Indenter is run at night so no outside vibrations can impact the results. Following tests displacement into the surface, load on the sample, time on the sample, harmonic contact stiffness, hardness, and modulus were retrieved. We applied the Oliver-Pharr method to calculate the average hardness, average modulus, and elastic modulus for each indentation [1]. Through the elastic modulus results, we were able to determine where based on the indentation pattern, and at what week of the healing process the objects' resistivity to elastic deformation is greater on the callus thus determining the parts of the callus are bone compared to cartilage.

Abstract Name: Social Media Usage and Levels of Consumerism of College Students in the United States

The increasing sophistication of the Internet and technological devices, especially those developed after the turn of the 21st century, have opened previously unseen pathways of communication. Social media usage has steadily increased over the past two decades with ever-changing and expanding opportunities to connect with other people. Companies and brands have kept up with this move to online interaction and as a result, they are able to market to a wider audience instantly and at any time. Other side-effects of social media including social comparison and lower self-esteem may also indirectly influence people's consumerism levels. This project will examine social media usage in college-age students in the United States and how this usage may impact their levels of consumerism. The primary method of data collection is a survey that will be distributed to college-age students at Moravian University, a small, liberal-arts college in the United States. Expanding upon already existing studies of social media, this study aims to provide a more specific and detailed picture of how different social media platforms might affect levels of consumerism. Currently, while there have been numerous studies on social media and its various effects, many have been limited to a small group of social media platforms, specifically Instagram, Twitter, and Facebook. This study includes a wider range of platforms, including Tiktok, which has become popular over the past few years. This study will also examine the relationships between social media usage, self-esteem levels, and materialism across different demographic groups.

Abstract Name: Diversification Factors Affecting Meal Service Recruitment

This study focuses on exploring the impact of diversity at Meals on Wheels and the factors involved in the limited number of participants of color who are part of the underserved population.There are clients that are unable to communicate with the agency because of language barriers.The type of research design is exploratory. The research explores a new topic and seeks to discover the effect that Meals on Wheels staff has on clients.Researchers created a 17-question survey that included open ended and closed ended questions to ask 100 community residents of color.

Abstract Name: Drug screening using Bioinformatics based tools to identify lead compounds against Naegleria Fowleri

Naegleria fowleri, also known as the brain-eating amoeba, causes primary amoebic meningoencephalitis (PAM), that affects the central nervous system (CNS). Patients with N. fowleri infection are unresponsive to current treatments with a survival rate of only 3%. Thus, it is essential to identify novel pharmacological targets and screen drugs. Naegleria fowleri protein library was explored to identify potential drug targets that have least similarity to any known human protein. Nfa1 (Uniprot: Q9NH76) was identified as one of the potential targets because it has no human homolog. Amoebae have cell surface features called feeding cups that are used to consume food, including host nerve cell membranes. Food cups are created during phagocytosis which includes the Nfa1 protein facilitating absorption through the cup-like structure. Nfa1 protein is involved in the formation of food vacuoles, locomotion, and importantly, also serves as an oxygen-binding protein. It is hypothesized that Nfa1 inhibition would arrest locomotion and restrict their foraging capacity, starving the amoeba to death. Based on the hypothesis, Nfa1 structure was predicted using Alphafold and the protein structure was minimized prior to docking. The minimized structure was validated using the Ramchandran plot. The Molprobity score was 0.83 with 2.5% of outliers towards C-terminal of the protein. Using various bioinformatic tools, binding pockets of Nfa1 were predicted. Drug library was screened after docking in Pyrx. Potential ligands that showed strong binding affinity and good pharmacokinetic properties were selected. Ligands were validated based on the blood brain barrier crossing, good GI absorption, ADME analysis, toxicity, and bioactivity profiling. The top compounds showed high binding affinities ranging from -7 kcal/mol to -9 kcal/mol. Selected compounds will be validated using toxicity assays against Naegleria and human cell lines for future studies.

Abstract Name: **Beyond Translation: A Qualitative Inquiry Study for Refining a Culturally and Linguistically Adapted Health Coach Intervention for Latina Breast Cancer Survivors**

Background: Latina breast cancer survivors historically lack linguistic and culturally tailored coping and management interventions. Traditional adaptation of English education materials for a Latina audience often address surface cultural features such as language, but lack nuances garnered through formative research with the target audience. This study implemented a collaborative community-academic partnership to develop a multi-module health coach intervention and coinciding workbook tailored to the needs of Latina breast cancer survivors (LBCS). All materials used in development were adapted from nationally recognized guidelines for cancer survivors. Thus, this study aimed to gather qualitative data assessing cultural relevance of the transcreated (translated + culturally adapted) health coaching intervention for LBCS. Methods: Following best practice for cultural adaptations, English materials were reviewed by cancer survivorship experts and transcreated into Spanish. Two focus groups (6-8 participants each) were held in Spanish to assess the cultural relevance of the transcreated materials to LBCS. Focus group guide questions were informed by two theories (Social Cognitive Theory, Help-Seeking Behavior Model), learner verification (a methodological approach for education message design). Guide also included questions on feasibility. Transcripts were translated into English and analyzed using thematic analysis. Community expert review confirmed findings.Results/Discussion: Emerging themes included content relevance, applicability, saliency of messages for comprehension, and areas for further refinement.Verification checks with our community partner confirmed content revision and solutions for incorporating participant feedback in future implementation. Data from focus groups allowed for further verification of acceptable content and method expansion prior to piloting with LBCS as a final refining step in the transcreation process. Conclusion: Reflection of cultural reality during program development is crucial for intervention adaptation in diverse populations while building social capital. Transcreation allowed for a collaborative process guided by the integration of cultural nuances, while participant first-hand experiences led modules toward cultural accuracy.

Abstract Name: **The Effects of Salamander Skin Peptides on Microbes, Virus, and Red Blood Cell Hemolysis for Future Therapeutic Treatment**

Herpes simplex virus type 1 (HSV-1) infects the majority of the human population, causing negative consequences like meningitis and encephalopathy. Current treatment options run the risk of antiviral resistance. A promising new treatment option is antimicrobial peptides (AMPS).AMPs are found in all vertebrates, including salamanders. We hypothesized that skin peptides from Hellbender salamanders (Cryptobranchus alleganiensis) have antimicrobial, are not cytotoxic to human cells, and antiviral properties. MicroBCA assay was used to determine the concentration of Hellbender peptides. Growth Inhibition Assays (GIAs) were conducted to determine rather or not these peptides had antimicrobial properties againist E. coli and S. Aureus. CellTiter Glo Assay tested the peptides' cytotoxicity on human cell lines. Viral Yield Assay determined if crude mixtures of skin peptides are virucidal and inhibited the viral life cycle of HSV-1. We found that the crude peptides have relatively low cytotoxicity to human cells. Therefore, if the peptides are antiviral, they inhibit the virus not the cells in the Viral Yield Assay. We found that the crude peptides have antimicrobial,are notcytotoxicto human cells, and do not have antiviral properties. Due to the promising antimicrobial properties of Hellbender skin peptides, I am currently further examining the cytotoxicity of these peptides ind ifferent cell types including human red blood cells. Our future aims are for these Hellbender peptides to help found new therapeutic antibiotictreatments.

Abstract Name: **Modeling human observer detection for varying data acquisition in undersampled magnetic resonance imaging (MRI)**

Undersampling in the frequency domain (k-space) in magnetic resonance imaging (MRI) accelerates the data acquisition. We used a fixed one-dimensional undersampling factor of 5x where 20% of the k-space lines are collected. The fraction of the low k-space frequencies that are fully sampled were varied from 0% where the primary artifact is aliasing to 20% where the primary artifact is blurring. We conducted a human observer two-alternative forced choice (2-AFC) task with a known signal for each of the acquisitions. In the 2-AFC study, a synthetic signal was placed in the center of one of two anatomical backgrounds of the brain. The observer had to choose which of the two images had the signal. Each of the 4 observers conducted 200 such trails for each experimental condition. In the 2-AFC studies, it was clear that the observers performed better with more low frequencies being fully sampled. In other words, blurring is preferable to aliasing for this task. Our goal is to develop a mathematical model that will predict these experimental results. To achieve this, we modified the three-channel sparse difference of Gaussians model observer (S-DOG). The S-DOG model uses frequency domain channels to model the human visual system. Adding a fourth channel improved our prediction of human performance. Noise models are used to account for uncertainty in human decision making. We implemented an independent noise model, rather than the previously employed proportional noise model. The independent noise model introduces the same uncertainty for all images and the proportional model has noise that depends on the image. The independent noise model more accurately predicted the average human performance. Our future research includes modeling a detection task where the observer needs to search for the signal in the anatomical background and developing a mathematical model to predict the experimental results.

Abstract Name: **Yearly Survival and Growth Rates of Propagated Fatmuckets (Lampsilis siliquoidea) in Central Wisconsin**

Freshwater mussels are key members of riverine ecosystems and are crucial for improving water quality. Mussels serve as valuable indicator species and suffer from many environmental disturbances, but despite their importance, large gaps remain in knowledge of freshwater mussels in Wisconsin. We measured the survival and growth of mussels exposed to ambient conditions in two streams in Central Wisconsin. Both selected streams included those that support diverse mussel assemblies. On October 29th, 2021, we received 120 Fat Muckets (Lampsilis siliquoidea) from the Genoa Fish Hatchery, measured, then released them into suitable areas on the Mill Creek; the Plover River Near Stevens Point, WI. Before release, mussels at the Mill Creek site averaged 1.853 cm in length, 1.03 cm in width, and 0.52 cm in thickness. At the Plover River site, mussels averaged 1.859 cm in length, 1.068 cm in width, and 0.546 cm in thickness. We utilized silos to encompass the 1.5-year-old mussels. Each site has 1 silo, containing 15 individuals per silo. Our objective is to determine seasonal survivorship and growth rates throughout our year-long study. Experimentation at these sites will provide an indication to determine which areas are suitable for future reintroductions. We expect 1) Mussel growth and survival will be significantly reduced in the winter months, compared to the summer months. 2) Mussel growth and survival will be significantly different between the two sites. These sites were measured monthly beginning April 21st and lastly October 21st, 2022. This is part of an ongoing study through the University of Wisconsin – Stevens Point's student chapter of The Wildlife Society.

Abstract Name: **Do Drinking Motives Mediate the Relationship between Anxiety Sensitivity and Alcohol-related Blackouts among College Students**

Anxiety sensitivity is the fear that anxiety symptoms are indicative of greater harm, and is a risk factor for heavy alcohol use and substance use disorders. In existing research, there are gaps on the exact alcohol-related consequences and how anxiety sensitivity may be related to those consequences. One important gap is the link between anxiety sensitivity and alcohol-induced blackouts (alcohol-induced amnesia). Blackouts have negative emotional and social consequences for college-aged students. Drinking motives may be a pathway through which anxiety sensitivity could be related to blackouts. Drinking motives regulate the final decision to drink or not drink, meaning that they are the most proximal factor for engaging in drinking. The current project proposal includes a two-aim study to address the relationship between anxiety sensitivity, drinking motives, and blackouts. Aim 1 will focus on evaluating the potential relations between alcohol sensitivity and alcohol-related blackouts in college-aged students while examining the possibility of drinking motives being a mediating factor underlying that relationship. We hypothesize that there is a positive relationship between anxiety sensitivity and blackouts through drinking motives. Aim 2 is to evaluate if there are additional potential modifiers that could amplify or buffer the relationship between anxiety sensitivity, drinking motives, and blackouts such as gender and perceived norms. The data for Aim 1 will be taken from an annual student health survey. The participants were recruited through email invitations at a mid-sized midwestern university. Both aspects of the study will use questions from the Anxiety Sensitivity Index to measure Anxiety sensitivity, the Modified Drinking Motives Questionnaire to measure drinking motives, and lab-created questions to measure blackouts. Aim 2 will also involve self-report demographic questions as well as the Drinking Norms Rating form and the Injunctive Norms Questionnaire to measure perceived drinking norms. Data analysis is ongoing. Implications will be discussed.

Abstract Name: **Paternal Family Versus Maternal Family Involvement for Children in the Foster Care System of Chicago**

Prior work on the impact of parenting on children's emotional and behavioral outcomes focused on maternal parenting and continued this path when exploring extended family involvement. When research began demonstrating the critical role fathers can play in children's mental health outcomes (Amato; Gilbreth, 1999), this work lacked the involvement of paternal extended family. Given that most children in foster care come from non-resident father homes, research regarding paternal involvement has fallen behind. Nonetheless, recent research has found that fathers of children in foster care can play an important role in supporting their children's mental health outcomes (Leon et al., 2016). Little to no research has explored paternal relatives' support of children in foster care. It seems feasible that if maternal relatives play an important role in supporting children in foster care, then paternal relatives might as well. For this study, 204 children (six to 13 years) from Chicago's foster care system were sampled and received family-finding intervention. Family finders reported on all available relatives of kin, fictive kin, and their involvement with the child. This research aimed to expand upon the Leon et al. (2016) study to compare the frequency of maternal versus paternal kinship systems involved in raising children in foster care. Through file reviews from trained family finders, it was found that maternal kin had greater involvement in childrearing; one in two reporting positive attachment figures from the maternal family. However, a significant minority of children (1 in 4) received support via a positive attachment figure from paternal kin. Though fathers and paternal family members have historically been overlooked, the current study underlines the importance of examining social support from paternal kin. Thus, the importance of the father's family in child welfare case planning should not be overlooked, and further research should be done on the subject.

Abstract Name: Curiosity Detection in Student Text Responses

To advance a student's learning process, cultivating their curiosity can be rewarding. How can we assess curiosity in students in learning topics of a course? We present a unique question-based student text responses analysis that can help instructors better identify what drives students to be more engaged in their learning. To determine the level of inquisitiveness among students engaging in upper-level computer science courses, data is collected utilizing the Question Formation Technique (QFT). The latter collects text responses from students via a process with three phases, namely, divergent, convergent, and prioritization. Data collection involves presenting students with thought-provoking QFocus statements, prompting them to formulate their responses in form of questions. Subsequently, the data is analyzed and interpreted through Natural Language Processing for which Python-based scripts are developed toward an efficient organization of the student text responses, which is then analyzed using the WEKA machine learning tool. Feature (word token) selection is performed using several feature rankers and wrapper-based feature subset algorithms in WEKA. It was determined that the extracted features provide meaningful insight into the "Propensity for Exploration" (PE) within the student text responses as a measure of their curiosity degree levels. The PE metric was selected to represent student curiosity primarily due to the following beneficial insights it provides, namely, degree to which a question identifies characteristics of the subject on the question, degree to which the relationship between the primary subject and other course topics is identifiable, and degree of capturing how relevant the characteristics of are/or relationships between tokens in the question. Through an empirical mining of words/sentences that prove a curious disposition in text data produced by students in response to thought-provoking and critical thinking analysis, we obtained promising results, including an interesting distribution of results among the different applied feature ranker and subset algorithms.

Abstract Name: Self-Evaluation & Validation for Mathematical Modelling

Complex systems are those which encompass their interactions between an environment, sensitive dependence on initial conditions, and emergent behavior. Modelling problems that arise in the real world with increasing complexity are difficult to manage. The gap is even wider for undergraduate students that have little to no exposure to model systems that continuously change. The reason for this is the lack of cognition to pursue and or perform such research. The main objective of this study is to boost the confidence in undergraduate students to understand complex systems through the development of a mathematical model. The rubric created in this project aims to help students self-evaluate and validate their mathematical models using a systematic approach. To augment this study, a review of Self-Efficacy, Implicit Bias, and Marzano's/Bloom's Taxonomy are necessary to highlight areas in human cognition related to the completion of a task. In addition, ABET's student outcomes and SCUDEM's rubric will be used as a reference to structure the Self-Evaluation; Validation (SEV) rubric's criteria. Ultimately, the academic weight of this work resides in the idea for students enhancing their capabilities to model complex problems through higher cognitive states.

Abstract Name: **Future Healthcare Providers' Reflections on the Impact of Reproductive and Sexual Health Knowledge and Religion During Childhood**

While there is growing interest in researching the impact of faith and religion on the sexual and reproductive health experiences of youth in higher education settings (Ahrold; Meston, 2010; Freitas, 2015; Yarhouse et al., 2018), we still do not know enough about the experiences and perspectives of religious young adults working towards a career in the medical and health sciences. Using a variety of qualitative data collection methods (interviews, ethnographic observation notes, and focus groups), we seek to answer the following questions: How do health sciences students of various faith backgrounds make sense of past experiences learning about sex and reproduction? How do religious students in the health sciences add to their sexual knowledge "toolbox" or increase their sexual know-how while in college? What might these unique experiences tell us about the range of reproductive health practices for other U.S. young people in college? Participants involved in these conversations were part of a target population that self-identified as having a current or past association with a religion or faith. In addition to presenting preliminary findings on religious students in the health sciences and their experiences learning about sexual health during adolescence as well as their continued knowledge needs, our presentation will explore and expand the methodological choices we implemented to generate participant conversation around a potentially stigmatizing topic. This aspect of the presentation will focus on the process in designing an interactive focus group with an educational component and the success in creating a space to discuss these issues.

Abstract Name: **Deformity and Mortality in Zebrafish Larvae Exposed to Valproic Acid**

Congenital disorders are medical conditions in pregnancy leading to neurodevelopmental problems such as neural tube defects and autism spectrum disorder (ASD). Studies show in utero exposure to the anticonvulsant medication, valproic acid (VPA), has been associated with increased risk for malformations and neurodevelopmental disorders, such as ASD. Prenatal exposure to VPA may mediate dysfunction through the inhibition of histone deacetylases and antagonism of folate. Despite the potential risks of VPA exposure to the developing fetus, VPA is still commonly prescribed to pregnant women to prevent migraines, control epileptic seizures, and treat mental disorders such as bipolar disorder.Zebrafish (Danio rerio) are ideal model species to investigate the consequences of early developmental exposure to drugs, such as VPA, due to their ex utero development, small size, high fecundity, translucency, and amenability to genetic manipulation. In this study, we examined various concentrations of VPA early in the life cycle of zebrafish to assess mortality and deformation. We exposed zebrafish larvae (0-5 days post-fertilization) to VPA (0-X μM) to determine the highest VPA dosage that fails to elicit increased mortality and deformity. We found that exposure of zebrafish to VPA at levels higher than 15 μM increased mortality and deformity risk.

Abstract Name: Acute Effects of Aerobic Activity Compared to Sauna Exposure on Plasma Uric Acid Concentration

Aerobic exercise provides multiple health benefits, some of these benefits are modulated by increased body temperature, vasodilation, sweating, and others. Previous studies have shown that exercising results in plasma uric acid (UA) increased concentrations. In this study, we sought to investigate if a 30-minute session of sauna-induced heat therapy has similar effects as exercising aerobically for the same amount of time on plasma UA. We hypothesize that heat therapy and exercise will increase concentrations of plasma UA.Plasma from fourteen participants (age 23 ± 2 y, ht 1.74 ± 0.08 m, wt 80.9 ± 19.7, BMI 26.5 ± 5.5 kg/m^2) was collected and tested. Each participant completed a randomized crossover, counterbalanced control study. This trial consisted of a 20-minute resting period lying supine that was followed by 30 minutes of either sauna heat therapy (SAU: ~132°F/~56°C), cycling exercise (EXER: ~40-50% HRR), or upright sitting that served as the control (CON: control). At the completion of the trial, participants completed a 60-minute recovery period lying supine. Plasma samples were taken both pre- and post-completion of each activity for research evaluation.Cycling exercise was the only treatment to increase UA concentration, EXER (pre 3.52 ± 0.16 vs post 3.67 ± 0.15; P = 0.03), SAU (pre 3.70 ± 0.17 vs post 3.73 ± 0.15; P = 0.85), CON (pre 3.90 ± 0.18 vs post 3.74 ± 0.14; P = 0.11).Cycling for 30 minutes (40-50% HRR) was enough to increase UA levels. This is in accordance with previous studies showing that exercise increases vasopressin which concentrates plasma UA; in addition exercise results in lactic acid build up that prevents plasma UA excretion.Sauna heat therapy for 30 min at ~132°F/~56°C did not affect plasma UA levels. Longer exposure or/and intensity may be required to observe noticeable changes in this marker.

Abstract Name: Models and Myths: Unmaking the Bounds Between Gods and Saints

This poetry portfolio project contemplates the figure of the Catholic saint and their patronages in the context of pagan gods and spirits. Catholic saints are understood to be canonized because they are deemed good examples of Christian virtue; they are figures to be emulated as examples of leading a good Christian life. Furthermore, the saints are so important to the Church and its history because they are incredibly personal. The saints are, in essence, ancestors; they are the Christians who came before and whom Catholics ask for help because of their virtue. Unlike the saints, though, many pagan gods are not meant to be imitated; they are merely worshipped, and often, worshipped with the wary understanding that the gods are necessarily apart from us in a way that the saints are not. They may teach lessons or values, yes, but the gods themselves are not modes of living in the same way that the saints are. With this understanding, what becomes of the saint when they are not prayed to as a mentor, but as a myth? How do the saints function when their patronage is muddied, when they are seen as monarchist and imperial, as marriage and mourning, when they are liars, arsonists, demons, and gods? As someone with a strong connection to Catholic and pagan faiths, I have created this collection of poetry to wrestle with these questions. The pieces in this collection build upon each other to offer a new conception of the saints alongside the gods where neither category should be understood as strictly figures of emulation or figures of wary-worship, rather, the line between saint and god is not a rule, but merely a suggestion.

Abstract Name: **Investigating the #MeToo Movement: A quasi-experimental study exploring the impact on intersectionality and reporting sexual misconduct**

The rise of the #MeToo Movement, originally founded by Tarana Burke in 2006, began as a public statement on a social media platform to bring attention to the severity and frequency of sexual assault and harassment occurring in gender and racially-based communities, specifically with women of color. Although the movement began as a stride toward raising awareness for communities of color, the face of the movement shifted in mid-October 2017. Actress, Alyssa Milano, spoke out against Harvey Weinstein, a film producer, for sexually harming her and many other actresses. Milano then encouraged individuals across the internet to post #MeToo in the event that they had experienced sexual misconduct without consent, thus leading to the viral expansion of the Movement. As a result, the hashtag was retweeted approximately half a million times within 24 hours. The rise of #MeToo increased recognition of unwanted sexual experiences in individuals, while also increasing disclosures of sexual misconduct online. Despite the #MeToo Movement gaining tremendous popularity and momentum, social critiques and researchers have noted the change in representation ultimately becoming a movement for white-hetero-cis-gendered females. Although there is numerous sexual violence research with samples containing white cis-gendered hetero females, it is essential that research focus on the impact among marginalized identities by utilizing an intersectionality approach. This quasi-experimental study explores the impact of the #MeToo Movement on intersectionality using a difference in difference method by investigating the correlation of reporting sexual violence to a rape crisis center versus law enforcement among cis-gendered women, women of color, and women from the LGBTQIA+ community. The results from this analysis will provide implications for future research and training surrounding sexual violence and marginalized identities in addition to promoting changes within the way service providers, such as law enforcement, provide interventions for SV survivors.

Abstract Name: **The effects of chronic mild stress on traumatic brain injury recovery**

Traumatic brain injury (TBI) is a debilitating condition which results from a concussive blow to the head and can produce epilepsy, mental health issues, and cognitive and behavioral impairments. The long-term impacts of TBI include brain edema, hypoxia, as well as damage to neural processes, the effects of which may compromise blood-brain barrier function and promote inflammatory responses. It is not clear if prolonged exposure to stress exacerbates symptoms associated with TBI thus the current experiment addresses the impact of chronic mild stress (CMS) on anxiety-like and depressive-like behaviors in a mouse model of TBI. The current study also assesses the combined effect of CMS and TBI on gliosis, the process through which glial cells respond to central nervous system damage. Using S100β staining, we quantified the extent of gliosis in the cortex and hippocampus of mice exposed to CMS, TBI or a combined treatment of both CMS and TBI.

Abstract Name: Developing a Machine Learning Algorithm using Pattern Recognition to Analyze Experimental Data from Photoelectrochemical Systems

The purpose of this research is to develop a machine learning algorithm that will use pattern recognition to match experimental voltammograms with model responses to understand the physical parameters of an artificial photosynthetic system. Photosynthesis, the process in which plants convert light energy from the sun into chemical energy, can be replicated artificially in a photoelectrochemical reaction powered by natural light that generates hydrogen fuel at a semiconductor electrode. Semiconductors, such as silicon, are an essential part of converting light into usable energy. The potential and current recorded with semiconductor electrodes as working electrodes and separate reference; counter electrodes contain useful information about the reactions if proper analysis can be performed. Performing data analysis on the data collected from cyclic voltammetry allows the photoelectrochemical reactions to be examined in a systematic manner to determine the best conditions for conducting the reactions. Experimental variables include the type of semiconductor used to construct the electrode, the surface area of the semiconductor, and the dopant density of the semiconductor. The developed algorithm allows for more precise measurement of the system parameters that control the reaction properties. The present data were recorded in the absence of light to control the variability of the experiment. Future experiments will utilize visible light to drive the current that powers the reactions. This algorithm will aid in the understanding of the reactions taking place to move forward towards the end goal of creating hydrogen fuel solely through the use of natural light.

Abstract Name: Passive Acoustic Monitoring of Cao-Vit Gibbons (Nomascus nasutus) Utilizing Multilaterations of Vocalizations

Since their rediscovery in 2002, the cao-vit gibbon population has remained critically endangered and thus, a limited amount of information regarding their vocalization and general behaviors has been discovered. The use of Passive Acoustic Monitoring has been utilized as a non-invasive method to monitor individuals and wildlife populations alike. In this study, twenty GPS-synced audio recording units were deployed in a limestone karst rainforest in Northern Vietnam. The goal of the deployment was to determine the feasibility of finding precise locations of these individuals. Approximately 3,000 hours of audio data was collected and manually marked to locate times in which male or female calls were received at the units. The results of the multilateration analysis successfully generated a map showing the locations that different groups of cao-vit gibbons were calling. Future goals that have arisen from this research include gathering data for long-term research on gibbon communication, intraspecific behavioral interactions, as well as the potential development of technologically based solutions for applied conservation.

Abstract Name: Does the CIO's Gender matter more than her Expertise and Leadership Style in affecting IT security policy compliance?

Information security threats have become a major concern for organizational leadership. Research suggests that IT leadership is vital in influencing employees' IT security compliance with security policy; however, there is little research measuring the role of the CIO's gender in influencing employees toward IT security compliance. The IT field has progressed, and there are more women CIOs now, but women leaders are still a minority in IT. According to a Pew Research report published in 2018, societal role expectations and barriers have discouraged women from going into the IT domain. Barriers to learning and advancing in IT careers have also hampered women's self-confidence to pursue careers in this industry. Thus, perceived credibility or IT expertise becomes another serious challenge women IT leaders face.While it is known that women leaders are more transformational than transactional, men, in contrast, are known to follow a transactional leadership style in general. Prior studies provide overwhelming evidence that the transformational leadership style is more effective in influencing behavior change and positively related to team and organization performance.Thus, this paper seeks to understand the role of CIO gender, perceived IT expertise, and leadership style in influencing employees' behavior change and intention to comply with cyber-security recommendations. The 2x2x2 controlled experiment uses various vignettes in Qualtrics to manipulate gender, IT expertise (low/ high), and leadership style (transactional/ transformational). Data will be collected from all over the US using MTurk during December 2022 and analyzed during January 2023. The findings of the study will have theoretical and practical implications. It will help inform IT literature on the role of the security message sender's characteristics and the contextual outcomes; on the other hand, they will guide CIOs, particularly women, on how they can tailor their leadership style and security recommendations to achieve greater behavior change.

Abstract Name: Social Media and Self-esteem

Social media, what did we do before it existed? Were we better off before or are we now? The debates around social media use are endless. There are strong viewpoints on both sides. Some believe it is literally the demise of human society, contributing to the delinquency of minors and providing negativeinformation that molds the minds of the young. Others believe it is entertainment and provides no harm to society and has no impact to the changing world we live in. Still others are cautiously in the middle. While social media has been around for some time now, we still know very little about the potential long-term impact. The population most influenced is the young. This research study explores the association between age of beginning use of soical media and the impact on various aspects of development.The key areas of interest are mental health, self-esteem, sexualization, achievement and addiction. Correlational analysis will be completed in the spring semester of 2023.

Abstract Name: **Effects of Social Media**

Social media has become one of the biggest aspects of our everyday lives. They allow us to share our lives with loved ones, research our interests, and expose ourselves to all kinds of new things. Due to how ubiquitous the sites are, they inevitably will have a profound effect on mental health. Existing literature shows that there are many ways that social media can affect people's lives. It shows that social media can affect people's health choices and personal lifestyle decisions. Research also shows that people tend to compare themselves to others more when using social media often, which can lead to a multitude of mental health and self-perception issues. This research focuses on mental health and social media use. Using a survey implemented to a diverse sample of individuals through various social media outlets, a wide variety of different trends emerged. The main focus of the research was to determine whether social media was linked to self-esteem. The research shows a wide variety of ways social media is affecting people's mental health and their assessments of their own physical and intellectual attributes.

Abstract Name: **Handbooks, Policies, and Power: Discursive Language and LGBTQIA+ Representation in Christian University Handbooks**

For many years, tensions have existed between the Christianity and LGBTQ communities, most apparent in contexts such as politics and education. One site of conflict lies within the realm of Christian higher education, specifically in regards to campus-wide regulation of same-sex behaviors. Though some such schools file exemptions from the Title IX that prohibits sex-based discrimination, others draft language that flies under the radar. This research examines the language surrounding rules for LGBTQ students and their rationale as communicated in five Christian universities' handbooks. Bakhtin; Holquist (1981) demonstrate the innate tension between dialogue and the social context within which it is understood. Therefore, since language is not neutral, the words creating these rules are in themselves a site of tension for the university, its contributors, its students, and the greater society. Additionally, Derrida's (1973) idea of differance creates another dimension when it comes to discourses – we know what something is through knowing its negative. This tension and use of the negative suggest also a power dynamic in place through language. McKerrow (1989) and Foucault (1982) provide the framework for uncovering these dynamics. Using critical theory with a focus on Bakhtin's perspective on dialogue, this paper will work to show the organizational and dialectical tensions that these rules create. I demonstrate ways in which Christian university mission statements and same-sex rules in student handbooks represent dialectical tensions for Christian universities to engage in order to best serve LGBTQ students.

Abstract Name: **Quantifying organic phases in coral skeletons at the nanoscale**

Nanoscale mineral structures of coral are not well understood. When corals build their skeletons, they are composed of nanoscale crystalline structures. It is known that coral skeletons are affected by ocean acidification and climate change at the macroscale. However, understanding how the coral skeleton-building process functions at the nanoscale would allow for better modeling and prediction of how coral might fare under varying ocean conditions and climate changes. Specific isotopes in coral skeletons can mark the organic or mineral parts of the skeletons, and thus can be used as indicators of different phases in the coral skeletons. Our goal is to statistically investigate quantitative relationships that exist between different organic and mineral associated isotopes in coral skeletons. Multiple corals were lab-grown under various controlled conditions at St. Olaf College, and they were analyzed at the nanoscale by a mass spectrometer to extract concentration data for specific isotopes present throughout the skeletons. We use Pearson correlation to measure the strength of the relationship across coral isotopes and Mander's coefficient to measure co-occurrence. Co-ocurrence looks at the high concentration clusters of isotopes across isotope pairs. Knowing the quantitative co-occurrence of isotope pairs in the coral skeletons helps in understanding the spatial distribution of organic molecules within the coral skeleton, which in turn can help us better understand the growth process of the coral skeleton itself.

Abstract Name: **Undershot Waterwheel Energy Optimization**

A waterwheel is a device that is used to take advantage of the energy produced by flowing water. In locations where the water flows horizontally, referred to as low-head conditions, an "undershot waterwheel" is employed. The head of a location is by definition the height difference between the point in which the water enters the system, and the point at which the water leaves the system. Taking into consideration the value for the head (v22G) of the location, the optimal overall diameter (3 to 6 times the head) of the wheel can be determined. We can take advantage of the low speed caused by the low- head conditions by designing a wheel with an optimal number of blades. The rationale for this lies in the fact that a higher number of blades would increase the torque, and consequently, the kinetic energy. The optimal number of blades is determined by the ratio between the working circumference and the head, where the working circumference is the difference of the overall diameter and the head multiplied by . This project aims to evaluate the effect that: 1. The number of blades, 2. The thickness and 3. The flow of water, will have on the energy production of the system. We will test each alternative design for the system individually, as well as collectively.

Abstract Name: **Spider functional community assembly along a stress gradient in Northern and Southern Wisconsin forests**

Ecological communities are smaller subsets of overall larger species pools.Ecological selection can cause a community to have less than expected functional trait diversity, narrowing it to a small subset of features (trait clustering). There are also processes, such as competition, that can cause communities to have greater than expected trait diversity (trait overdispersion), especially where ecological stress is low (i.e., the stress-dominance hypothesis). Ecological selection can also alter the mean trait values of communities.There has been considerable work on the functional assembly of plants and fish, but little is known about assembly of terrestrial invertebrate animals. We placed three pitfall traps in 40 locations in Northern forests (i.e., mainly evergreen conifers) and Southern forests (i.e., mainly deciduous trees) across a strong gradient in soil moisture. We measured the size and asymmetry of spider body, leg, eye, and mouthpart traits because they are related to resource acquisition.We used Monte Carlo simulations to estimate the amount of functional trait diversity and mean trait values that would be found if community assembly was caused by random ecological drift. The simulations used three species pool scales: regional (all species), within Northern or Southern Wisconsin forests, within specific forest types. Overall, trait diversity was less than expected by chance, but the effect size was smaller when using smaller species pools.Spiders were larger in Southern forests, but mean trait values were unrelated to soil moisture.Size trait diversity increased with moisture in Northern forests, but not in Southern forests.This partially supports the stress-dominance hypothesis.Asymmetry trait diversity was also unrelated to moisture.Functional community assembly differed in Northern versus Southern forests, and so there are unique assembly rules for each region.

Abstract Name: **Examining the impact of abiotic and biotic factors on early establishment of Morella cerifera**

Shrub encroachment is occurring on Virginia barrier islands in part because of the expansion of native shrub, Morella cerifera. Previous studies on Hog Island, Virginia, show that M. cerifera is protected behind elevated dunes where grass cover is variable. Grass cover plays a role in successful establishment into grasslands; however, when grass density is too high M. cerifera establishment is impeded. What is unknown is the level of grass cover that is beneficial for M. cerifera establishment. The hypothesis is that low grass density (≤70% cover) will change the surrounding microenvironment and increase the establishment of M. cerifera seedlings. The current research is important to understand the role of grass cover on the successful encroachment of M. cerifera on barrier islands. To address the impact of grass density on M. cerifera seedling establishment ten 3m x 3m observational plots were set up to document the natural establishment of M. cerifera seedlings. Five plots were high grass density plots (95-99% grass cover) and five plots were low density grass plots (40-70% grass cover). Within these observational plots the abiotic environment was also characterized specifically, seedling number, temperature, chlorides, species richness, and light availability. Experimental plots (1m x1m) were set up adjacent to each of the observational plots. Five seedlings were transplanted per 1m x 1m plot for a total of 50 seedlings. At the end of four weeks seedling survival was quantified. Results show that there were no naturally occurring M. cerifera seedings in the high density observational plots; however, after four weeks there was 88% survival in high density plots compared to 80% survival from the low density plots during the summer. Grass cover may be more important for the survival of M. cerifera seedlings during the summer months.

Abstract Name: Bumblebee Distribution on UW-Parkside's Campus

Purpose: Bumblebees are known pollinators and contributors to healthy ecosystems. In Wisconsin, UW-Parkside is a known location for the federally endangered Rusty-patched-bumblebee (Bombus affinis) and other bumblebee species. The objective of this project was to locate and identify various members of Bombus in four distinct campus phases (phase 1 and 2: completed restoration, phase 3: current restoration, phase 4: pre-restoration). Artificial nests were deployed into phases to encourage nesting and assess feasibility of monitoring resident bumblebee populations. Methods and Materials Weekly, one-hour, surveys were conducted under appropriate conditions from 11 May to 5 October, 2022. Sites of ~15m radius within each phase were surveyed for Bombus activity. Information regarding location, weather, and topography were recorded. During surveys, specimens were tallied and photographed for later identification. In each phase, six randomly placed artificial nests were either wood-covered or unsheltered to resemble natural nesting conditions. Early in the season nests were regularly inspected for activity.ResultsDuring 50 surveys, 199 bumblebees were recorded on the UW-Parkside campus; no Rusty patched bumblebees were observed during the first year of this project. Bumblebees appeared to prefer phases based on habitat composition rather than levels of restoration. In spring, it appeared queens frequented wooded areas, presumably for nesting purposes. Artificial nests were unoccupied this season perhaps due to delayed placement and challenges from vegetation encroachment. This pilot project provides guidelines for future artificial nesting placement and construction. Overall, our first season of survey data provides needed information on the current state of bumblebee activity on campus which serves as a guide for further restoration.

Abstract Name: Decadal Variations of Six Criteria Air Pollutants Over Texas

The Clean Air Act requires the US Environmental Protection Agency (EPA) to set National Ambient Air Quality Standards (NAAQS) for six common air pollutants (also known as “criteria air pollutants”). These six pollutants are carbon monoxide, lead, nitrogen oxides, ground-level ozone, particulate matter, and sulfur oxides. These pollutants are found all over the U.S. They can harm health and the environment and cause property damage. The EPA must designate areas as meeting (attainment) or not meeting (nonattainment) the standard in accordance to the Clean Air Act. States must develop a general plan to attain and maintain the NAAQS in all areas of the country and a specific plan to achieve the criteria for each area designated nonattainment for a NAAQS. This study presents in-situ surface measurements from the Air Quality System (AQS) EPA for six air pollutants from 2005 to 2022, as well as the weekly, monthly, and yearly trends for these pollutants over Texas’ major population centers. This study will analyze these trends for any correlation with petrochemical industry, vehicle usage, technological advancement, and natural events. Although the overall trend is that of a decrease in the concentration of these pollutants over time, it is worthwhile to explore more granular trends in an effort to identify their underlying causes.

Abstract Name: **Intersectional Effects of Race and Gender on Age of Special Education Service Receipt for Autistic Children**

Early diagnosis of autism spectrum disorder (ASD) is important for providing early intervention to improve later developmental outcomes. Race and gender are associated with differential age of diagnosis (AOD) for children with ASD. Females often have a later AOD than males, but there are conflicting results in previous studies regarding the effect of race on AOD, and a lack of studies generally focused on intersectional effects ofrace and gender. Using existing data from the Miami School Readiness Project (MSRP), in which over 40,000 ethnically diverse children were followed from pre-K through 12th grade, I will examine intersectionality effects in the grade at which a subsample of MSRP children with autism (n = 2,000) first received ASD as their primary exceptionality in the public school system for special education services. Multiple regression analyses (in SPSS) will be performed to determine the relationship between race and gender (and their interaction) in predicting the grade at which students first received their autism exceptionality (0 = K, 1=1st grade, 2=2nd grade. Etc. through 12th grade), controlling for poverty status, DLL status, and child behavioral and cognitive functioning directly assessed at age four. Questions include: 1) Is the grade of special education receipt for ASD similar between males and females, and for White, Black, Asian, and Latino children? and 2) Are there intersectional effects between race and gender on the age of special education service receipt? Data are currently being cleaned/prepared and preliminary exploratory data analyses are being done to look for distributional shape and outliers in the variables. Analyses/results will easily be complete in time for the conference. Results will have important implications for school systems in how they provide special education service for diverse groups of students with ASD.

Abstract Name: **Security Selection Model for the Gordon Spellman Fund Phase 2**

In 2005, a student-directed portfolio was created at the University of Wisconsin-La Crosse where an alumnus, Kevin Spellman, donated funds in his grandfather's name. Since 2005, the fund has approximately $383,500 in value and is invested in common stock and cash. The fund is managed by the investment club and students in Investment Analysis and Portfolio Management (FIN 475), with finance faculty and Spellman Fund advisors (investment professionals) providing oversight. The fund follows a value-investment strategy but has yet to establish a formal method to analyze potential investments. This research will test the performance of my stock selection model focused on twelve financial measures and assess how well it can explain future returns on 3,915 stocks. The analysis will also examine each stock's composite score rating from 0-100 based on how correlated each financial measure is with future returns and will determine average returns over time based on specific percentiles. Refining the model will allow future students to select superior stocks to analyze and potentially add to the Spellman Fund based on the investment criteria. I have applied for this analysis to be part of the poster presentation given atthe National Conference on Undergraduate Research.

Abstract Name: **Assessing Lupine as an Environmental Conservation Tool in Iceland**

Iceland's environment is highly prone to erosion and has conditions that make plant growth challenging. The plant lupine is a divisive solution to soil erosion and reforestation that has been found successful in some regions of Iceland but not all. We researched the issue through extensive document research, expert interviews from different perspectives, and surveys of native Icelanders, to get as complete and unbiased a picture of the issue as possible. We used this to create a decision guide that gives a comprehensive account any person in Iceland can use in order to choose what they would like to do to address soil conservation and reforestation issues on their land. Key issues the decision guide covers are soil conservation, reforestation, and removal of lupine. Along with the decision guide, we include a decisional balance sheet to show the pros and cons of lupine usage in Iceland and a plant infographic to teach about the plants in the decision guide. These tools can be used by land owners in Iceland to make decisions about restoration and reforestation on their land.

Abstract Name: **Assessment of At-Home Genetic Testing Kit Consistency Between Identical Twins**

Since their arrival on the market in the early 2000s, direct to consumer (DTC) genetic testing kits (at-home kits) have exploded in popularity. As the industry has continued to grow, questions have emerged over the accuracy and consistency of the results of these ancestry reports. Despite claims by all companies studied here of over 99% accuracy, previous research in this lab has shown significant inconsistencies between the results provided by each company. Of 42 individuals previously tested, 39 had large discrepancies in their genetic ancestry categories from company to company; results varied by up to 40% for some participants. The goal of the current study was to examine the DNA of identical twins to determine if these testing discrepancies exist within companies (since the DNA of identical twins should be the same) or only between them. The same three genetic testing companies that were previously studied were used here - Ancestry, 23&Me, and MyHeritage. To date, five sets of identical twins have received full results, and several additional sets of twins are in process. Results have remained consistent with the previous study, with discrepancies between ancestry categories reported by each company. Surprisingly, in addition to the discrepancies between companies, differences were found between twins in data reported by the same company. No set of twins had results that completely matched. In some twins, one individual was noted to have an ancestry category that the other didn't have at all. Given the claims of near-perfect accuracy reported by the companies, and the fact that some of them also market genetic health screenings for certain diseases and health conditions, these inconsistencies raise serious ethical concerns about the way on which they market and report data to under-informed consumers.

Abstract Name: **Social network connections reflect gut microbiome of California ground squirrels**

The gut microbiome, defined as the microbial ecosystem in the digestive tract, has wide-ranging effects on animal health, but its social correlates are poorly understood in wild mammals. The microbiome is likely impacted by many factors such as social behaviors. Horizontal transmission is expected during social interactions among individuals within a lifetime. This research focused on a highly tractable social mammalian species, the California ground squirrels (Otospermophilus beecheyi), as part of a long-term study at Briones Regional Park. We sequenced bacterial 16s rRNA from fecal DNA from these free-living mammals. First, we report on the results of a validation study in which we assessed the effects of sample collection and storage methods on fecal bacterial diversity in field conditions. We collected fecal samples from twelve adult female squirrels either from the soil beneath traps in which individuals had been captured or from tubs placed under squirrels during handling. Samples were then either frozen immediately in liquid nitrogen or stored on ice for several hours before being transferred to a -80oC freezer. We found no differences among methods with regard to sequence read depth or alpha (within individual) diversity of bacteria, confirming the validity of this measure. Second, we examined the social networks of marked individuals over time to evaluate the relationship between social network connectivity and fecal bacterial diversity. We predicted a positive relationship between the node degree (average number of squirrels interacted with in a day across the entire summer) in social networks and fecal microbial diversity. We performed social network analyses to assess the effects of social connectivity on an individual's microbiome diversity and composition. We found a correlation between the bacterial diversity of the gut microbiome and the node degree of the squirrel, suggesting that increased social interactions are having a positive effect on microbiome diversity.

Miller, Ailee

Ailee Miller,
Shanna Nifoussi

Abstract Name: **Stress & Risk: The Effect of Online vs. In-Person Stress**

Stress research is imperative due to the health consequences associated with stress, and with the switch to online formats, telehealth appointments have become commonplace. The study here aims to identify if stress research could be conducted online, and to determine if there is an effect of risk-aversion on the level of stress response. It was hypothesized that there would be a similar stress response in both the online and in-person groups, and that those who are risk-averse would have a higher stress-response. Participants were recruited from UW-Superior and split into online and in-person groups. Everyone completed a pre-meeting survey to gather baseline heart rates and fill out a risk-aversion survey. Both groups were tested on memory and heart rates. At a second meeting, the participants were exposed to a social stressor in between tests and completed a lottery activity to gauge risk-aversion. It was found that there were similar stress responses based on heart rate among the online and in-person groups, and the lottery activity produced similar results to the survey. This provides promising results to indicate that the same stress response is elicited in both contexts, however, a larger group will need to be tested in order to gain significant results.

Abstract Name: Minority Status and Mental Health B

Discriminatory behaviors live througout society today and all generations of the past. How do these behaviors impact groups with minority status? The aim of this study is to research how chronic stress experienced by people with minority status impact mental health. There will be multiple angles applied to this study. The first area of interest is how social media either contributes to or gives a community for discriminatory behaviors or does social media allow for an outlet for those with minority status to build support and community. The second area of interest is how does stress related to chronic discrimination exposure contribute to the mental health of individuals with minority status. Previous research has shown disparities in mental health, substance use, and other factors related to mental health among groups with minority status when compared to the same age group of the majority stauts. This study will identify factors associated with positive and negative mental health development across multiple minority status groups through a survey implemented and analyzed in the spring semester of 2023.

Abstract Name: The Development of the Y?kai Fox in Print and Literature

The earliest records of these supernatural creatures are from official documents in the third century C.E. China, but they can be fund all over the region in folktales, literature, and prints. One of the most prolific varieties was the Yokai, a manifestation of supernatural creatures in Japanese society. They played a promient role in Edo Period Japan and were so impactful that thye persist in contemporary media. The role these creatures had in society has evolved, yet these supernatural beings remain an integral part of the culture of East Asia. This presentation will look at four examples of the yokai fox in prints that support not jsut their cultural importance, but how their roles and powers have been adapted across time and culture since their inception.

Abstract Name: 73 Hours: The Making of a Domestic Terrorist

On April 19 of 1995, the Alfred P. Murrah building was bombed using a deadly cocktail of fertilizer, diesel, and other chemicals. Timothy McVeigh, a Gulf War veteran, was the mastermind behind this explosion. After the incident on Mount Carmel in Waco, McVeigh became enraged with the U.S. government. That act combined with the fear that McVeigh may lose his right to bear arms led him to plot revenge against them.This research aims to analyze both the childhood and young adulthood of Timothy McVeigh to determine if he exhibited psychopathic behaviors using an indirect personality assessment and a series of interview tapes. The assessment will consider various factors which will all be used to conclude behaviors, if any, reflecting psychopathy. The factors include the family details of McVeigh's family such as their dynamic and environmental conditions during his childhood. The assessment also focuses on the physical characteristics, health, employment, personal relationships, and hobbies/passions. The most important factor is the behavior of the individual under assessment. The details of McVeigh's behavior are discussed in the biography American Terrorist: Timothy McVeigh and the Oklahoma City Bombing by Dan Herbeck and Lou Michel. The biography discusses thoughts and feelings of McVeigh throughout his life: childhood up to before and after the bombing. Interview tapes were conducted and recorded by the two authors of the biography. The interview tapes will be utilized to listen for emotional inflection in the voice. Emotion such as excitement which can be indicated by the increased speech or the change in tone. The factors mentioned above will be used to come to the conclusion of whether Timothy McVeigh is a psychopath according to societal standards. This research hopes to validate an indirect personality assessment and compile a list of precautionary questions to assess other individuals in the future.

Abstract Name: Enhancing Instruction With Video Tutorial In The Arts

The goal of this project is to evaluate students' percieved effectiveness of instructional video tutorials in a photography class. The instructional video tutorials will be used to supplement the traditional teaching methods in the course. The research question is: Are instructional video tutorials perceived as effective by students in a photography course? The project will be assessed by student surveys that ask students to reflect on the aspects of the instructional video tutorials the are helpful or not. The student researchers for this project will help research best methods of creating instructional videos, organize content, capture and edit the tutorial videos for the course.

Abstract Name: **Performance on Executive Functioning and Attention Measures in Children with Neurofibromatosis Type 1 Compared to Unaffected Controls**

Neurofibromatosis type 1 (NF1) is a neurogenetic condition caused by a pathogenic variant of the NF1 gene. Cognitive problems in executive functioning and attention are prevalent in children with NF1. Executive function is an umbrella term for the cognitive processes that drive goal-directed and self-regulatory behavior. Executive function deficits in NF1 have been identified in the domains of inhibition, working memory, planning, and organization. Attention is the ability to focus one's cognitive resources on a relevant stimulus while ignoring irrelevant stimuli. In NF1, attentional difficulties have been identified in the areas of sustained, selective, divided, and switching attention. This project will examine measures of attention and executive function in children ages 7-11 years with NF1 compared to an age-matched unaffected group. Attention and executive functioning will be assessed using behavioral measures and caregiver rating scales. The Conners Continuous Performance Test-Third Edition (CPT-3) is a computer software-based neuropsychological assessment that yields information about four dimensions of attention: inattentiveness, impulsivity, sustained attention, and vigilance. Dependent measures include: omission errors (missed responses), commission errors (incorrect responses), and variability (speed consistency). The NEPSY-2 Auditory Attention and Response Set subtest (AARS) is an instrument used to assess auditory attention and impulsivity. Dependent measures include: omission errors, commission errors, and inhibitory errors (responses which indicate impulsivity or deficits in shifting). The Behavior Rating Inventory of Executive Function-Second Edition (BRIEF-2), a caregiver rating scale, assesses executive function and self-regulatory behavior. Dependent measures include ratings on scales assessing: behavior regulation, emotion regulation, and cognitive regulation indexes. We will characterize the performance of the NF1 group using descriptive statistics and compare the performances of children with NF1 and unaffected children using independent samples t-tests. We expect the NF1 group will show difficulty in comparison to normative data and to the unaffected group across all dependent measures.

Abstract Name: **Diet Preferences of the Two Native Crayfish Species of Northwest Iowa, Faxonius immunis and Faxonius virilis**

Only two native species of crayfish, the pond-dwelling F. immunis and stream-dwelling F. virilis, are native to Northwest Iowa. These species live in ecologically isolated habitats and inhabit a diverse range of water resources in the area. The two species occupy distinct niches that can, on occasion, overlap. Due to their generalized diets and diverse environments, there have been many conflicting reports in the scientific literature of which method and bait are preferred to capture these two species. This study tests the most frequently reported crayfish-catching approaches and refines them into the best method for capturing the highest number of these two species of crayfish. Silver, cylindrical, wire mesh crayfish traps were used at 43°24'39.1"N 95°14'59.9"W and at 43°26'14.4"N 95°21'55.6"W. Each trap was set out in shallow water and allowed to sit for a 24-hour period before checking and replenishing the bait. Each type of bait was set out in the traps for two periods with a check in between. At each check, the crayfish present were counted, and bait was replenished. After two periods, the bait was discarded and replaced with the new bait for the next 2 periods. During the three-week collecting period in July and August of 2022, a total of 31 crayfish specimens, including F. immunis (21) and F. virilis (10) were captured. A Welch two-sample t-test at the 95% confidence level indicated that there was a statistically significant difference between the number of individuals of each crayfish species caught using 3 types of bait. This study is the starting point in refining the exact methods needed to catch the highest number of individuals of various crayfish species used in scientific studies. This could create a standardized procedure for catching crayfish across all of invertebrate and aquatic ecology, potentially reducing costs on limited grant budgets.

Abstract Name: **Mosquito communities and West Nile virus detection in central Oklahoma**

Understanding mosquito communities is a crucial approach to mitigating public health risks. In this study, we characterized the mosquito community in the greater Oklahoma City area and used molecular assays to detect West Nile Virus (WNV) between May and June 2022. We sampled at 19 locations with varying landscape characteristics across four counties in central Oklahoma using host-seeking and gravid traps to capture the community diversity. In total, 5,589 mosquitoes were caught comprising 27 species representing 7 genera with the majority of the specimens belonging to the Culex genus and Culex pipiens (n= 3100) as the dominant species collected. We found a correlation between the phenology of mosquito genera with clusters of similarity amongst landscapes based on ANOSIM analysis (p=0.049) with suburban areas clustered together as well as rural areas. The mosquito phenology in the early mosquito season was mostly represented by the Aedes genera, with Aedes vexans being the most abundant specimens in our traps but subsequently surpassed by culicine mosquitoes, particularly, the Culex pipiens/quadrimaculatus complex. Female mosquitoes of the same species were pooled (5 ≤ n ≤ 30) and purified RNA used for WNV RT-qPCR screening; five out of the 248 pools were positive. Three of the positive pools were Culex pipiens with the other two pools composed of Aedes vexans and Aedes albopictus, respectively. Altogether, mosquito assemblage varied across locations; Culex complex peaked towards the end of the early season, coinciding with WNV detection, suggesting Culex pipiens major role as vectors of WNV in central Oklahoma. Knowledge of changes in mosquito communities and arboviral detection can inform vector-borne disease control.

Abstract Name: **Exploring the Mediating Role of Social Dominance Orientation in Stigmatizing Attitudes Exhibited in Sports Fans**

While previous studies on sports fan environments reveal correlations between high sports fan identification and endorsement of sexist attitudes, the effect of sports fan identification on negative attitudes towards issues related to gender and sexuality outside of fan environments have not yet been investigated. In this study, we aim to examine the link between levels of sports fan identification and negative attitudes towards women, homosexual individuals, and transgender individuals. We predict that higher levels of sports fan identification will correlate with more negative attitudes toward women, homosexual individuals, and transgender individuals as compared to those with lower levels of sports fan identification. With level of sports fan identification as the predictor variable and stigmatizing attitudes as the outcome variables, correlational analyses will be performed to assess relationship between sports fan identification and attitudes toward women, homosexual individuals, and transgender individuals. The predictor variable will be measured using a composite score obtained from two measures evaluating sports fan identification, and the outcome variables will be obtained from three measures each separately designed to measure sexism, homophobia, and transphobia, respectively. Consistent with our hypotheses, we expect to find correlations between levels of sports fan identification and the specific attitude measures. Additionally, we will investigate political orientation and social dominance orientation as possible mechanisms underlying the connection between sports fan identification and attitudes towards women, homosexual individuals, and transgender individuals. These mechanisms will be investigated via mediation analyses; for example, we will explore whether the link between sports fan identification and attitudes toward women is mediated by social dominance orientation.<p class="MsoNormal">This study is currently in progress and has received IRB approval. Data collection is scheduled to begin January 23, 2023 and conclude March 1, 2023. We anticipate all data analyses and report writing will be completed prior to the conference.

Abstract Name: **Examining different cultural and chemical options for control of Fusarium bulb rot in onions**

Onions are grown in 1,600 acres in northern Utah and are a large part of growers' income. In the fall of 2021, 30% of a grower's onion yield was affected by Fusarium bulb rot (caused by a fungus known as Fusarium proliferatum) and the onions were unmarketable. The literature surrounding this pathogen is sparse and losses of this magnitude could cause growers to lose between six and seven thousand dollars per acre. Samples of the fungus were plated onto potato dextrose agar at half strength and maintained fresh throughout the winter. In vitro experiments were performed with various fungicides at different rates to determine which would most effectively inhibit the growth of F. proliferatum. The study also performed inoculation tests with onions in a greenhouse to discover proper inoculation methods for a field trial. The field trial was conducted to examine the effects of fungicides and different cultural practices in conditions similar to the growers of northern Utah. The field trial was the culmination of the entire study and it showed that two different treatments had a lower incidence of Fusarium bulb rot. This project was a big first step in filling in gaps on the literature surrounding F. proliferatum. These results will help refine future research when testing cultural and chemical treatments.

Abstract Name: **The impact of belonging to minority-based organizations on minority stress experiences in college**

Among colleges nationwide, minoritized students face additional unique stressors due to their identities being devalued in the broader climate. Further, students holding minoritized identities (vs. those do not) report higher levels of mental health concerns. Institutions of higher education often provide a range of resources to students to help assist them in their individual growth. One such source is minority-based student organizations, wherein students holding similar minoritized identities can be in community and share in similar experiences and values. Extent work suggests minority-based organizations may buffer against minority stress, specifically through increased sense of belonging. However, more research is needed to confirm this. As such, the purpose of this study is to determine whether level of involvement in a minority-based organizations reduces the experience of minority stress (both perceived and physiological), and whether that change can be explained by a higher sense of belonging. Data collection is ongoing as a midsized midwestern university. It is anticipated that minoritized students belonging to minority based organizations will report lower levels of mental concerns compared to minoritized students who do not belong to these organizations. Implications will be discussed.

Abstract Name: **Mindfulness and Memory**

Purpose: Mindfulness may improve memory through promoting awareness of, attention to, and openness to information presented. The positive effects of mindfulness on memory may be seen even after brief, one-time interventions. However, mindfulness may only affect memory performance if the intervention is administered directly before retrieval rather than at encoding. Additionally, mindfulness might selectively affect some types of memory tasks and not others.Procedure: Participants will be randomly assigned to a mindfulness condition (a ten-minute mindfulness meditation) or a control condition (a ten-minute podcast about the history of mindfulness). All participants will study a list of words, either presented individually or as word pairs, and asked to memorize them for a later memory test. Participants will then take a memory test,item recognition for those who studied individual words or associative recognition for those who studied pairs. Some participants will listen to the podcast (mindfulness or control) before encoding the study list while others will listen to the podcast before retrieving the words at testing.Expected results: We will compare memory recognition performance, specifically false alarms, of participants in the mindfulness condition to those in the control condition. We expect that mindfulness should reduce false alarms only if the intervention is given directly before retrieval. However, we might find that mindfulness facilitates familiarity as a cue when making memory judgments. We expect larger differences in false alarms between the mindfulness and control groups for the item recognition task compared to the associative recognition task.Data collection is currently underway.Conclusions: Advancing or amending theories of mindfulness and memory could improve our understanding of human memory and also aid potential translations of research findings to practical applications. For example, would a brief mindfulness intervention presented before administering a classroom exam improve student performance?

Abstract Name: **Change in Gene Expression in Green Crabs in Response to Environmental Salinity Change**

When exposed to low salinities, the green crab Carcinus maenas experiences elevated hemolymph levels of methyl farnesoate (MF), a putative hormone that may be involved incrab osmoregulation. The final step of the MF biosynthetic pathway is catalyzed by the enzyme farnesoic acid o-methyltransferase (FAOMeT). Previous work in our lab has identified a long isoform and a short isoform of FAOMeT in the green crab; the cDNA sequences of the two isoforms wereidentical, except that the short isoform had a 15 bp deletion.Sequencing of genomic DNA determined that there were no introns present in the area of the 15 bp deletion, which suggestedthat the presence of two isoforms of FAOMeT was due to gene duplication rather to than alternate splicing. In a time-course study of crabs that had been transferred to low salinity (10 ppt), the relative amount of mRNA for the short form increased after several hours of exposure to low salinity, whereas the relative amount of mRNA for the long form did not increase significantly until the crab hadacclimated to low salinity (21 days after transfer).

Abstract Name: **Accessible Learning for College Students**

For most individuals, college proves difficult in some capacity. However, students with learning disabilities face additional challenges. Disability services are a resource that many colleges offer on their campuses, but how accessible are they and are these services operating in a way that truly benefits college students? In this study, I seek to answer that research question by examining the experiences of students at a large regional university. Specifically, I aim to better understand what struggles and barriers students face when learning and how they feel about their campus's learning support. To answer my research questions, I use data from a survey of college students (n=130) and qualitative data from 8 interviews whose participants are also college students. Quantitative and qualitative data analysis show that students need better support from their professors, which could be implemented by first supporting students with better access to learning accommodations. Additionally, my analysis shows that there is a strong, negative correlation between students that feel like they may have a learning disability and a feeling of being unsupported by their professors. I also find that students that feel they may have a learning disability (but have not been diagnosed) are more likely to feel that school is hard for them. Through my interviews, I noticed a pattern that students lack a feeling of support from their professors. This research and its findings are important because it shows a disconnect between student learning and the support that universities provide. My results suggest that students could benefit from having stronger connections with faculty within the university, which would help students feel more connected to their university and obtain a more personalized learning experience.

Abstract Name: **Contemporary Sustainable Architecture**

Architecture and design often reflect socio-political concerns. For example, contemporary architectural practices focused on sustainable design and materials evidence the increasingly important role art, architecture, and design occupy at the forefront of conversations and solutions around climate change. As carbon emissions continue to rise and global climate change is becoming ever harder to ignore, it is imperative that architectural design incorporate sustainable materials and practices accessible to all. Using data from artists, architects, and designers, who are often working in geographic areas more susceptible to climate change, my presentation will focus on answers to the following questions: i. How does contemporary architecture and design reflect increased awareness of environmental concerns? ii. How have architectural and design practices changed in response to demands for sustainability?· Do developments in sustainable design correlate with changes in carbon emissions? iii. How are regions that are more susceptible to the effects of climate change leading discussions around sustainable architecture, technology, and design?· How is Utah addressing this at State and University levels?My presentation will focus on sustainable architecture, its historical roots, and its contemporary application to areas particularly susceptible to climate change. I will share my research and analysis of Utah-specific solutions to climate change, including the state's overall sustainability practices, the construction of LEED-certified buildings and environment-friendly designs on university campuses, and site-specific examples of sustainable design. This includes a case study I will conduct on-site of Community Rebuilds in Moab, UT, as well as first-hand study examples of sustainable architecture in Salt Lake City.Sustainable architecture is an exceptionally relevant and pressing issue. By bringing these disciplines into conversation with each other, my presentation will address the impactful ways art and design may lead the discourse around sustainability.

Abstract Name: **No Human is Illegal: The Peregrination of the Nomadic Homeless in Pittsburgh**

Homelessness is a propagating global crisis. In many US cities the unhoused face discrimination through bureaucratic legislation. These ordinances prohibit an individual from soliciting in urban settings. This legal exile of the unhoused revokes their 'right to the city', hence, alienating them from society based on their socio-economic status. These anti-solicitation laws are reinforced through architecture, policing, and public surveillance. Today, scholars identify this phenomenon as hostile or anti-homeless architecture; these designs mutate previously 'public' areas into derelict environments. These obstructions include, but are not limited to: armrests in the middle of benches, lids atop trash cans, and spiked ledges under roofed areas. Hostile and anti-homeless architecture differ in appearance. Hostile or defensive architecture's callousness led to its own demise; however, urban classist antagonisms ensued. Anti-homeless architecture (AHA) emerged as the latest 'solution' for the homeless epidemic. The inconspicuous nature of this architecture allows this practice to continue in modern America.My research, focusing largely on urban Pittsburgh, identifies inhibitive architecture and its resulting consequences. I utilized non-obstructive observations, geo-demographic analyses, and peer-reviewed secondary sources to depict the baneful effects of this architecture. These empirical methods postulate an increase in violent crimes due to inadequate food, shelter, and safety available in Pittsburgh. My research explores ways to design inclusive architecture coupled with redistribution of basic needs for the unhoused.

Abstract Name: **Experiences of water insecurity and its relation to food insecurity, health, and well-being**

Water insecurity, characterized by uncertain access to, and availability of, clean water and poor water quality is an emerging concept in the field of nutrition. While most studies on water insecurity have been conducted in low- and middle-income country settings, water insecurity in the U.S. is documented, particularly among low-income and black, indigenous, and people of color (BIPOC) communities in both urban and rural settings. Provided the interconnections between food and water, scholars increasingly recognize the need for research strategies to better understand the role that water insecurity plays in human nutrition and well-being. Survey data were collected from residents of central Wisconsin. Chi-square tests of independence and logistic regressions were used to examine associations among key variables. Experiences of water insecurity and food insecurity were co-occurring among low-income participants but more frequently they were experienced independently. Experiences of water insecurity were associated with psychosocial stressors detrimental to mental well-being that may also impact nutrition. Most participants reported treating their water associated with a lack of trust with the quality of their drinking water. These findings have important implications for developing responsive interventions to support access to adequate food and water. Future studies to test the relationships between the characteristics of water insecurity identified in this study with food insecurity among low-income populations are warranted.

Abstract Name: **Continuous Mobile Authentication with Multi Finger Touch Dynamics**

Mobile Devices are growing in use day by day causing a need for better mobile security. Mobile devices have some security features built into them already, but if the intruder has already unlocked the device those features will not work. Identifying where this security can be improved is a difficult task, however improvements in Touch Dynamics Authentication show that it could be used as a form of continuous authentication once the device has been unlocked. Often times users on a device will have very repetitive movements that humans can not detect, but a program can be trained to understand these patterns. In this research we will be looking into specifically Multi-Finger Touch Dynamics and attempting to work out three models that are able to detect an authentic user from an imposter. We will be extracting several features in order to train these programs and some include velocity, acceleration, and how many pixels each finger covers

Abstract Name: **Martha's Vineyard: The Island with Flying Hands**

Before the island was the epitome of New England culture and home to prestigious wealthy members of society, dozens of pristine beaches, and historic lighthouses, Martha's Vineyard was once a utopia for the Deaf. For more than two hundred years, Martha's Vineyard residents manifested an extremely high rate of profound hereditary deafness. They lived in blissful ignorance, unaware of the mainland ideas of disabilities and isolationism of those who differ from the "perfect human condition." Close-knit communities and multiple Deaf persons per family gave way to the island's unique version of sign language, Vineyard Sign Language, in which everyone was fluent. Vineyard Sign Language provided the island with a practical and functional communication system, and it later laid the foundation for American Sign language, a creole language composed of home signs and French Sign Language. As a result, the Deaf Vineyarders enjoyed access to every aspect of island society, including jobs, wealth, and relationships unhindered by their loss of hearing. The Deaf were church members, government officials, business owners, neighbors, and spouses, just like their hearing counterparts. Furthermore, "handicapped" was a mainland idea that never crossed islanders' minds. Instead, they viewed deafness merely as a normal variation of the human condition, like brown or green eyes, and blonde or brown hair. By the mid-1900s, the last of Martha's Vineyard's native signers passed away, and with them, the Vineyard Sign Language, the rich history of Deaf culture, and the normalization of disabilities in an ableist world.

Abstract Name: **Nightcap**

This piece was composed over the past year for a trio consisting of clarinet, alto saxophone, and piano by recent UWEC alum Jack Ford. It was written for clarinetist Rafael Puga and saxophonist Nick Miskemen. Performing new works help move classical music forward by ensuring that fresh perspectives are being heard. It also celebrates the collaboration between composer and performers. The preparation of this piece goes beyond a practice room and rehearsals and requires communication by everyone involved. This piece has an unusual instrumentation as clarinet, saxophone, and piano repertoire is very limited, thus adding more music options for future musicians.

Abstract Name: **Short and Long-term Effects of Child Maltreatment**

The consequences of childhood maltreatment can and will cause both short term and long term problems on children. Yet how we help is important besides knowing the effects. What I have found through others research,childhood maltreatment can cause both short and long-term physical, psychological, and behavioral problems. Short-term effects could be physical and psychological. The physical effects are bruises, broken bones, and concussions. Besides the physical issues, abuse can cause psychological issues. Short term effects include but are not limited to sadness,anxiety, not being interested in their hobbies, and stress. These effects could lead to something more serious in the future or stay as they are and not lead into anything. Children might also have to grow up too fast and learn how to fend for themselves is a severe case of child neglect. The child abuse could be generational and is taught. Long term consequences could lead to issues contributing to society. The child may suffer health issues, such as impaired brain development. Other health issues that the abuse could cause are shaken baby syndrome, physical deformities, permanent scarring, and other disabilities. The possible psychological long-term effects are depression, anxiety, attention deficit hyperactivity disorder and other mental illnesses. Child maltreatment is a serious topic and the effects are as important as the child being abused and neglected. From the research I have found it is highly important to be aware of the short and long term effects. So for the future, people can know the effects. I’m doing this research for people to be able to look for the signs even in children while they're being abused to have the right plan and policies in action.

Abstract Name: **Refining the Scaling Relations in Galaxy Cluster Velocity Dispersion Bias Empirically**

The masses of galaxy clusters can be used to constrain cosmological parameters, as galaxy cluster formation and evolution depend on the abundance of dark matter and dark energy, which are represented in the cosmological parameters. Masses can be estimated as a function of richness, or the number of galaxies determined to contribute to a cluster's halo. Velocity bias bv, the ratio of galaxy and dark matter velocity dispersions, is introduced through each cluster's properties, conditioned on redshift, halo size, and stellar mass threshold. Recent research from four independent cosmological simulations indicates a "brighter is cooler" effect: more massive galaxies should have slightly smaller velocity dispersion than less massive ones. The current study attempts to validate and refine these scaling relations using data from recent large surveys. Effects due to cosmological redshift, galactic extinction, and impurities in the observed signal must be corrected. It is anticipated that newly obtained scaling relations will decrease the uncertainty in the method of estimating cluster mass as a function of richness. Methods for obtaining these scaling relations empirically will be developed and results will be presented.

Abstract Name: **A Model System of Anesthetic Binding Sites in the Blood Investigated by NMR Spectroscopy & Spectrofluorometry?**

In biochemistry, macromolecular binding sites are regions of specificity in interaction with othermolecules. The aim of our current research is to investigate anesthetic binding to bovine serum albumin(BSA). The preliminary thought process of our research extends upon the work of Duboiset al.(1992,1993) and Xuet al. (1996) in their 19F-NMR investigations. In adapting from previous literature studies, we have constructed an overarching goal of our model study and initiated anapplicable setup for our respective studies using the anesthetic, isoflurane, and the protein, BSA. We aimto create a model system for anesthetic binding in the blood investigated through Nuclear MagneticResonance Spectroscopy (NMR);spectrofluorometry(Johansson, 1997). T2(spin-spin relaxation) measurements in NMR and intrinsic protein fluorescence are the selected targetedmethods. The work will result in an outline for relevant biophysical and biochemical experiments whereNMR and fluorometry methods are emphasized.

Mitchell, Tiya

Tiya Mitchell,
Anna Harper

Abstract Name: The Impacts of the Social Environment on Psychological Distress among Whites and Racially Minoritized Students

A lot of work has been done to describe the stressors associated with the experience of people in minority racial and ethnic groups in the United States. There are specific experiences in the world that impact psychological distress more directly than a person's race or ethnicity, as a general identity marker. These impacts include: attachment experiences, stigma and negative attitudes toward mental health diagnosis and treatment, and experience or lack of experience with psychological help seeking. Participants responded to questions regarding their attachment relationships, their attitudes about and intentions toward mental health support seeking, their level of psychological distress, and their personal demographic information. Results show that race and ethnicity did not predict psychological distress, nor did it account for a significant proportion of the variance in psychological distress. However, attachment styles and other-focused mental health stigma were significantly correlated with psychological distress. The study highlights the importance of attachment relationships in producing a positive sense of self and others, which impacts our ability to navigate stressors.

Abstract Name: Parent-child weight-related conversations and body image development: Investigating the moderating effects of the parent-child relationship

The current research question explores how parent-child relationships can contribute to the effects of conversation about diet or weight on adolescent body image. Past research has shown the negative effects of mothers encouraging daughter's weight loss or dieting is buffered by mother's conversations about her own weight or diet. One possible explanation for this is that these bi-directional conversations are happening in a close, more cohesive relational context between mothers and daughters. This research uses a survey design to measure responses from participants on current relationship with parents (e.g., perceived mutuality, cohesion, parent-adolescent attachment), parent-child conversations about weight and diet, body image and disordered eating outcomes. Data in this study was collected from psychology students at the University of Wisconsin-Parkside, who responded to survey questionnaires via qualtrics. We predict that the stronger the parent-child relationship, the less negative impact conversations about body image and diet will have on adolescent body image and disordered eating. This research can help show the major effects of parent contributions to adolescent's perspective on diet and weight, in addition to highlighting key issues that could influence the impact of these types of conversation. With the growing amount of individuals experiencing low self-esteem due to poor body image and weight concerns, this research question is an important topic in today's society. Answering this research question will aid in understanding the effects of parent-child relationships on adolescent body image and disordered eating concerns.

Abstract Name: **The Development of a Three-Dimensional Fluorescence Imaging Microscope**

The quality and cost of three dimensional imaging of live tissue in real time can be reduced by utilizing three dimensional scanning technology. This technology has already been developed in other areas of biology for looking at the topographical surface of snake skins and geology for testing the accuracy of ground penetrating radar. Adapting three dimensional scanning technology to create an inexpensive method of imaging live tissue requires utilizing open source software already in use and different methods of microscopy. Multiple open source software have been used in other experiments, including MeshLab, gprMax and QuSTo. The designs utilized in other experiments are either expensive, such is the case in the Martinez et al. paper published in 2021, which was used to study snake skins. On the other hand, some researchers use handheld three dimensional scanners and a turn-table. This method is the cheapest method so far and can be adapted further, by utilizing multiple cameras fixed in place and rotating the sample platform. With the collection of images from multiple angles at the same time and the rotation of the platform, the scanning process would be faster. A faster scanning process would improve scanning for time sensitive cases that can be seen in biology, and allow for three dimensional models that change over time.Theability to create three dimensional models of an environment in real-time is a tool that has many uses including molecule tracking. In the future, the addition of magnification would improve this set up allowing for the tracking of smaller molecules or bacteria.This research is working towards creating a fluorescence microscope that can be used for constructingthree dimensional models.

Abstract Name: **Isolation of Jumbo Bacteriophages**

To date, there are relatively few known phages with genomes 200kbp or greater, which are classified as jumbo phages. This is likely due to their large physical size making them difficult to isolate using traditional methods as opposed to jumbo phages being rare. Their large size makes it difficult for jumbo phages to diffuse into typical top agar and allows jumbo phages to get caught in the filters used to remove bacteria from environmental samples. The goal of this project is to isolate jumbo phages from soil samples collected on campus. To overcome the barriers to isolating jumbo phages, several changes to the typical methods of isolation were tried. Larger pore filters and chloroform were used to remove bacteria from our samples without removing large phages. Low concentration top agar was also used during isolation and purification to better allow large phages to diffuse into the media, and we favored selection of pin-point plaques that could suggest physically large phages. Several phages have been isolated using these strategies and are being analyzed using transmission electron microscopy and gel electrophoresis techniques such as pulsed field gel electrophoresis. A selection of phages will also be sequenced to determine the length of their genome. At least one phage genome will be annotated using bioinformatics tools such as Glimmer, Genemark, BLAST, Phamerator, and HHPred.

Abstract Name: **Factors that Affect Perceptions of Gig-Workers**

According to Pew Research Center, 16% Americans have earned money on online gig platforms such as Uber or TaskRabbit at some point. However, research on how consumers select gig workers is still mostly underexplored. The purpose of this study is to investigate the potential impact of a gig worker's gender and self-presentation in their profile picture on consumer perceptions and choices. Specifically, we propose that smiling and quality of profile picture in terms of professionalism positively influence consumers' perceptions on the gig worker's competence, trustworthiness, and the likelihood of hiring them for a task. We also propose that these two factors will interact with gender, such that the positive effect of smiling is greater for female than for male workers, and the positive effect of professionalism is greater for male than for female workers. Lastly, we hypothesize that gender bias exists on gig platforms, such that male and female gig workers are more likely to be selected for tasks that are stereotypically aligned with their traditional gender roles. We conducted a 2 (gender: male vs. female) x 2 (smile: smiling vs. neutral) x 2 (professionalism: professional headshot vs. selfie) between-subjects experiment on Qualtrics to test our hypotheses. Eight fake worker profiles were created with different profile pictures to reflect the experimental manipulation. Undergraduate psychology students took an online survey where they were randomized to view one of the eight worker profiles. Additionally, we created one more worker profile that showed a smiling male in a professional headshot, which served as a comparison in each condition. We are currently in the process of data collection, which will be completed by December 2022. Data analyses will be completed by March 2023. Our findings will provide practical implications to gig workers regarding how to enhance their chance of being selected.

Abstract Name: **Creation of Anxa2 Deletion Mutants in Zebrafish Using CRISPR/Cas9 Gene Editing**

Annexin A2 is a calcium-dependent phospholipid-binding protein that facilitates angiogenesis via endothelial barrier maintenance and sprout formation. However, the functions of Annexin A2 are not well established in endothelial cells in vivo. The Annexin A2 gene in humans corresponds to a duplicated locus in zebrafish, called anxa2a and anxa2b. We are using CRISPR-Cas9 to make mutations of the Annexin A2 homologs in zebrafish to take advantage of the optical clarity of the early embryo to follow endothelial morphogenesis. Due to the possible overlapping functions of these homologs, we designed gRNAs that, when complexed with Cas9, targeted the 5' and 3' UTRs of both anxa2a and anxa2b. This was done to induce whole gene deletions instead of creating loss-of-function mutants through indel formation. These whole gene deletions would allow us to avoid genetic compensation induced by mutant transcripts. We also designed a tag-RFP construct flanked by short homology arms for integration into the deleted locus to visually track anxa2a and anxa2b expression during development. Here, we describe a whole gene deletion of anxa2a (14,172 base pairs) via CRISPR-Cas9 injection in fli1-egfp embryos. We have recovered a stable germline deletion in anxa2a. Our next steps are to induce a whole gene deletion in anxa2b for further functional analysis and create mutants homozygous for both deletions. This will allow for loss-of-function analysis of the Annexin A2 duplicated locus in zebrafish for a more complete phenotypic analysis and characterization of the genetic requirements of anxa2a and b during endothelial morphogenesis.

Maria Gini

Abstract Name: **Towards Cooperative Intelligence in Multi-Agent Systems using Deep Reinforcement Learning**

Much progress has been made in creating multi-agent AI systems in whichindividual agents cooperate to perform complex tasks, such as processing speech or performing real-time object recognition. This is possible through deep reinforcement learning, where agents learn how to behave through exploration and reward systems. Each agent's goal is to maximize reward, which occurs when probabilistic action is taken within the environment that aligns with the task specified. Action is determined through neural networks, algorithms that take inspiration from biological functions of the brain. My research asks, can a single neural network learn a short sequence of tasks and facilitate multi-agent cooperation? To test this, the ability of agents to work together without explicit instruction in a simulated environment to haul a heavy load from one place to another will be observed. The effectiveness of the neural network algorithm will be tested by measuring loss, or error, over time while varying environment size, starting location, and number of loads and agents. The experiments will be carried out with an existing two neural network algorithm baseline followed by a one neural network algorithm candidate which I create. I will analyze the performance of both approaches and compute if the algorithms can learn similar sequences of tasks and yield a comparable loss. For each experiment, the loss should change in real time as the agents try actions and either receive a reward or a penalty in response. I hypothesize that the learning of sequences of actions is possible, provided the architecture of the single neural network is sufficiently powerful. Exploring how agents learn and cooperate in simulation gives insight into how agents might behave when the scope of the problem and size of the environment are larger.

Abstract Name: **Community Engaged Partnerships With Southeast Asian Community Health Liaisons, Leaders, and Health Care Professionals: A Pilot Project on Opiate Awareness, Overdose and Psychoeducation**

Opiate addiction and overdose is a major public health concern that disproportionately affects minority communities, yet little is known about the impact in Southeast Asian communities.1) Pilot a sustainable program of opiate awareness, pharmaceutical awareness, and education in Southeast Asian (SEA) communities. 2) Assess community needs around opiate education, prevention, and medical care for opiate addiction, and 3) Engage professionals (stakeholders) on SE Asian community needs.A three-part model included: 1) A train-the-trainer psychoeducational program delivered by community health liaisons (CHLs), 2) Stakeholder engagement around SEA opiate prevention, overdose prevention/reversal, and care (medical, mental health, pharmacy, and Narcan distribution professionals) and 3) Guided conversations with community leaders. Training sessions were delivered virtually, whereas community sessions varied in their delivery methods (verbally in a community's native language). Three community health liaison training sessions involved a train-the-trainer psychoeducational model on the nature of opiates, drug effects, pharmacist-patient communication, stigma, and community comfort in discussing opiates. A pharmacy professor delivered five two-hour training sessions for the CHLs. We held stakeholder conversations with pharmacy students, physicians, addiction counselors, and clinic supervisors. Common barriers identified were funding and availability of translators, stigma, transportation, and community awareness of resources available. Significant needs exist in SEA communities. First, we observed a lack of knowledge and awareness around opiates across communities. Program materials delivered in a narrative format were useful (per leader feedback). Several leaders and community members expressed concern about the community proliferation of online purchases of drugs marketed as painkillers. Third, community members may lack awareness of risks around opiates and addictive potential. Cultural factors and stigma prevent community members from seeking information and treatment, and there is a need for Narcan education and linguistically and culturally competent providers.

Abstract Name: **Racial-Ethnic Identity and Academic Success B**

There is immense discussion on what helps orhinders academic success. A person knowing who they are, no matter who, tends to know what they want and how to get it. This is not different in the academic setting. There are many different levels of understanding who we are within the culture from which we come. This study aims to connect several components of identity development with the resulting success in college. The aim is to see how the level of connection with one's racial-ethnic group, awareness of the perceptions by others and how one's racial-ethnic group is seen through the lens of academic achievement will impact the overall success in college. Other areas of interest in this study include college experience and how it impacts the motivation to attend classes and involvement in on campus activities connecting the student to the college leading to academic success. The final area that will be considered in this research is the level of college preparedness of the student and how the family or culture contributed to that preparedness. Correlational analysis will be completed through data collection in the spring semester of 2023.

Abstract Name: **Implications of COVID-19 on College Counseling Services**

Many aspects of college life were impacted by the restrictions set in place due to the Covid pandemic, especially when it came to mental health. During this time, the demand for counseling services increased and many students were reporting that the pandemic had negatively impacted their mental health (APA, 2020; Castonguay et al., 2021). Prior to Covid, studies have found that some of the most common concerns students present tocounseling with include anxiety, depression, and relationship difficulties (Cairns et al., 2010; Barr et al., 2011). It is unclear how the pandemic may have impacted the prevalence of these concerns on college campuses. One focus of our study was to uncover whether the most common presenting concerns have changed from pre-covid compared to post-covid. Another adjustment that was made due to Covid was the transition to treatment through an online setting. While these changes have been beneficial in managing depression, anxiety, stress, and other concerns, there have been mixed results when it comes to effectiveness compared to in-person treatments (Bambling et al., 2021). A second focus of our study sought to identify how satisfied patients of college counseling services were with online treatment. To complete our study, we looked at archival deidentified program evaluation data collected from a large Midwestern University System's counseling outcome evaluation tool including responses from our local campus. Our findings note that both at our campus and throughout thesystem, the most prominentpresenting concern both pre-covid (2017-2018) and post-covid (2021-2022) was anxiety, followed by stress and depression. Additionally, a majority (57%) of those who received counseling post-covid chose a telehealth appointment compared to an in-person appointment. Additional analyses examining group differences in satisfaction with counseling services are currently being completed. Implications of the results for counseling services on college campuses will be discussed.

Abstract Name: **Titan Providence: Autonomous Drone System utilizing AI and GPS for Navigation**

Data and analysis of information have become a crucial aspect of society's current development, allowing accurate awareness of our environments, and benefitting maintenance, safety, and overall innovation. At the same time, the big data trend has grown in popularity, and the use of drones has also taken off to be considered valuable data collection devices. However, the control of the drone always lies with the pilot who uses visual tracking to determine its position and orientation. To overcome these issues, we propose an advanced technology that allows a drone to autonomously fly with little to no input from a human pilot. Differing from common Unmanned Aerial Vehicle (UAV) systems, Titan Providence implements AI vision with a GPS system, allowing for fully autonomous completion of a given "mission". Our objectives for this project include the construction and design of the drone framework, adaptive pathfinding, and awareness, in addition to task assignments.To achieve our goals, we integrated a Raspberry Pi with a compatible flight control module with additional telemetry and peripherals docked on a custom quadcopter chassis that allows modularity and expansions in accordance with a task's outline and requirements. By using these two systems in conjunction, we passively maintain the stability of the system through its inertial measurement unit (IMU) and individual multirotor electronic speed controllers (ESC), allowing further independence of the system's microcomputer. Regarding autonomy, the Raspberry Pi hosts the machine learning platform known as Tensorflow lite which would allow the drone to recognize obstacles and relay this information to the flight computer to avoid them. We also plan to utilize OSMNx which would allow the drone to create routes through urban environments where extra care and consideration for the law, powerlines, and private property is needed.

Abstract Name: **Utilizing Machine Learning algorithms trained on Recent Music-Listening Activity in Predicting Big Five Personality Traits: A Novel On-going Investigation**

Music has been important to everyday life since long before modern civilization and has been a subject of study for many years. It has been known to be a positive predictor of personality traits due to the individuality of personal preference. These personality metrics are typically evaluated using a Big 5 trait inventory that measures personality into 5 categories: Openness, Conscientiousness, Extraversion, Agreeableness, and Neuroticism. The study will attempt to assess the prediction quality of an individual's Big Five personality traits from a week worth of recent participant music listening activity from the Spotify Application Programming Interface using machine learning (ML). The created dataset will allow for correlating each of the 5 Ten Item Personality Inventory dimensions with music genres, artists, year, beats per minute, energy, danceability, loudness, length, acoustic, popularity, and other features in a vector. The dataset will be standardized and used to train on ML models such as Random Forest, Decision Tree, K-Nearest Neighbors, Logistic Regression, Support Vector Machine, etc. Prediction accuracy will be compared to previous works. Metrics include accuracy, FPR, TPR, and ROC/AUC scores. Both regression (continuous numeric value) and classification (Likert scale) will be used. A full literature review showed this is the first study to use both Spotify API data, rather than self-reported music preference, and ML classification, rather than traditional statistical tests and regression models, to predict the personality of a college student demographic. Applications of this study include custom advertisement recommendations and music therapy. Approval has been granted to administer the survey by Irvine Valley College's Institutional Review Board.

Abstract Name: **Expression of ADAR1 and RBFOX2 in a Pediatric Leukemia Cell Line**

In this study, we performed quantitative real-time polymerase chain reaction (qRT-PCR) to determine gene expression levels of adenosine deaminase acting on RNA 1 (ADAR1) and <a href="https://www.ncbi.nlm.nih.gov/gene/23543">RNA binding fox-1 homolog 2 (RBFOX2) in the pediatric acute myeloid leukemia (pAML) cell line Kasumi-1, derived from a 7-week-old male leukemia patient. Previous studies have shown that RNA and protein expression levels of ADAR1, an RNA editing enzyme, are increased in hematologic malignancies (Zipeto et al, Cell Stem Cell, 2016). RBFOX2 encodes an RNA binding protein that is thought to be a key regulator of pre-mRNA splicing, a process shown to be dysregulated in certain cancers (Brautigam et al, Oncogene, 2014; Crews et al, Cell Stem Cell, 2016; Bonnal et al, Nature Reviews Clinical Oncology, 2020). We are interested in determining the levels of ADAR1 and RBFOX2 gene expression in Kasumi-1 cells to establish a baseline level of expression and better understand pAML and the connection to RNA splicing. Limitations include that we conducted the qRT-PCR reaction one time and pipetting errors could have resulted in unreliable data.Our results show low levels of RBFOX2 mRNA compared to ADAR1 in Kasumi-1 cells, indicating decreased expression of RBFOX2 compared to ADAR1 at the RNA level (Figure 1). This data contributes to our understanding of pAML and allows us to assess the expression of ADAR1 and RBFOX2 in Kasumi-1 cells. Future studies should be designed to understand the mechanistic role of ADAR1 and RBFOX2 in pAML and determine expression levels of additional genes in Kasumi-1 cells.

Abstract Name: **Disparities Affecting the Knowledge of Female Pelvic Floor Disorders**

Pelvic floor dysfunctions (PFDs) are the most common problems faced by women post-partum, however, only a few have access to and awareness of physical therapy (PT). Due to its prevalence, PFD is now considered a public health issue, including urinary incontinence, fecal bowel incontinence, pain during intercourse, and pelvic organ prolapse. White women and women of color had no significant difference in experiencing PFDs, and yet women of color had statistically less knowledge of PFD conditions. African Americans and other women of color are also less likely than white women to recognize childbirth as a risk factor for urinary incontinence and pelvic organ prolapse. Research demonstrates that women with a higher level of education have greater proficiency of PFDs compared to those with a lower level of education. Socioeconomic factors play a major role in the knowledge of PFDs because a higher annual income can provide better access to education and medical care. The aim of this study is to assess women's knowledge of PFDs and raise awareness about the importance of pelvic PT and its benefits for women after childbirth in order to prevent PFDs. Given that there is a lack of research in this area, we aim to bridge the existing gaps regarding the roles that age, racial, and socioeconomic disparities play in the need for education about PFDs, as we believe that this knowledge will help lower PFD cases with the help of pelvic physical therapy. The subjects will be 30 females between the ages of 20 and 40, recruited from college campuses, community centers, and healthcare providers. Data will be collected via a survey consisting of open- and close-ended questions to ascertain women's knowledge and awareness of post-partum PFDs and available therapy options. The survey will be developed in consultation with two licensed pelvic physical therapists.

Abstract Name: **Investigation into Brain Chemistry and the Chemical Hardness of Neurotransmitters and Antidepressants**

Antidepressants are prescribed to countless individuals worldwide to treat depression. It is crucial to understand brain chemistry and how various parts of the brain interact with different antidepressants. In the present study, using the Blugold Supercomputing Cluster, quantum chemical calculations have been performed to determine the chemical hardness of common antidepressants; chemical hardness is an important chemical property that provides information about molecular reactivity and selectivity. The present study provides an insight into the receptors within the human brain that interact with antidepressants following the Hard-Soft Acid-Base theory.1,2 The preliminary results of this computational study are presented here. The successful completion of this project could help develop new drug molecules with more specificity towards the target receptor and will have a more direct and immediate effect on patients dealing with prolonged depression.

Abstract Name: **UWEC Campus Environmental Monitoring of PM 2.5 using Purple Air Monitors during residence hall demolition**

During September and October 2022, construction crews conducted demolition projects on two residence halls (Putnam Hall and Katherine Thomas Hall) on the University of Wisconsin- Eau Claire campus.Elevated PM 2.5 levels on campus could present a risk of throat and lung irritation, decreased respiratory function, and long-term health impacts to students, faculty and the workers on this project. Two EPA- and Wisconsin Department of Natural Resources-testedPurple Air monitors provided real-time monitoring of PM 2.5 levels in two locations on campus within 50 meters of the worksites. Hourly PM 2.5 measurements from each Purple Air monitor were corrected using the EPA correction factors and graphed alongside PM 2.5 measurements recorded by the WDNR, which served as a control. Periods when demolition activity occurred were established and detailed in data. Environmental monitoring was conducted to determine if the demolition activity was a source of increased PM 2.5 pollution as a health risk to the general campus population of students, staff, and faculty. The hourly and average PM2.5 levels measured on the UWEC campus were typically higher than the WDNR monitor between September 5th and October 5th, 2022. However, increases during or immediately following demolition activities were not apparent.

Abstract Name: An Autoethnography Exploring the Relation Between Fashion, Self-exploration, and Perceived Power in Milan

Dating back to the Renaissance, fashion has been an expressive means to share identity as well as showcase status and power (Currie, 2017). Starting off as a male-dominated practice, it quickly became a channel for women to voice their opinions and beliefs. Despite its stereotype of being used only for shallow, appearance-based purposes, society heavily relies on fashion for a variety of significant reasons. For example, governments trying to control certain populations and those populations protesting back. The current hijab protest in Iran which started October of 2022 is a perfect example. Fashion is also a way to improve one's mood or to project a specific message. The research at hand organizes data into an autoethnographic format, which provides reflective data analysis based on personal observations taken during time spent abroad in Milan, Italy, fashion capital of the world. Autoethnography is a qualitative research method used to "systematically analyze" a researcher's experiences when interacting with a specific community, often from a different lifestyle, in order to understand the culture (Adams, Bochner, Ellis, 2011). Using photographs, audio recordings of interviews and personal reflections, as well as written observations of Milanese everyday fashion and culture, the importance of cultural background, childhood experiences, and identity-based beliefs were found to be some of the most defining features when creating and adhering to specific fashion styles and tastes. Fashion is much more than the surface level act of clothing the body or conforming to the latest trends. It is a story through which people express themselves to the world. It is an embodiment of our attitudes, values, and experiences. This autoethnography adds to the growth of an emerging conversation about changing the narrative through which fashion is seen and used in relation to self-exploration and perceived power.

Abstract Name: Comparisons of Open-Source Automatic Speech Recognition Programs on Heterogeneous English Speakers

The growing mainstream appeal of virtual assistants, such as Amazon's Alexa and Apple's Siri, leaves users with heavy non-native English accents and even regional American English accents and dialects, such as unable African-American Vernacular English, to successfully use virtual assistants without the intentional modification of their speech or pronunciation. Our research study compares current open-source Automatic Speech Recognition (ASR) packages in their default state "factory" pre-trained model settings from Mozilla's DeepSpeech, Nvidia's NEMO, and Meta's (formerly Facebook) Flashlight ASR based on Wave2Letter++ on their ability to transcribe accented English from various non-native English speakers.We choose four non-native English speakers of Cantonese, Vietnamese, Arabic, Portuguese, and our control group of native American English speakers. Two noise audio tracks (city park, and subway station) are overlaid on clean speech files at -20db to simulate real-world conditions and then sent to a denoiser. These files are fed into the ASRs and text outputs are compiled into a python script used to find the Word Error Rate (WER). Our results show that ASRs do have issues transcribing non-native English accents versus English. Even native regional non-standard English accents produce an increase in WER compared to their counterparts. This study aims to raise awareness and highlight these inequalities for minorities whose inclusion is left as an afterthought. Companies that design these ASRs need to be mindful of the growing number of users who speak in various dialects, accents, and languages and ensure that their technology is inclusive to all people.

Moland, Katryna

Katryna Moland *Emma Tennant* *Emilie DiGiacomo-Hippenstiel*

Abstract Name: **Burnout, Compassion Fatigue, and Compassion Satisfaction in the Social Work Field Practicum**

Field social work students are often in contact with traumatized clients who go through a variety of negative life experiences such as abuse, disaster, drug dependency, crime, and illness. These students are experiencing vicarious exposure to such negative life events, and therefore, may develop compassion fatigue and burnout. Whereas both compassion fatigue and burnout report negative consequences of working with traumatized clients, compassion satisfaction adversely contributes to the positive well-being of the workers themselves. Compassion satisfaction stems from the satisfaction that is gained from helping others, and this feeling may serve to limit the effects of both burnout and compassion fatigue.This research serves the following purposes: addressing the existence and implications of burnout and compassion fatigue among social work students in field practicum; assisting in determining the need for additional attention in burnout- and compassion-fatigue-prevention for future field practicum students; determining the prevalence of compassion satisfaction among students; and drawing on the benefits of compassion satisfaction to provide strategies to better social work education.The research uses a classic experimental design: pretest/posttest, control/experimental group design. Social Work students who are in field practicum of the Spring 2023 semester are the experimental group, while students who are in Preparation for Practicum class, will be the control group. Both groups took a 30 item self-report questionnaire called the Professional Quality of Life Scale (ProQOL). This scale is equipped with subscales for burnout, compassion fatigue, and compassion satisfaction, thus measuring both the positive and negative effects in working with vulnerable and traumatized clients. As this is an experimental design, both groups took the questionnaire twice – once in the Fall and once in the Spring. This questionnaire assesses the three variables to see if they have fluctuated with more prolonged experience to working with clients, in terms of the experimental group.

Abstract Name: **An Exploration into the Relationship of Disabilities and the Risk of Sexual Assault Victimization Among Female College Students**

Sexual assault on college campuses is a well-documented, yet still pervasive issue among U.S. colleges and universities. Female college students are three times more likely to experience sexual assault compared to all women. To combat sexual assault victimization, previous studies have identified certain risk factors that increase the odds of college-campus sexual assault. This study explored the relationship of female college students with disabilities and the risk of experiencing sexual assault. Specifically, the study examined the possible influence and increased odds of risk factors identified in previous studies. The research questions guiding this study include: 1) Do female students with disabilities have a greater risk of experiencing sexual assault victimization than those without disabilities? 2) Do previously identified risk factors increase the odds of sexual assault for students with disabilities? 3) Does a specific disability impact the odds of sexual assault victimization?This quantitative study utilizes a survey research design. The national data derived from the American College Health Association's National College Health Assessment III (ACHA-NCHA III). This survey collects data on student health habits, behaviors, and perceptions and highlights the salience of emotional well-being. The sample includes female respondents (n=100,000+) attending public and private four-year institutions in Fall 2020, Spring 2021, Fall 2021, and Spring 2022.Data were analyzed using descriptive and inferential statistics (e.g., frequencies, independent samples t-tests, and logistic regression).Preliminary results indicate female students with disabilities have higher frequency of being sexually assaulted than those without disabilities.The logistic regression analysis results found disability status produced greater increased odds for sexual assault than other commonly cited risk factors. The results could inform university leaders, student support services, and student affairs professionals about disability factors as potential risk factors for sexual assault victimization.

Abstract Name: **3D printed flexible piezoelectric sensor array with BTO-PDMS**

Recent research and advancements in the Direct Ink Write 3D printing technique have enabled the possibility to incorporate multi-material 3D printing of different materials with freedom of design to complete functional and integrated sensors in one-step fabrication methods. This work implemented multi-material DIW printing method to manufacture a lead free flexible piezo electric sensor array for pressure mapping and characterized the printed sensor array for different applications. Barium titanate (BTO) was selected as the piezoelectric component and was mixed with 50wt% ratio to PDMS to form the elastic composite with great piezoelectric properties. For better polarization and output voltage collection, 11wt% multi-walled carbon nano tubes (MWCNTs) with PDMS electrodes were also 3D printed as part of the multi-material printing. SEM of the cross section of the printed parts were checked to evaluate the proper dispersion of the filler into the PDMS matrix and to confirm the interlayer bonding between the BTO-PDMS and MWCNTs-PDMS layers. A graphical user interface (GUI) was designed to showcase the pressure mapping ability of the sensor array and it was validated using irregular loads on multiple nodes of a 4x4 3D printed array sensor. To further evaluate the sensor array, constant cyclic loads of 30N, 60N, 90N and 130N were applied on a single node and the sensor generated responses are highly repeatable for each of the loads and do not drift with repeated cycles. It was also identified that, with the increase of force, the output peak-to-peak voltage also increased linearly and the variation of output voltages at each cyclic loads are negligible compared to the output voltages. Since the BTO-PDMS sensor can turn mechanical deformations into electrical energy, it can have several applications such as wearable sensors for health monitoring, energy harvesting, powering electronics, manufacturing of soft robotics devices with properly integrated materials, etc.

Monatukwa, Yuliet

Yuliet Monatukwa,
Vlastimil Vyskočil

Abstract Name: **Silver Solid Amalgam Electrode Electrochemical Detection of Nitroxoline**

Nitroxoline is a nitroquinoline derivative that has clinical applications in the treatments of cancers and cardiovascular diseases, but there are limitations to the ability to monitor its metabolization within the body after the initial dose and to detect nitroxoline within the environment at large. The bioreductive properties that these treatments capitalize on also make nitroxoline an ideal analyte for voltammetric detection methods. Voltammetric methods have the advantages of being less expensive and time intensive than other spectroscopic methods while still maintaining sensitivity. To determine the limits of detection (LODs) and quantitation (LOQs) of nitroxoline in various water samples, direct current voltammetry (DCV) and differential pulse voltammetry (DPV) methods were optimized using a mercury meniscus modified silver solid amalgam electrode (m-AgSAE) and nitroxoline standard. The optimal pH of the solutions was determined with and without electrode regeneration for both DCV and DPV to be pH 5.0. Calibration curves were then created for deionized water, drinking water, and river water. For deionized water, use of DCV obtained LOQ values four times lower (0.18 μM) than DPV (0.85 μM); however for river water, the LOQ values were similar for both DCV (0.34 μM) and DPV (0.37 μM). The results suggest that both techniques provide comparable detections, but that DPV has a higher upper limit of linearity (60 μM) than DCV (10 μM) in river water.

Abstract Name: **The Most Influential Women to Combine the Women's Suffrage and the Birth Control and Abortion Movements**

The most influential women that combine the women's suffrage movement and the birth control and abortion movements in America are not agreed upon among historians. Due to there being a lack of agreement among historians there is no specific literature labeling any of the women that participated in both movements as the most influential. This paper addresses the two most instrumental women to combine the women's suffrage and birth control and abortion movements, Emma Goldman, and Margaret Sanger. Through the study of historians Simone Caron, Linda Gordon, James C. Mohr, and Leslie Reagan's studies of abortion and birth control laws and policies in the United States between 1880 and 1940 this paper shows how the birth control and abortion movements began and proceeded. Next through the actions of Emma Goldman and Margaret Sanger, as explained by Candace Falk and David M. Kennedy, as well as their own writings, between 1880 and 1940 in both the women's suffrage and the birth control and abortion movements, this paper will show why these two women are the most influential women to combine these social movements in the United States. This paper argues that Emma Goldman and Margaret Sanger were the most influential women in the United States regarding the combination of the women's suffrage movement and the birth control and abortion movements. In conclusion this paper through its study of the history of abortion and birth control policy and the actions of Emma Goldman and Margaret Sanger, labels these two women as the most influential women in connecting the women's suffrage and the birth control and abortion movements.

Abstract Name: **The Mythology of Baseball: How the New York Yankees Used the American Dream to Achieve Cultural Ubiquity**

Professional baseball relies on the ethos of America to retain the social significance granted to the sport in the early twentieth century. Deemed America's National Pastime, baseball continues to evoke feelings of tradition and leisure, where friendly competition opens the door for America's values (simultaneous sportsmanship and self-actualization) to shine. The New York Yankees, one of the sport's most historically successful organizations, provide a prime lens through which to view baseball's relationship with Americana. While various works of scholarship analyze the different factors connecting the American Dream to baseball, or use the Yankees as a path to understanding, for example, economic trends in sports, this research project aims to synthesize those sources and external phenomena to answer the question: How do the New York Yankees utilize the American Dream to maintain cultural ubiquity? The team, through both reputable and infamous popularity, has become a symbol of success and tradition within and exceeding the world of sport. In our research, several features of Yankee history were examined with a focus on iconography and mythology creation. First, timing, or the importance of when the Yankees were created, moved to the Bronx, and dominated on-field competition. Second, location, or the impact of holding residency in New York City, and specifically the South Bronx, on the cultural significance of the Yankees. Finally, personnel, or the Yankees' constant production of transcendent players who, in themselves, represent the ideals of the American Dream. When these features are brought together, along with the aforementioned studies of both baseball's connection to American ideals and the business of the New York Yankees, it becomes clear that the team's past is synonymous with the narratives of America. The Yankees, therefore, maintain their cultural ubiquity by being a thematic extension of America's valued concepts of meritocracy, opportunity, and tradition.

Abstract Name: Transsexual Sex Ed: Understanding Body, Identity, and the Self

There is a large stigma surrounding comprehensive sexual education, even worse so for one that actively engages with and includes the queer community. The lack of sexual education causes a lack of understanding in all persons regarding not just sex and intimacy, but consent, reproductive health, mental health, self-esteem, and body positivity. While there is more accessible sexual education for lesbian, gay, and bisexual individuals, there is a large disregard for the sexual well-being of transgender individuals. This project intends to investigatethe sexual habits of transmasculine individuals and the ways transgender people navigate sexual relationships and intimacy in order to fill the void of transgender sexual health but to also create a zine at the completion of the project with the findings and advice gained from research interviews. Themes within the project include deconstructing medicalized language, de-pathologizing trans people's sexualities with the sharing of sexual education and stories, and helping improve not just the sexual knowledge, but the intersections of it with intimacy and self-esteem for trans people and people who engage intimately with trans people. The primary method of data collection is to compare and contrast established knowledge (books, articles, journals) on transgender sexual education with research interviews conducted with transgender individuals and partners. Participants sought out will be transmasculine individuals and their partners, all over the age of 18. These research interviews will seek to gather first-hand experiences from a diverse group of transgender and cisgender individuals into the unspoken aspects of sexual intimacy, including navigating intimacy with endocrinologically changed bodies, negotiating sex with dysphoria, and more. These research interviews intend to both affirm and add to established texts on sex, intimacy, identity, sexuality, and bodies.

Abstract Name: Negative Affect Across the Menstrual Cycle in Individuals with ADHD

Attention-deficit/hyperactivity disorder (ADHD) is a neurodevelopmental disorder that exhibits striking gender differences in symptoms, comorbidity, and associated problems. Females with ADHD become particularly impaired across adolescence and around puberty, experiencing increased rates of depression, anxiety, conduct problems, and suicide attempts. Adolescence may be particularly risky due to the dramatic rises in reproductive hormones and onset of menstrual cycle characterized by cyclical hormonal changes. The goal of the current study was to examine hormonal effects on affective symptoms across throughout the menstrual cycle in individuals overrecruited for ADHD. We have hypothesized that mood symptoms such as depressed mood, anger, anxiety, and feeling overwhelmed would increase at the end of the menstrual cycle as estrogen levels decrease. Participants were 43 individuals aged 18 to 25 who menstruate and were not taking any hormone-based medications. Participants completed the Daily Record of Severity of Problems (DSRP), a 23-item measure used to assess affective symptoms, at four time points across their menstrual cycle (mid-follicular, post-ovulatory, mid-luteal, perimenstrual). Within-person averages and deviations from average at each time point were calculated then averaged across participants by phase.Linear mixed-effects models were used to determine significant changes in symptoms across the menstrual cycle. Results indicated significant decreases in anger (p=.018) during the mid-follicular phase and anxiety seemed to increase near the end of the cycle but did not reach significance (p=.078). Significant changes in depression and feeling overwhelmed were not apparent. Altogether, individuals with ADHD appear to experience some significant changes in mood symptoms across the menstrual cycle that may impact comorbidity and impairment. These findings contribute to understanding of sex differences in ADHD and reveal possible mechanisms for the increased impairment seen during adolescence in females

Abstract Name: **Kendo_Fighter_Trainer**

The first computer controller machine for Kendo self-training was invented in 2005 by Prof Young-Bong. Bang from the Manufacturing and Mechatronics Lab of Seoul National University in South Korea. The Japanese kendo fighting robot, known as MUSA, weighed 150 pounds, and was 65 inches tall with a central processing unit that employs several sensors and digital cameras for tracking opponent's motion and assist in counterstrikes. Despite the accuracy and strength of counterattack maneuvers, the response time of the Kendo fighting companion was relatively slow mostly because of the insufficient speed of its processing unit, and the limited mobility of its motion transmission mechanisms. Several design upgrades were made to improve its mobility at a marketable price. Unfortunately, to our knowledge, an affordable self-training Kendo fighting companion is yet to be developed and manufactured, which bring us to the subject of our current investigation. In our ongoing project, we reinvented the original kendo companion blueprint and designed a lightweight self-training arm that is capable of reproducing Kendo attack and defense maneuvers. For improved mobility, the kendo-Arm is driven by a set of spherical and monopolar gears housed in a ball and socket joint. The spherical motor concept was first developed in 2021 by researchers Kazuki Abe, Kenjiro Tadakuma and Riichiro Tadakuma from the Yamagata University, Yamagata Japan and Tohoku University, Miyagi Japan. An improved version of this concept will use a Raspberry Pi single board computer to repeatedly processes several digital camera images of a color labeled arm from the computer. Then it will transmit motion coordinates to an imbedded driving mechanism that employs DC geared motors and Arduino controllers. The driving mechanism carefully adjusts the rotation and precession of the monopolar gears for precise and reliable counter strikes.

Abstract Name: **Designing and Synthesizing a Warhead-Fragment Inhibitory Ligand for Ivyp1 through Fragment-Based Drug Discovery**

Fragment-based drug discovery (FBDD) is a powerful tool for developing anticancer and antimicrobial agents. Within this, magnetic resonance spectroscopy (NMR) provides a comprehensive qualitative and quantitative approach to screening and validating weak and robust binders with targeted proteins, making NMR among the most attractive strategies in FBDD. Inhibitor of vertebrate lysozyme (Ivyp1) of Pseudomonasaeruginosa serves as an excellent target because of its potential druggability and bacterial implications in clinical prognosis for cystic fibrosis and immunocompromised patients. This study uses current NMR and biophysical techniques to develop a covalent, fragment-linked warhead inhibitor for Ivyp1 through synthetic methods, warhead linking, and intentional fragment growth. The protein of interest was expressed using commonly recognized biochemical and chromatographic techniques, with supplemental procedures for isotopic labeling as required in multinuclear NMR experiments. This work has chemically elaborated a prior fragment hit with yield and purity suitable for subsequent studies. Coupling this product with promising warheads is ongoing and preliminary results of this process will be presented. While this work is grounded within biophysical and synthetic chemistry, this project will include several visual elements that integrate graphical and scientific ideas for a broader audience. One primary component will involve visualization of fragment binding using structural and graphical software and three-dimensional ray-traced rendering to suggest modes of interactions. Subsequent efforts will determine the structure-activity relationships between the warhead-fragment complex and Ivyp1, compared with standalone compounds, to indicate how calculated ligand growth increases potency.

Abstract Name: **Fashion, Resistance, and Black Liberation: 1970s and Today**

Dress showcases cultural, social, and political attitudes. Historically, and today, dress has been used to articulate liberation, representation, and resistance. Black Americans have continued to fight for equity within White society through personal fashions, styles, and aesthetics. In the 1970s, members of the Black Panther Party and other activists developed and wore different styles representing Black liberation. These activists contributed to soul style development by wearing berets, pins, patches, leather and dark colors. Today, Black Americans who are part of The Black Lives Matter movement are also engaging in style narratives of resistance, such as shirts with powerful statements. The Black Lives Matter movement is about conquering economic, racial, and social injustice in society. Our exhibition showcases the evolution of fashion by incorporating the most powerful fashion pieces capturing the transformation of style over decades of black generations. This presentation is illustrating the exhibit and research held at the Textiles and Clothing Museum at Iowa State University on April 28th, 2022. We usedvarious primary and secondary sources, as well as textiles and clothing from Iowa State University's Textile and Clothing Museum. For secondary sources, we researched "When they call you a terrorist: A Black Lives Matter Memoir" by Patrisse Khan-Cullors, "Liberated Threads" by Tanisha C. Ford, and several other sources to help articulate the goals of fashion resistance. The exhibition is important in highlighting the shift of Black fashion from the 1970's and today by incorporating apparel and accessories that capture the ways in which Black people use fashion in liberation and resistance movements across time.

Abstract Name: **Use of Nanobodies to Measure PSD-95 Synaptic Nanoclusters in Dendritic Spines**

Precise localization of proteins within micrometer sized compartments like synapses is vital for normal brain function and plasticity. Super-resolution imaging has begun to reveal exquisite organization of proteins in pre- and post-synaptic compartments with unprecedented resolution. However, the use of primary and secondary antibodies in immunostaining procedures to visualize endogenous proteins has placed an upper limit on the resolution that is possible with super-resolution imaging. Additionally, protein-rich post-synaptic densities (PSDs) have been especially hard to label using conventional antibodies. Here we use tau-Stimulated Emission Depletion (STED) super-resolution imaging and photon counting to compare the efficiency of synapses between conventional antibodies and single-domain fluorescently conjugated camelid nanobodies that are 10x smaller than antibodies. Focusing on the most abundant protein of PSDs – PSD-95, we demonstrate that nanobodies significantly improve resolution compared to conventional primary-secondary antibody protocols. Furthermore, nanobodies show improved efficiency of labeling of post-synaptic specializations as determined by colocalization with pre- synaptic protein Bassoon. These findings demonstrate that nanobodies reveal more detail about nano-scale organization of subdifraction synaptic compartments providing opportunities to discover critical gaps in knowledge about synaptic function and dysfunction. In the future, we aim to use this methodology to study homeostatic plasticity of dendritic spines and their corresponding synapses in response to amyloid-beta produced during Alzheimer's disease.

Abstract Name: **Efficacy of Social and Physical Support for Cancer Patients**

Cancer is the second leading cause of death in the United States. In addition, cancer treatments provoke harsh side effects that demand extra strength from the patient. Cancer causes lifestyle modifications that can be detrimental on the patients' health; however, healthy habits can potentially increase the chances of a positive prognosis. Additionally, physical, and social support has proven to help patients in their fight against cancer. Since the lack of physical and social activity in patients with cancer has been shown to correlate with mental and cognitive decline, ultimately reducing quality of life, the purpose of this study is to examine the relationship between physical activity and quality of life in patients with cancer And increase their overall quality of life.This project included eight female participants that are currently struggling with cancer, or the cancer is in remission. The program consisted of group discussions, fine motor movements, and various physical activities twice a week for three weeks. Using pre/post intervention questionnaires and a dependent t-test, the significance of social and physical activities amongst the participants were analyzed. The dependent t-test showed a significant difference (t=-3.729, p=0.007) in the overall quality of life between pre and post program. These preliminary results imply that implementing a support group such as Healthy Habits that includes the use of physical and social activity, improves the overall quality of life of patients with cancer. In conclusion, the program created an additional outlet for individuals with cancer to find a relatable support group that can aid with daily struggles. Further analyses in a larger sample and with longer duration will provide stronger evidence about the relationship between physical activity and quality of life in patients with cancer.

Abstract Name: **Obtaining a complete set of reference DNA sequences for North American bladderworts (Utricularia)**

Carnivorous aquatic plants in the genus Utricularia, known as bladderworts, are fascinating for having complex snap-traps, for lacking roots, and for having branched shoots that function like underwater leaves. There are 19 bladderwort species in North America, including nine that are native to Wisconsin. Bladderwort diversity has been studied in a phylogenetic context before, but curiously the existing data are incomplete for North American species. Specifically, there are gene regions for which not every species has been sequenced, and the missing data make it impossible to identify any one plant using DNA sequence comparisons, or truly to construct an effective phylogeny for the genus.We plan on using the findings of this study to enable new methods for identifying unknown species. Further studies can be conducted once a full catalog of DNA sequences for nuclear and chloroplast DNA is acquired because currently there are species that are missing DNA sequence data for one or more of the gene regions that are commonly used for Utricularia. There are several species in this genus that have not been sequenced for one or more gene regions, and this makes it impossible to identify the plants confidently using DNA sequence data.We used genes from the nucleus (internal transcribed spacer, or ITS) and the chloroplast (rps16 gene, matK gene, rpl20-rps12 intergenic spacer, trnL-F intergenic spacer) to fill in missing data and construct updated phylogenetic trees for Utricularia. These regions were chosen because they have already been sequenced for a large number of Utricularia species, as part of a phylogenetic study of the genus. For the first time ever, we confirmed close relationships between species pairs (e.g., U. inflata and U. radiata) that could not be compared effectively before.

Abstract Name: **The Grandparent Study**

According to the results from a study done by “Zero To Three,” the grandparents of one in four children under the age of five are the main caregivers (2017). Therefore, it is important to understand the experiences that grandparents have in locations that they frequent with their grandchildren. This study seeks to improve the understanding of the motivations and the possible challenges faced by grandparents when visiting informal learning spaces with their grandchildren.Data were collected at two suburban museums serving young children and their families. All participants were grandparents recruited during their visit to the museums. The survey utilized 12 statements to assess the motivators and 13 statements to assess possible challenges faced by the participants. A 5-point rating scale was used to respond to the statements. In addition, a comment section was included for additional motivators and challenges. The survey concluded with a section addressing the participant's basic demographic information.163 total surveys were collected including grandmothers (N=119) and grandfathers (N=39). The survey found that the top three motivators were: quality time, family time, and learning about children’s interests. The top three challenges faced by grandparents were: physical demands, not being comfortable taking my grandchildren by myself, and other places available. Our results found that grandfathers, in comparison to grandmothers, report a decreased level of enjoyment in museums (p=.007) and an increased concern about the cost of museums (p=.005).Grandparents often have a strong influence in the lives of their grandchildren. It is important to further understand the motivations and challenges faced by grandparents. By better understanding, the motivation and challenges institutions can adapt current systems and offer improved and effective programming.

Abstract Name: **Assessment of Damage and Recovery of Infrastructure in Puerto Rico after Recent Hurricanes**

Puerto Rico is a tropical island, and due to its location, many hurricanes occur. This research consists of analyzing the resilience of the electrical infrastructure in Puerto Rico before extreme weather events such as floods, tropical storms, and hurricanes. In 2017 Puerto Rico suffered from Hurricane Maria (category 5), leaving the island without electricity for more than a year. Then in 2022, Hurricane Fiona (category 1) impacted the south of Puerto Rico, leaving the island without electricity for more than 2 weeks. The investigation was carried out based on obtaining information from various sources, such as an interview with the community that was affected, a 3D lidar scanning of the affected electrical infrastructures, photographs, documents made by the LUMA electricity company, and observations. The combination of 3D lidar scanning with drone footage of the affected area gave an idea of the damages in the distribution systems and the surrounding terrains. After obtaining the results of our investigation, the recommendations that can be offered so that the electrical infrastructure of Puerto Rico requires a major upgrade and the design standards for the distribution systems need to be more stringent and consistent to be able to stop outages from happening for a long period of time.

Abstract Name: **Justifying Juvenile Justice: Good-Faith Decision-Making to Protect Children?s Futures**

While the juvenile punishment system in the United States purports to punish on the basis of rehabilitation, this goal is often not reached. Aside from the general problems that rehabilitative models of punishment pose in determining when a person has been adequately rehabilitated, many juveniles are often isolated and not provided with the resources to appropriately address the problems that may have led to committing a crime and are not provided with a sufficient path for reintegration to the community. The most egregious example of which occurs in the sentencing and parole decisions for individuals that have been sentenced to life in prison with the possibility of parole for crimes committed as juveniles.In order to respond to juvenile crime effectively, we need to look to the child's right to an open future as set out by philosopher Joel Feinberg and adopt a narrative-integrity approach to decision-making that embraces elements of restorative justice. The child's right to an open future is a right possessed by children to have their future rights and interests protected until they are able to assume them, and it is the duty of the adults in the child's life to safeguard them (Feinberg 2007). In this research, I argue that responding to crime using this as a guide for decision-making and approaching our judgment with an interpretive lens that makes repentance a collaborative endeavor is a better model for protecting children's futures than rehabilitation.

Abstract Name: **Sustainability of Resources for College Food Pantries**

Over 40% of college students are food insecure. Students in need are 43% more likely to fall behind in classwork and drop out of college. Students with food insecurity are also more likely to develop severe mental health conditions like depression, anxiety, low self-esteem, and loneliness. This study seeks to explain what factors contribute to sustainability of resources in university food pantries. The purpose of sustainability research is to find new and efficient ways to meet the needs of students who are food insecure in college. The student researchers explore the issue of sustainability of resources within college settings and how it impacts the resources obtained by grants and donors. The student researchers developed the following question: What are the factors involved in the sustainability of resources within college food pantries? The student researchers used 16 scholarly journal articles to inform their research on the factors that contribute to the long-term sustainability of food pantries in institutions of higher learning. Researchers using purposive and snowball sampling to identify a minimum of 100 participants with the help of the public directories to complete the questionnaire.The student researchers identified three common concepts within articles: factors of sustainability of food pantries, barriers and obstacles to successful food pantry use, and pantry development. The information gathered from the articles assisted the student researchers in question development for their survey.This research aims to identify the factors in sustaining a college food pantry through increased use. This information is important in attaining the researchers' overall goal of aiding the Tarleton Purple Pantry in developing a plan to sustain resources through Tarleton State College's rapid growth in enrollment.

Abstract Name: Synthesis and Characterization of Polar Magnetic Materials

Materials with a polar crystal structure that show magnetic properties have applications in laser technology, access memory elements, energy conversion, and spintronics. However, it is challenging to design such materials. In this project, a series of novel polar materials were designed by introducing the disorder of transition metal ions into nonpolar parent compounds. Phase-pure samples were prepared using the high-temperature solid-state method. The polar crystal structure was determined by powder X-ray and neutron diffraction, and transmission electron microscopy. The chemical composition of the prepared compounds was confirmed by scanning electron microscopy and energy-dispersive X-ray spectroscopy. The magnetic properties, resistivity, magnetoresistivity, and Hall effect of prepared compounds will also be presented.

Abstract Name: Course-Based Undergraduate Research and Community Science with The Village Community Gardens

Inclusion of undergraduates in authentic research is an effective tool to bridge the gap between theoretical and practical aspects of biology and increase competency and interest in research careers. In an effort to increase student access and engagement to research we developed a course-based undergraduate research experience (CURE). In addition, we aim to develop a project that would foster a mutually beneficial collaboration with The Village Community Garden, a local nonprofit aimed at food sovereignty and the provision of land and resources for culturally relevant food growth. Here, we aim to foster a collaboration between our community partner, students, and faculty that would promote outreach, engagement, learning, and scholarship. Students will 1) compare microbial numbers in soils of Rochester MN community gardens, 2) investigate microbial antibiotic resistance contamination within the community gardens, and 3) investigate soil microbial species with and without soil inoculant. Laboratory techniques employed to determine soil microbial counts are foundational procedures that students will benefit from performing. Furthermore, microbial soil populations are influenced by numerous biotic and abiotic features; growers are interested in learning these results. We aim to contribute to the national surveillance of antibiotic resistance of soil-dwelling bacteria to tetracycline. In addition, the students will investigate soil microbial species for resistance to three other antimicrobial agents employed in agriculture. The gardens are subject to community-grower fertilizer applications and the planting of inoculated legumes may mitigate the surplus nitrogen. We aim to identify soil microbial species with and without soil inoculant using molecular techniques. This CURE will be implemented during the summer of 2023 within the microbiology course at the University of Minnesota Rochester. Here, we are presenting our pedagogical approach and preliminary results.

Abstract Name: **The Link Between Obesity and Post-Menopausal Breast Cancer**

Cancer is a leading cause of death and previous research has shown that obesity can increase the risk of cancer andcancer-related mortality. For breast cancer, studies have shown that obesity increases risk after menopause. The overall goal of the Giles lab is to better understand the link between breast cancer and obesity in different stages of life, and to determine how different lifestyle modifications (diet, exercise, etc) and medications could decrease risk.There are several methods used to understand these relationships, such as small animal models with breast cancer and various hormonal levels, nutrient tracers, and in vitro studies where cancer cells and adipose cells can be isolated and manipulated.Healthy lifestyles that emphasized physical activity, weight control, and anti-inflammatory practices have been shown to decrease cancer risk and we expect our results to reflect this information. One of the ongoing projects in the lab is aimed at understanding the mechanisms by which decreasing obesity-assocated inflammation with ibuprofen decreases cancer risk. Similarly, the lab is investigating how exercise may also decrease breast cancer risk and slow tumor progression. It is anticipated that a healthy lifestyle can be one of the most effective ways to decrease the risk of breast cancer. Medications such as ibuprofen may not be as effective because they react differently in each individuals' body.These results will increase our understating of how lifestyle changes can be significant; however, it is known that maintaining a healthy lifestyle is not always feasible for all individuals. We hope that results of the current study will help identify how diet and exercise decrease breast cancer risk. This knowledge will help us identify alternative methods that may be more feasible to attain in a shorter period of time, such as medications and treatments that can regulate hormones, weight, and tumor growth.

Abstract Name: **String in Switch ? Usage Analysis and Maintainability**

The release of Java 7 in 2011 introduced the capability of using character sequences, hereby referred to as String objects, in switch expressions and their corresponding case statements. This String in Switch language feature allows producing readable and better-performing code when compared to commonly used alternatives like if-else statements, often nested and difficult to modify and maintain. As a consequence, code maintainability can be simplified by incorporating this feature into a project. Our research focuses on the usability analysis of this new language feature, with the goal of observing its usage over time across selected Java-based open source projects. In addition, we perform a comparative analysis between sample String in Switch statements and equivalent if-else expressions to discuss the maintainability of the code as it relates to the advantages of String in Switch. For analyzing a project, we perform a file expansion that generates revisions for every commit in the project's repository. Subsequently, we build Abstract Syntax Trees (ASTs), allowing us to identify the presence of String in Switch statements present in a target file. With this information, usage-over-time plots are derived, allowing us to observe the occurrence of String objects in switch expressions throughout a project's development history. Of the analyzed projects, our research shows that the String in Switch feature is not widely used, despite its capability of generating cleaner and readable code. We conclude that some of the analyzed projects may be mature, which reduces the need to rewrite functional code into equivalent String in Switch statements. These findings are useful not only for programming language designers in understanding the tendency to utilize new features, but also for instructors in teaching programming languages in a limited amount of time.

Abstract Name: **The processes of conducting a scoping review in the discipline of nursing among an international team**

Background and Purpose: Research is a significant aspect of developing any discipline, but within the discipline of nursing there are a variety of essential steps required to execute impactful research. Scoping reviews are used to survey many studies from a section of time or focus to determine the state of the science and apply findings to current practices. This study intends to describe the process of conducting a scoping review among an international nursing team.Method: The guiding scoping review for this study focused on what nursing actions were used during COVID-19 to connect patients and families, including communication methods, frequency of contact, differences amongst countries, or intervention length. An observation of the processes used by experienced international researchers was conducted through examining emails, meeting agendas and minutes of virtual meetings, and interactions within the software used to conduct the analysis during the process of the scoping review. Data were drawn from these observations and used to determine essential elements for conducting a scoping review by an international team in the discipline of nursing.Results: Results revealed steps that can be applied in planning future scoping reviews. Developing and implementing a scoping review protocol, regular communication between the team leader and team members, regular virtual meetings, maintenance of a common OneDrive site for document storage, and use of a designated scoping review software were essential to process effectiveness.Conclusion: Conducting a thorough scoping review requires a rigorous review of existing literature followed by meticulous data extraction. Collaboration as an international nursing research team in conducting a scoping review can be facilitated by using a specific protocol, designated leadership, and regular communication.

Abstract Name: **SYNTHESIZING TETRAPHENYLPORPHRINS AND METALLOPORPHYRINS USING MICROWAVE AND ULTRASONIC REACTORS**

Introduction: Tetraphenylporphyrin (TPP) is a macrocyclic molecule found in biological compounds. TPP's UV-Vis spectrum ranges from 380-500 nanometers. Metalloporphyrins (MeP) are considered “bioinspired oxidation catalysts” and are synthesized from TPP and metal anhydrous salts. Therefore, hypothesizing that the UV-Vis spectrum of the MeP will be altered by the type of benzaldehyde (electron-donating and electron-withdrawing groups attached to the benzene ring) added to the TPP ligand during the MeP synthesis reaction.Methods: The project investigated solvent-free conditions, first with a silica gel support and then without it. The TPPs were produced in a Chemical Explorer Microwave (CEM) Reactor with a commercial 950W/1000W microwave oven. The conventional reflux method and an ultrasonic reactor were used to develop the MePs. TPPs were synthesized with substituted and unsubstituted benzaldehydes to investigate the effect of electron-donating and electron-withdrawing groups on the complex synthesis and the UV shift.Results: The UV-Vis spectra for each MeP confirmed the formation of complexes with p-block metals. The data displayed that the Tin MeP showed a red-shift UV-Vis spectrum (446 nm) compared to the initial TPP (417 nm). Complexation of Tin with the 4-chloroTPP displayed a maximum peak at 473 nm.Conclusion: This reaffirms that the electron-withdrawing benzaldehydes worked better than the electron-donating when added to the TPP. Thus, causing the UV-Vis spectra to have a red shift compared to the initial product.

Abstract Name: Political Divide

The current climate in the US is more than contentious. The current state of the us verses them attitude divided along the political lines is ever worsening. What informaiton is fact and what is political rhetoric? How can the divide be bridged? What are the potential dangers of such a divide in a powerful country? This research is designed to study how the political attitudes across the US are shaped by unfriendly dialog and news media bias. The goal is to understand how the varying forces around the political disconnect predict the perspective of adults in the US. This research will focus on political knowledge, willingness to connect with people of differing views, commitment to current political views, and news seeking behaviors when identifying underlying reasons for the unwillingness to accept otherswith different viewpoints and what can be done to mediate the negative behaviors creating an even wider divide between the groups. How does having friends with widely different political views impact inter-political group discourse? What communication skill sets can be cultivated to foster necessary listening and dialogue techniques? Data analysis will be completed in the spring semester of 2023.

Abstract Name: Yoga As An Approach to Mental Recovery 48 Hours After an Intense Workout

Background: Along with physiological changes, knowledge about yoga and meditation strategies for post workout mental recovery has been investigated. Results show that it improves mental clarity and reduces stress and anxiety levels. Purpose: The purpose of this study is to examine the effects of a 30 min yoga session on mental recovery 48 hours after a high intensity workout. Hypothesis: We hypothesize that if a yoga session is done immediately after an intense workout, it will produce greater mental recovery compared to those who do not participate in the yoga session. Methods: Twenty undergraduate students will complete a 30 minute intense workout. Following the workout, the intervention group will complete a thirty minute yoga/meditation session. The control group will not do anything outside of their usual routine. Conclusion: If our results align with our hypothesis, individuals can incorporate yoga into their exercise routine to benefit overall mental health and recovery.

Abstract Name: **A New Dimension in Science Education: Augmented Reality as an Instructional Tool**

With the personal use of tablets and smart devices growing more popular at young ages, educators are looking for ways to capitalize on interest in technology to engage children with educational media and learning apps. Augmented reality (AR) is a growing technology field that enhances the real world with digital media anchored to the location and content. There is a gap in literature regarding efficacy of AR apps compared to more familiar media sources in teaching STEM content. In this quasi-experiment, children (ages 8 to 12) were given an opportunity to view a YouTube video and an AR app to learn about an animal at the Greensboro Science Center. Half of the children watched the video first and half used the AR first. They answered post-test questions and made a video about what they had learned. We hypothesized that they would retain and share more information from the second source of media because it was fresher in their memory. However, results showed a trend for students to learn more from the media than they viewed first, particularly regarding facts from the YouTube video. This finding suggests that there could be oversaturation of information when given too much media regarding one topic in a short amount of time. Our questionnaire also measured student and parent STEM identity and STEM value. There was a trend for students with higher STEM identities to learn more from the AR program (p=.059). When kids view themselves as a scientist, they are more likely to learn from new tools compared to their peers that do not view themselves as scientists, whereas there was no significant difference between STEM identity levels and YouTube score.

Abstract Name: **Dickinson College: How a Denominational Institution Provided Civic Education in the Early American Republic**

By the close of the Constitutional Convention in 1787, the United States'Founders understood that the republican government they created relied on participation from virtuous citizens to survive.Virtue, defined as one's willingness to sacrifice one's private interests for the good of the community, would be acquired through religion and education, both of which instructed citizens on the necessity of selflessness and the welfare of humanity. These citizens would not appear spontaneously, so the Founders believed deliberate instruction was needed to prepare Americans for citizenship, giving meaning to the concept of civic education. How this instruction was to be undertaken, and by whom, was the question. Amidst Jeffersonians' attempts to secularize education by limiting denominational involvement in schools, Benjamin Rush and John Dickinson, as founding administrators of Dickinson College in Carlisle, Pennsylvania, believed religion was an essential pillar of civic education.Animosity between Pennsylvania's Quakers and Scotch-Irish Presbyterians caused by Pontiac's War (1763-1766) and the rise of the Paxton Boys persisted through the 1780s and threatened civil and religious liberty in the republic. Believing their own amicable relationship was made possible by their liberal arts education, Rush, a Presbyterian, and Dickinson, a Quaker fellow traveler, wished to replicate the tolerance they extended one another by bringing collegiate learning to the Pennsylvania frontier. Dickinson's and Rush's collaboration modeled the desired relationship between Quakers and Presbyterians, and an examination of Dickinson College's founding principles—ecumenical administration and faculty, denominational association, and classical curriculum—will reveal how the institution's founders believed civic education could promote greater religious and civil harmony. By instilling common republican values, the geographically, politically, and religiously divided Pennsylvanians would be unified by their shared identity as citizens of the American republic.

Abstract Name: Readout Software for the NOPTREX Experiment

The Neutron Optics Parity and Time Reversal Experiment (NOPTREX) is investigating violations of time-reversal symmetry in the hopes to explain the baryon asymmetry of the early universe. In pursuit of this, members of the NOPTREX collaboration are constructing an array of twenty-four sodium-iodide scintillation gamma detectors to measure n-gamma resonances in heavy nuclei. This system will produce a large amount of data in a matter of milliseconds, necessitating a high-speed data acquisition system to read the detectors' output and deliver the data in a usable format. A custom firmware for a CAEN digitizer has already been developed that implements a trapezoid filter and charge integration to ensure the energy of each pulse is recorded. But, the firmware is limited by the basic readout software provided with the digitizer and cannot generate the required file output. We have developed a custom readout software in C++ that reads out data from the digitizer's firmware and analyzes it in real time before recording it to a file in the ROOT format to take advantage of the high-performance computing software developed at CERN.

Abstract Name: Ventral Tegmental Area Amylin Receptor Activation Does Not Alter Prefrontal Cortex Dopamine Activity

The World Health Organization (WHO) estimates 650 million adults worldwide suffer from obesity, and these numbers rapidly grow. Amylin, one promising drug to treat this condition, induces satiety to reduce food intake. Reduced dopamine (DA) signaling in the mesolimbic DA system by amylin receptor (AmyR) activation on DA neurons in the ventral tegmental area (VTA) likely contributes to amylin's anorectic effects. However, little is known about which downstream areas mediate these effects. Prefrontal Cortex (PFC) DA activity is likely altered by VTA amylin. We trained food-deprived rats for 10 days (10 sessions) to non-contingent, high-fat, and high-sugar pellets. We infused 0.4μg/100nL amylin or a vehicle into the VTA and used in-vivo fiber photometry to capture phasic medial PFC (mPFC) DA release during pellet retrieval. While mPFC DA activity during pellet drops is potentiated and latency to retrieval decreases over training days, VTA amylin infusion did not alter mPFC DA dynamics during the pellet retrieval task. Based on these findings, it is likely that PFC DA has a role in reward learning, specifically in learning the availability of reward, but not in producing amylin-induced hypophagia.

Abstract Name: **"We Are a Despised People": Moravian Identity in Mid-18th Century Pennsylvania**

Mid-eighteenth-century Pennsylvania had a diverse landscape of Protestant denominations, including the Unitas Fratrum, or the Moravian church. Historian Scott Paul Gordon has argued that the eighteenth-century Moravian church in Bethlehem, Pennsylvania kept its congregation small on purpose, despite a wave of religious revivalism that expanded other denominations. My paper takes this premise and asks why the Moravians chose to stay small. I argue that the Moravians had a closely guarded identity rooted in their three-hundred-year history of oppression in Europe and the demanding nature of their mission work in Pennsylvania, during which they traveled the frontier and lived in Native American towns. Moravian history and their difficult mission to the Native Americans formed an identity as a "despised people," who were disliked and distrusted by their neighbors and committed to dangerous itinerant work on the frontier. This identity as despised martyrs helps us understand why the Moravian church chose to stay small, in an environment primed for growth. I use Bethlehem diary entries, meeting minutes, and Moravian missionaries' accounts to explain the Moravians' strange behavior. I also use Lutheran missionary records from the eighteenth and nineteenth centuries to provide a normative case that shows how the Moravians differed from their Protestant contemporaries, and to further examine the difficulties of mission work on the frontier. While historians have often observed that the Moravians did not fit into the eighteenth-century Pennsylvania frontier's religious and cultural landscape, I draw out unique facets of Moravian identity, making their choice to live as misfits make more sense.

Abstract Name: **Measuring Perceptions of Creativity Through Collaborative Experience**

Many consider the world of visual art to be a strictly individualistic field; an individual sculptor sculpting or an individual painter painting. In fact, community and collaboration often aid the creativity of those working in the visual arts. Large scale artistic endeavors such as Yves Klein's "Anthropometries" and Christo and Jean Claude's "Running Fence" required many people all working towards one artistic vision. My own experience as a collaborative artist has indicated to me that the creative efforts of a group of people can often be more inspired than that of a single artist. Having staged many collaborative art pieces, I have become curious as to exactly what impact collaborative art has on its participants. To investigate my inquiry, I plan to stage an ongoing exploration of participants' creative evolution while making collaborative art. Over a six month period, I will stage and document a controlled collaborative environment in which subjects will participate in a shared artistic experience; expressive wall painting in a site specific setting. Before the experience, they will complete a questionnaire to determine their own perceptions of creativity. After participating in the collaboration, the subjects will receive a post-survey of the same questions. The surveys will be written acknowledging Rita Irwin's essay "Communities of A/r/tographic Practice" and Allan Kaprow's essay "Manifesto." Using the pre and post surveys, I will track the subjects' creative growth after each collaborative experience. These results will determine how collaboration in the visual arts impacts creativity. Further outcomes may demonstrate how this creative evolution is mutually beneficial to both the facilitators and the participants of a collaboration. This valuable data will inform my future creative endeavors, and further establish the significance of collaborative art in the visual arts community.

Abstract Name: **Determining the Direction of Magnetic Fields Using Optically Pumped Atomic Magnetometers**

An optically pumped atomic magnetometer (OPAM) detects magnetic fields within a two-dimensional plane. Previously, radio frequency magnetometers could not be used to determine the exact direction of the field within the plane. In this experiment, two magnetometers were used to determine the direction of test signals created by running current through coils of wire. In an OPAM, alkali atoms are made to rotate around an applied static magnetic field. Only components of a magnetic field that rotate in the same sense and at the same frequency as the atoms are detected by the OPAM. The magnetic fields used in this experiment had directions that either alternated linearly or rotated. Since an alternating magnetic field is equivalent to the sum of two oppositely rotating components, a magnetometer detects only the component that rotates in the same sense as the atoms. This experiment used two magnetometers with their applied fields equal and opposite to each other to separately detect both of the rotating components. The directions of the test signals were then determined from the measurements of the two rotating components. Knowing the direction of the detected magnetic field would be useful in applications where noise from radio interference is known to be perpendicular to the signal. In this case, the direction could be used to distinguish between the signal and interference. One such application is the detection of landmines.

Abstract Name: **The Stream Mitigation Market and its Effect on Water Quality**

Developers often desire to relocate or channelize streams when building new structures. To allow development and prevent net loss and degradation of streams, states, followed by the Federal Government, designed stream restoration credits, banking, and exchange markets. By restoring nearby streams in a specified manner, the process allows firms to obtain, bank, and trade restoration credits within each HUC 8 watershed (an area where all the water flows into) to offset the streams degraded by developers. Restoration credits can be thought of as a tool used by a third party to sell the rights of a nearby stream that they restored to developers. Once developers purchase said credits, they can begin degradation of the onsite stream as the loss has been mitigated. While the primary metric of successful stream restoration is on hydrologic and geologic stability, water quality is an equally important metric that is rarely used when assessing stream health and granting restoration credits. Regulators often attempt to indirectly address the issue of stream water quality inequivalence between natural streams and restored streams through trading ratios. For example, if 100 acres of natural stream system is degraded by development, 300 acres of restored stream is needed to remain compliant. This would be considered a 3:1 trading ratio. However, these trading ratiopolicies mean that the government agencies in charge of credit enforcing and approval rarely acutally measure water quality and biological stream health post-restoration and trade. Using data on all mitigation sites in the United States, their respective credits per site, and United States Geological Surveyor (USGS) water quality data at the HUC 8 watershed level, we seek to determine if the current mitigation bank policy has improved water quality, remained neutral, or decreased water quality on the HUC 8 watershed scale.

Abstract Name: **Kendo_Fighter_Trainer**

The first computer controller machine for Kendo self-training was invented in 2005 by Prof Young-Bong. Bang from the Manufacturing and Mechatronics Lab of Seoul National University in South Korea. The Japanese kendo fighting robot, known as MUSA, weighed 150 pounds, and was 65 inches tall with a central processing unit that employs several sensors and digital cameras for tracking opponent's motion and assist in counterstrikes. Despite the accuracy and strength of counterattack maneuvers, the response time of the Kendo fighting companion was relatively slow mostly because of the insufficient speed of its processing unit, and the limited mobility of its motion transmission mechanisms. Several design upgrades were made to improve its mobility at a marketable price. Unfortunately, to our knowledge, an affordable self-training Kendo fighting companion is yet to be developed and manufactured, which bring us to the subject of our current investigation. In our ongoing project, we reinvented the original kendo companion blueprint and designed a lightweight self-training arm that is capable of reproducing Kendo attack and defense maneuvers. For improved mobility, the kendo-Arm is driven by a set of spherical and monopolar gears housed in a ball and socket joint. The spherical motor concept was first developed in 2021 by researchers Kazuki Abe, Kenjiro Tadakuma and Riichiro Tadakuma from the Yamagata University, Yamagata Japan and Tohoku University, Miyagi Japan. An improved version of this concept will use a Raspberry Pi single board computer to repeatedly processes several digital camera images of a color labeled arm from the computer. Then it will transmit motion coordinates to an imbedded driving mechanism that employs DC geared motors and Arduino controllers. The driving mechanism carefully adjusts the rotation and precession of the monopolar gears for precise and reliable counter strikes.

Abstract Name: **The Cardiorespiratory Response while Nordic Walking vs. Regular Walking Among Middle-Aged to Older Adults**

Background/Purpose: Around 60-80% of waking hours for adults are spent in sedentary behavior while physical inactivity accounts for 9% of all deaths worldwide. Furthermore, there is a strong dose-response relationship between physical inactivity and all-cause mortality, cardiovascular health, and metabolic health. Recently, Nordic walking (NW) has been introduced as a superior mode of exercise where one can increase energy expenditure due to increased engagement of upper body musculature while walking at a moderate intensity pace. NW is like regular walking except for using walking poles. Within established findings, most work has been done in a laboratory which can interrupt natural NW mechanics. Therefore, the purpose of this study was to measure the cardiorespiratory and energy expenditure differences in Nordic walking and regular walking in a field setting. Methods: Twenty middle-aged and older adults participated in this study. Each participant's initial session included Nordic walking familiarization, 10-m gait speed test, and a peak oxygen uptake (VO2peak) test. The two exercise sessions consisted of either NW or regular walking on an indoor track for 30 minutes. All metabolic variables were measured via the COSMED K5. Results: A paired-sample t-test revealed a significant difference between NW and regular walking for %VO2peak values ($p = .008$), kcal·min-1 ($p = .005$), and total kcal expenditure ($p = .001$). No significant difference was found for preferred gait speed ($p = .485$) between NW and regular walking. Conclusion: NW is superior to regular walking in eliciting a higher %VO2peak despite similar walking speeds, a higher kcal·min-1, and greater total kcal expenditure. In turn, these data agree with previous research and supports the use of NW to increase energy expenditure to potentially prevent the risk of one's metabolic and cardiovascular risk.

Abstract Name: **Synthesis of Yttrium Iron Garnet Thin Films on Gadolinium Gallium Garnet Substrate**

In thin films, Yttrium Iron Garnet (YIG) can be considered the most prominent material in spin dynamics due to its ultra-low damping. This ongoing project aims to synthesize a high-quality thin film of YIG on Gadolinium Gallium Garnet (GGG). Due to their lattice match, GGG is considered an ideal substrate for YIG. The sample was developed using a set of parameters inspired by previously published works. The production of YIG includes deposition and annealing processes. For the deposition, a DCmagnetron with RF with a base pressure of 10 mTorr and sputtering power of 75 W was utilized. The sample was then annealed in a tube furnace with constant oxygen flow overnight. In the following week, we plan to measure the thickness and surface roughness of the sampleusing Atomic Force Microscopy (AFM). Additionally, we plan to examine the sample's magnetic property using a magnetometer to confirm the sample's quality. Since our recipe follows other published works closely, our measurements are expected to be close to existing results in related studies. We expect our measurementto yield an approximate thickness between 20 to 40 nm. However, the results of the surface roughness and magnetization measurements are more challenging to predict.

Abstract Name: **Sex differences in the interactions of nicotine and food deprivation on anxiety-like behavior**

Cigarette use is highly associated with weight loss, and many people begin smoking to lose weight. As such, calorie-restrictive diets are often used in conjunction with smoking, particularly in women. Yet, the interaction of nicotine and food deprivation in males and females is not fully understood. This study aims to analyze the impact that sex and calorie restriction may have on the body's response to nicotine through the observation of anxiety-associated behaviors in rodent animal models. Food-deprived female rodents exposed to nicotine are expected to present fewer anxiety-associated behaviors than free-feeding female rodents and all male rodents. If our hypothesis is supported by the results, this will indicate that women who diet and use nicotine may experience less anxiety than non-dieting females and males. This may result in a more pleasurable smoking experience for female smokers and decreased rates of nicotine cessation. Due to the abundance of negative health effects of nicotine, this makes dieting and smoking more hazardous to women's health than simply smoking alone.

Abstract Name: **The Mesoscale Conditions that Contributed to the development of the Morton, Texas Tornado on 23 May 2022**

On 23 May 2022, the participants of UW-Whitewater's Field Course on the Forecasting and Verification of Extreme Weather witnessed a tornado in west Texas. The official tornado report had tornado genesis occurring at approximately 0007 UTC 24 May 2022 (7:07 pm CST 23 May 2022). Based on synoptic-scale (i.e., large scale) conditions most of west Texas from the US-Mexico border into the Texas panhandle were under the threat of severe weather on this day. While in the field and in the post-mortem analysis of this day it was determined the mesoscale conditions were the main factor as to why a significant tornado occurred in the west Texas region near Morton. Mesoscale conditions were evident during the course's morning weather briefing using various mesoscale forecast models. As the day progressed and conditions changed slightly, adjustments were made by the course participants that allowed them to witness the development of the thunderstorm that would end up producing a dust storm (with straight-line wind gust up to 80 mph) and large hail (1.5 – 2.5 inches in diameter). In the post-mortem analysis, a detailed analysis of the mesoscale conditions was performed with additional data from mesoscale networks around the west Texas region. This post-event analysis did find that a localized area of enhanced shear formed near the Morton area due to a surge of dry air out of eastern New Mexico. Preliminary results show that this surge of dry air interacted with an outflow boundary from the earlier developing thunderstorms. The interaction of these differing boundaries created a small area of enhanced lift and wind shear that allowed one of the on-going thunderstorms to intensify and produce an EF2 tornado that occurred 7 miles north of Morton, which the course participants witnessed.

Abstract Name: **Mathematical Modeling of Polio with Emphasis on Vaccination Strategies**

Poliomyelitis is an infectious viral disease that affects the central nervous system leading to permanent or temporary paralysis. Like other infectious diseases, the spread of the disease in a population with a known size structure can be analyzed and represented using a mathematical model. In this paper, we use a Susceptible-Infected-Removed (SIR) model to study the rate of the spread of polio between the susceptible, infected, and removed individuals who are immune to the pathogen in a population sufficiently large enough. There are two types of vaccinations for Poliomyelitis available which are live Oral Polio Vaccine (OPV) and Inactivated Polio Vaccine (IPV). We investigated different vaccination strategies toward the goal of eradicating Poliomyelitis. A computational study will be shown to illustrate the dynamics of the various scenarios of polio virus transmission and the effectiveness of vaccination strategies in combating polio.

Abstract Name: **Exploring the Raman Scattering Response of Meteoritic Fragments**

Raman spectroscopy is a technique that has been used extensively on different kind of samples (carbon allotropes, semiconductors, polymers, microplastic particles, microorganisms, cells, etc.) since it is a nondestructive tool that provides information about their structure and material composition. In particular, it has been employed on meteoritic samples which in general are mainly composed of micro/millimeter sized inclusions, surrounded by a matrix of microparticles, that date from around the time of the formation of our solar system. The study of the physical properties of these relics using Raman spectroscopy can help to understand how planets formed since they can give evidence of the conditions (e.g., thermal, temporal and barometric) in which the materials found in the meteoritic samples developed in our solar system. However, not all the constituents of meteoritic samples have a Raman signal with a high signal-to-noise ratio, or other phenomena present in those materials (e.g., fluorescence) can hide some Raman features. In this work, we examine several meteoritic fragments that have recently been acquired by our group, such as carbonaceous chondrites Northwest Africa (NWA) 7184 and Aguas Zarcas, using this experimental technique. We explore the surface of these samples carrying out Raman spectroscopy measurements on numerous inclusions and surrounding matrix to find materials with high signal-to-noise ratios to analyze the mineralogical composition of the fragments. We correlate these results with other experimental techniques (e.g., optical microscopy, scanning electron microscopy, energy dispersive X-ray spectroscopy and/or atomic force microscopy) to look for signatures of the physical processes that drove the formation of these meteorites.

Abstract Name: **In-silico Characterization of Potential SRF Inhibitors in HCT116 Colorectal Cancer**

SRF (Serum Response Factor) is a transcription factor that is activated by growth factor stimulation and mitosis, leading to the expression of genes that influence growth and the cytoskeleton. Additionally, HOPX, which is associated with reduced cell proliferation and tumor suppression, inhibits the binding of SRF to DNA. Additionally, SRF in gastric cancer is associated with an aggressive phenotype and a poor outcome due to the downregulation of E-cadherin which promotes the epithelial-mesenchymal transition. Furthermore, in colorectal cancer, SRF is overexpressed in metastatic tissues, leading to increased cell motility and invasiveness. Based on this, we decided to look for potential SRF inhibitors. We are currently working with chemical similarity algorithms and clustering techniques, like Tanimoto similarity and UMAP, to determine SRF inhibitor candidates based on limited existing inhibitors. Those candidates will then be docked to the target using Autodock Vina. Molecules with high binding affinities will be tested for drug-induced liver injury (DILI) and toxicity in cells (DeepCDR). Furthermore AutoGrow, an open-source program which uses a genetic algorithm to 'evolve' known ligands based on binding affinity to the target, will be used for de-novo drug design. Preliminary results reveal several inhibitors with better binding affinities than our positive controls from the ChemBL dataset along with preliminary drugs from Autogrow with even better binding affinities. We anticipate that these drugs will eventually be tested in-vitro on colorectal cancer cell models, such as the HCT116 cancer cell line.

Abstract Name: **Characterization of Immune Cell Pathology in Corynebacterium amycolatum Gut Microbiome in the Thy1-SNCA Parkinson's Disease Mouse Model**

Parkinson's Disease (PD) is a neurodegenerative movement disorder that is characterized by tremors, rigidity, and unsteady gait. Symptoms are caused by the degeneration of neurons in the substantianigra of the basal ganglia, an area of the brain that initiates movement, due to abnormal accumulation of the misfolded alpha-synuclein protein.Prior to motor symptoms, PD patients often have preclinical symptoms, such as constipation and anosmia. Recent research suggests that the gut microbiome is important in this early pathology of PD via modulating neuroinflammation, a key mechanism of neurodegeneration. A recent study identified Corynebacterium amycolatum, a pathogenic microbial species, as disproportionately present in the gut of human PD patients, but how or if the pathogenic species contributes to pathogenesis is unknown. We hypothesized that Corynebacterium amycolatum will increase neuroinflammation and enhance Parkinsonian symptoms. For this study, we used Germ-Free transgenic alpha-synuclein overexpressing mice. The mice, along with non-transgenic controls, either received or did not receive a C. amycolatum transplant. 1-month and 6-months post-transfer, brain tissues were immunolabeled with pSer-129, a misfolded alpha-synuclein marker, as well as GFAP and IBA-1, markers for the neuroinflammatory cells astrocytes and microglia, respectively, through immunohistochemistry.The tissues werevisualized using light microscopy and quantified with ImageJ. After 1-month, transgenic C. amycolatumtransplant mice exhibited an increasing trend of greater astrogliosis and alteration of microglial activation morphology in the cerebral cortex compared to non-transplant mice. This trend continued in the 6-month mice but was accompanied by a decrease in pSer-129 in the striatum. Therefore, our study provides intriguing evidence of glial changes due to the presence of C. amycolatum and suggests an early protective role in the onset of PD of the microbial species. Since the gut microbiome can be easily modified, C. amycolatum may be utilized to create a therapeutic microbiome for PD.

Abstract Name: **Home Range and Habitat Selection of Rehabilitated and Released Female Black Bears in Northern Wisconsin**

The Eastern American Black Bear (Ursus americanus americanus) is a valued species among many for its biological, intrinsic, and cultural significance. Black bears are considered habitat generalists, taking advantage of the resources available to them. In the state of Wisconsin, previous studies suggest black bears select for habitats in northern hardwood forests and near beaver flowages. Habitat selection data from rehabilitated and released bears is lacking in Wisconsin, although this is a practiced management technique. The purpose of our study is to investigate the home range and habitat selection of rehabilitated and released female black bears in northern Wisconsin. The rehabilitated yearlings are fixed with GPS radio-collars prior to release, and location data is received every four hours. Habitat data from the received GPS points are compared to habitat data from random locations within the bears' home range (third-order analysis). Habitat data such as landcover type and distance to nearest road, stream, and open water source is collected. Understanding habitat selection of rehabilitated black bears in comparison to previously known black bear selection behavior is important for determining the impacts of rehabilitation and release as a management technique.

Abstract Name: Inversion of In-Group Favoritism in Adversarial Conditions

Introduction: In-group favoritism (Sumner, 1906; Taijfel & Turner, 1986) is the phenomenon of giving preferential treatment towards individuals within the same perceived social group (e.g., age, race, gender).
Purpose: To experimentally assess whether in-group effects will negate and even invert when one party exhibits actions / demands that exceed the boundaries of a normal in-group association.
Procedure: See Appendix. We created a workplace scenario where the participant assumes the role of a co-worker. In the first segment, the participant is assigned to work with Mary, who requests some minor favors (baseline condition), and responds to the five assessment items shown in the Appendix. In the second segment, Brittany joins the workgroup, and does things that should go beyond in-group boundaries (inversion condition), and then the participant responds to the same five items.
Hypotheses: (1) sum of the five ratings will be significantly lower in the inversion (I) condition relative to the baseline (B); (2) participants who are around the same age as the scenario models will show a stronger inversion difference relative to those who are not; (3) because of its nurturing facets, the Big Five trait agreeableness will moderate the effect such that more agreeable participants will be less affected by the inversion effect.
Participants: 63 total from convenience and classroom samples, age ranging from 16 to 62.Results:Hypothesis 1: Baseline (mean=17.4, sd=3.0), Inversion (mean=10.8, sd=3.3), t=14.82 (p<.00001)Hypothesis 2: Same age (B-I mean=3.94, sd=3.6), different age (5.1 / 2.9), t=2.09 Hypothesis 3: Correlation Agreeableness vs B-I difference r = -.24 (p<.05)Discussion: H1 was supported, H2 was significant but in the wrong direction (non-matching aged participants showed a larger inversion effect), H3 was supported (more agreeable, smaller B-I difference). Follow-up research suggested for H2.

Abstract Name: Verification of a qPCR Assay for Detection of Phialophora gregata in varied Soybean Tissues and Brown Stem Rot suspect samples

Phialophora gregatais the causal agent of the disease Brown Stem Rot of soybean. As a common pathogen found in fields across the Midwest, it is important that extension services provided by land-grant universities, like the Plant; Insect Diagnostic Clinic at Iowa State University, have effective methods of detecting and diagnosing the disease so proper management practices may be implemented.P. gregatagrows slowly in culture and is difficult to isolate from infected tissues with media, which creates a need for a rapid yet accurate detection method. An article published by Malvick et al. 2007 titled "Detection and Quantification of Phialophora gregata in Soybean and Soil Samples with a Quantitative, Real-Time PCR Assay" presents a promising detection strategy that uses quantitative polymerase chain reaction (qPCR) to detect and quantifyP. gregatawithin a plant sample. This article is the first qPCR assay forP. gregataever published, which demands the need to evaluate the materials and methods used in the assay to verify the procedure. The reproducibility of Malvick et al. 2007's detection method was tested to examine its effectiveness as a diagnostic tool by determining whether the method could detect the pathogen at various concentrations within soybean plants of varying conditions. The project was conducted by planting soybean seeds in soil inoculated with the pathogen, harvesting plant tissue at various plant growth stages, extracting DNA from different categories of plant tissue, and executing a series of qPCR reactions using the reagents outlined within the publication. We found that the qPCR assay recorded by Malvick et al. 2007 successfully detected and quantifiedP. gregataDNA in soybean plant tissue of varying conditions.

Abstract Name: **Pionír: An Illustrated Novella Inspired by the Historical Pioneering Heritage of a Family from Transylvania**

The creative thesis Pionír developed an illustrated novella inspired by accounts told to the author, Gréti Müller, by older generations of her family who lived under the Romanian communist regime and witnessed its overthrow in 1989. The title of the novella, "pionír" /ˌpaɪəˈnɪəɹ /—the Hungarian term for the English word "pioneer"— is meant to capture a central theme in the history of the author's family, a motif reappearing throughout generations and enacted again in the 21st century in a pioneering move to the United States. Pionír was written to acknowledge and honor the individuals on whom the characters of the narrative are shaped. Their story of struggle, pioneering, overcoming, changing, growing, and moving forward can also hopefully bring richness and depth to the stories that comprise the immigrant heritage of the United States.The work Pionír found its current expression through envelopes sewn together to form an artist's book. Each envelope holds a chapter of the narrative along with works of art that reference parts of the storyline. At the expense of the aesthtetics of traditional illustration, the artistic component of Pionír is meant to engage the five senses of the "reader," and to translate synesthesia into a form of art.Through a narrative inspired by history and through the immediate experience of it as a work of art, Pionír tells a story that becomes an invitation open to everyone. The "reader" is called to make sense of it by relating the work to his/her life and cultural-historical heritage.

Abstract Name: **Continuous Compliance Monitoring of Water Quality to Determine the Effects of Urbanization on Richland Creek**

This project aims to establish a long-term water quality compliance monitoring system to determine the degree to which urbanization is impacting physical and chemical indicators crucial to the health of Richland Creek and Schenck Forest. Continuous monitoring allows us to observe the changes in these indicators as commercial, residential, and transportation development expand in the surrounding area. The area of study consisted of two sites situated along Richland Creek, located in Raleigh, North Carolina, where biweekly YSI and nutrient testing were conducted. The sites' data were compared to observe two trends: (1) the initial contrasts stemming from their different existing degrees of urbanization, and (2) the changes in these contrasts due to their differing rates of increasing urbanization. Our goal is to influence city and community programs in Schenck Forest to protect water resources for the people who consume them and the ecosystems that depend on them. We hope this research can help establish a baseline for these indicators to inform future research around water quality, aquatic life, and human health in Richland Creek and the field as a whole.

Abstract Name: **EFFECTS OF ATYPICAL ANTIPSYCHOTICS IN RATS TRAINED TO DISCRIMINATE BETWEEN 22 AND 2 HOURS FOOD DEPRIVATION**

In humans, weight gain is a side effect of atypical antipsychotics. In rats, clozapine increases eating, but reduces food-related, operant behaviors. Ziprasidone has smaller or no effects on eating in rats. Given the short half-life of clozapine in rats, we tested the effects of acutely administered clozapine and ziprasidone on the discriminative stimulus effects of food deprivation. Male, Sprague-Dawley rats were trained to discriminate between 22 and 2 hrs(hours) of food deprivation in a two-lever operant task. Under 22 hrs deprivation, left lever presses were reinforced by a 45 mg food pellet. Right lever presses were punished with 8 seconds of darkness. Under 2 hrs deprivation conditions, the contingencies were reversed. Training sessions lasted until 10 reinforcers were earned or 15 minutes elapsed. Training continued until rats emitted 80% or greater condition appropriate responding before the first reinforcer was earned for 8 out of 10 sessions. After acquiring the discrimination (M = 71, SEM = 6 sessions), subjects were food deprived for 2 or 22 hrs and injected subcutaneously with either clozapine (1.0-5.6 mg/kg), ziprasidone (0.32-1.0 mg/kg) or vehicle (1.0 ml/kg). For the 5 minute or 5 reinforcer test sessions, responses toward either lever were reinforced under the FR 15. Test trials were conducted every 15 min for 2 hrs. After test session, food intake was recorded for 1 hour. Clozapine and ziprasidone did not induce hunger-like responses under 2 hrs deprivation. After 22 hrs food deprivation, clozapine (1.0-5.6 mg/kg) significantly reduced hunger-like stimuli induced by 22 hr deprivation, whereas ziprasidone had no effect. Under both deprivation conditions, clozapine decreased food intake, but ziprasidone did not. These data indicate clozapine decreases feeding-related behaviors in rats. Atypical antipsychotic medications have different effects on food-related behaviors in rats and humans

Abstract Name: **Farmworker Health Study (FWHS): Language Barriers in Utilizing Health Care Among Farmworkers in California**

For farmworkers to access healthcare, it must be affordable, readily available, and delivered in a manner that is appropriate to their needs and culture. This project examines the extent to which farmworkers report facing language barriers when accessing healthcare, and the issues that healthcare providers face when providing translation services to farmworkers and their families. This mixed method study combined information from the recently completed Farmworker Health Study (n=1199), the largest study regarding farm workers in California, with qualitative data from interviews with healthcare providers. Results from the quantitative analysis were examined based on the various California regions from the FWHS. The results from a search of the literature and the interviews with healthcare providers identified a number of barriers and facilitators that farmworkers face, including language proficiency and the need for appropriate translations. Taken together, these results put forward an introduction to current language barriers among farmworkers and the healthcare providers who assist these individuals.

Abstract Name: **The Impact of Covid-19 on Services Supporting People with Intellectual and Developmental Disabilities**

Covid-19 had devastating impacts on millions of people throughout the world, especially for underprivileged populations such as those with disabilities. People with intellectual and developmental disabilities (IDD) are at greater risk of both contracting and becoming severely ill or dying from Covid-19. Services supporting people with IDD work with a medically vulnerable population, especially during the Covid-19 pandemic. The increased risk and needs of this population are key considerations when it comes to modifying operations and other decisions within an organization. These organizations had to quickly adapt in order to serve the needs of their clients and employees. Existing issues, like the workforce shortage, were exacerbated by the Covid-19 pandemic; Meanwhile, new issues arose, like frequently changing regulatory policies. Providers had to be responsive when faced with limited resources, high staff turnover, and new regulations. Organizations explored alternative methods of service delivery when their regular operations were forced to cease. In many cases, this meant a transition from in-person activities to using a virtual platform. When IDD service providers encountered a number of challenges presented by the Covid-19 pandemic, organization leaders had to decide what strategies to implement in order to continue serving their clients. This study aims to find the relationship between factors that have affected IDD service organizations during the pandemic. Using 11 in-depth interviews with leaders of organizations that support individuals with IDD, six main areas of impact were identified and analyzed using Integrative Structural Modeling (ISM). The six major themes analyzed were staff recruitment and retention, accessing medical resources, the special needs of the service population, utilizing technology, implementing public policy changes, and leadership practices. Note: This project is currently in the analysis phase. It is expected to be completed by February 2023.

Abstract Name: **Vidutolimod uptake by leukocytes: elucidating the role of granulocytes & the impact on their activation**

Many types of cancer are difficult to treat due to the body's ineffective immune response to the tumors. Using immunotherapy, we can activate the body's immune cells to kill tumor cells. Vidutolimod (VIDU) is a novel immunostimulatory drug for treating cancer. It is a virus-like particle with a TLR-9 agonist delivered in situ. It is currently in preclinical studies, and in clinical trials. Research focus has been on T-cells, B-cells, and plasmacytoid dendritic cells (pDCs). VIDU has shown to activate pDCs which eventually activates an anti-tumorigenic response through NK cells, and t-cells. Neutrophils although being the most prominent leukocyte, have not been studied with relation to VIDU. The purpose of this study was to isolate the neutrophils, then treat with VIDU, and anti-Qßin two dosages. The cells were analyzed in the flow cytometer. Twenty-four-hour supernatant of the cells was analyzed using a 27-plex ELISA. The results showed very effective uptake of VIDU by neutrophils. Improved uptake of VIDU was observed with the addition of anti-Qßantibody which scaled with increased dosage. ELISA data showed no upregulation of any neutrophil cytokine/chemokines except for IL-8. Sample methods such as the PBL, which have more neutrophils than the PBMC layer, showed less effective production of IFN-αby pDCs; which is essential for the anti-tumor response. The effects of VIDU on the immune cells are better understood after this preliminary data on neutrophil-VIDU interactions. However, there is need for more research in understanding the immunological interactions leading to anti-tumorigenic effects using VIDU.

Abstract Name: **Perception of Social and Physical Environmental Risk Factors Affecting Women Experiencing Homelessness: A Mixed Method Study**

Homeless people in general confront many difficulties that make their lives very challenging. However, when it comes to women experiencing homelessness, those challenges can threaten their own well-being by increasing the risk of victimization and decreasing the levels of personal safety. This research project has three aims: first, to better understand the link between victimization and social and physical environment as it relates to homeless women; second, to recognize which aspects of the social and physical environment homeless women find threatening and difficult to overcome; and third, to examine the areas of conflict within the coexistence of homeless women in a mixed-gender transitional shelter. This study is based on a mixed-method approach. The data are drawn from fivein-depth interviews and from secondary survey data collected by Ozanam Manor, a faith-based agency. The qualitative analysis uses a naturalistic perspective to study homeless women in their own living settings in a transitional shelter and provides a rich, contextualized understanding of homeless women's perception of risk. We also analyze secondary survey data collected by Ozanam Manor and use correlation analyses to understand the relationship between social environments and respondents' safety perceptions.Our research goes a step further by assisting Ozanam Manor in identifying and comprehending areas for improvements, such as security and staffing, in order to better accommodate and meet the needs of the individuals of their institution, as communicated by the women in our study.

Abstract Name: **Parent-child weight-related conversations and body image development: Investigating the moderating effects of the parent-child relationship**

The current research question explores how parent-child relationships can contribute to the effects of conversation about diet or weight on adolescent body image. Past research has shown the negative effects of mothers encouraging daughter's weight loss or dieting is buffered by mother's conversations about her own weight or diet. One possible explanation for this is that these bi-directional conversations are happening in a close, more cohesive relational context between mothers and daughters. This research uses a survey design to measure responses from participants on current relationship with parents (e.g., perceived mutuality, cohesion, parent-adolescent attachment), parent-child conversations about weight and diet, body image and disordered eating outcomes. Data in this study was collected from psychology students at the University of Wisconsin-Parkside, who responded to survey questionnaires via qualtrics. We predict that the stronger the parent-child relationship, the less negative impact conversations about body image and diet will have on adolescent body image and disordered eating. This research can help show the major effects of parent contributions to adolescent's perspective on diet and weight, in addition to highlighting key issues that could influence the impact of these types of conversation. With the growing amount of individuals experiencing low self-esteem due to poor body image and weight concerns, this research question is an important topic in today's society. Answering this research question will aid in understanding the effects of parent-child relationships on adolescent body image and disordered eating concerns.

Abstract Name: **Vicon sensed Post-stroke rehabilitation exercise assessment using Attention-based CNN**

Cardiovascular diseases are one of the concerning problems in the United States. According to CDC, approximately 805,000 people suffer heart-related problems every year, out of which 605,000 are the first time. Physicians suggest rehabilitation exercises to the surviving patients as these exercises will help the patients in bringing back their physical function and mobility before the injury. Due to recent technology amelioration, many are using Motion Capture Systems to perform the suggested movements. To improve the performance of these sensors, we develop a model that concentrates only on dominant parameters skipping the rest. With the help of optimization techniques and algorithms, built models will identify the critical parameters from the inputted data. We introduce an Attention-based CNN model on 117-dimensional Vicon sensor angle data to enhance the sensor's performance in identifying the performed exercise. Convolutional layers in the network will help extract the input data's in-depth features, and LSTM layers mine the long-time series features. We have used the UI-PRMD - Vicon ten movements data for building the proposed model. Our attention model has outperformed many complex architectures with an overall average of 0.007881 MAD and 0.012343 RMSE for ten movements.

Abstract Name: **An Analysis of Youth in an Upward Bound Program**

This research project focused on a strength-based assessment for youth entering the Upward Bound program. The Upward Bound program is a program at UW-Eau Claire that is federally funded and dedicated to the preparation for, admission to, and successful completion of a college degree. This program applies to first-generation and/or low-income high school students. The research collection focused on identifying assets in the students' lives and the strengths they possess, rather than analyzing the hardships they face and skills they may lack. The reason for this positive approach is that it has been found in past Upward Bound programs to better cultivate concrete change. This prompts students to first acknowledge and celebrate the networks they already have built around them. In order to further understand their environments a mixed-method approach was used. The qualitative data was collected through interviews, in which the questions focused on the participant's school experience, neighborhoods, and what their typical day at home would look like. In addition, the participants created ecomaps, timelines of important life events, and genograms. This process allowed for a connection to be built between the researcher and the participant. As for the quantitative data, the participants were given a Strengths and Difficulties Questionnaire (SDQ) that focused on their emotional well-being. Through this research, it was shown that COVID-19 has negatively impacted youth and their environments. The SDQ total of 2022 has shown an increase in conduct problems, peer problems, hyperactivity, and prosocial skills in comparison to 2019. As for the qualitative analysis, key themes were safety issues (drug use/ fighting) at school as well as racism/inclusivity.

Abstract Name: **Hospital Employee Assistant Programs: Reducing Mental-health-related Surgical Mistakes for Oncology Surgeons**

Oncology surgeons statistically suffer from one of the highest stress and mental health issue rates in the medical field. Previous research states that effective Employee Assistance Programs (EAPs) have been put into place within hospitals to assist with these issues. However, the programs are underutilized and currently not reaching their intended potential. Stress in the medical field is climbing with a rapid decrease in thenumber of oncology surgeons available and multitudes of sick patients post-covidthat have capacitated hospitals. It is necessary now more than ever to implement mental health changes before the mental decline of oncology surgeons furthers. Oncology surgeons mainly suffer from a stigmatism that currently encompassesreceiving mental help due to thepotentiallynegative effect it may have ontheir medical license and the judgmental workplace interactions that may follow any employee-based mental-health-related conference. Due to an inability to seek help, oncology surgeons are enduring mass amounts of stress and burnout fatigue resulting in a rise in mental-health-related surgical mistakes made during operations. Throughanalyzing multiple journals based on self-reported surveys analyzingmental health, burnout, and stress, as well as electrocardiogram data, I have created steps forward to better implement EAPs. These steps include but are not limited to leadership training on mental health awareness, increasing awareness of the signs of mental health strain, and teaching oncology surgeons stress management practices that they can implementwithin their workplace. By taking these steps among others to implement better workplace environment standards in hospitals, oncology surgeons will be more likely to participate in already effective EAPs, therefore, improving their mental health, and decreasing the amount of mental-health-related surgical mistakes made during operations.

Abstract Name: **Investigating Preservice Teachers' Understandings of the Causes of the Seasons**

Understanding the causes of the seasons is a major concept addressed in A Framework for K-12 Science Education and the Next Generation Science Standards (NGSS) in grades K-12, and a concept preservice K-12 teachers are expected to understand. The purpose of this explanatory mixed-methods study was to assess preservice teachers' understanding of causes of the seasons and categorize prevalent alternative conceptions they have about this domain. Seventy-two undergraduate students enrolled in education courses at a large midwestern university and a small midwestern liberal arts college participated in the study. A multiple-choice concept inventory survey including two open response tasks was developed from the research literature for the study. The survey data were then used to purposefully select a stratified sample of students to participate in a follow-up conceptual interview. Descriptive statistics were used to analyze concept inventory data, and qualitative deductive coding using a constant comparative method was used to analyze interview responses. Preliminary survey findings collected from the liberal arts college indicated an average score of 5.39 out of 15 (35.9%) with a range from 2 to 12 and a median of 5. Overall, they demonstrated greater understanding on questions answerable from an Earth-based perspective with a mean of 65% on three questions. These tasks addressed the time of year their region experiences the greatest amount of sunlight and naming the corresponding season in the southern hemisphere given the northern hemisphere season. Students scored the lowest (mean of 28% on 10 tasks) on tasks that required explanations from a space-based perspective, such as causes of the seasons and why there is more sunlight during summer in the northern hemisphere. Details from the entire data set from 72 students and concept interview also will be presented.

Abstract Name: **Influence of Social Media and News Apps on Anxiety in College Students**

Social media and news applications (SMNA) are widely used across the globe, especially among college age individuals. With this technology comes many benefits, like networking and sharing ideas and thoughts, however, it also comes with plenty of costs. These costs seem to manifest as poor mental well-being, heightened levels of anxiety, and a negative body-image (Bashir; Bhat, 2017). The purpose of this study is to examine the relationship between use of SMNA and levels of anxiety. This will be accomplished by comparing two groups of college students, roughly 50 participants,and their use of social media and news applications along with a self-report of anxiety over the course of two weeks. Data collection will take place during the first two weeks of February 2023. To analyze the statistical data, use of SPSS software and a One-Way Paired-Samples t-test will be optimal. Results of the study will be compiled into deliverable outcomes which area written research paper and a poster presentation. These will be completed before March 30th, 2023. Based on previous literature reviews by Bashir; Bhat (2017) and Saiphoo; Vahedi (2019),results are expected to show a positive relationship between use of social media and news applications and levels of anxiety in sampled college students. The results of this study will impact future research examining the effects of social media and news applications on mental health which is important in an age with unprecedented technological developments.

Abstract Name: **Automated Temperature Control of a DBD Plasma Jet Through Feedback Loop**

Low temperature, non-thermal Dielectric Barrier Discharge (DBD) plasmas find wide applications in plasma medicine. Due to their low gas temperatures, along with numerous radicals such as Nitrogen and Oxygen reactive species, plasmas are able to heal and sterilize wounds. A plasma jet is formed when voltage (~5-10 kV, 20-40 kHz) is applied to a Helium gas (~10-20 slpm). During medical application, it is important to limit the temperature of the plasma jet to avoid any damage to the exposed cells. For practical purposes, the control of plasma gas temperatures in real time is required. In this study, an automated system has been designed using stepper motors, a power supply, a K-type thermocouple, motor controllers, and an Arduino microprocessor. The system is designed to constantly read the plasma jet temperatures, light the green or red LED indicating the safe temperature zone, and controlling the power supply through a feedback loop control by adjusting the power knob of the power supply in an automated fashion. The optimum operating temperature was fixed at 30 degrees centigrade (obtained from literature for safe plasma operation) and the system was activated as soon as the temperature deviated from this targeted value. In this study both a helium plasma jet and a helium plasma sheet were scanned by a thermocouple to obtain two-dimensional temperature distribution with and without the automated system. Experimental results show that the feed back control system was able to control the temperature by adjusting the power supply in a correct manner. The plasma temperatures near the exit of the plasma device were found lot higher than 30 degrees Centigrade. The plasma jet exhibited lower temperatures as it propagated through the air. The presentation will describe the automation process in a greater detail and will discuss the experimental results from biomedical application perspective.

Abstract Name: **Finite Element Analysis of Trabecular Bone Microstructure with Passive Joint Loads Following Brachial Plexus Birth Injury**

Plate- and rod-like struts within trabecular bone have distinct mechanical roles. Typically, plates are primary load-bearing structures associated with elevated stress, whereas rods preferentially concentrate strain to protect plates from microdamage. Our unique approach combining finite element analysis (FEA) with topological characterization of trabecular plates and rods enables the analysis of stress and strain distributions to evaluate this specificity of plate and rod roles. Brachial plexus birth injury (BPBI) occurs in 1-3 per 1,000 births due to excessive stretching of the infant neck and shoulder. Postganglionic injury (Post) commonly results in muscle contracture, limb disuse, and deformity of the shoulder joint, whereas preganglionic injury (Pre) results in limb disuse without contracture or deformity. In both cases, trabecular bone mass and structural organization are reduced. Although bone changes following BPBI may limit functional use of the arm, current treatments primarily target nerve and muscle tissue, not bone. Understanding deficiencies in joint shape and trabecular bone structure, and their interactions, is essential for developing better approaches to target bone. To investigate we are performing contact FEA on micro-computed tomography-based models of rat shoulders that received one of three surgical interventions – Post, Pre, and Sham (uninjured control) neurectomies – using joint reaction forces (JRFs) for these groups from a previous musculoskeletal modeling study. JRFs will simulate passive loading from group-specific resting muscle tensions, and resulting element stresses and strains will be analyzed for a select volume of scapular trabecular bone, comparing median values between plates and rods. We anticipate stress concentrations in plates and strain concentrations in rods will correlate with the degree of joint deformity, previously quantified in a shape analysis study. These results will provide stronger evidence forcausal links between altered joint loading, trabecular bone deterioration, and joint deformity post-BPBI, and will inform better treatments that target bone morbidities.

Abstract Name: **Does Class Size Matter: Pupil Teacher Ratios Impact on Student Achievement**

Educational practices and policies have been debated among educators, policymakers, and others for ages. The idea of class size and pupil teacher ratio (PTR) exemplify this idea. In the existing literature, there are varied opinions as to how we should handle the number of students per classroom. Some researchers show that smaller class sizes can be beneficial to both student achievement and closing the educational gap for students of color. Others are concerned that both class size research and policies lack supporting evidence and therefore should not be attempted. Meanwhile, lawmakers and policymakers continue to invest large amounts of money into class size reduction (CSR) policies including states like California and Florida. This research seeks to reframe and question current policies by determining to what extent low pupil teacher ratios influence student achievement. Using regression and correlation tests, the results produce the conclusions that while math achievement is not affected by class size, ELA achievement in combination with the percentage of African American students does influence test scores. The results lend themselves to a plan for future class size policies that are more in tune with the current state of education and the students who will be affected.

Abstract Name: **The 1980s and the Cold War: Understanding the Climax of the Cold War Through the Lens of Historical Narratives.**

The Cold War has long been understood to be a decade's long conflict of hostile interactions between the United States and the Soviet Union, defined by open distaste and resentment from both sides. The 1980s saw a pivotal change in the standard Cold War mindset of conflict and disagreement, in favor of collaboration and negotiation, motivated by global social, political, and economic realities that made the current state of the Cold War unsustainable. The historical narratives in secondary literature provide conflicting stories relating to the crucial role Ronald Reagan and Mikhail Gorbachev played in shifting the tone of the Cold War. And it is essential to investigate the truthfulness of these narratives, by comparing the constructed stories to the facts and evidence in primary literature. This study is focused on understanding how constructed narratives shape and influence our perception of Cold War leaders, how these leaders influenced their narrative and how secondary literature can sometimes mislead one into believing something untruthful. Using primary sources from presidential archives, the Foreign Relations of the United States Archive, and other collections, historical narratives can be analyzed in relation to the facts presented in such documents to create a better understanding of what actually occurred. Investigating the narratives around Gorbachev and Reagan is key to better understanding their relationship, goals, and desires for ending the Cold War and reforming the international diplomatic standard set in the aftermath of the Second World War.

Abstract Name: **What do humans perceive in asset returns?**

Hasanhodzic et al. (2019) challenge Malkiel's (1973) asserting that market returns are visibly differentiable from fabrication. In the authors of the original study conducted a game to determine if humans can differentiate real and randomly generated stock market trend. Concluding that humans can perceive differences between which was generated, and which was sampled from real price markets. Moreover, when indicated if they were guessing correctly as they played, participants improved their scores. These findings have implications for the Efficient Market Hypothesis, Technical Analysis, and regulatory guidance. There are three pivotal aspects motivating replication. First, the original study was done with less than 56 subjects collected via Amazon Mechanical Turk, and none of the participants information was used. The factors at which the game is conducted clearly influenced results. Secondly, subjects were presented information live, meaning participants are given information accurate to real markets. Thirdly, participants were presented with two options, then reveal whether they were correct with their choice, providing players with an advantage that isn't available to every investor in the stock market. Being presented with an extremely binary decision, everyday investors are weighing over 3,000 individual choices every day.The study's intention is to replicate the original under its initial conditions. Further iterations of the game will have individuals be presented with static charts, in which they will be presented with two random stocks. The only moderation will be gauging the results of the game, conducted after trial periods. Researchers will send out surveys documenting participants age, gender, and education level. All data regarding participants information will be strictly confidential and remain disconnected from game results. This is to ensure strict control variable for data analysis. Once completed, the game will be released will run via a private server. All participants will be sourced from Northern Arizona University.

Abstract Name: **Investigating the Role of HpaBC in Modulating Host Nematode Development**

Nematodes are useful models for understanding the molecular basis of animal-microbe interactions, including how bacterial products impact animal development and behavior. Their utility as a model is based on their ease to rear in captivity, their genetic tractability, and the plethora of genetic tools already available for their analysis. Entomopathogenic nematodes, like those of the genus Steinernema, are especially useful because they engage in a co-evolved, specific symbiosis with members of the bacterial genus Xenorhabdus. Steinernema carpocapsae nematodes cultivated with its specific Xenorhabdus nematophila symbiont exhibit defects in growth and egg-laying behavior when grown on a mutant form of X. nematophila that lacks the stress-response transcription factor rpoS, compared to wild-type controls. The X. nematophila RpoS regulon includes the hpaBC locus, encoding enzymes that could act on dopamine metabolite intermediates. We hypothesize that the growth and egg-laying phenotypes observed in nematodes reared on the rpoS mutant symbiont result from modulating nematode dopamine levels through differential expression of HpaBC. To test this hypothesis, we created Xenorhabdus strains with tunable rpoS and hpaBC expression using Xenorhabdus griffiniae, the endosymbiont of Steinernema hermaphroditum, a species for which genetic tools are rapidly emerging. We then grew S. hermaphroditum on lawns of these inducible strains, both with and without an arabinose inducer present, and compared body length against nematodes grown on wild-type X. griffiniae. Arabinose induction produced significant changes in nematode size across treatment conditions, indicating that the activity of RpoS and HpaBC in bacteria have effects on host growth. These assays on developmental phenotypes will be paired with assays on behavioral phenotypes, such as those mediating egg-laying. Additionally, since HpaBC is well-conserved across nearly all bacterial phyla, future investigations may highlight HpaBC homologs as dopamine synthesis modulators in other animal hosts.

Abstract Name: **Breaking Down Barriers: Providing Adequate Sexual and Reproductive Health Education, Access, and Awareness in Health Science Focused University**

The majority of students in colleges and universities in the United States are sexually active. Unintended pregnancies, contraction of sexually transmitted infections, and relationship/sexual violence negatively impact students' educational trajectories. College students who lack access to sexual health education, resources, and preventative services are at greater risk of adverse outcomes. Students attending the University of Minnesota Rochester (UMR) do not have readily accessible, or adequate, sexual and reproductive health resources. This newly developed satellite campus is comprised of 78% women and 82% of the students are aged 18-21. A student-driven inquiry of 95 UMR students revealed that 70% indicate no or uncertain access to sexual health education on campus. Only 12% of UMR students report easy access to sexual health services. Nearly 70% of students report cost, privacy and/or confidentiality contribute to significant barriers to contraceptive attainment on campus.As part of a pilot study, graduates of UMR implemented a grant-funded system to provide increased accessibility of contraceptives and reproductive products on campus. This pilot program assures confidentiality as access to sexual health resources is provided. In addition, a survey was designed and implemented to assess socio-demographic information, understand perceived and real barriers to sexual health services, resource acquisition on campus, and to briefly assess UMR student sexual health behaviors. Here we report our findings and lessons learned from this innovative solution to meet student reproductive and sexual health needs.

Abstract Name: **The Toxicological Effects of Duloxetine as a Polymeric Nanoparticle Drug Delivery System in Rats**

Duloxetine (Cymbalta), a serotonin-norepinephrine reuptake inhibitor (SNRI) is an antidepressant which has previously shown relatively low negative toxicological effects and promising depressive symptom management. However, Duloxetine (DLX) encounters an issue in its drug delivery performance due to its high metabolic dissolution rate which can influence both potency and efficacy. Nanoparticles, in particular, Solid Lipid Nanoparticles (SLNs) can be used as an effective drug carrier system for DLX. If DLX is paired with a SLN (SLN-DLX) for depression treatment, it could provide a relatively low toxicity effect while increasing the concentration of the drug's potency in particular to the brainstem and 5-HT terminal areas. While using nano-template engineering techniques, SLN-DLX solutions were fabricated to be further analyzed for toxicological analysis in a rodent model. Equal numbers of 3-month-old male and female Long-Evans Rats received daily 10 mL/kg intraperitoneal (IP) injections of either 5 mg/kg DLX, 5 mg/kg SLN-DLX, SLN, or saline vehicle on four consecutive days. General physical appearance and daily weights were recorded during treatment. Rats were euthanized and brains collected and post-fixed in paraformaldehyde on the fifth experimental day for further histological analysis. We hypothesized that rats with SLN injections and SLN-DLX injections will exhibit no toxicological differences when compared to the saline group. There was no significant effect on weight in any treatment group, p > .05. Histological analyses are forthcoming, but we hypothesize that there will be no significant toxicological difference between treatment groups. For future directions, we hope to conduct a study looking into behavioral differences in chronic stress induced rodent models from the same administration of treatments

Abstract Name: **Pedagogical shift and parental mental health during the COVID-19 pandemic: Evidence from the United States**

The global COVID-19 pandemic has negatively affected the mental health of individuals around the country. As a part of social distancing measures, the pedagogical shift from in-person to online learning and class cancellation for primary and secondary schools has increased the stress and anxiety of parents during the pandemic. In this study, we aim to explore the effect of pedagogical shifts, including in-person to distance learning or class cancellation, on the mental health of parents with school-aged children in the United States. Our study utilizes a national dataset from the Household Pulse Survey collected by the Census Bureau from April 23, 2020, through December 21, 2020. After applying the data to the multivariate regression models, we found that pedagogical shifts significantly increased the severity of anxiety and depression symptoms and worsened parents' mental health. Notably, parents with children who had their classes canceled experienced significantly higher levels of anxiety and depression symptoms than those with children who switched to distance learning. These findings were first verified robustly using an alternative model - the ordered logit regression - by considering the anxiety and depression levels as discrete variables with ranking. We then checked our results by using alternative mental health measures for anxiety and depression disorders and estimated the effects of pedagogical shifts using the linear probability model. We further conducted a heterogeneous analysis by exploringpedagogical shiftingeffects by gender, race, working status, and political affiliation by the 2020 presidential elections. Our results reveal complex variations by different groups of parents affected by the pedagogical shift due to the Pandemic. These findings highlight an urgency for state, federal, and societal policy changes to address the growing mental health issues and disparities among parents with children during these challenging times in the United States.

Abstract Name: **Current Determinations of the Biochemical Mechanisms of the Amatoxin Alpha-Amanitin: A Literature Review**

Destroying angel mushrooms are the leading cause of macrofungi poisoning deaths across Eastern Europe and Asia. These mushrooms, scientifically known as Amanita Verna and Amanita Virosa, are incredibly deadly due to their high concentrations of the amatoxin α-amanitin which causes liver and kidney shutdown, oxidative stress, and necrosis. This paper is a reflection on ongoing research on α-amanitin to provide a comprehensive overview of current knowledge of this deadly chemical. Scientists have determined that α-amanitin inhibits transcription of RNA polymerase II but are still unsure of the exact mechanisms. Recent literature shows that these transcription issues may be partially caused by pyrophosphate release inhibition and by blocking bridge helix bending, but other discoveries, such as RNA pol II showing an ability to form multiple phosphodiester bonds without alpha-amanitin dissociating, show that these theories are not the full picture. Due to a lack of understanding of the true protection mechanisms of α-amanitin, there is no specificantidote for the toxin. Current treatment methods are relatively ineffective, focusing on symptom treatment and supportive therapy. New research into mechanisms of action of α-amanitin is beginning to provide insight into the root causes of α-amanitin-induced cytotoxicity, opening new opportunities for the development of tailored antidotes.

Abstract Name: **Detecting Bias in Intelligent Autonomous Hiring Systems**

This project analyzed if artificial intelligence (AI) hiring systems demonstrate prestige bias, and how that bias may be mitigated. We chose to look at prestige bias since the quality of a candidate's education will naturally be reflected in their skills and experience; a school's reputation should not additionally be factored into a hiring decision. Of note, this project analyzed prestige bias against Historically Black Colleges and Universities (HBCUs). The majority of students attending HBCUs are people of color who are already marginalized members of society. We examined how hiring site Indeed utilizes AI to list candidate resumes by relevance and measured the relationship between a candidate's resume ranking and the university they attended. We expect to find a negative association between HBCU status and ranking, which is stronger than the association between ranking and other confounding variables such as experience type, degree level, field of study, etc. Subsequently, we will develop our own AI system, utilizing hiring decision data that we collected from Indeed, to observe if it will present a similar bias. If so, then we will apply debiasing techniques to our model to create a new AI hiring system that is not biased against HBCU applicants. With businesses considering AI as a tool for hiring, companies must understand that AI hiring systems can perpetuate the same biases found in human hiring on a larger scale.

Abstract Name: **The Audiovisual Time-Flow Illusion's Implication On Speech Comprehension In Noise**

We (the Shahin Lab) recently introduced the Audiovisual Time-Flow Illusion (ATFI). The ATFI is a novel phenomenon in audiovisual speech perception whereby an illusory "pausing/slowing down" or "skipping/speeding up" is perceived in the visual modality when temporally intact visual speech is merged with auditory speech containing skipping or pausing. The reverse stimulus manipulation does not induce "pausing/slowing down" or "skipping/speeding up" in the auditory modality. Thus, the ATFI signifies the auditory modality's role in setting the pace of the visual modality, whereby visual perception of incoming speech, skips and pauses to keep pace with temporal changes in the auditory discourse. In natural speech, mouth movements typically precede sound production, suggesting that the visual modality has a predictive role in unfolding speech signals. The ATFI suggests that the visual modality realigns its pace to that of the auditory modality to maintain its predictive impact on audiovisual speech processing. In the present study, we are investigating the relationship between ATFI perception and comprehension of speech in noise.In one condition, participants will be presented ATFI stimuli in which auditory speech containing pausing or skipping are merged with temporally unaltered visual speech. In the second condition, the same participants will be presented with audiovisual speech samples (sentences of varying lengths) merged with white noise. The stimuli and condition order will be randomized for counterbalance.Due to the visual modality's predictive quality in natural speech, we hypothesize that individuals who perceive the ATFI more strongly will have stronger predictive impact and, as a result, will be better at comprehending speech in noisy environments.

Abstract Name: **Computational Investigation of Triplet Excited States of Alpha-pyrone**

Electronic excited states are key intermediates in photochemical reactionmechanisms. An excited state is formed via the promotion of an electron from a ground-state molecular orbital to a molecular orbital of higher energy. In this study, we are investigating the excited triplet states of the α-pyrone molecule. The excited triplet state describes a molecular species in which an electron has undergone a spin flip in addition to orbital promotion. In the field of quantum chemistry, popular density-functional theory (DFT) methods can calculate the ground-state molecular properties accurately; however, DFT methods have limited success for molecular excited states. Density-functional based calculations are reputedly worse at calculating molecular excited-state energies compared to more rigorous wave-function based methods. In this work, we propose an enhancement to the DFT-based Grimme method [Grimme, S.; Izgorodina, E. Chem. Phys. 2004, 305, 223.] for the calculation of triplet excitation energies. Our approach retains DFT for calculating the triplet-state geometry but involves a highly reliable wavefunction-based method for calculating the energy of the excited state. We have tested our “enhanced Grimme method” on a well known control system, 2-cyclohexenone and find that the predicted and experimental excitation energies differ by less than 5% of the experimental value. Using the enhanced Grimme method, we have investigated the structural and energetic properties of the T1(n,π*) and T1(π,π*) states of α-pyrone. Our calculations onα-pyrone yield unexpected results that depart significantly from experimentally known features of the γ-pyrone isomer.

Abstract Name: **Do Prisoners Need Ethics or Does Ethics Need Prisoners?: Ethics Education in Prison Combats Epistemic Injustice**

Prisoners are harmed in their capacity as epistemic agents. That is, they are discounted and marginalized as knowers, reasoners, and questioners. I argue, they are particularly harmed as epistemic agents of ethics due to their criminal background and assumed lack of moral and ethical integrity. This status removes them from activities such as ethical debate, reflection, and dialogue, which would aid in rehabilitation: steadying themoralmind, developing moral integrity,forming an ethical identity and a personal moral history and ultimately reconciliation with society. Beginning with a workshop around the text Ethics fo rEveryone(Churchill, 2020), my mentors and I have developed a flexible ethics-based curriculum into the context of a prison volunteer program. The ethics activities are facilitated by students and faculty,which increases trust and dialogue between the prisoners and the wider campus community. Volunteer programs led by students and faculty break down prejudice through exposure and allow prisoners to reach a degree of credibility that would have existed if not for the prejudice. Educational opportunities are limited and often restricted to those serving long-term or life sentences and volunteer programs bridge the educational gap in prisons. This kind of program also allows for the knowledge exchange that would typically be lacking from one institution to another. I argue that prisoners’ participation in ethics based activities will not only work to combat epistemic injustice (Fricker, 2007), but until we include the excluded, we will only scratch the surface of many ethical issues and considerations.

Abstract Name: **University of Wisconsin-Superior Writing Center: Collaboratively Creating an Equity, Diversity, and Inclusion Statement**

In this presentation, we will be discussing the content and process of creating an Equity, Diversity, and Inclusion (EDI) statement. We specifically worked on an EDI statement for the University of Wisconsin-Superior Writing Center. We, as Writing Center staff, felt it was important to have our own EDI statement in addition to our University's general statement. We wanted to make it specific to what we do: meet students where they are in their writing journey and give them the tools to expand their writing skills. With our EDI statement, we wanted to emphasize that the Writing Center is a place of learning for everyone regardless of their race, ethnicity, sexuality, cognitive ability, etc. In addition, we wanted to emphasize that we, as writing consultants, are committed to having a growth mindset. After the idea was pitched in a staff meeting, we analyzed Inclusivity/Anti-Racism statements from four organizations outside the University. We then identified ideas we felt were important before combining them into three themes relevant to the Writing Center: linguistic freedom, anti-racism and inclusivity, and safe spaces. With these themes in mind, we drafted a statement and got feedback from other campus organizations. After several revisions, the final EDI statement was published on the UW-Superior website. One major benefit of collaboratively creating our EDI Statement is that it helps us to reflect and prioritize our shared goals and values—plus, it communicates our values and priorities to the entire campus. Our EDI Statement encourages diverse voices and welcomes people of all identities, including those based on neurodiversity, which echoes our mission statement.

Abstract Name: **Mapping Functional Performance Degradation in mdx5CV Mouse Model**

Introduction: Duchenne muscular dystrophy (DMD) is a fatal X-linked recessive disorder resulting in progressive muscle degeneration and weakness. The mdx5CV mouse model of DMD is a more severe mouse than the more commonly used 10ScSn-Dmdmdx/J (mdx) model of DMD. This is an important because the classical mdx mouse model is mildly affected. However, the in vivo grip motor function performance of the mdx5CV is not known at disease specific timepoints. Thus, we proposed to measure grip strength function of the mdx5CV at advancing stages of disease progression.Methods: The grip strength test measures the force which mice pull on a force transducer. We measured maximum grip strength in control mice to assess performance characteristics at 1, 2, 3, and 6 months of mice age.Results: The preliminary experiments demonstrate maximum grip strength mean of 5.54±0.6 g force/g weight in a 17-week-old control cohort.Interpretation: This study quantifies the grip strength performance in a control cohort which will then be used for comparison in mdx5CV mouse model. Specific grip strength mean and variability were comparable to previously reported data in control mice.Conclusion: Through data collected through the grip strength assay, we can measure the physical capabilities of mdx5CV mouse model over time. This data will be pivotal in understanding temporal evolution of weakness in mdx5CV model forming a basis for assessing pre-clinical interventions on in vivo motor function.

Abstract Name: **Unconscious Bias or Trainable Attitudes? Training Implicit Biases That May Be Detected in the Implicit Association Test**

Implicit Association Tests (IAT) are intended to measure beliefs that people are unable to admit (Project Implicit).Architects of the IAT acknowledge that results are only weakly correlated with measurable behaviors.The purpose of the current research was to determine whether a neutral implicit association could be trained into participants and subsequently be detected on an IAT. Participants were trained to associate negative words with angular shapes, and positive words with rounded shapes. Training sessions presented angular or rounded shapes, followed bypositive or negative words. Participants had to press “correct” or “incorrect” buttons depending on the shape and word association shown. After completing all training sessions, participants were given an IAT to determine whether they showed an implicit preference for rounded shapes. The IAT was created using the experimental design utilized by the IAT Website according to the methodological designs provided by the authors (Project Implicit) and replication studies (Jain et al, 2022). Data collection is currently ongoing. During the training session, trainees’ reaction times were tracked to measure the strength of the associations being developed between shapes and positive and negative stimuli. After completing the IAT, trainees’ scores on the rounded/angular shape IAT will be analyzed using the standard chi-squared analyses to identify the presence and strength of implicit associations. Additionally, using a X2 test of independence, trainees’ IAT scores will be compared to scores of untrained participants who complete the same IAT. If results indicate that trainees exhibit implicit associations between rounded shapes/positive words, and angular shapes/negative words, and do so to a greater extent than control participants, this will suggest that implicit associations detectable by IATs can be formed quickly, and with relatively few exposures to previously nonexistent associations. These findings hold implications for understanding implicit associations and contribute to conversations on developing bias awareness training.

Abstract Name: **Discrepancies Between Cleaning Procedures in Medical Settings Regarding Clostridioides difficile Prevention**

Clostridioides difficile (C.diff), a common healthcare-associated infection (HAI), is a gram positive bacteria that causes life-threatening diarrhea (12,800 deaths in the US in 2017) especially in immunocompromised individuals. Patients who receive extensive broad-spectrum antibiotic treatment develop this infection and it is highly contagious in clinical environments. Despite it being primarily spread through exposure in medical settings, there are no standardized procedures between facilites on sanitizing surfaces after coming into contact with a patient who is positive for C.diff. The goal of this research is to compare cleaning procedures and determine which is most effective at killing C.diff on surfaces as it survives common disinfection due to sporulation. Surveys will be sent to various medical facilities nationwide inquiring about patient history, cleaning techniques, and follow up testing to see if the C.diff spores were eradicated. Following their responses, each procedure will be evaluated on its efficacy to eliminate spores based on CDC guidelines. After the research is performed, it will be evident by the variation of C.diff isolates between regimens that some policies are superior to others and there should be standardization between healthcare facilitesto better prevent the spread of severe HAIs.

Abstract Name: **Analysis of Sedimentary Phosphorus in Rice Lake, Whitewater WI**

As a result of anthropogenic inputs and use, lakes are experiencing increased eutrophication. This accumulation has led to increased algae blooms which can be detrimental to the aquatic ecosystem. Rice Lake, just south of Whitewater WI, faces increased aquatic plant growth and harmful algal blooms. Currently, there is a lack of understanding on potential internal loading of nutrients into the basin and how those nutrients persist in the system. Thus, the aim of this study was to determine the total phosphorus (TP) and total organic carbon (TOC) sediment load across the lake at the sediment surface and at depth. Sediment cores were collected at 30 locations distributed throughout the lake. TOC was determined via loss upon ignition while TP was extracted from dried sediment samples using HNO3 and H2O2 and subsequently analyzed using ICP-OES. In the top 0 –7.3cm level of sediment, the average TP load was found to be 834.871(+/- 37.526) mg/kg while TOC was 541.671(+/- 4.558) g/kg. In the 7.3 –14.6cm layer, TP 837.549 (+/- 27.95) mg/kg and TOC 621.779 (+/- 5.455) g/kg. The bottom 14.6 – 21.9cm level had a TP load of 826.853 (+/- 39.096) mg/kg, and TOC 632.021 (+/- 4.588) g/kg. No significant stratification or sediment horizons were found between the layers of sediment. This coinciding with the similar TP and TOC levels at all depths suggests that the lake sediment is organically derived and most likely a significant source of labile Phosphorus.

Abstract Name: **Modeling a Bifacial Solar Panel for Characterization and Performance Evaluation**

Bifacial solar panels are gaining attention due to their superior performance that comes from their ability to generate additional output power (5-10%) by absorbing the solar irradiance from the back surface. Bifacial PV modules still need to be characterized for their overall performance. To evaluate the performance of the bifacial PV modules, attempts are underway at San Jose State University to develop a solar model along with a thermal analysis model that will be then validated by our experimental data. In the current presentation, a thermal analysis model developed for a bifacial PV model is included. For this purpose, a JJN Solar Panel 200 W bifacial PV panel was selected. Basic measurements include the short circuit current and open circuit voltages at various operating conditions. The thermal analysis model includes the basic structure of the panel by considering various layers of the PV module e.g., front surface with antireflection (AR) coating, followed by an emitter layer (P+ Si) and N type wafer that is followed by aluminum back surface layer with AR coating. Thermal conductivities and respective thicknesses of all layers were used to complete the thermal resistance model that was then used to find panel's surface temperatures by keeping a constant flux condition on both the front and back surfaces. Depending on the incident flux, surface temperatures were found varying from 50 to 60 C at the front side as compared to 35 – 30 degrees on the back side of the PV model. For he electrical modeling, five parameters equivalent circuit model proposed by MA et. al. [2019] was employed. Skockley diode equation was modified for the PV panel and IV characteristics were plotted by obtaining the data from the experiment. Final poster will include the details on our experiments and the associated results.

Abstract Name: **How People Assign Causal Blame: Prototypical Rules vs. 'Phantom Rules'?**

My project focuses on recognizing how people assign causal responsibility for punishments that happen because of rules that are rarely enforced vs. those that are frequently enforced. Rules are supposed to hold everyone together in a community. However, many rules are frequently broken without consequence, e.g. jaywalking and downloading illegal music, which fit into a certain category: “phantom rules.” On the other hand, prototypical rules exist which involve rules that are non-negotiable and often result in punishment when broken, e.g. not wearing a seatbelt when driving or not stopping at a stop sign.Prototypical rules are associated with the expectation of punishment which causes people to fear breaking it or they expect to get caught. ‘Phantom rules’ become a special case where people believe the action is not wrong, although it is illegal. So, when a ‘phantom rule’ is enforced, the blame goes to the enforcer such as a large company instead of the person who breaks the rule, and the enforcer is seen as more causally responsible. This is a different reaction from prototypical rules, where rules are constantly enforced, and punishment is given.My research aims to analyze how people judge causal responsibility and assign blame and punishment when certain rules are broken compared to others. I plan on using data collected from scenario-based assessments where participants would be given out of the two versions created; each version would be the same except one would have a rule being enforced with punishment while the other would not, that rule is rarely enforced. This would be followed up by asking the participant to scale different factors, blame, wrongness, etc. Some of the variables I plan on examining are age, gender, and political ideology. This research will help identify how people feel about codified rules and the law.

Abstract Name: **Cognitive Mapping: An Examination of the Mercator Effect Hypothesis**

In his theory of the “Mercator Effect”, Arno Peters claimed that because the Mercator Map Projection, one of the most commonly used map projections world-wide,distorts the northern hemisphere to appear larger than it is and the southern hemisphere smaller, people most familiar with this map projection will have their cognitive maps, i.e., their mental image of the world, distorted to assume that the northern landmasses are much bigger than in reality. Peters named this cognitive distortion the “Mercator Effect”, explaining that the Mercator Effect contributes to the already prominent first-world centricity and unjust white supremacy of written history and understanding of the present. However,as research cited in this paper regarding the creation of maps explains, it is impossible to depict a spherical object as a two-dimensional image without some level of distortion, and it is up to the cartographer to decide which distortion is necessary to accomplish their map’s intended purpose. Furthermore, as displayed by 2020 studies "The Influence of Map Projections on People’s Global-Scale Cognitive Map: A Worldwide Study" and “The Influence of Web Maps and Education on Adolescents’ Global-Scale Cognitive Map”, it is not just the Mercator’s specific distortions that create cognitive distortions, but all maps that contribute to our view of the world. Therefore, this paper argues that the specific theory of the “Mercator Effect” fails to acknowledge the fact that it is not solely the Mercator Projection that creates inaccurate mental images of the world, but all projections. Specifically, I contend that there is little evidence in support of the “Mercator Effect” in the sense that it was originally proposed. Rather, all types of map projections come with a level of bias that distorts our perspectives of how we view the world.

Abstract Name: **On the Kinematics of Sneezing Droplets (Experimental Design and Implementation)**

The key to the mitigation of the spread of coronavirus disease such as COVID-19 is to understand how microbial pathogens travel once they leavethe source. Tracking the trajectories of viral particles as asymptomatic carriers sneeze, cough, and even speak would provide a very good picture of what measures to take to curb disease transmission.Under this CURE project, students of Physics 251 and Physics 271employed two-dimensional kinematic equations to investigate the trajectories of the particles leaving a simulated infected person.The novelty of this study is that we base our investigation on a single-particle approach where we follow trajectory of single particle instead of bulk movement of fluids. Using the height of the asymptomatic carriers as a controlling parameter, we assess the extent of infective range for a variety of solutions. It is worth mentioning that both groups of students, of 251 and 271, used their own recipes and method of data collection distinct from each another. As an extension of the simulation of the trajectories, 271 students used the collected data to produce computer-simulated visualizations of the individual trajectories using statistical mode approach.

Abstract Name: **La Bella Vita: Rediscovering Community in a Post Pandemic World**

Following the 2020 COVID-19 pandemic, many students continue to struggle with engagement outside of online activity and the classroom, returning to pandemic comfort zones. In a smaller university community, such as Jacksonville University, and across a variety of majors, students self-selected to participate in a five-week study abroad program during the summer of 2022 on location in Southern Italy. The purpose of this video project is to creatively share undergraduate student stories about how participation in the Communication, Culture, and Amalfi Coast program reignited student participation through engaged learning, while fostering a sense of community among the group. This creative work explores student understandings of the influence of social components on individual learning and the effect these social learning communities have on student health and well-being. Through qualitative video interviews with the Jacksonville University study abroad participants, students share their cultural experiences, discuss observations, and explainthe personal growth that took place because of this program. Presented over a series of videos stories, this project is a compilation of student narratives focused on growth through personal experience and global understanding. This project was produced on the campus of Jacksonville University and on location in Southern Italy. Featuring in-depth interviews, digital content creation, and personal artifacts from the study abroad program, the participants explain how the experience changed their understanding and helped them reconnect to a vibrant engaged learning community. This project includes on-camera interviews and video content produced as part of an advanced communication course.

Abstract Name: **E-Cigarette Use Patterns among Young Adults between Rural and Urban Areas Over Time**

Young adults (YAs, 18-24 years) use Electronic Nicotine Delivery Systems (ENDS; e.g., e-cigarettes) the most compared to other age groups. ENDS is the most consumed tobacco products among this population. Rural areas have been disproportionately affected by tobacco-related health disparities than urban areas. However, there is a gap in knowledge about the differences in ENDS use patterns among YAs between rural and urban areas. This study aimed to (1) document ENDS use patterns among YAs and (2) compare ENDS use patterns among YAs across rural and urban areas over time. This secondary analysis used data from the Behavioral Risk Factor Surveillance System (BRFSS). The BRFSS is a state-based telephone health behavior survey of U.S. adults. We estimated ENDS use trends over time using weight of the parent data set. To meet study parameters, the 2016 N=1237102), 2017 (N=1477726), 2018 (N=1636823) and 2020 (N=658286) data sets accomplished aim 1 and the 2018 (N=15174) and 2020 (N=15612) data sets accomplished aim 2. Rates of YAs who currently use ENDS, exclusively use ENDS, and who never smoked but now exclusively use ENDS steadily increased from 2016 through 2020. Between 2018 and 2020, the prevalence of current ENDS use among urban YAs remained constant at 11.0%, but its prevalence among rural YAs increased from 13.3% to 15.9%. The prevalence of exclusive ENDS use among urban YAs increased from 7.5% to 7.8%. However, its prevalence among rural YAs exhibited a greater increase from 8.6% to 12.6%. Similarly, while the prevalence of urban YAs reporting exclusive ENDS use increased from 5.7% to 5.9%, its prevalence among rural YAs exhibited a greater increase from 6.7% to 9.9%. The prevalence of YA ENDS use has increased across the nation, particularly in rural areas. There is a critical public health need for rural-, ENDS-specific cessation treatments for this population.

Abstract Name: **Effects of Aromatic Prenal Chromene Oxime Derivatives on A375 Cancer Cells**

New anticancer drugs are in demand due to the undesirable side effects of preexisting drugs and the tendency of cancer cells to become resistant to highly effective treatments. Oximes are highly selective kinase inhibitors, which makes them ideal for drug design. Six aromatic prenal chromene oxime derivatives were synthesized and examined for apoptosis induction when tested on A375 human melanoma cells. The compounds were compared to etoposide and dimethyl sulfoxide as positive and negative controls for their ability to induce apoptosis. A375 cells were cultured in DMEM supplemented with 10% FBS and passaged onto glass coverslips in 6 well plates. 50 micromolar concentrations of each derivative were added to two milliliters of cells in supplemented DMEM. After 24 hours in culture in the presence of the derivative, DAPI and Caspase stain were added to each well. After 1 hour of staining, live cells were imaged and then fixed with 4% formaldehyde for 15 minutes. To determine the percentage of cells undergoing apoptosis, cover slips were viewed under a fluorescent microscope. Cells that appeared green were scored as undergoing apoptosis, while the cells that appeared blue allowed us to identify the total number of cells. We calculated the percentage of cells undergoing apoptosis after exposure to each derivative. All 6 derivatives increased the number of apoptotic cells, relative to the DMSO control. The compounds M-Prenal oxime, oxime benzoate, and oxime cinnamate seem to have the strongest effects, although none of them were as effective as an identical concentration of etoposide. We are working to improve the consistency of results and to determine the concentration dependence of each derivative. Our initial results suggest that chromene oxime derivatives have potential as anti-cancer drugs and can induce apoptosis in a human cancer cell line.

Abstract Name: **Patient Satisfaction for Suicide Care in the Emergency Department**

Self-inflicted injuries continue to be major public health concerns in the United States with 312,000 related emergency department visits in 2018 (CDC, 2022). Patients with self-inflicted injuries often report to the emergency department to seek help, where staff must accurately assess the patient's lethality and manage their care. Admittedpatients for self-inflicted injuries present variation insatisfaction across departments. Satisfactionis commonly rated lower in the emergency department compared to other units where they may have received care. (Hutchison, Brian et al., 2003). Patients who receive poor care during this time are not only more likely to report lower satisfaction but also may leave with an increased level of risk.The purpose of this study is to compare responses on the Hospital Consumer Assessment of Healthcare Providers and Systems (HCAHPS) of patients visiting the emergency department with self-inflicted injuries to patients visiting the emergency department without self-inflicted injuries. Permission to access the deidentified data from patients presenting to a local hospital emergency department between January 2021-December 2022 has been granted and we are awaiting the data. Continuous satisfaction variables will be analyzed using independent sample t-tests and Chi-Square analyses for Categorical Data. We expect patients who visit the emergency department with self-inflicted injuries to report less satisfaction on the HCAHPS than patients who visit the emergency department with other injuries. Implications of the results will be presented and shared with the selected hospital emergency department to guide care quality improvements.

Abstract Name: **Variability in Deer Mouse Diet With Habitat Type and the Implications for Future Food Utilization Influenced by Climate Change**

Climate change is projected to shift the range of biomes and subsequently the distribution of food resources within. Consumers are then faced with the challenge of following their primary food resources, utilizing different food resources, or face reduced survivorship. Deer mice (Peromyscus maniculatus) have a broad distribution across North America that includes multiple habitat types and boast a generalist diet that I predict will vary with food resource availability. I measured the cusp shapes and depth of valleys in the three molars ofPeromyscus maniculatusto determine if diet varies with habitat type. The results from this study will help project the effects of climate change on consumer diet ecology, which will be useful information for conservation efforts, land managers, and policymakers.

Abstract Name: **WEPPR - An R package for the Water Erosion prediction project (WEPP)**

Soil loss in Iowa is estimated to lose the state $1 billion annually. The water erosion prediction project (WEPP) helps alleviate this issue by estimating soil loss due to water erosion allowing us to implement solutions to counter these effects, ultimately saving money. WEPP is the engine behind the daily erosion project (DEP, dailyerosion.org) which provides daily estimates of soil loss in Iowa, some surrounding regions, and watersheds. Unfortunately running WEPP for all of Iowa takes approximately 6 hours every day as the software takes all the historical data it has on the soil and land data in Iowa and produces a prediction for the current day. We would like to speed up this process by building a Gaussian Process model to emulate WEPP. In order to facilitate this emulation, we are constructing an R package, WEPPR, where users can upload WEPP files to WEPPR and obtain WEPP estimates instantly. This requires the construction of R functions that read in WEPP input files, transform those files to an appropriate format, and visualize results. With the construction of WEPPR and a Gaussian Process model, we will be able to expand DEP from Iowa to the United States and, possibly, worldwide.

Abstract Name: **Kinetic Analysis of the Effect of Crowding on Silver Nanoparticle Surface Bound N-hydroxysuccinimide Ester Reactions with Imidazole**

The attachment of proteins as recognition systems is important for both the function and the design of most biosensors. However, crowding at the surface can often affect surface reactions such as these. An understanding of how surface crowding affects the speed and extent of reactions commonly used to tether proteins to a surface is thus important. The kinetics of the reaction between solution-phase imidazole and a surface bound N-hydroxysuccinimide ester of 4-mercaptobenzoic acid have been investigated using surface-enhanced Raman scattering. The rate constant and extent of reaction were monitored as a function of the ratio of 4-mercaptobenzoic acid to benzenethiol, the latter of which acted as an inert spacer on the surface. Reactions on surfaces with increasing mole ratios of benzenethiol were found to go further to completion with approximately the same magnitude of the second order rate constant which was found to be 0.005 mM-1s-1.

Abstract Name: **The Determinants of Income Inequality in Rural Wisconsin and Policy Implications**

Rural communities in Wisconsin are currently facing many economic challenges, namely high levels of poverty, declining population, lack of high-quality services, and poor infrastructure. These are issues that call for innovative and creative approaches and require prompt attention. This project is a collaboration of three faculty members at the Department of Economics at our institution. Our project has three main goals. First, we propose to measure regional, particularly rural, income disparities while identifying the main explanatory factors with American Community Survey data and quantile regression analysis. Second, we will examine and quantify the impact of entrepreneurship, growth of immigrant populations and access to broadband on rural incomes in Wisconsin. Third, we will offer insights and recommendations to Wisconsin policy makers. Our research findings will help assess economic needs and resources and provide policy options to address challenges facing rural communities.

Abstract Name: **Fostering Creative Inquiry on the Two-Year Campuses: A Discussion at the Confluence of Humanities, Sciences, and Academic Support**

As undergraduate research is a high-impact pedagogical practice, offering our students opportunities for meaningful and creative inquiry and guiding them as they undertake that inquiry is especially important on the two-year campus. Some of our students will graduate with an associate degree, meaning that this is the only chance they will have to do this work. Others will transition to four-year institutions, where they will need to be prepared for higher-level research when they arrive. At the same time, two-year colleges present unique challenges in supporting undergraduate research and embedding it into the curriculum. This panel will share some of the challenges faced by students, faculty, and staff in our two-year colleges from three perspectives—the sciences, the humanities, and academic support—then guide a discussion about strategies for meeting those challenges to enrich undergraduate research and creative inquiry. By bringing together these perspectives, we will examine undergraduate research on the two-year campuses at the confluence of the humanities, the sciences, and academic support with the goal of fostering creative inquiry and preparing our students to succeed in the next stage of their intellectual growth.

Abstract Name: **Quantifying the Effects of Tissue Biomechanical Properties Using Fluid-Structure Interaction Analysis**

Developing computational models and predictive frameworks for biomedical systems is crucial to advancing research on pathological conditions, considering that certain in vivo studies are particularly challenging due to invasive procedures, and in some cases, improper diagnostic and treatment tools. One type of computational mode of analysis is known as a fluid-structure interaction (FSI) which is the Multiphysics interaction of a fluid flow with a deformable structure. In FSI both fluid and mechanical properties of the tissue are important factors and contribute significantly to the model predictions. Young's modulus and Poisson's ratio are two essential mechanical properties that are necessary to describe the elastic behavior of the tissue, however,wide range of elastic modulus values have been reported in the literature. This study aims to provide a better understanding of biomechanical properties that can be used to build computational simulations. We investigate the influence of tissue elasticity on the structural and fluid dynamic response of models, with application to human cardiovascular and phonation systems. Specifically, the interaction between turbulent glottal airflow in the larynx and vibrating vocal fold during phonation is simulated using a fully coupled FSI approach. We have also explored the interaction between the blood flow and arterial wall deformation in patient-specific abdominal aortic aneurysm models.The fluid flow is described by the unsteady, viscous, incompressible Navier–Stokes equation, and the dynamics of tissue is modeled by the Navier equation. Tissue is considered as a transversely isotropic material for which the stiffness parameters include the transverse elastic modulus and longitudinal elastic modulus. Parametric simulations are performed by systematically varying the transverse and longitudinal stiffness parameters. Important model predictions including flow rate, fluid pressure, maximum tissue displacement and spatiotemporal stress metrics, as well as the effect of the stiffness parameters on these output parameters are analyzed.

Abstract Name: **Circadian oscillator proteins xBMAL1 and xPERIOD1 affect the metabolic shift during mesoderm differentiation Xenopus laevis animal cap ectoderm**

Most cells in adult animals keep time over a 24-hour period. This is known as circadian rhythm. Two important circadian genes associated with circadian rhythm are Bmal1 and Period1. BMAL1 is a transcriptional activator and PERIOD1 is a transcriptional repressor. Together, they are part of a negative transcriptional feedback loop that times approximately 24 hours. We hypothesize that in late blastula stage embryonic cells, xBMAL1 and xPERIOD1 coordinate inducing signals (activin) with changes in metabolism (REDOX state) associated with specification of dorsal mesoderm. To test this hypothesis, we injected xBmal1 or xPeriod1 guide RNA and CAS9 protein into single-cell Xenopus laevis embryos. Later, we isolated the roof of late blastula stage Xenopus laevis embryos (animal cap). The isolated animal caps were then treated with 50ng/ml activin to induce dorsal mesoderm. The change in REDOX state is detectable using Promega's REAL TIME GLO MT Viability Assay. When comparing untreated animal caps, xBmal1 KO animal caps had a higher reducing potential compared to control. Conversely, untreated xPeriod1 animal caps had a lower reducing potential compared to control. Activin treated xBmal1 KO animal caps were metabolically similar to activin treated control animal caps. xPeriod1 KO animal caps treated with activin had a lower reducing potential when compared to activin treated control animal caps. xBmal1 KO animal caps experienced a large decrease in REDOX state with activin treatment. Surprisingly, when comparing untreated and activin treated xPeriod1 KO animal caps we observed no difference in REDOX state. This result may indicate that repression of xPeriod1 expression may be involved in regulating the metabolic shift in the response to mesoderm induction. Therefore, we conclude that Bmal1 and Period1 play a role in the metabolic response to mesoderm induction.

Abstract Name: **Effects of implementing a mandatory and consequential annual fitness assessment in a large county fire department: a case study**

Current evidence indicates firefighters may not possess adequate fitness levels to effectively perform their duties.The purpose of the study was to examine the effects of implementing a consequential fitness assessment within a fire department. Retrospective data regarding 1364 professional firefighters was examined (88% male, age:40.0±8.8yrs, years of service: 11.9±6.8 yrs) from 2019-2021. The data included a fitness assessment of maximum pull-ups (PL), maximum curl-ups (CU), maximum push-ups (PS), and aerobic capacity, which was measured through the application of a 3-minute step test (3MST). Analyses were conducted to compare the effect of exam year, age, and sex on the fitness components measured.There was a significant small effect of exam year on PL($F(2, 2848)=5.92$, 0.01,$\eta2=0.003$), CU ($F(2, 2848)=17.57$, 0.001,$\eta2=0.01$) PS ($F(2, 2848)=18.50$, 0.001,$\eta2=0.01$) and aerobic capacity ($F(2, 2848)=26.19$, 0.001,$\eta2=0.02$). Post-hoc testing revealed that generally departmental performance onfitness assessments improved over the 3-year period. Older firefighters had significantly worse on performance on all measures of fitness except for aerobic capacity (p=0.185). Males outperformed females on all fitness assessments except CU (p=0.288).The results suggest the implementation of a consequential fitness assessment may be a plausible method for fire departments to support the fitness of firefighters. Since age and sex differences were observed, fire departments should consider these factors when interpreting fitness assessment scores and exercise training interventions. Although there was a significant difference between fitness measures by exam year, it's not evident whether the fitness changes lead to increased performance of occupational tasks as this was not measured in the study. Future research should explore whether changes in fitness lead to meaningful improvements in firefighting in terms of the ability to perform occupational tasks, timeliness, injury rates, and overall effectiveness.

Abstract Name: **Magnetic moment of deuteron quark-gluon plasma**

A deuteron is a proton fused with a neutron. Recent deuteron quark-gluon plasma experiments indicate an hourglass structure. This project proposes that the quarks decouple from the Higgs field in a deuteron quark-gluon plasma. The massless charge is then assumed to form two interacting oppositely-charged surfaces. The positively charged surface is an hourglass shell. The negatively charged surface is a torus shell wrapped around the hourglass neck. The structure's stability is assumed to be provided by electrostatic attraction balanced by magnetic repulsion. This implies that the strong interaction transforms into electromagnetic interactions. This proposed deuteron model is an extension of a recently published proton model based on the circular Unruh effect, zitterbewegung effect, quantum electrodynamics, classical electromagnetism, and quantum chromodynamics. A magnetic moment, equaling that of a proton is assumed to be generated by each of the hourglass lobes. The neutron's magnetic moment is supposed to dissociate into two pieces. These are one hourglass lobe and the negatively charged torus. It will be shown that a small misalignment of the hourglass relative to the torus can explain the deuteron's magnetic moment. The amount of misalignment can be directly related to the deuteron's mass-energy distribution. This project involves algebra and calculus that can be understood by undergraduate physics students. The long-term goal is to apply this method to modeling larger nuclear structures.

Abstract Name: **Isolation, Characterization, and Host Range of Novel Microbacterium foliorum Bacteriophages**

Abstract Bacteriophages are viruses that thrive by infecting bacteria, using the host to replicate, and ultimately killing the host. Bacteriophages are essential viruses, and they can be found in different ecosystems and living organisms. Studies on bacteriophages have shown that these organisms have the potential to treat antibiotic-resistant bacteria, given their ability to infect and disrupt a variety of bacterial cells.3 Phage therapy has been a subject of interest in the medical field since the end of WW2, and clinical trials are being conducted to further understand the phage's antibacterial properties. This research focused on bacteriophage isolation, identification, and a host-range test. DNA extraction and sequencing were performed on three out of five phages, and transmission electron microscopy was also performed to identify the family type to which all five phages belonged. Since the phages were collected from different places, upon their successful isolation and purification, their lysates were diluted to the same titers for the host range test to reveal each phage's potential to infect different Microbacterium species, Staphylococcus epidermidis, and Escherichia coli. We found that the five phages have differing host ranges; some also infect S. epidermidis. Genome annotation of the phages Cedar Bank, Extercus, and Guetzie will reveal further information on why each phage has its unique host behavior toward different Microbacterium. Furthermore, genome annotation will also be used to analyze the spike protein, which allows the phages to adsorb to their host species. The genomes of the Microbacterium species will also be compared to elucidate what makes some species more susceptible to different phages, in this case, the Cedar Bank, Extercus, and Guetzie. Further testing is still needed to determine the isolated phages' potential uses.

Abstract Name: **Amyloid-Beta (A?) Plaque Deposition in the Human Eye for Alzheimer's Disease (AD) Diagnosis**

The aggregation and deposition of the Amyloid Beta peptide (Aβ) plaques are a hallmark of Alzheimer's disease (AD). Aβ is detectable through polarized light microscopy in the eye's retina, however, it is a problematic imaging target due to its posterior position in the eye. Recent studies have shown Aβ microaggregates deposit in the eye's lens, a more accessible imaging target, pre-symptomatically. There are two significant forms of Aβ: the 42-residue (Aβ42) and the 40-residue (Aβ40). The primary difference between Aβ42 and Aβ40 is the amino acid sequence which changes its secondary structure and aggregation mechanisms. This project focuses on collecting current literature data on Aβ's linear to reverse calculate the expected refractive index difference from various tissues. The data collected revealed the refractive index difference of amyloid beta deposits is roughly in the order of 1E-2, similar to a prior study involving collagen. As a result, when light passes the two materials there will be minimal scattering and refraction. The amyloid can be on a nanometer to micrometer scale similar to the dyes used to enhance its birefringence since the effects of amyloid by itself are difficult to detect. Through these calculations, it was possible to create a target of what emerging optics and nanophotonics technologies could overcome: the weak birefringence of Aβ deposits. The polarization properties and light-matter interactions of Aβ deposits can be implemented for quantitative, colorimetric, and non-invasive detection of Aβ plaques and ultimately assist in creating innovative diagnostic and prognostic modifications to existing ophthalmoscopes.

Abstract Name: **Development of Shiny Web Application of Multiple Testing Procedures Based on Covering Principle**

Statistical multiple-testing problems have arisen in a variety of research areas. In clinical trials, researchers want to study multiple objectives simultaneously. We proposed a novel covering principle to construct multiple testing procedures from the perspective of rejection regions in the sample space, which is different from the closed testing and the partitioning principles working in the parameter space. It has been proven that multiple testing procedures based on the covering principle strongly control the familywise error rate if the type I error is strongly controlled in each decomposed subfamily. Strong control of the familywise error rate for a multiple testing procedure is mandated by the US FDA in all confirmatory clinical trials. Computer simulation shows that our new method rejects more hypotheses on the primary endpoints in most scenarios compared to both the graphical and the gate-keeping approaches. This research project has developed several computer algorithms in R Studio to implement the covering principle in the construction of powerful multiple-testing procedures. Furthermore, a Shiny web application with a graphical user interface (GUI) has been developed. Equipped with our Shiny web app, any user can build the objective-tailored multiple testing procedure based on the covering principle by a smart phone or a tablet with a web browser without carrying out the mathematical calculation by hand or learning software languages. Therefore, the new method can be easily used in many other research areas when multiple comparisons are needed. For example, one can compare different demographic groups in terms of their attitudes toward the issues of interest in the social and behavioral sciences. In marketing research, one can compare a number of new advertisement methods with an existing one to decide whether one of the new methods is better than the existing one.

Abstract Name: **Modine Capacitive Liquid Level Sensor**

The purpose of this project is to create a capacitive liquid level sensor that will be equipped in automotives created by the Modine Manufacturing company. The Modine Manufacturing company would like to replace their current liquid level sensor with a new one that is more cost effective and has additional features. The current sensor costs Modine over eighty dollars per piece. The current sensor's only waterproofing is a sticker that must be removed to calibrate, and the sensor has no CAN communication. Modine would like our team to design a drop-in replacement for this sensor that has better waterproofing, CAN J1939 communication, and can be produced in house. The team is utilizing a pre-existing integrated circuit to save space, money, and time in the final design. Since the team will be implementing software calibration, we will be able to forgo openings for physical calibration and end with a far more water-resistant device. Much of our electronic design is complete and being followed closely by development in other areas of our project. The design of our power electronics is complete. Programming of the current IC, design of the sensor's internal PCB, and integration of CAN communication are all well under way. There are prototype devices being worked on and the group will soon be sending out Gerber files for final construction of our printed circuits.This device will be able to accurately measure and relay quantities of coolant inside automotive coolant tanks while remaining robust enough to resist liquid damage. It will be inexpensive to produce and feature up to date vehicle communication protocols.

Abstract Name: Distribution of an Anti-Leishmanial Miltefosine between Blood Plasma and Brain

Leishmaniasis is a parasitic disease caused by Leishmaniaspecies and transmitted by infected sandflies. Infection of human internal organs results in visceral leishmaniasis, which is almost always fatal if left untreated. Miltefosine (MTS) is an alkylphospholipid compound and the only approved oral anti-leishmaniasis drug. Studies showed that MTS had a slow absorption rate, long half-life, and high volume of distribution. These unusual pharmacokinetic (PK) properties necessitate better understanding of the distribution of MTS in different organs. This study describes the determination of tissue partition coefficient (Kp) value for MTS, which is an important PK parameter governing the tissue distribution of a drug at steady state. First, we employed an in-silico approach and estimated the Kp value using the Rodger and Rowland equation. To achieve this, the partition coefficient (logP) value of MTS was measured by the slow-stirring method. The procedure for logP determination was chosen with careful consideration of the critical micelle concentration and the surfactant nature of MTS. Next, we estimated the Kp value using the unbound fraction (fu) approach and performed in vitro rapid equilibrium dialysis to determine fu values using mouse plasma and brain tissue homogenates. Furthermore, we compared the Kp value of 5.20 obtained from in vitro method with the Kp value of 0.742 obtained using in vivo data. Results from in vitro methods showed at least 5-fold variation in comparison to the in vivo Kp value. This could be due to the pseudo steady-state achieved by a single dose in the in vivo study. Nonetheless, these estimated Kp values, either from in vitro or in vivo methods, will inform our physiologically-based pharmacokinetic (PBPK) model of MTS to predict tissue distribution and PK in general population, as well as special populations, e.g., diseased and pediatric.

Abstract Name: Under-ice light and nutrient limitation of attached primary producers and phytoplankton

Eutrophication is the natural process of lakes becoming richer in nutrients and organic matter over time. However, human activities on land increase the transport of nutrients into lakes, accelerating the rate of eutrophication. This phenomenon will also lead to massive algal blooms, especially Cyanobacteria harmful algal blooms. Cyanobacteria is a common primary producer in aquatic habitats. In eutrophic lakes, however, they produce toxins that are harmful to people, pets, and the aquatic food web, contributing to fish kills and the formation of anoxic dead zones. Eutrophication and algal blooms are causing water quality declines across the globe. Most studies focused on lake nutrient limitation patterns in the growing seasons, leaving the role of primary production under the ice in worsening water quality questionable. Recent research shows that phytoplankton, including cyanobacteria, still grow in the winter under ice-covered conditions. Ice also creates an additional habitat that primary producers grow on to increase access to light. Nutrients, specifically nitrogen, phosphorus, and silica, and light availability differ under the ice in ways that may favor taxa that are associated with poor water quality.This study focuses on measuring the growth of primary producers growing attached to the ice and in the water under different nutrient and light conditions in Lake Menomin. This is a hyper-eutrophic reservoir in centralwestern Wisconsin. The paper will identify which habitats support more primary production and what environmental factors are limiting phytoplankton growth under the ice. These insights are the first step towards determining if water quality management needs to consider the under-ice phenomenon.

Abstract Name: Fourier Transform Infrared (FTIR) Spectroscopic Analysis Human Tumor and Healthy Tissues

Fourier Transform Infrared (FTIR) spectroscopy is a method of seeing chemical changes on a molecular level.1 The use of FTIR Spectroscopic techniques for analyzing biological tissues has been rapidly expanding. In this work we focus on the 2.5-3.7 mm (2800 cm-1 to 4000 cm-1) spectral region where C—H (methyl), O—H (alcohol), and N—H (amide) exhibit absorption signatures. We show that absorption around 3-um is greater in tumor tissue compared to healthy tissue. The higher absorption in tumor tissue shows that we could selectively ablate tumors, for example, by lasers emitting radiation at 3-µm, enabling significantly less damage to healthy tissue and possibly faster recovery post laser surgery and improved patient outcomes. Applying multivariate data analysis techniques such as Fourier deconvolution or second derivative spectroscopy can help differentiate overlapping peaks.2 By continuing to build a spectral library of various human tissue samples will help in the development of a hand-held laser sensor for a surgical drill.

Abstract Name: Reading Between the Lines: Identifying TESS Exoplanet Candidates

The Transiting Exoplanet Survey Satellite (TESS) builds on the work of the Kepler Mission to discover new planets transiting nearby stars. Since its launch in 2018, TESS has identified over 200 exoplanets and a total of over 5000 exoplanet candidates. With the conclusion of the Prime Mission, TESS began its extended mission in 2020 with the goal of observing 20,000 selected targets at 2-minute cadence per sector; up to 1,000 targets at 20-second cadence per sector; and 10-minute full frame images. We sought to analyze these 10 minute full frame images for potential exoplanet candidates and now report the detection of 20 new objects of interest. These objects of interest were distilled by searching the light curves produced by the TESS Science Processing Operations Center pipeline for TESS Sectors 48 through 50, observations of the Northern hemisphere. In total, 9257 Threshold Crossing Events (TCEs), which are periodic exoplanet transit-like dips in the light curve, were found. Then, the program TESS-ExoClass was used to run diagnostic tests on the TCEs, resulting in a list of probable candidates to be manually vetted. The manual vetting process involved reviewing the results of the diagnostic tests performed by TESS-ExoClass, transit light curve modeling, a comparison against various catalogs to ensure that the targets had not already been identified, and reviewing other sectors in which the TCEs were detected by TESS-SPOC. Our compilation of 20 promising exoplanet candidates have been submitted to the Exoplanet Follow-up Observing Program as Community TESS Objects of Interest. The target pixels, light curves, and data validation reports are available on the Mikulski Archive for Space Telescopes (MAST) for community use.

Abstract Name: Blooming, Beautiful, Baroque

The Baroque period started around the 1600s and ended around the 1750s. This period consisted of lavish, ornamental, and decorative designs. The most prominent design that affected graphic design would be typography, engravings, and book production. Romain du Roi was the most influential typeface that was created for the French king Louis XIV. Baskerville, Fournier, and other typefaces were influenced by Romain du Roi. Copperplate engravings made a massive impact on book production as well. Most engravers would pronounce their hand skills by creating their own books with illustrations and text. Engravers took a lot of time perfecting the fine lines, details, and legibility. Book production also had multiple printers and engravers cooperate in making a book. Most of the books would have an essence of baroque characteristics. The connection between typography, engraver, and book production conveys the impact the baroque period had on graphic design.

Abstract Name: Developing A Community-Engaged Design Framework for Community Environmental Justice Efforts

Due to information accessibility and lack of technical resources, disenfranchised communities risk being spoken over by protective agencies in environmental justice (EJ) efforts. However, academics can use community-engaged research methods to understand the afflicted population's needs and vision for remediative action. In previous academic-community collaborations, methods emphasizing stakeholder participation have shown to encourage residents to think creatively about their needs and potential solutions by allowing participation in the design process. This study evaluates the benefits of allowing community members greater control in design decisions by collaborating with a community in Garland, Texas concerned with their neighborhood's history of industrial pollution and possibly-related epidemiological concerns. Over the course of the study, the research team developed a new design framework geared towards enabling citizen autonomy after short-term community-academic partnerships. This framework modified the traditional design thinking (DT) process by increasing the frequency of "choice points" which allow stakeholder feedback to alter the product during all stages of the design process. Ethnographic interviews were used to collect community perceptions as site conditions evolved. Then, insights derived using qualitative data methods were used to drive the design process. By the end of the study, use of the framework resulted in multiple product prototypes for community use and a positive relationship with the citizens involved in the EJ effort. Moreover, retrospective stakeholder feedback It is expected that applications of the design framework in other EJ sites and disciplines will contribute to continuing research efforts to establish ethical and equitable methodologies for community-engaged and community-based work.

Abstract Name: **The Effects of Pair Bonding and Monogamy on Gonadal Characteristics and Cauda Epididymal Sperm Count in Prairie Voles (Microtus ochrogaster)**

Prairie Voles are a social, monogamous species which have gained traction in the fields of neurobiology, neuroendocrinology, and psychology as a potential model species for studying human social behavior and associated biology, due to similarities in brain chemistry and social tendencies as well as the similarities between rodent and human physiology. Reproductive work in prairie voles is somewhat limited, with more emphasis placed on behavior than physiology. The female prairie vole estrus cycle is unique in that the females do not begin estrus cycling until exposed to a non-relative male. It is unknown if/how female exposure and pair bonding affect male sperm characteristics and/or production. Here we utilize male prairie voles as a study model for if/how pair bonding, potential sperm competition, and monogamy affect sperm production and characteristics. Prior to comparing sperm characteristics between these groups, we established an effective methodology for epididymal sperm extraction utilizing established techniques in other rodents, modern theriogenology concepts, and trial and error. This methodology displays statistical significance and consistency based on established reproductive parameters in mammals, and is thus appropriate to utilize for study group comparisons moving forward. We now turn our attention to the differences between unmated males, mated monogamous males, and males exposed to a variety of sperm competition. Preliminary data indicates a statistical difference in sperm characteristics between unmated males and mated monogamous males, but more data is needed to reach an objective conclusion. This study will contribute to a better understanding of the relationship between monogamy, sperm competition, and pair bonding and their effects on reproductive physiology.

Abstract Name: **Editing Rasd1 and Cdk1na in a Cell Culture System**

In sexual reproduction, both sexes require functional sexual organs to produce offspring. Problems with germ cell differentiation and development are associated with infertility. Interestingly, males experience infertility at a similar rate to women. This study aims to create a molecular tool box to identify genes important for proper spermatogenesis in mouse primary spermatogonia stem cells and a testicular cancer human cell line using CRISPR/Cas9–a gene editing technology that modifies, cuts, and deletes targeted regions within genomic DNA. Through our work, weare interested in Rasd1, a gene that encodes for cell morphology, and Cdkn1a, known for controlling cellular proliferation. Our lab designed primers utilizing multiple bioinformatics databases to amplify the genes of interest and made specific single guide RNAs (gRNAs), which will signal to Cas9 where to cut the genomic DNA and produce a frameshift mutation. Thus far, we have verified our primers using PCR and gel electrophoresis, isolated and cleaned up the product, and are testing CRISPR/Cas9 in vitro. Once confirmed, our aim will be to electroporate CRISPR/Cas9 into cell culture and investigate changes in gene expression using quantitative RT PCR.

Abstract Name: **Synthesis of Substituted Isatins as Potential Antibacterial Agents**

The decline in the development of new antibiotics, combined with their overprescription against bacterial pathogens, has resulted in an increase in the antibiotic resistance cycle and accounts for much of the hospitalized-infection rates. Therefore, this represents an urgent health priority in the synthesis of novel antibiotics. Our research focuses on the expansion of substituted indole-1H-2,3-dione derivatives, most commonly known as isatin. Isatin is a heterocyclic compound with significant synthetic versatility for its highly reactive C-3 carbonyl group and N-1 amino group, whose derivatives can serve as a precursor for potential antibiotics and pharmaceuticals. The unique properties of isatin's structure lend it to perform a broad variety of structural modifications to synthesize structurally diverse derivatives and yield a large spectrum of biological activity that are dependent on the substituent properties. Many of the synthetic routes involve substitutions at positions C-3, C-5, C-7, and N-alkylation reactions. Previous studies have observed the greatest antimicrobial activity when substituting electron-withdrawing groups at the C-3 and C-5 positions due to the increase in the overall lipophilic character to facilitate transport across the hydrophobic membrane. We synthesized a library of substituted isatin derivatives to investigate how substitutions on the C-3 carbonyl and the bromination of the aromatic moiety at the C-5 and C-7 positions can affect the antibacterial properties. These derivatives involve Henry reactions, Grignard reactions, Hydroxyalkylation, and Schiff base formations through modifications on the C-3 carbonyl of isatin, 5-bromoisatin, and 7-bromoisatin. Each compound's identity was verified through NMR to ensure the success of the synthesis. We have successfully synthesized and identified 13 isatin derivatives, with product yields ranging from 51% to 90% yield. The synthesized compound library will be screened againstE. colito measure the potential antimicrobial activity.

Abstract Name: **A small stem assay using hypovirulent Cryphonectria parasitica to screen Castanea dentata backcross F2 families may set the stage for long-term survival**

By combining the results of blight resistance breeding and the application of hypovirulence as a biocontrol, populations of resistant hybrid trees could be deployed together with a less pathogenic strain of Cryphonectria parasitica (Murr.) Barr. I used a small stem assay to screen seedlings in thirteen half-sibling backcross F2 families with an attenuated strain of C. parasitica containing the Cryphonectria parasitica hypovirus-1 (CHV-1) Euro7 virus. The experiment was set up as a randomized complete block design in 2-gallon containers. Measurements of canker length and morphology were gathered at four, eight, 12-, and 16- weeks post-inoculation. A secondary experiment was conducted to further understand the in vivo effects of hypovirulence. Trees from five of the thirteen half-sibling families were inoculated with isogenic virulent (virus-free) and hypovirulent (virus-containing) strains of the fungus. Virulence of the virus-free (V) and virus-containing (H) strains was measured using the Granny Smith apple assay. The possibility of in vivo canker conversion from V to H was tested after five weeks by inoculating half of the V-infected trees with the H strain. Measurements of canker length and morphology were measured weekly for another five weeks post-inoculation. Data analysis for both portions of the project are ongoing. All surviving trees will be planted in an experimental orchard in Middle Tennessee to create a potentially long-lasting population of disease tolerant trees together with an effective, long-term biocontrol for chestnut blight.

Abstract Name: **Effects of Multiple Stressors on Caenorhabditis Elegans**

Silver Nanoparticles (Ag-NP) have been used extensively in products due to their antibacterial properties. During use and after disposal of such products, Ag-NPs are being released into soils. Invertebrates in the soil have an important role in breaking down large carbon sources and releasing nutrients that increase soil quality. Exposure to Ag-NP has been found to cause toxicity at low Ag concentrations in different soil invertebrates, including a model soil nematode Caenorhabditis elegans. In addition to NP, soil invertebrates are also being exposed to other stressors, such as Klebsiella pneumoniae, which is a common gram-negative pathogen found in soils and was shown to induce immune stress in C. elegans. There is plethora of studies examining toxicity of each of these stressors alone, there is lack of knowledge on the combined effects of these stressors in soil invertebrates. This study aimed to determine whether reproductive toxicity was enhanced after combined versus individual exposures of C. elegans to silver nanoparticles (or silver ions) and K. pneumoniae. To select the Ag concentrations for the combined exposures, the concentration response relationship for mortality and reproduction were identified first after individual exposures. To stay below 10% for mortality, the concentration of Ag ions and Ag-NP should not exceed 11 ug/L and 325ug/L, respectively. From individual reproduction experiments, we selected concentration that decreases reproduction by 30% (EC30), which corresponded to 11 ug/L and 275 ug/L for Ag ions and Ag-NP, respectively. The combined exposure at EC30 of C. elegans to Ag-NP (or Ag ions) and K. pneumonia can increase reproductive toxicity. The effect of AgNP on K. pneumoniae biofilm formation is currently being investigated. Thus, our results demonstrate that despite Ag antimicrobial properties, which should decrease K. pneumoniae pathogenicity, there is a synergistic adverse effect of Ag and pathogen on C. elegans

Abstract Name: **Electrical ring resonator: Experiments and program development**

Since the large-scale commercialization of fiber optics in the 1970s, there has been an explosion in research to find ways to optimize and further its applicability.Primarily applied in the field of optics, ring resonators have been found to haveincreasing potential in such areas as photonic switching, signal filters, and optical sensing. Similar in its applicability, electrical ring resonator can be created to serve a variety of functions. In this research, electrical filters made from ring resonators were created both experimentally and computationally. The filter was built in a physics laboratory by using co-axial cables connected in various configurations with different numbers of cable rings join to a straight signal cable path. The filter properties were measured by an impulse method using a frequency generator and an oscilloscope. The extracted data from the oscilloscope are analyzed computationally to determine the characteristics of frequency transmission for each configuration.Additionally, thecomputational model developed allows us totest various configurations of ring resonator structures by employingthe transfer matrix method. This allows us to compare the experimental values with expected computational values and enablefuture researchers to test increasingly complex resonator structures that are too difficult to create in the lab.

Abstract Name: **Neuromorphic Computing with Josephson Junction Neurons**

Josephson Junctions are superconducting circuit components whose behavior can be described by a second-order, non-linear differential equation. This makes them an ideal tool for exploring and modeling complicated systems, such as neurons. This abstract gives the background for studying fluxon dynamics (the behavior of a quantized amount of magnetic flux) in Josephson Junctions arrays and the possibility of demonstrating learning in a neural circuit. When cooled below TC, current loops in the array can cause fluxons to become trapped between junctions in the array. At a certain switching current, Isw, or thermal energy level, a fluxon will begin to move around the array, and a voltage is detectable. Isw, however, can vary significantly. It is strongly suspected that this variation is caused by production uncertainty in the size of the junctions, akin to a particle moving over hills of different sizes. Macroscopic quantum tunneling of fluxons is also a suspect for these variations. The demonstration of learning involves splitting artificial neuron spikes down two different “axons” composed of more Josephson Junctions and observing the difference in arrival time of these spikes to a “learning gate” composed of an inductor and a SQUID. What we are able to observe here is called spike-timing dependent plasticity (if the spikes are close, the coupling strength is increased and vice versa). In simulations, unsupervised learning and pattern recognition have been successfully demonstrated. Our experimental results match thus far.

Abstract Name: **Seed Treatment by a Cold Plasma**

Food quality and production is a growing issue with an increasing world population, which has led to the involvement of the plasma agriculture field in the search for a solution to these problems. The field has expanded the spheres of disease control and growth stimulation, with the ability of plasma to safely kill pathogenic bacteria, fungi, and viruses. The purpose of this project was to determine the effects of cold-atmospheric plasma (CAP) on the seed performance of three plants when exposed to a pin to water discharge cold atmospheric pressure plasma, plasma that is ignited by air gas between a tungsten electrode pin and a water surface, and watered with plasma activated water (PAW) respectively: Arabidopsis thaliana, Brassica rapa, and Lactuca sativa. Brassica rapa seeds showed a significant increase in water uptake after being treated with a cold-atmospheric plasma jet for 1000 seconds with 95% confidence. Lactuca sativa seeds, which have a softer seed coat, did not show an increase in water uptake after CAP treatments, indicating that CAP treatment may affect seeds differently with varying seed coat types. CAP treated Brassica rapa plants showed significantly taller growth than their control at every measuring period except at 18 and 21 days after planting, along with CAP treated Arabidopsis thaliana plants showing significantly taller growth than their control after 16 days of planting, at a 95% confidence interval.This further indicates that CAP treatment was the most effective plasma treatment for improving plant performance, but affects varying seeds in different ways, most likely due to differences in their seed coats. Furthermore, CAP does not produce dangerous by-products, nor does it require wasteful or precious resources, making it a promising green technology for the agricultural industry.

Abstract Name: Fostering collaboration between parents and speech language pathologists : What impact do motivational interviewing strategies have on parent-child reminiscing intervention?

The literature on parent-child reminiscing conversations from the various disciplines, including developmental psychology and communication sciences and disorders, indicates that these brief and routine conversations about shared, past experiences can have a positive impact on a child's developing language, cognitive, and socio-emotional skills. However, families can reminisce in a variety of styles depending on their culture. Motivational interviewing is a counseling style that aims toguide clients toward developing their own solutions as grounded in their personal values and priorities. With our project we ask the question, "What impact do motivational interviewing strategies have on the collaborations of parents and clinicians of different cultural backgrounds during reminiscing interventions?" To answer this question, we have thus far recruited two families- onemonolingual English speaking family with a preschooler diagnosed with a language delay.; onebilingual family (English and Japanese) with an adolescent boy diagnosed with ASD and TBI. We are video recording our collaborations and parent-child reminiscing. Inductive methods of analysis are employed to identify behaviors that contribute or interfere with effective collaboration between the clinician and parents. Collaboration methods will be refined after initial analysis and additional families recruited for further study. Understanding ways to foster better collaboration with families is essential to creating individualized and culturally sensitive interventions.

Abstract Name: Unconventional Heroines: Rethinking Feminine Characters in The Three Kingdoms

The sixteenth-century Chinese novel The Three Kingdoms by Luo Guan Zhong offers an enchanting account of wardom, military strategies, dramas of life and death as well as contested gender roles in a patriarchal society. Although it mostly discussed the interactions of men, the novel offers riveting illustrations of unconventional heroines who managed to gain agency within the moralistic parameters of Confucianism. Some representative examples include: the well-known femme-fatale Diao Chan who plays a important role in the fall of Dong Zhuo, Xu Shu's mother who displays moral power through political chastity, Liu Bei's bride Lady Sun who proves to be a faithful, courageous, and resourceful wife. These particular women were brave, strategic, and quietly powerful. Amid the novel's rich depictions of political alliances and deceiving military strategies, these heroines display that gender is another battlefield for talent and skill amongst unconventional, gentry-class women. Though often depicted as minor characters, women have occupied an important status in the narrative space.

Abstract Name: Computational Analysis of Pop Music Across Cultures

Songs are heavily influenced by culture. This project focuses on finding similarities and differences in both the lyrics and chords of popular songs in Spanish, English, Japanese, and Chinese. First, we collect a database containing the songs' title, lyrics, and artists by scraping several online websites. We then analyze the lyrics of the songs, performing sentiment analysis and analyzing other psycholinguistic categories on the songs as a whole and also as a word usage time series. Using clustering and topic models, we identify commonalities in songs across languages. This project also includes a chordal analysis to determine whether there are common chord structures and key signatures that are inherent to a specific culture's music. The result of this analysis provides an exact cultural interpretation of the lyrics for non-native speakers.

Abstract Name: Carbon Capture by Icelandic Basalts: A Potential Way to Address Global Climate Change

Many ecosystems can only survive in a very slim temperature range, but our increased use of greenhouse gasses, such as CO2, change global temperatures significantly. This results in those ecosystems dying off, like coral reefs for example. Iceland currently has one of the largest carbon capture plants in the world. They have implemented a way to take CO2 from the atmosphere and pump it underground.The research question we will be answering with our project relates to carbon capture. We will be exploring how carbon can be contained within bedrock through multiple experiments and observation of basalt samples. We collected olivine and basalt samples fromthe Fagradalsfjall volcanoin Iceland. The collected samples were micronized and analyzed with a powder x-ray diffractometer (PXRD) before being exposed to dissolved CO2. Preliminary results show no change in mineralization after 31 days. This is unsurprising, as a study published by researchers in Iceland showed significant mineralization after running experiments for upwards of 140 days. Future steps include letting the two existing samples continue to react with the carbonated water, as well as running an additional experiment. This set-up is designed to continually measure pH and CO2 levels in a closed system. We will also use a scanning electron microscope (SEM) to look for any changes on the sample surfaces before and after this set-up. This experiment will attempt to minimize human error while collecting as much data as possible that would indicate mineralization.The contributing factor of our research would be assisting in ways to lessen climate change. As we know CO2 is a greenhouse gas which largely contributes to the warming of the earth. With scientists discovering new ways to contain CO2, we have the potential to slow global warming.

Abstract Name: **Acculturation of Children**

Migration can be a large shift in a child's life, affecting their mental psyche. Studying this impact through the lens of acculturation to see how well a child can adapt to Western Society can provide? Acculturation is when immigrants from one culturetry to integrate into another by taking in the characteristic of another culture. Berry's model of acculturationis the different ways an immigrant can acculturate through assimilation, integration, marginalization, or separation. The parent of the child has an impact on how the child acculturates, also depending on which characteristics the parent uses in the parenting model. The way a child acculturates will influence the child's wellbeing. This research hypothesizes that parenting style affects a child's acculturation, which in turn affects a child's wellbeing. Another area to examine is how cultural intelligence and empathy affect how a child acculturates, which can also affect a child's wellbeing. Cultural intelligence is when a person understands another culture's norms, practices, and conventions. At the same time, cultural empathy is the capacity to understand experiences from different cultures. We hypothesized that cultural intelligence and cultural empathy affect how much a person acculturates, which leads to their wellbeing. These hypotheses were tested using a Qualtrics survey and a set of questionnaires. The target demographic is people over 18 years old who moved to the United States before 14 years old. We believe that parents with authoritative characteristics will lead to a child having an integration type of acculturation and a higher wellbeing. I integration acculturation will lead to a child having a higher cultural empathy and intelligence and higher wellbeing. As the world becomes more and more connected, this research will contribute to understanding the experiences of children who migrate.

Abstract Name: **That Girl vs. New Girl: The Perils of Choice Feminism**

In recent years, Elizabeth Meriwether's television show New Girl has begun to reach the status of a cult classic. The show's sharp humor and quirky protagonist have captured the hearts and minds of many. But is this all for the good? New Girl features a controversial protagonist, Jessica Day, whose personality grates on some and resonates with others. Jessica represents stereotypically feminine interests and ideals yet takes on a leading role and independence not always afforded to female characters. This opens her, and the larger show, up to feminist readings and critiques. Surprisingly, little scholarly research has been conducted on New Girl. In my paper, I examined the feminist implications of the show. I researched choice feminism and investigated its manifestations within New Girl. I compared and contrasted New Girl with the 1960s television show That Girl, to consider how both shows reacted to and exemplified the feminism of their times. I explored the similarities and differences between the shows and determined what this meant for New Girl's politics. Through my research, I determined that New Girl amplifies harmful aspects of choice feminism, a subsect of third wave feminism. The ways in which New Girl addresses feminism frames misogyny and oppression as a matter of personal responsibility, and ignores systemic issues and their impact. A show that is as culturally significant as New Girl has a wide audience, and the ideas presented within it will be spread. We can see this research as a call to more critically develop future television and media.

Abstract Name: **Using Enzyme-Linked Immunosorbent Assays (ELISA) to Understand Insulin-Degrading Enzyme (IDE)-Phosphatidylinositol Phosphate (PIP) Lipid Interactions**

Insulin-degrading enzyme (IDE) has been linked to Alzheimer's Disease and Type II Diabetes due to its function in degrading insulin and the amyloid-beta peptide. IDE is, therefore, a potential therapeutic target for these diseases. This research aims to identify how IDE produced in the cell cytosol accesses its substrates, which are likely cleaved within the cellular endosomal system. It is hypothesized that some IDE localizes to endosomes by initially binding to phosphatidylinositol phosphate (PIP) lipids located in the endosome membranes. Computational docking studies suggested a site on IDE that might mediate an interaction with PIP lipid head groups. An enzyme-linked immunosorbent assay (ELISA) was used to evaluate whether mutations in this putative binding site disrupt interactions with artificial liposome membranes doped with PIP lipids. Results show that the mutations do affect PIP binding, with the variants IDER824A,H885A,R892A and IDEQ813A,N821A,H885A having reduced or no detectable interaction with liposomes bearing phosphatidylinositol 4,5-bisphosphate (PI(4,5)P2). This loss or reduction of PIP interaction supports the hypothesis that IDE interacts specifically with PIP head groups and that this interaction is mediated by the proposed binding site. Improved understanding of this mechanism could someday enable the development of therapeutics for AD and/or diabetes mellitus and explain why these diseases are frequent comorbidities. While studying IDE-PIP interactions it was also observed that PIP lipids can bind in the inner chamber of the clamshell-like IDE molecule. The lab previously obtained a crystal structure detailing this binding interaction. Future work will investigate the possibility of IDE having a second function as a lipid transfer protein, which the lab is beginning to explore using a liposome-based lipid transfer assay.

Abstract Name: **Women of War: The Role of Female Spies in World War II?s French Resistance**

World War II marked the first war in history where women were legally combatants, employed by government organizations. Great Britain's Special Operations Executive (SOE) was one such organization. When Nazi forces occupied France in the summer of 1940, Great Britain began the SOE with the intention of liberating France from the occupation Vichy Regime and defending against the German forces across the English Channel. In the years following the war, many stories of heroism emerged. These stories often involved the female spies whose major contributions were crucial to the eventual victory of the Allied Powers. While many of these stories remain untold, the roles of five women were widely publicized, dramatized, and celebrated around the world. Andree Borrel, Virginia D'Albert-Lake, Odette Sansom, and Betty Pack have become examples of the bravery, discipline, dedication, and quick-mindedness of the female warriors ofWorld War II. However, not all of these women worked exclusively for the French Resistance. Mathilde-Lily Carrè gave her loyalty to the Nazis, despite her role as a founding member of one of the SOE's key espionage circuits. Her role as a double agent also mirrors the stories of many other women. Though their methods were different from one another and the norm, the impact of each of these women was profound in the defeat of Nazi ideology and forces in France during the war. These women and many others who served in the Second World War proved the value of their skills, talents, and devotion to a cause through their work during World War II.

Abstract Name: **Smell Ya Later (but hopefully not): Ammonia, Fish, and their Toxic Relationship**

Ammonia, NH3, is a common substance that has many encounters on a regular basis but are unaware of its impact on wildlife, particularly water dwelling species, such as fish. Ammonia is toxic and this component causes a multitude of problems upon human or animal contact. The primary objective of this project is to explore the structure of this compound, the impact of it on fish, their ways to negate the hazardous effects of ammonia, and the reason and importance of ammonia's existence. To understand how ammonia is regulated, its composition, creation, and relationship to these creatures is analyzed in this study. This information is relevant to how ammonia plays a greater role in natural processes that support aquatic life, such as the nitrogen cycle. Understanding how ammonia is created and enters in aquatic environments is the key to grasping the drawbacks and benefits of its part in the greater world. The research also extends to the analysis of ammonia content in water samples collected from different areas in Houston, Texas using ammonia test kit and pH tester.

Abstract Name: **Investigating male infertility: Investigating genes important for spermatogenesis in a cell culture system**

Infertility affects 4.5-6% of North American males and up to 15% of couples worldwide. Infertility may be caused by unknown genetic factors, as up to 2,300 genes are pertinent to male fertility. This research project aims to create the molecular toolbox needed to evaluate gene function in male germ cells. We will use mouse primary spermatogonial stem cells and a human testicular cancer cell line to knock out the functions of genes Phosphoprotein 1 (Spp1) and Inhibitor of DNA Binding 4 (Id4) in the testis to determine the effect of the knockouts on male germ cell proliferation and cell death. We designed single guide RNAs (gRNAs) using online bioinformatic tools and amplified the genes from human and mouse genomic DNA to demonstrate the effectiveness of our gRNAs in vitro. These primers and Cas9 compose the beginnings of the molecular toolbox used to electroporate cultured cells. This research will contribute to the greater scientific community by providing insight into the function of Spp1 and Id4relating to male fertility and providing a methodology for future research.

Abstract Name: **Barriers and Facilitators to Mental and Behavioral Health in a Primary Care Setting**

Due to barriers including immigration status, acculturation, trauma, or generational conflicts, Hispanics/Latinos have difficulty accessing mental and behavioral health (MBH) services compared to non-Hispanic whites. To address this healthcare disparity, we wanted to identify best practices for forthcoming MBH services in St. Mary's Medical and Rehabilitation Therapies (SMMART) Clinic at St. Catherine University in St. Paul. The SMMART clinic serves an uninsured, predominantly Hispanic population and operates under a collaborative care model, referring to a primary care setting with several medical professionals from different disciplines. We conducted a rapid literature review. After compiling 1795 articles from six online databases, we narrowed down articles based on criteria including but not limited to: articles with clear research methodology, available in English, and not more than ten years old. Subsequently, we analyzed 28 full-text articles for different themes. The emerging themes included barriers (access, culture, racial bias) and facilitators (cultural relevance and collaborative care) for Hispanics/Latinos seeking MBH services. Noteworthy findings suggest that many Hispanics/Latinos somatize their symptoms (manifest psychological distress through physical symptoms), hence mental illness goes undetected by physicians. Hispanics/Latinos may also have difficulty accessing care because of cultural stigma of mental health disorders and racial bias from providers, among other factors that limit accessibility. Meanwhile, reviewed articles also suggested that many Hispanic/Latino patients prefer collaborative care models where communication between their primary care providers (PCPs) and MBH specialists is apparent, and care is culturally relevant. We hope to use our data to inform best practices for MBH care at the SMMART clinic in understanding how to make services more accessible to a Hispanic/Latino population. Still, future research is needed to address assessment and intervention.

Abstract Name: **Monandrous females regain sexual receptivity after produce eggs**

Male fitness is a function of the number of mates they can inseminate, yet males often engage in prolonged copulations. Potential explanations for this behavior include the ejaculate transfer hypothesis, whereby longer copulations achieve higher levels of insemination, and the mate-guarding hypothesis, in which males increase their association with females for longer than required for sufficient sperm transfer. Interestingly, prolonged copulations can occur in monandrous species where these benefits presumably do not apply. We investigated prolonged mating in a monandrous-polygynous species, a member of the Enchenopa binotata complex of treehoppers (Hemiptera: Membracidae). These insects communicate with plant-borne vibrational signals and use male-female duets in pair formation. Copulation can last up to three hours. We tested a version of the mate-guarding hypothesis by which prolonged copulation has the function of allowing males to transfer ejaculate which reduces female receptivity and promotes egg laying. If so, females would be more likely to duet with male signals and less likely to produce eggs as mating duration declines. We randomly assigned receptive females to copulation duration treatments of either 10, 30, 45, or 60 minutes before we separated the pairs. We also included a control group where the pairs were not interrupted during copulations. We found that females that experienced copulations lasting 30 minutes or less were more likely to duet with playbacks the following day and 1 week later compared to those that were uninterrupted. These control females (copulations lasting 104 minutes, on average) rarely duetted with subsequentplaybacks. Further, we foundthat females that mated for 10 minutes were less likely to lay eggs than any other treatment.Our results support the mate-guarding hypothesis and suggest that extreme copulation length may function to lower female receptivity and promote egg laying by the transfer of ejaculate substances or even effectively cause monandry.

Abstract Name: Gravity Irrigation Subsystem for Watering Plants

Plants need water to survive. One problem is knowing when and how much to water them. The overall purpose of this project was to design and engineer a simple and useful planter irrigation box that effectively waters plants the needed amount. This portion of the project was to develop a subsystem that brings water from a water reservoir to soaker hoses with a solenoid powered by an Arduino that controls when water goes through. The project also includes tubing, and a manifold 3D printed using CAD software (Creo, Parametric Technologies Corporation, Boston, Massachusetts). The mechanical aspect of this project was simple. The water reservoir, a five-gallon bucket, had a hole drilled into it to fit a half inch fitting along with a nut and washer. Clear tubing was connected to this fitting with the other end connected to the solenoid. More tubing was connected to the other end of the solenoid and to a 3D printed manifold. Three outlets were designed on this manifold with soaker hoses connected to these outlets. The electrical aspect includes an Arduino coded to control the solenoid. The Arduino is connected to a relay on a breadboard using cables. More cables are connected to the solenoid, a power source, and a neutral ground source. When the components were assembled, it was tested by putting water through the design. All aspects of the design held together and did not leak. When the Arduino was coded and connected it was tested by connecting it to a power source. The Arduino was able to control when the solenoid opened allowing water to come through and closed to stop the flow. The finished project would include this and the other two subsystems to integrate to complete the electromechanical design. The other two subsystems are working properly as well.

Abstract Name: Minority Status and Mental Health

Discriminatory behaviors live throughout society today and all generations of the past. How do these behaviors impact groups with minority status? The aim of this study is to research how chronic stress expereinced by people with minortity status impact mental health. There will be multiple angles applied to this study. The first area of interest is how social media either contributes to or gives a community for discriminatory behaviors or does social media allow for an outlet for those with minority status to build support and community. The second area of interest is how does stress related to choronic discrimination exposure contribute to the mental health of individuals with minority status. Previous research has shown disparities in mental health, substance use, and other factors related to mental health among groups with minority status when compared to the same age group of majority status individuals. This study will identify factors associated with positive and negative mental helath development across multiple minority status groups through a survey implemented and analyzed in the spring semester of 2023.

Abstract Name: Testing the Effectiveness of Antimicrobial Surfaces

It's no surprise public restrooms can host an ample amount and variety of various microbes-specifically on bathroom toilet handles. To make public restrooms more sanitary, institutions have implemented antimicrobial technology such as antimicrobial toilet handles. In this study, the effectiveness of antimicrobial toilet handles were examined by directly comparing the amount and characteristics of bacteria present on the surface to "regular" toilet handles. Toilet handles were swabbed in 5 different locations across campus during the last three weeks of spring semester and first two weeks of fall semester. Aseptic techniques were used to transfer swabbed bacteria to LB plates for initial growth and characterization. Following isolation, 3-5 bacteria per plate were selected for further biochemical characterization. In terms of colony counts, the antimicrobial handles had a higher average round bacteria count, while the regular toilet handles had a higher average count of irregular shaped bacteria. There was roughly the same amount of Gram-positive and Gram-negative bacteria present on both types of handles. However, over 50% of the acid-producing samples (indicating pathogenicity) originated from the antimicrobial handles. These results indicate the antimicrobial handles weren't significantly more effective at preventing the growth and attachment of bacteria compared to the regular handles.

Abstract Name: Intimate Partner Violence Against Transgender and Gender Expansive Individuals: A Review of Existing Literature

In the past 20 years, more research and awareness has been directed toward intimate partner violence (IPV) within lesbian, gay, and bisexual relationships. However, few studies have examined the prevalence of IPV among transgender and gender expansive individuals. This is concerning, given that transgender individuals may be at a particularly high risk for IPV victimization. A large, national study in the United States surveyed transgender individuals, and 54% of respondents reported experiencing at least one form of IPV. Given the unique oppressions that place transgender and gender-expansive populations at risk for violence, as well as the dearth of research inclusive of these populations, a thorough synthesis and review of the literature is warranted. In the current study, a literature review was conducted that examined published articles between 2004 and 2022. This review sought to better understand the prevalence, impact, and correlates of IPV victimization among transgender and gender expansive individuals. Articles were searched for on Google Scholar and PsycInfo between September and November of 2022 using the following search terms: ("intimate partner violence" or "domestic abuse" or "domestic violence") AND ((LGBT or LGBTQ) OR (transgender or “gender expansive” or “gender nonbinary” or “gender nonconforming)). A synthesis of the articles included in this analysis will be provided. Implications for IPV prevention and response will be discussed, with attention to systems prevention and response efforts (e.g. domestic violence shelters, spiritual organizations, LGBTQ+ groups, law enforcement, etc.) to better serve and support survivors of IPV within transgender and gender expansive communities.

Abstract Name: Development of Laboratory Instructions for Hydrology Apparatus

Civil Engineers must consider stormwater management whenever they design a structure such as a building, bridge, or culvert that interacts with the stormwater. These concepts are taught both in undergraduate and graduate hydraulics and hydrology courses together with some lab demonstrations and experiments. The Hydrology and Rainfall Apparatus such as H313 from TecQuipment is a very versatile apparatus to study various hydrology principles. H313 is also relatively sophisticated with various control and measurement components. Despite all the capabilities of the apparatus, there is no well-defined experimentation instructions available for this apparatus. This study aims to develop two structured hydrology experiments using the H313 Hydrology and Rainfall Apparatus. These experiments are 1) areal averaging of rainfall data within a basin using Arithmetic Mean, Thiessen Polygon, and Isohyetal Map methods 2) calculating the runoff coefficient of a basin using rational method. These experiments are designed after several tests, trials, and data collection. The collected data is processed and visualized using various software such as QGIS, Civil 3D, Microsoft Excel. For each experiment a Student Instruction, Data Collection sheet, and Instructor Instruction with Sample Data and Analyses is produced. Also an apparatus appendix is developed providing the technical details of the control and measurement components of the apparatus such as weir coefficient. The documents are shared in platforms such as GitHub. These documents will help instructors to conduct structured experimentation using H313 or similar apparatus.

Abstract Name: **Botanical Composition, Yield, Horse Preference, and Forage Nutrient Value of Pasture Treated with Different Soil Amendments**

Forage is the foundation of a horse's diet, therefore, pasture management is critical to improve horse health, nutrition, and pasture productivity. The objective of this study was to evaluate botanical composition, horse preference, yield, and forage nutrient value of pasture treated with horse manure, horse compost, commercial urea fertilizer, and a no product control. Plots were 3 x 6 m and soil amendments were applied at recommended or commonly used rates in May 2022. Sample collection and grazing periods occurred in May, June, July, August, and October, each over a two-day period. Botanical composition, average height, maturity, and yield of the pasture was taken on the day prior to grazing. The next day, horses were allowed to graze for four hours with preference visually assessed at two- and four-hours post-grazing based on percent removal. Data were analyzed as a randomized complete block design using PROC MIXED in SAS with significance set at P ≤ 0.05. Season-long yield ranged from 1.2 to 1.5 tons per acre and did not differ across treatments (P>0.05). Botanical composition differed across treatments with the control having the most weeds (32%) and the least grass (62%) while manure treatments had the most bare ground (11%; P ≤ 0.05). Forage nutrients did not differ across treatments (P>0.05). Horses did not prefer pasture treated with manure and only 15 and 33% of forage was consumed after two and four hours, respectively (P ≤ 0.001). All other treatments averaged 53 and 78% removal after two and four hours, respectively. Based on differences observed in botanical composition and preference, commercial fertilizer and compost appear to be the most beneficial soil amendments to be applied on horse pastures.

Abstract Name: **Identification of Potential Inhibitors Targeting SARS-CoV-2 Main Protease Through Virtual Screening and Molecular Dynamics Simulations**

The main protease is a key enzyme responsible for Severe Acute Respiratory Syndrome-Coronavirus 2 (SARS-CoV-2) replication that causes the spread of the global pandemic novel coronavirus (nCOVID-19) infection. In the present study, we have performed SARS-CoV-2 main protease sequence analysis and then we used structure-based virtual screening to identify potential inhibitors that target main protease. SARS-CoV-2 main protease sequence analysis is done through MEGA X software to identify mutations and exploring phylogenetic relationships among various sequences collected from different geographical regions. Further, we have used SAR-CoV-2 main protease structure as a target and performed virtual screening of all FDA approved drugs. We have identified top 20 compounds having high affinity with main protease and are further validated using molecular dynamics simulations and binding free energy calculations. Four compounds were subjected more expensive simulations, which revealed that the ligand binding didn't alter the overall main protease structural features. The overall results from the current investigation might be valuable for designing novel main protease inhibitors.

Abstract Name: **Low-Carbon Footprint Concrete for 3D Printed Buildings**

3D printing concrete has recently emerged as a revolutionary technology. Over the past two decades, developments in the technology have allowed a wide variety of applications, e.g., the fabrication of buildings. Cement manufacturing accounts for approximately 5% of anthropogenic CO2 emissions worldwide. The carbon footprint created from concrete is unsustainable for the environment. New forms of concrete containing alternative materials such as waste products and bio-aggregates are being implemented to reduce the overall carbon footprint. In our research, we are testing various mixes of concrete containing shredded wind turbine fibers, recycled glass powder, corn stover, and biochar. These materials were chosen as they provided a balance of strength, workability with the 3D concrete printer, and lower carbon emissions. To test our mixtures, we developed the following workflow: mix, cure, test, and evaluate. Each concrete mixture contained varying mix ratios of cement, sand, water, and one of the alternative materials. To ensure proper test results, we made 4 test mixtures containing 3 specimens for each material. This resulted in a total of 12 specimens for each material. Each specimen was cured for 28 days under water. After curing, we tested the compressive strength of each specimen on a hydraulic press machine and analyzed measurements of the load and stress. We then calculated the carbon footprint of the concrete mix with each alternative material. This data allowed us to analyze the mixtures and determine the most suitable candidate for 3D concrete printing. The new concrete mixes showed a varying level of compressive strength and showed a noticeable reduction in carbon footprint compared to the standard concrete mix. The technology of 3D concrete printing in combination with eco-friendly concrete will lay the foundation for a more sustainable future for housing.

Abstract Name: **Valve control for the improvement of the main network of an aqueduct for human supply**

In Panama, there are problems with the hydraulic network for the supply of drinking water. In different provinces and towns, there is the problem that, for the distribution of the vital liquid, there is no automatic valve control system to control the pressures according to the demand of each section of the hydraulic network. This causes overpressure in the network and, consequently, an inefficient supply. These overpressures in the pipelines bring about different unfavorable situations such as shortening their useful life, increasing maintenance costs and, in the worst case, a rupture, thus causing the community to constantly remain without water for several days. Using a PLC and the outputs of voltage variables, and being able to close or open the valve depending on differences in pressure and flow and, at the same time, performing a remote monitoring of these variables through telemetry. The objective is to distribute water more efficiently, avoiding waste and extending the useful life of the hydraulic network and, more importantly, guaranteeing the availability of the vital liquid. Currently in the country there is the necessary equipment for the automatic control of the mains installed in multiple points of the country, but they are currently underutilized since they are activated manually by an operator on site. Without the knowledge of how to do it, so the idea was born to make a project that automatically avoids overpressure in the lines, thus avoiding waste of vital liquid, increasing the life of the matrix network, and lowering operating costs, since it avoids having to send an operator to the site for the activation of the valves.

Abstract Name: **Effects of Morphological Awareness on College Student Reading Comprehension**

Morphological awareness is understanding how words are composed of smaller units, such as roots, prefixes, and suffixes. Morphological awareness in early childhood leads to reading achievement and resilience in adulthood. Morphological awareness is developed through activities which also develop writing and reading skills. Difficulty with understanding morphemes can be tied to late acquisition of structuring words, identifying parts of speech or correct grammar, and issues with overall reading comprehension. Previous research suggests that morphology can be learned as a way to combat literacy development delays and is a predictor of word reading and reading comprehension in students in elementary school. This study aims to better understand the skills involved in college students' reading comprehension. Participants will first play a variety of word games. Next, students will read a short passage from a college textbook and answer a series of study guide questions. The study is online and should take no more than 45 minutes to complete. These findings will provide valuable insight into THE importance of morphological awareness and the role it plays in college student achievement.Keywords: Morphological awareness, reading comprehension, morphemes

Abstract Name: **Middle School Teacher Experiences regarding Implementation of a Learning how to Learn Course via Student-Engaged Design**

This study examined teachers' experiences and perceptions of the function, utility, and implementation of a Learning how to Learn Course via Student-Engaged Design (LhL-SED) which focused on developing middle school students' self-regulatory skills. Teachers were involved in the implementation of the LhL- SED and received professional development on how to cultivate students' self-regulation, curiosity, deep learning, growth mindset, self-advocacy, and school connectedness. Nine (N=9) in-service middle school teachers shared their experiences through semi-structured focus group interviews and reflections. Classroom observations were also conducted. A thematic analysis revealed a number of themes such as promoting personally-relevant activities and self-regulatory skill development (focus group interviews), as well as providing self-directed learning experiences and fostering co-regulation (teacher reflections). Descriptive and qualitative analyses of the classroom observations showed that teachers promoted and supported student self-regulation, collaboration, and growth mindset in the classroom. Findings indicated that teachers provided students with a choice and a voice in selecting projects that were meaningful to them which resulted in higher levels of self-regulation and motivation. Findings also showed that working collaboratively with peers to achieve targeted goals also helped students become self-regulated learners. Overall, teachers found that the LhL-SED promoted students' self-regulatory skills, motivation, task engagement, and curiosity. Educational implications will be discussed in relation to teacher and curriculum development.

Abstract Name: **Student Identity Shapes Approaches to Justice-Oriented Learning**

Issues of race, gender, and sexual orientation have become increasingly controversial in recent political discourse, as several states throughout America have proposed legislation banning discussions of socially sensitive topics in public schools. Regardless of the success or failure of attempts to control curricula, social identities will always be a component of classroom discussions and learning processes. Previous research has shown that identity plays a critical role in the classroom, particularly with respect to how students with privileged identities approach justice-oriented learning. For example, the acute discomfort associated with confronting one's own unfair advantages causes students with white privilege to suppress or deemphasize their racial identity to downplay their membership in a problematic social group. As calls have been made to curate pedagogical approaches that address systemic inequality in ways that do not impugn the personal self-worth of students with privileged identities, it's important to understand how privilege shapes the attitudes that students bring into the classroom. Using data collected from upper-level psychology students, the current study compares the central identities of privileged and non-privileged groups to determine how attitudes about diversity and social justice differ at baseline. Keywords: Identity Centrality, Privilege, Marginalization, Attitudes, Transformative Learning

Abstract Name: **Future Healthcare Providers' Reflections on the Impact of Reproductive and Sexual Health Knowledge and Religion During Childhood**

While there is growing interest in researching the impact of faith and religion on the sexual and reproductive health experiences of youth in higher education settings (Ahrold; Meston, 2010; Freitas, 2015; Yarhouse et al., 2018), we still do not know enough about the experiences and perspectives of religious young adults working towards a career in the medical and health sciences. Using a variety of qualitative data collection methods (interviews, ethnographic observation notes, and focus groups), we seek to answer the following questions: How do health sciences students of various faith backgrounds make sense of past experiences learning about sex and reproduction? How do religious students in the health sciences add to their sexual knowledge "toolbox" or increase their sexual know-how while in college? What might these unique experiences tell us about the range of reproductive health practices for other U.S. young people in college? Participants involved in these conversations were part of a target population that self-identified as having a current or past association with a religion or faith.In addition to presenting preliminary findings on religious students in the health sciences and their experiences learning about sexual health during adolescence as well as their continued knowledge needs, our presentation will explore and expand the methodological choices we implemented to generate participant conversation around a potentially stigmatizing topic. This aspect of the presentation will focus on the process in designing an interactive focus group with an educational component and the success in creating a space to discuss these issues.

Abstract Name: **Compact Disc Album: Solo Works for Alto and Bass Flute by Francophone Composers**

My research comprises the promotion, preparation and recording of a CD containing eight contemporary works for alto and bass flute written by francophone composers. My CD is the first of its kind, as one containing solely music for alto and bass flutes has never been published by any artist in this country. These compositions span from 1937 to 2020 and require mastery of both traditional and contemporary techniques of the Boehm flute. Within these works I execute a variety of extended techniques; techniques that transcend the limits of traditional flute playing. The purpose of this project was to gain the experience and skill necessary to planning and completing a Compact Disc Album. This is combined with a personal fascination in French culture. In addition, this research was conducted with the intention of instituting acknowledgement, indoctrination, and representation of contemporary music on an international scale, contributing to the exposure of composers and their work in the United States. Methodology involved carefully selecting relevant works to record, learning the music with an efficient daily practice plan, connecting with the composers through research on their works and direct communication, sharing my preparation process online, and spending strategically planned hours in the recording studio.

Abstract Name: **Problems and Possibilities of Digitization: Imagining Kievðs Church of the Tithes**

The now destroyed Church of the Tithes (Desiatynna Tservka) in Kyiv is distinguished as the first stone church in Ukraine. Completed in 996, the church introduced a modified Byzantine style to the region, presenting the major source for monumental architecture across the Kievan-Rus. However, it was destroyed in a siege in 1240. Because of its utmost importance for the religious and cultural history of the region, the reconstruction of this monument was attempted many times, most notably in 1635, the 1700s, and in 1828; it was destroyed yet again in the 1930s.Interestingly enough, none of the reconstructions could be reliably related to the structure's original design.My own research was prompted by a digital reconstruction of the Tithes published in 2021. Like its physical predecessors, this digital reconstruction begs questions about the availability and reliability of archaeological and textual sources that would allow accurate reconstruction: what has been conjectured about the Church of theTithesand why? How should theTithesbe imagined? My project utilizes traditional art historical methods to parse the accuracy of this digital reconstruction.I examined original descriptions of the church, such as theeleventh-century manuscript,Chronicon of Thietmar of Merseburg(c. 1018) and theRussian Primary Chronicle(c. 1113) and discovered that these sources, often evoked in the 20thcentury secondary historiographies of the Tithes, only call attention to auxiliary features of the building. The textual evidence, however, does not contain architectural descriptions sufficient to create a cohesive model. Instead, the Tithesas it has been reconstructed in the 21stcentury is a product of the imagination, informed mostly by unsubstantiated hypotheses. In my presentation, I will offer the Tithesas a lesson in vigilance towards digital models of art historical objects, and of the continued importance of primary sources.

Abstract Name: **Analysis of Bi-2212 Superconducting Filament Joining using Deep Learning Methods**

Composite Bi2Sr2CaCu2O8-x (Bi-2212) wire has great potential as a material for high temperature superconducting magnets, which can conduct with no resistance. Bi-2212 is being considered for large magnet systems due to its ability to operate under high magnetic fields, its high current density, and its ability to operate under liquid nitrogen temperatures, rather than the much colder and more scarce liquid helium. However, the individual Bi-2212 filaments created using state of the art methods sometimes bridge or agglomerate during heat treatment, which can have a negative impact on the ultimate performance of the wire. To quantitatively assess the extent of filament agglomeration, it is difficult to perform traditional image analysis techniques, particularly since the filament joining can be seen in a continuous range of expression from lightly bridged to intimately conjoined. In this project we created a U-NET like image segmentation algorithm to be able to classify filaments from transverse cross-sectional wire images as either conjoined or individual in nature, based on a manually curated set of training images. The model, after training and fine tuning its batch size, learning rate, optimizer, and class weight hyperparameters, can then subsequently classify filament pixels without human intervention. Overall, the fine-tuned model runs with an average accuracy of 95% for total image pixels, and over 75% for filament specific pixel categorization. Furthermore, the model has been shown to perform in a manner consistent with human intuition when predicting filament conjoinment. With this model, a standardized quality control process for Bi-2212 wire production can be envisioned, and a more quantitative assessment of extent of conjoining can be provided to analyze the impact of bridging and agglomeration on performance.

Abstract Name: **Course-Based Undergraduate Research and Community Science with The Village Community Gardens**

Inclusion of undergraduates in authentic research is an effective tool to bridge the gap between theoretical and practical aspects of biology and increase competency and interest in research careers. In an effort to increase student access and engagement to research we developed a course-based undergraduate research experience (CURE). In addition, we aim to develop a project that would foster a mutually beneficial collaboration with The Village Community Garden, a local nonprofit aimed at food sovereignty and the provision of land and resources for culturally relevant food growth. Here, we aim to foster a collaboration between our community partner, students, and faculty that would promote outreach, engagement, learning, and scholarship. Students will 1) compare microbial numbers in soils of Rochester MN community gardens, 2) investigate microbial antibiotic resistance contamination within the community gardens, and 3) investigate soil microbial species with and without soil inoculant. Laboratory techniques employed to determine soil microbial counts are foundational procedures that students will benefit from performing. Furthermore, microbial soil populations are influenced by numerous biotic and abiotic features; growers are interested in learning these results. We aim to contribute to the national surveillance of antibiotic resistance of soil-dwelling bacteria to tetracycline. In addition, the students will investigate soil microbial species for resistance to three other antimicrobial agents employed in agriculture. The gardens are subject to community-grower fertilizer applications and the planting of inoculated legumes may mitigate the surplus nitrogen. We aim to identify soil microbial species with and without soil inoculant using molecular techniques. This CURE will be implemented during the summer of 2023 within the microbiology course at the University of Minnesota Rochester. Here, we are presenting our pedagogical approach and preliminary results.

Abstract Name: **Shining a Light on Experimental Theatre Practices: A dissection of Neo-Futurism as it is and how it is applied in a modern performance context.**

This project seeks to explore the tenets of an experimental style of theatre in a modern performance context while working with passionate students to help expand their means of artistic expression. Neo-Futurism is an active creative force and is continuing to evolve within the theatrical community. I will be basing my project on the work of The Infinite Wrench, a neo-futurist ensemble that is based in Chicago, Illinois. They are an ensemble of writers, directors, and actors that perform thirty plays in sixty minutes, all while following the four basic tenets of neo-futurism: no suspension of disbelief, speed and brevity, scripted and planned, reliance on chance. My goal is to create an ensemble of students at UWEC that mirrors this aesthetic of truthful communication between the audience and the performer. The main research questions I want to explore are 1. What exactly is futurism? 2. How did it evolve into neo-futurism? 3. How can we, as writers and performers, apply this specific style in a modern performance context and 4. How does a theatre practitioner develop this style of theatre? My objective for myself and the ensemble is to break out from the robotic tendencies of realism based writing and thinking and creating a new heightened theatrical sensibility. I want the audience to leave with a newfound appreciation for experimental theatre. In addition, I want our plays to evoke a particular atmosphere that challenges the audience to think for themselves. Moreover in executing this project, I want to gain dexterity in performing, writing, and directing within an experimental environment while also developing my skills as a leader amongst fellow creators. Lastly, I would like to develop this material into something suitable for a possible confrence presentation, a poster and/or a short performance at NCUR.

Abstract Name: **Role of Srcap in Hematopoiesis and Leukemogenesis**

The development of acute myeloid leukemia (AML) is driven by the accumulation of mutations in hematopoietic stem cells (HSCs), and leukemic clones are often characterized by a defective response to DNA damage. Mutations in SRCAP have been recurrently identified in AML, suggesting the importance of this gene in its evolution. SRCAP is an epigenetic modifier responsible for exchanging the canonical H2A histone with its H2A.Z variant. However, how mutations in this gene and disruption of this epigenetic pathway promote leukemogenesis remains unknown. In our lab, we previously determined that loss of Srcap results in increased DNA damage in murine HSCs, and we hypothesize that loss of this gene may lead to defective DNA damage repair, increased mutational frequency, and the development of leukemia. We propose to study how loss of SRCAP impacts the response to DNA damage in both normal hematopoietic and leukemic cells using a mouse model with conditional knockout of SRCAP and hematopoietic cell lines with shRNA-induced knockdown of SRCAP. We hypothesize that loss of SRCAP will result in decreased H2A.Z genome deposition. We also hypothesize that the genomic sites with decreased H2A.Z deposition upon SRCAP loss will also have evidence of increased DNA damage. To test these hypotheses, we will use H2A.Z and -H2A.X ChIP-seq to determine how SRCAP loss impacts H2A.Z distribution and DNA damage in a site-specific manner. By understanding how SRCAP loss impacts the response to DNA damage in HSCs, we will better understand how HSCs respond to DNA damage and how disruption of this process contributes to the development of leukemia. Understanding how HSCs evolve into leukemia may allow for more effective treatments of this disease.

Abstract Name: **Factors Associated with Lower Range of Biology Exam Scores**

Tuition rates across American colleges and universities are rising, contributing to the mounting financial strain on students. Joining the workforce in an attempt to ease that burden represents an emerging option. However, the loss of time due to work commitments likely represent a substantial impasse towards effective exam preparation. Specifically, we observed this relationship in archival data from the spring 2022 BIOL-211 Genetics course at Minnesota State University (MNSU) (IRBNet ID: 1899658). Comparing exam scores between students working (or committed to) a substantial schedule of 20+ hours per week versus those faced with lesser commitments revealed significant differences in course performance. Consistently low exam scores typically contribute to course failure, the subsequent obligation to re-take courses, further financial commitments, and ultimately the greater likelihood of lowered student retention. Herein, we report that students working/committing 20+ hours per week performed significantly inferior to non-working students, and we assess specific consequences and discuss potential remedies. Students committed to 20+ hours per week fared significantly worse in terms of total class points (P = 0.0089), with this population averaging a collective total of 75.5% (N = 44) compared to counterparts with less commitments, who averaged 82.2% (N = 30). These differences were most felt in the three class exams which accounted for 300 of the 500 total points (P = 0.0255, P = 0.0028, P = 0.0311). Consequently, of the 16 students that failed, 75% of them belonged to the 20+ hours population. We are the first group to report the statistical influence of out-of-class commitment levels vs. Biology exam scores. These findings represent important steps towards the identification of further underlying factors associated with reduced student exam performance, capable of informing on student retention, well-being, and an emerging benchmark for higher education to consider as the student-financial landscape evolves.

Abstract Name: **Determining the effects of Phosphorus on growth and biofortified finger millet (Eleusine coracana L.) germplasms in making baby foods in Kenya**

Communities throughout Africa, especially in Kenya, are experiencing food insecurity as a result of the drought. Although arid and semi-arid lands (ASALs) account for more than 80% of Kenya's land mass, there has not been a significant focus on utilizing a native "climate smart" drought resistant crop such as finger millet. The crop is nutrient-rich and has the potential to resolve worsening malnutrition, a lack of agricultural diversification, and economic stagnation due to its drought resilience, high nutrient levels and health benefits. The objective of this study was to determine how phosphorus levels and seed priming (acidic and alkaline) influence the growth and root structure of finger millet. Furthermore, the possibility for improving the low nutritional contents of finger millet by adding protein sources in the formulation of infant food was evaluated.The trial was conducted at Egerton University labs using 3 finger millet genotypes (Nakuru FM1, U-15, Snapping Green) in 3 replications. Data on germination rates, imbibition rates and nutrient profiles were analyzed. Results showed that water (control) highest germination rates (68%) while acidic and alkaline conditions reduced germination and growth of finger millet seeds. Nutrient analysis showed that, though biofortification increased phosphorus, calcium, and zinc for the baby formula, there was no significant difference in available protein against unfortified baby formula. Future research will investigate different protein sources to biofortify finger millet baby formula. Furthermore, germination tests will include additional concentrations of priming solutions to reflect the different oil abiotic stress conditions in drylands and its effects on growth and to yields. The research was completed at Egerton University in Njoro, Kenya, in the summer of 2022, under the supervision of PI Dr.Anne Osano of Bowie State University and Paul Kimurto of Egerton University, with assistance from Anne Amayu.

Abstract Name: **Studying the Effects of Aging on the Structure and Properties of Off-Eutectic Pb-Sn Solder Joints for In-Space Applications**

Soldering is a process in which molten metal is used to metallurgically bond two components together without melting the components themselves, predominantly used to create electrical and pressure joints. Metal joining processes such as soldering are currently being considered at NASA as possible techniques for use in in-space joint repairs and Mars rover sample return mission. However, the reliability of these solder joints is compromised when subjected to extreme conditions. Soldering studies during the in-space soldering investigation (ISSI) in 2003-04 aboard the International Space Station (ISS) were designed to gain a better understanding of solder porosity development, surface wetting, and equilibrium shape formation in microgravity. But these investigations have not considered the effect of aging on the solder microstructure and properties. Previous investigations have shown that near-eutectic 40Pb-60Sn soldering alloys exhibit grain coarsening and reduced mechanical properties with age, even at room temperature. Additionally, these investigations have shown that microgravity samples follow a similar aging pattern as terrestrial samples.In our current NASA EPSCoR project, solder samples will be produced in microgravity onboard the ISS and sent back to Earth for testing. The new experiments will include off-eutectic 50wt%Pb-50wt%Sn solder, a composition where the effect of aging is unknown. Understanding the effect of aging on off-eutectic solder is critical to understanding the properties of new samples produced onboard ISS in the coming years, as samples will not be returned to the lab and tested immediately. In this work, we report results from the microstructural characterization using scanning electron microscopy and resultant micro-to-nano mechanical response of 50wt%Pb-50wt%Sn solder produced in terrestrial environments as a function of aging time under room temperature conditions. The understanding gained in this study will enable robust and reliable protocols for solder-based solutions to address repair and fabrication needs in space exploration for years to come.

Abstract Name: **Why Do Countries Not Commit to Paris Climate Deal? Analyzing the Implementation of the Paris Agreement**

In 2015, in response to the pressing issue of climate change, 195 countries gathered together at COP 21 and signed the Paris Climate Agreement. The deal aimed to limit global warming to below 2 (preferably 1.5) degrees Celsius, as compared to pre-industrial levels. For the agreement's implementation, each country promised to submit a Nationally Determined Contribution (NDC) and a new updated NDC by 2020 and every five years thereafter. The NDCs conveyed how each country would formally commit to a low-carbon-production-based, climate-resilient society. The updated NDCs represent a progression from the previous NDC and reflect the country's highest ambitions. Despite the agreement to submit NDCs by 2020, there have been varying responses to the submissions — with some countries not submitting any at all. Little is known why certain countries did not keep their pledge while others did. This study aims to understand the factors that may have contributed to a country's continued commitments to the Paris climate deal via the submission of their updated NDC. To this end, I relied on the UNFCCC (United Nations Framework Convention on Climate Change)'s NDC submission data in 2020. A multivariate regression analysis was employed to determine the relationship between countries' NDC updates and multi-dimensional factors, including socio-economic, political, and environmental factors. The major findings indicate that a country with high political stability but low physical vulnerability to climate change is more likely to commit to the Paris climate deal. This study offers a timely insight into how to uphold the Paris climate deal in order to achieve carbon neutrality by 2050.

Abstract Name: **Impact of COVID-19 on Consumer Behavior Change: The US Case**

The COVID-19 Pandemic has led to a dramatic change in our daily lives and an unprecedented challenge to marketplaces with disrupted consumer shopping behaviors. It is evident that the chance of contracting the virus caused consumer behavior changes, as most grocery shoppers did not conceive the health concerns over grocery shopping before the Pandemic. This study aimed to investigate the overall impact of the Pandemic 19 on consumers' shopping preferences and behaviors in the US context. It also examined how gender and age played a role in shoppers' perceptions during the peak of the Pandemic. It hypothesized that the older are more likely to alter their shopping behaviors. For the empirical assessment, this study relied on the Pew Research Center's American Trends Panel Survey, sent to 11,537 Americans, and employed the difference-and-difference statistical modeling technique. The survey asked how personal lives were affected and how well the US government has been responding, and a series of categorial variables were created. The major findings indicate that most male shoppers tended to want to go out more than female shoppers and that younger generations of shoppers grew to use delivery services more than the older. The younger generations of shoppers also felt comfortable with online shopping and carry-out services, illustrating the quicker and stronger shopping behavior changes. This research provides insights into variations in peoples' resilience over public health concerns and suggests how business managers and policymakers alike may respond to the ongoing shopping behavior changes nowadays.

Abstract Name: **The short-term impact of Instagram commerce on the livelihoods of artisans at the Accra Arts Centre**

A sustainable livelihood can withstand shocks and stresses. The artisans at the Accra Arts Centre, the biggest locally made art district in Ghana, face a stressor for their livelihoods. This tension emanates from the ongoing Marine Drive Project. This aims to transform parts of the Accra coastline into a business residential district and will involve demolishing the Accra Arts Centre. As a result, these artisans must translate their livelihoods into sustainable ones that can withstand stresses such as these. Due to the COVID-19 pandemic, consumers' usage rate has increased across social media. Instagram is a unique social media platform because its value proposition is visual sharing and incorporates an embedded e-commerce system. This makes the platform a keen option for artisans relying on image sharing to exhibit their work online. However, many of these artisans in Ghana lack knowledge of how to use these tools to boost their business. This thesis studies a phenomenology known as the Digital Business Transformation Initiative. This social initiative teaches artisans how to create, manage and optimize Instagram accounts to further their businesses. From the initial findings of a sample of 120 artisans, there is a trend of artisans that frequently use Instagram tools, gaining more brand awareness. The following steps of this research are to understand the trends identified when the artisans have optimized accounts and if this will directly impact sales. One of the hypotheses is that Instagram commerce leads to increased sales. In that case, Instagram trade may be considered a sustainable livelihood for artisans.

Abstract Name: **Breaking Down Barriers: Providing Adequate Sexual and Reproductive Health Education, Access, and Awareness in Health Science Focused University**

The majority of students in colleges and universities in the United States are sexually active. Unintended pregnancies, contraction of sexually transmitted infections, and relationship/sexual violence negatively impact students' educational trajectories. College students who lack access to sexual health education, resources, and preventative services are at greater risk of adverse outcomes. Students attending the University of Minnesota Rochester (UMR) do not have readily accessible, or adequate, sexual and reproductive health resources. This newly developed satellite campus is comprised of 78% women and 82% of the students are aged 18-21. A student-driven inquiry of 95 UMR students revealed that 70% indicate no or uncertain access to sexual health education on campus. Only 12% of UMR students report easy access to sexual health services. Nearly 70% of students report cost, privacy and/or confidentiality contribute to significant barriers to contraceptive attainment on campus.As part of a pilot study, graduates of UMR implemented a grant-funded system to provide increased accessibility of contraceptives and reproductive products on campus. This pilot program assures confidentiality as access to sexual health resources is provided. In addition, a survey was designed and implemented to assess socio-demographic information, understand perceived and real barriers to sexual health services, resource acquisition on campus, and to briefly assess UMR student sexual health behaviors. Here we report our findings and lessons learned from this innovative solution to meet student reproductive and sexual health needs.

Abstract Name: **Effects of Microplastics Exposure in the Sea Anemone, Exaiptasia pallida**

Microplastics are one of the most common forms of pollution found in marine environments, and their small size (<5mm) allows them to be easily ingested by marine biota. Exaiptasia pallida is a solitary anemone native to the western Atlantic that harbors symbiotic dinoflagellates like those of reef building corals, and passively feed on prey such as brine shrimp. To assess the influence of microplastics on E. pallida, a series 48-hour laboratory experiments were conducted in which symbiotic and aposymbiotic anemones were exposed to 100 µm polystyrene microplastic beads in the presence and absence of brine shrimp. Ingestion and egestion of microplastics, and photosynthetic parameters were measured at 3, 24, and 48 hours following initial exposure. At 48 h, anemone tentacles were harvested and analyzed for algal symbiont density. Physiological stress in the anemones was investigated via assessment of antioxidant enzymes, superoxide dismutase, catalase, and glutathione peroxidase. E. pallida consumed polystyrene beads in every microplastic treatment, and both presence of brine shrimp and symbiotic state significantly increased microplastic ingestion. Aposymbiotic anemones ingested more microplastics than symbiotic anemones, suggesting that bleached anemone communities may be more susceptible to microplastic pollution.

Abstract Name: **The Risk at Birth: Racial Health Disparities among Pregnant Black Women**

The aim of this study was to examine health disparities amongst pregnant Black women and other racial ethnicities. The leading choice of research was descriptive research using quantitative data. Data were collected by scouring medical databases ranging from 2008-2021. Sources revealed that Black women are 3-4 times more likely to die in childbirth than white women. Interestingly, it was discovered that 60% of pregnancy-related deaths were preventable, and there were no significant differences in preventability by race/ethnicity. The largest discrepancies were found with cardiomyopathy and pre-eclampsia conditions.Conclusions for the impacts of health disparity upon pregnant Black women are provided.

Abstract Name: **Using Machine Learning Techniques in Breast Cancer Prediction**

Cancer is one of the leading health problems worldwide. Breast cancer is one of the frequent types of cancer affecting mostly women. Statistics show that at least 8% of women are affected by breast cancer in their lifetime, and it is currently the leading cause of death among women. Early detection of breast cancer improves the timely treatment of the affected individuals and, in most cases, increases the survival rate. This paper compares different machine-learning techniques used in breast cancer tumor detection. In this study, the Wisconsin breast cancer data will be used. The aim of this project is to come up with a comparative study of the different techniques. In addition, also highlight the strengths of each technique used. The dataset is classification data with 569 samples and 31 features which we will use to make the prediction. The machine learning models are logistic regression, random forests, decision trees, neural networks, and support vector machines (SVM). The machine learning model's performance is evaluated based on the test accuracy.

Abstract Name: **Understanding the Molecular Mechanism of Opioid Action in the Human Body Through a Course Embedded Computational Research Project**

Chemistry has and will continue to play an essential role in the development of new drugs. Specifically, chemical synthesis has resulted in several synthetic opioids, for example, morphine, oxycodone, and codeine. In this research, the goal is to gain an improved understanding of the interaction between an opioid and the opioid receptors present in the human nervous system and determine which pain relievers are the most effective. In general, the two chemical properties that regulate the reactivity of a molecule are its electronegativity, or the ability of an atom in a molecule to attract electrons, and chemical hardness, which is the ease with which the atom's valence electron clouds can be distorted. The chemical properties of twelve prescription pain medications are investigated computationally. The drug molecules are constructed using a web-based tool WebMO, and their electronegativity and hardness are determined using a quantum chemistry program called Q-Chem. Also, the interactions between prescribed opioids and opioid receptors are analyzed using the online resource SWISSDOCK. Additionally, SwissADME is used to investigate the pharmacokinetics of each drug molecule. Our findings will offer insight into how different opioids interact with opioid receptors and how that information could be used in developing better pain medications. The preliminary results of the research will be presented.

Abstract Name: **Effectiveness of Steel Wires in Compressed Stabilized Earth Bricks (CSEB)**

The purpose of this research project is to contribute to the development of interlocking Compressed Stabilized Earth Bricks (CSEBs) by studying crucial engineering properties (e.g., strength) of various highly compressed soil/stabilizers mixes of CSEBs. One of the many approaches involves steel wires' effect on the compressive strength and absorption of CESBs. We will examine three sets of samples with varying mix proportions (soil with 70% sand and 30% fines), then stabilize them with 10% Portland Cement. Two of the three sets will contain 1-inch cut steel wires. Afterward, our soil samples will be compressed with a (16-20) MPa hydraulic pressure compactor. Through experimentation and examination, the study will contribute to the knowledge of this evolving, aspiring green technology manufacturing environmental-friendly CSEBs. Unlike ordinary and modern construction materials like concrete and Fired Clay Bricks (FCB), which foster environmental degradation, manufacturing CSEBs poses a potential solution for effective, environmentally friendly building materials. Furthermore, they are energy efficient and economical compared to the production of FCBs that significantly damage our environment (e.g., global warming and Ozone depletion) due to the high energy levels. Along with being environmentally friendly, there are numerous other benefits of CSEBs. For instance, they lower transportation costs, promote local resources, develop the local economy rather than spending on import materials and improve access to quality housing for many people. Ultimately, our goal is to contribute to developing CSEBs as green construction materials through mechanical and chemical stabilization techniques. The anticipated results are that incorporating steel wires in CSEBs will reinforce compression and absorption.

Abstract Name: **Rheological Investigation of Protein Mechanic**

Enzymatic proteins are crucial to cellular function, performing extremely important tasks within the human body. More specifically, cellular function and efficiency depend on chemical reactions facilitated by enzymatic proteins. Previous research has shown that proteins are non-static objects, undergoing conformational changes within their reaction cycle. Enzymes need to couple their chemical reactions to this mechanical motion in a very specific and regulated fashion. Enzymatic activity is well understood biochemically, but there is limited data on the mechanical properties of enzymes. Thus, further exploration of these macromolecules employing a biomechanical approach is necessary to obtain a comprehensive view of how proteins function. For this purpose, in this study a novel technique is used to investigate the physical properties of proteins. This technique, called Nano-rheology, can measure the conformational changes of the protein under different frequencies and amplitudes of the applied oscillatory force. In this setup gold nanoparticles, tethered to a gold surface by the protein, are driven by an ac electric field while their displacement is synchronously detected by evanescent wave scattering, yielding the mechanical response function of the macromolecule in the frequency domain. Collected data on the mechanics of proteins contributes to the larger encyclopedia on the relationship of protein structure and function and can be applied to advancements in many fields.

Abstract Name: **Fostering Creative Inquiry on the Two-Year Campuses: A Discussion at the Confluence of Humanities, Sciences, and Academic Support**

As undergraduate research is a high-impact pedagogical practice, offering our students opportunities for meaningful and creative inquiry and guiding them as they undertake that inquiry is especiallyimportant on the two-year campus. Some of our students will graduate with an associate degree, meaning that this is the only chance they will have to do this work. Others will transition to four-year institutions, where they will need to be prepared for higher-level research when they arrive. At the same time, two-year colleges present unique challenges in supporting undergraduate research and embedding it into the curriculum. This panel will share some of the challenges faced by students, faculty, and staff in our two-year colleges from three perspectives—the sciences, the humanities, and academic support—then guide a discussion about strategies for meeting those challenges to enrich undergraduate research and creative inquiry. By bringing together these perspectives, we will examine undergraduate research on the two-year campuses at the confluence of the humanities, the sciences, and academic support with the goal of fostering creative inquiry and preparing our students to succeed in the next stage of their intellectual growth.

Abstract Name: Retention Pond Recovery Practices and their Effects on Water Quality and Littoral Vegetation

There are more than 8,000 retention ponds in Lee County, which are critical for pollution reduction and flood prevention. Many of these retention ponds, however, do not fulfill their intended purpose of preventing flooding and reducing pollution; rather they suffer from an imbalance in the nutrient levels and vegetation die offs. A variety of littoral and aquatic plant life plays an important role in improving the pond's health by acting as a filter to sequester nutrients which aids in reducing pond pollution. By comparing the water quality and plant biodiversity of differing retention ponds, the effectiveness of various pond management strategies can be evaluated. In this study, three different Lee County retention ponds with various management practices and implementations were compared. The pond labeled FGCU Library Pondserved as the control because it is specifically designed to mimic natural conditions and resembles a wetland with lower nutrient levels and higher plant biodiversity. The ponds labeled Fairwinds and Southlandare in different stages of restoration. Since November 2021,Fairwindshas had a "no-mow" zone, eliminated pesticide and copper dye applications, and has removed an invasive plant species. Until May 2022 when the community implemented the same recovery program asFairwinds,Southlandmowed the littoral zone and used pesticides and copper dye which killed all vegetation.Water quality samples and data analysis evaluating the impact of the restoration strategies have shown significant lowering of nutrient levels after the change in management practices. As of May 2022, the Fairwinds pond showed similar nutrient levels as theFGCU Library Pond while the nutrient levels of the Southland pond are steadily decreasing. Our next phase of research—the continuation of plant composition surveys—looks to determine the impact of lower nutrient levels on plant biodiversity.

Abstract Name: Analysis of 2 variants of CERKL, a gene associated with ocular disease

Genetic testing, including whole genome and exome sequencing, is quickly becoming a standard healthcare practice, especially for patients with rare diseases. While some changes to DNA sequences can be benign, there are several variants that have not been characterized. One large group of these variants are classified as variants of uncertain significance (VUS), as the effects have not been directly studied yet. However, effectively interpreting the relationship between identified variants and disease remains challenging. VUS can include variants that are predicted in silico analyses to affect splicing of the pre-mRNA into mature mRNA. Disruption of splicing can result in loss of a functional gene product due to exon skipping, changes in the reading frame, or introduction of a premature stop codon. In collaboration with PreventionGenetics, our lab analyzes VUS predicted to affect splicing of genes using a minigene system. Briefly, the minigene system involves cloning a single gene segment into a plasmid vector which is transfected into eukaryotic cells. Processed mRNA transcripts are then sequenced to determine the effects of the variant on splicing. We will present our analysis of 2 variants in the CERKL gene and their potential clinical relevance.

Abstract Name: Psychology of Acting Disassociation Methodology

Breaking down a character's psyche is important as a way to help the actor disassociate themselves, and provide them with a fully round-rounded view of their character's world. A character is written for a specific audience, The research of an actor is to understand how the audience will respond and react based on their social, economic, and historical background. This methodology allows performers to really dissect the understanding of empathy, and with that is how we reach deep, rooted emotions to give the best performance. Using psychology as a tool for characterization is not only a way to give an accurate and authentic performance. However, many performers dive into the characters and have a hard time disassociating with their characters after the workday is done. This can lead to mental health issues and even tragedy. In this 15-minute talk, I will explain how a psychology-based methodology for character building allows the actor or performer to know the character deeply so that when they step into the character, they understand why that would be their response or reaction, giving the performer a chance to disassociate between character and human being.

Abstract Name: The Impact of COVID-19 on Recovery Communities in Appalachia

COVID-19 led to an evolution in substance use disorder (SUD) treatment where service providers and persons with SUD have faced various barriers in giving and receiving treatment (Mellis et al., 2021; Palacio-Gonzalez et al., 2022; Radfar et al., 2021). Therefore, the purpose of this study is to examine recovery meetings pre- and post-COVID-19. Data was collected through phone interviews and emails that were coded to account for the current state of recovery meetings from 2018-2022. The data was analyzed using a chi-square test of independence and a chi-square goodness of fit test. In our sample of recovery meetings, there was a significant difference between the expected number of meetings before and observed number after COVID-19 X2 (4, N = 350) = 39.303, .001. Furthermore, there is a significant relationship between the number of meetings offered in the noncore, micropolitan, small metro, and medium metros and their meeting status. This indicates that most rural locations are related to lower frequencies of meetings (12, N = 350) = 44.983, .001, Cramer's V = .207. An overwhelming majority of the meetings have an unsure status (N = 118). This indicates the meetings could not confirm or deny their availability of transportation. Meetings that do offer transportation (N = 10) and do not offer transportation (N = 77) lacked sufficient sample size to analyze differences in locations. Thus, we can only tentatively support our final hypothesis. Based on our results, we can posit that recovery meetings and communities have been negatively impacted by the COVID-19 pandemic in Appalachia.

Abstract Name: **Effects of Well Opacity, Well Shape, Length of Light-Dark Stimulus Time, and Larval Age on Zebrafish Larvae Swimming Behavior Development**

Zebrafish are an excellent model organism for high-throughput behavioral analysis. Measuring development of simple behaviors such as swimming can provide insight on underlying neurodevelopment of zebrafish larvae. Dark-induced hyperlocomotion is a common stimulated movement used to assay swimming behavior. Video tracking software allows analysis of swimming patterns in response to cycles of light and dark stimuli in a controlled environment to be conducted. However, the methods used in such zebrafish behavioral studies vary in the literature, and some intrinsic and extrinsic factors have been shown to significantly affect fish behavior. We investigated whether four additional factors (well opacity, well shape, length of light-dark stimulus time, and larval age) influence swimming behavior in larval zebrafish. 5 day post-fertilization (dpf) zebrafish in 96-well plates were exposed to an alternating light-dark protocol and tracked for movement using a commercial motor tracking system (Noldus DanioVision). 5 dpf fish in opaque wells showed higher average velocity compared with 5dpf fish in clear wells. Fish in square wells also showed higher average velocity in all lighting conditions compared to fish in circular wells. Fish exposed to differing lengths of light-dark stimulus time showed no difference in swimming behavior. Varying the age of zebrafish larvae tested also showed no effect on swimming behavior. Our results emphasize the importance of internal normalization per experiment and reporting protocol details to enable informed comparisons between these kinds of behavioral studies.

Abstract Name: **Accessibility in Receiving Accommodations in Higher Education: A Qualitative Case Study Analyzing Students with Disabilities at the University of Wisconsin- Eau Claire**

Since the enactment of The Americans with Disabilities Act (1990) and Section 504 of the Rehabilitation Act (1973), there has been an increase in students with disabilities in higher educational settings (Smith 2021; Taylor 2021). Despite legal protection against discrimination, students with disabilities continue to face barriers. This case study's aim is to answer the research question: Is the University of Wisconsin- Eau Claire accessible and accommodating to students with disabilities on an attitudinal basis? Informing this qualitative case study are three forms of data collection: reflective journaling, interviews, and pre/post-study surveys. The focus population was 20 undergraduate students enrolled with the Services for Students with Disabilities Office at the University of Wisconsin- Eau Claire. The expected results based on the data that has been collected to date indicate that students with disabilities perceptions of themselves are influenced by their interactions with their university instructors. These interactions include requesting and receiving accommodations. The need for continued research using evidence-based practices, such as Universal Design for Learning in higher education is also discussed.

Smith, S., Woodhead, E., & Chin-Newman, C. (2021) Disclosing accommodation needs: exploring experiences of higher education students with disabilities, International Journal of Inclusive Education, 25:12, 1358-1374, DOI:10.1080/13603116.2019.1610087

Abstract Name: **Italian Renaissance Cultural Values Represented in the Image of Children**

Cultural values of the artists and/or the Italian people in the Renaissance period are reflected in depictions of children in works of art in this period. Examples of indicators of cultural values include; the shapes of children's bodies, their facial expressions, other individuals within the image, objects that hold value, or a specific story being told in the work of art, are. The portrait of Giuseppe da Porto and his son Adriano (Paolo Veronese, 1555 AD) appears to portray a protective father with a firm hold on his child, who in return reaches for his father with admiration and innocence. This is a noteworthy image not only in the relationship between father and son, but also in the clothing and artifacts in the portrait that imply significant wealth and cultural values of that time, within a certain population. In addition to familial representations in art, children often appear in biblical stories and mythological fables in Renaissance art. Presentations of children's busts, specifically males, in the early Renaissance were often renderings of St. John the Baptist. Arnold Coonin argues that these images embody the destiny of a male child, so much so, the artist captures the vitality of a child's life in a way that differs from medieval sculptures. For Coonin, these Renaissance sculptures emphasized the corporeality of the human child, especially in their depiction of religious Christian figures. In this paper, I will explore how certain cultural values, set by societal norms, shaped and formed images of children throughout the Renaissance and how art can be an indicator of cultural values of the time.

Abstract Name: **Mindfulness Interventions for Vaping Management**

Background: Omoike (2020) reported that 43.2% of college students experienced vaping. Kava (2020) also reported that peers' increasing exposure to vaping and school-related stress are associated with vaping behaviors. There are several risky behaviors associated with vaping among college students. Hefner (2019) found that e-cigarette use was associated with drinking alcohol, binge drinking, and was more prevalent among those with psychiatric and substance use disorders. Since vaping is a rather new phenomenon, there are few interventional studies published.Searching PubMed with keywords of "vaping" and "randomized control trials" resulted in 2 publications. Walter (2019) found that the self-affirmation narrative increased self-appraisal and perceived risk among college-aged young adults about vaping. Prokhorov (2021) also found that eight weeks of receiving gain-framed positive SMS increased participants' perceived risk of vaping. Objective: This study aims to investigate University of Wisconsin-Eau Claire students' behaviors and rationales for vaping, along with the effectiveness of practicing mindfulness techniques in combination with weekly positive framed short message services (SMS) on vaping behaviors. Methods: A total of 80 participants who vape as a school stress intervention are asked to describe their habits with a pre-test questionnaire. Upon completion, they will be assigned to an experimental or control group, in which only the primary investigator will have an identification key. For four weeks, the experimental group will be provided vaping pamphlets, mindfulness techniques (4-square breathing, coloring books, meditation, journaling, etc.), and weekly positive SMS, while the control group will continue with their normal behaviors. Two and four weeks after the initial pre-test, participants will receive questionnaires, asking about their vaping habits and stress levels. From the data collection, we will determine how mindfulness techniques affect participants. Results: Results are pending until the study is completed. Conclusions: Conclusions are pending until the study is completed.

Abstract Name: Cyberbullying and Race

Cyberbullying is a behavior that can have numerous negative consequences for the youth victimized by it. Thus, investigating risk factors and protective factors for cyberbullying is a worthwhile endeavor. The current study, to be presented in a poster format, was first conducted as a literature review focusing on cyberbullying, both victimization and offending, in relation to the demographic race and expanded further. Numerous peer-reviewed studies from sources such as Google Scholar and Ebsco from the fields of criminal justice, psychology, and adolescent health were read and evaluated for this review. Although no one conclusive answer regarding race and cyberbullying was found, some patterns did emerge in the literature. Two trends are dominant in the research: the first being that white students are victimized by cyberbullying more often than non-white students and the second being the opposite, that non-white students are victimized by cyberbullying more than white students. There are numerous different reasons provided by researchers to back and attempt to explain these findings. The literature does not support one finding more strongly than the other, thus future research must be conducted in order to figure out which trend is more prominent. More research on race and cyberbullying offending would also be extremely beneficial.
Keywords: Cyberbullying, race, risk factor, protective factor, victimization, offending

Abstract Name: Biochemical Analysis of Non-Protein Coding RNA LINC00298 and Its Expression in Early Onset Alzhimers.

Alzheimer's is a terminal-neurodegenerative disease which causes neuronal loss in the brain. This disease affects 5.6 million people a year over the age of 65 and is the most common diagnosis among Dementia patients. Data meta-analysis of Alzheimer's patients has found that specific genes, when expressed, may lead to the development of Alzheimer's. One gene of interest is LINC00298 which is a non-protein coding RNA in the brain that is present in Early-Onset Alzheimer's. Very little is known about the impact of this gene during development. Our research team's focus is to biochemically and biophysically analyze LINC00298. Working in collaboration with the School of Pharmacy at North Dakota State University, using Circular Dichroism and Cell Mobility Shifts, researchers were able to identify that the gene depends on Mg2+ using the electrostatic interactions to undergo significant structural changes upon binding. Additionally, through the use of Mass Spectrometry in coordination with the University of Minnesota Minneapolis, Center of Mass Spectrometry and Proteomics. The LINC00298 gene was biotinylated at the 3' end and bound to streptavidin beads. This testing allowed for an understanding in its interactions with enzyme metabolism as well as protein translation. This new information gives insight on the importance of the gene and will potentially assist in finding solutions for Alzheimer's in the future.

Abstract Name: More than one victim: The mediating role of envy in the impostor phenomenon-workplace deviance relationship

PurposeThose who experience the impostor phenomenon (IP; Clance; Imes, 1978) believe they have tricked others into believing they are more competent than they believe themselves to be, and they fear being exposed, despite impressive records of achievement. While most research presents those who experience IP as victims to be pitied, little research has considered the dark side of IP and the lengths those who experience it will go to avoid discovery. The purpose of this study is to fill this gap and examine the dark side of IP.Hypothesis Drawing on conservation of resources theory (COR; Hobfoll, 1989), we hypothesize that IP is positively related to both episodic envy (EE; Duffy at al.,2021) and interpersonal workplace deviance (IWD; Bennett; Robinson, 2000). Next, we hypothesize that EE is positively related to IWD. Finally, building on our previous hypotheses, we expect IP to have an indirect, positive effect on IWD through EE.MethodWe collected survey data across three time periods utilizing Amazon's Mechanical Turk (MTurk; Burhmester et al., 2011), with IP and control variables (gender, age, race, and ethnicity) collected at Time 1, EE at Time 2, and IWD at Time 3. There was a minimum of 14 days between each wave of collection, and our final matched sample included 119 participants. FindingsUtilizing Preacher and Hayes' (2008) mediation procedure, our results provide support for our hypothesized positive relationships between IP and EE (B = 0.9699, .001) and between EE and IWD (B = 0.4283, .001). We found no direct effect of IP on IWD, however, we did find a significant indirect effect of IP on IWD through EE (b = .4154, SE = .1113, 95% CI [.2005, .6403]), suggesting full mediation and providing broad support for our hypothesized model

Abstract Name: Waveform Play Space

One major purpose of this group is to form a collaboration between Music and Visual Arts at UWEC. A group of 4 students from Music, Photography, Graphic Communications, Illustration, Painting and Drawing will work with faculty mentors over the summer to translate sounds from nature that create interesting visual patterns in real time. The vibratons from those sounds will be the basis for developing an interactive installation envirment between Visual Arts and Music; Theater Arts. The resulting installation will be displayed publicly in the Haas Fine Arts Center Lobby in October 2022. This student/faculty team will work for approximately 10 hours per week during the summer and early fall to complete the project. Faculty includes Professor Jyl Kelley from Art; Design, Professor Gary Don from Music Theory, and Assistant Professor Mykola Haleta

Abstract Name: Synthesis and miscibility characterization of stimuli-responsive polymers for applications in architectural coatings

Polymers are long repeating chains of atoms or molecules with applications as additives in a wide variety of products. Stimuli-responsive polymers change their properties when exposed to different environmental conditions such as temperature, pH level, and salt concentration. Controlling polymer structure through precise synthesis techniques directly determines the stimuli-responsive properties of these polymers. Stimuli-responsive polymers can be used as dispersants for titanium dioxide particles (TiO2) within architectural coatings, such as paints, primers, and stains. Titanium dioxide is an opacifier in architectural coatings, blocking light from passing through. By controlling the polymer environment, the stimuli-responsive polymers can improve the dispersion of titanium dioxide, lowering the amount of titanium dioxide needed in the coating while increasing the opacity of the coating. Lower amounts of TiO2 lowers cost for consumers as well as environmental impact from titanium mining and processing. Synthesis of diblock and triblock copolymers with controlled copolymer composition and stimuli-responsive properties using activators regenerated by electron transfer atom transfer radical polymerization has yielded smart polymers with observable switchable miscibility properties. Characterization methods of the properties of these polymers includes nuclear magnetic resonance spectroscopy, gel permeation chromatography, and pendant drop tensiometry. Nuclear magnetic resonance spectroscopy provides evidence of synthesis success and yield proportions by indicating which functional groups are present and whether stimuli-responsive structures have been synthesized. Gel permeation chromatography allows us to identify the polymer molecular weight and weight distribution, in order to predict the smart properties of each polymer. Pendant drop tensiometry provides data on interfacial tension at several temperatures, pH levels, and concentrations, to predict how the polymer will behave as dispersants for TiO2 in different architectural coating environments. Determining how stimuli-responsive structures and properties are related by polymer synthesis is essential to optimize materials for the dispersion of titanium dioxide in architectural coatings.

Abstract Name: The Next Generation of Super Heroes: Are Glasses The Future of Disguises?

Even a small change to someone's facial appearance, like wearing glasses, can negatively impact our ability to identify them, especially if we don't know them very well (Graham, D.L.; Ritchie, K. L., 2019). This study further explores how recognition of unfamiliar faces is affected by wearing glasses and whether a person's ability to form vivid images of faces correlates with their ability to recognize unfamiliar faces they have seen. Forty subjects from a regional midwestern state university were familiarized with a set of 20 images of white college-aged male faces, half with and half without glasses. This category of faces was used because university and state demographics suggest most subjects would have extensive experience recognizing them. Subjects saw each face for 3 seconds and rated how much fun they thought the person might be at a party. Subjects then performed a face visualization task. Finally, subjects' memory for the original faces was tested. The test contained new images of the previously seen faces and images of 20 new faces (half with and half without glasses). Of the previously shown faces with glasses, half of the test faces were of the same person with glasses (glasses/glasses) and half were of the same person without glasses (glasses/no glasses). Of the previously shown faces without glasses, half were of the same person with glasses (no glasses/glasses) and half were of the same person without glasses (no glasses/no glasses). Subjects indicated whether they thought the face was new or old. Subjects' accuracy at recognizing faces was the best in the non-switch glasses/glasses condition and the worst in the switch glasses/no glasses condition. Additionally, wearing glasses negatively impacted subjects' ability to recognize a previously seen person, even in the glass/glasses condition. Vividness ratings did not correlate with face recognition ability

Abstract Name: **First study of a mother aye-ayeðs (Daubentonia madagascariensis) anxiety behaviors peripartum**

Anxiety is a negative psychological state induced by stress triggers that can be seen in animals in the form of repetitive, rhythmic movements known as stereotypies. Primate mothers face anxiety due to birthing, infant health, and social relations. In this study, a mother aye-aye (Daubentonia madagascariensis) was observed to assess anxiety behaviors. It was hypothesized that the behaviors would change over time. With Duke IACUC approval, Pelco IMM12027-1S cameras were placed in a Duke Lemur Center (DLC) aye-aye mother's enclosure to record her activity. Over three days peripartum, three hours of footage (12:00-15:00) were viewed, and continuous focal animal sampling was used to note the time, duration, and type of repetitive scratching, grooming, etc. Data were then analyzed using a Kruskal-Wallis Test and a sample means test. The results showed that the day before birth, the mother repeatedly constructed and deconstructed nests three times more than engaging in any other behavior (ns), while on the day of birth, the mother groomed and scratched herself a lot (n=80x, n=62x, respectively, ns). The day after birth, the mother was hyper-alert (n=12x). Thus, the hypothesis was supported as the mother exhibited signs of anxiety by engaging in different stereotypies over the three-day period. While limitations such as a small sample size (n=1) and possible abnormal parturition behavior are evident, this study is the first to examine maternal anxiety in aye-ayes. The results can help husbandry staff create more comfortable environments for the rare and difficult-to-see captive aye-ayes.Funding generously provided by NC State's Provost's Professional Experience Program

Abstract Name: **Adult Perception on Outcomes of Child Custody Cases**

Custody cases are meant to find the best possible option for the child, the process the child experiences lead to negative mental developmental outcomes.Throughout the family court process the families often face challenges that may consist of stress, role confusion, financial struggles, depression, anxiety and many transitions and changes to their everyday lives. One major obstacle for many families that have to deal with family court orders are the financial overloads placed on families. Private information often causes tension in families and households. This mixed methods study focuses on adults who have experienced a child custody case at any point during their childhood using a pre-developed Perception Survey. The survey consisted of 15 questions including demographic, multiple choice and open ended. Twelve articles were reviewed by the student researchers focused mainly on parental alienation, including factors associated with child custody cases and family court proceedings and how they affect the child involved.The student researchers used the literature review to aid in developing their research. This exploratory study explores the effects of child custody cases on mental development of children. The student researchers plan to study the impact of child custody cases by identifying the mental development outcomes of adults, who were a part of a child custody case. The student research group developed the following research question: (1) What are the mental development outcomes of children who were part of a child custody case? The study includes participants older than 18, who were involved in a child custody case when they were under the age of 18. Through purposive sampling, the researchers survey 75 participants to gain a better understanding of their perception of their childhood experiences during their child custody case.

Abstract Name: **Food Restriction and Stress: A Rat Model of How Restricted Food Intake Affects Stress Resiliency**

The human body reacts the same to natural disasters, threats of violence, and bodily injury as it does to work pressure, financial difficulties, and traffic jams – which are now quotidian in most societies. Modern environments constantly present the individual with stressors, priming many for continued activation of their stress response system. In laboratory rats, exposure to a previous stressor leads to decreased stress resiliency when exposed to subsequent stressors, displayed by higher acoustic startle responses. Severely restricted food intake triggers the same physiological responses as life-threatening stressors, and therefore should constitute as a stressor to the rats and cause a decrease in stress resiliency. An archival analysis of startle data revealed higher startle amplitudes among rats previously involved in adeprivation-induced hyperactivity (DIH) study compared to both naïve rats, and rats involved inother studies. A second study adding a food-secure control group to the DIH study was conducted to draw conclusions more confidently on the effect of food restriction on stress resiliency. Results of Study 2 do not indicate a significant effect of feeding condition on startle response, however. Further studies with larger sample sizes and more procedural details held constant need to be conducted before making any confident conclusions and extending results tohuman populations.

Abstract Name: **The influence of CYP2B6 variants and administration of propofol on patient outcomes after traumatic brain injury**

A traumatic brain injury (TBI) is a disruption in normal brain function due to disturbance to the head. These injuries are usually devastating; leading to lifetime disability or early death, with considerable variation in patient outcomes. A treatment commonly used in these patients is sedation, usually with an opioid or propofol, with potentially life-threatening complications as a result. The cytochrome P450 enzyme CYP2B6 is involved in the biotransformation of many drugs, including those used for sedation. Studies have found that variants of CYP2B6 can lead to decreased systematic clearance of propofol. This study aimed to investigate the relationship of the CYP2B6 polymorphism and patient outcomes after TBI while also considering propofol administration. There have been no investigations regarding variation in the CYP2B6 gene and patient outcomes after a TBI, warranting a need for a study of this nature. This study used data and biospecimens from a prospectively conducted study through the Brain Trauma Research Center in the Department of Neurosurgery at the University of Pittsburgh Medical Center Presbyterian Hospital. Inclusion criteria for this study included: a severe blunt TBI, Glasgow Coma Scale score 3-8, and not following commands. Collection of the drugs admitted to each patient was abstracted from the electronic medical records. The *6 polymorphism of CYP2B6 was genotyped using Taqman Allelic Discrimination of two single nucleotide polymorphisms (rs2279343 and rs3745274). Neurological outcomes were evaluated using the Glasgow Outcome Scale and Disability Rating Scale. 440 participants were included in this study. Individuals with the rs3745274 TT genotype and rs2279343 GG genotype were more likely to have worse outcomes. This could be due to decreased metabolism or systematic clearance of drugs. These findings suggest that CYP2B6 may impact patient outcome through drug metabolism and further investigation should be done regarding the role of CYP2B6 variants on TBI patient outcome.

Abstract Name: Virtual Observation Does Not Magnify Perception of Performance

Previous research has demonstrated that people perceive their actions as more substantial when they are being observed (e.g., Steinmetz et al., 2016). The goal of the present research was to test whether this effect emerges in a virtual setting. In light of previous research demonstrating that people can indeed share reality via virtual interactions, we hypothesized that people would report a magnified experience when being observed on Zoom. To test this hypothesis, undergraduates (N = 19) participated in an experimental session with an experimenter via Zoom. All participants completed a bogus smile judgment task during which they were either observed (camera on, share screen) or not observed (camera off, screen not shared) by the experimenter. The task was rigged such that performance and performance feedback was constant across participants. After the smile task, participants answered questions about their experience completing the task and estimated how well they performed. Although participants did correctly follow the instructions stipulated by the manipulation, they did not report feeling more observed in the observed condition relative to the unobserved condition. And, contrary to predictions, participants did not report feeling like they performed better in the observed condition than in the unobserved condition. Since virtual communication is now so prevalent, researchers should continue investigating this important question using a larger sample size (to increase statistical power), more nuanced dependent variables, and a fuller experimental design that allows for a direct comparison of the original in-person conditions alongside the virtual conditions.

Abstract Name: Studying the downstream targets of miRNA "hsa-miR-130a-3p" as a promising diagnostic biomarker for the diagnosing of advanced epithelial ovarian cancer

Ovarian cancer is a group of diseases that develop in the ovaries or the related areas of the fallopian tubes and the peritoneum. Epithelial ovarian cancer (EOC) is considered the most common type of ovarian cancer. In order to diagnose EOC, miRNA biomarkers are used. Identifying biomarkers with high sensitivity and specificity for the diagnosis of cancer is a high priority in the research field. In this study, we investigated the expression of the downstream target of a molecular biomarker in EOC. The biomarker of interest is hsa-miR-130a-3p. It has been shown that hsa-miR-130a-3p is associated with advanced ovarian cancer. Different bioinformatics tools were used in this study, such as miRanda algorithm and Targetscan in silico tools. After that, the results were verified by using RNA obtained from human ovarian cancer cells. The regulation of the miRNA in tissues was examined using Q-PCR to see whether they are upregulated or downregulated in RNA of EOC tissues compared to that of non-cancerous ovarian tissues. The levels of the downstream target genes at the RNA and the protein levels were examined using western blot and the human protein atlas database. This study showed that hsa-miR-130a-3p has downstream targets that are being dysregulated in the case of EOC. This indicates that hsa-miR-130a-3p has the potential to be used as a biomarker in the diagnosing of EOC. However, this study used a small sample in investigating hsa-miR-130a-3p downstream targets. Hence, it is recommended to do more research concerning this biomarker.

Abstract Name: Cumulative-risk assessment of exposure to well water contaminates, Boulder River Sub Basin, Jefferson County, Montana

Introduction: An estimated more than 23 million US households rely on private well water. Private wells are not covered by the Safe Drinking Water Act. The Environmental Protection Agency (EPA) does not regulate private wells. Arsenic and Uranium levels in Montana's Boulder River sub-basin private well and stream water has not been assessed. Therefore, risk associated with consumption of this water has not been assessed.
Objectives: Assess cumulative health risk from lifetime consumption of private well water in Boulder River sub-basin in Jefferson County Montana. Improve knowledge of water quality, resources and education on effects of consumption of well water.
Methods: Ground water information was collected from Montana's Ground Water Information Center (GWIC) website. Health risks were assessed in comparison to EPA health standards, using established EPA cumulative risk methodology. Literature on water quality in sub-basin was reviewed and utilized to achieve comprehensive understanding of water quality. Flyer about sub-basin's water quality prepared for local County Health Department.
Results: Average cumulative risk for consumption of water in sub-basin is 4.632 and 9.029 for tested wells and streams respectively. Any value exceeding 1.0 is unsafe for lifetime consumption. Additionally, 55.25% of streams and 11.84% of wells tested exceed EPA's maximum contaminant level (MCL) arsenic. 97.27% of streams and 94.74% of wells tested in sub basin exceed EPA's maximum contaminant level goal (MCLG) for arsenic. Uranium levels also exceed MCL: 50.77% of streams and 52.38% of wells tested exceed this limit. 96.92% of streams and 98.41% of wells tested exceed uranium MCLG.
Conclusions: Assessed risks and scope of contaminants in Montana's Boulder River sub-basin. Resource for relevant well owners was created. This resource could be applicable in other areas.

Abstract Name: Public Opinion on Florida's Parental Rights in Education Bill

Florida's Parental Rights in Education Bill prohibits public school teachers from instructing students in grades K-3 about sexual orientation and gender identity or, "in a manner that is not age-appropriate or developmentally appropriate," as stated by the Bill. It allows parents to choose how they want to introduce LGBTQ+ topics to their children and sue schools if they feel the policy has been violated. After Governor Ron DeSantis signed the bill in late March 2022, it has faced criticism from parents, students, and public officials alike, with opponents calling it the "Don't Say Gay" Bill. I hypothesized that there would be a difference in support of the Bill among individuals with and without K-3 children. To test this hypothesis, I wrote a 14-question online survey using Survey Monkey and collected data using Amazon MTurk. The sample for analysis consists of 196 adult respondents within the United States. The results show that there is a statistically significant difference in opinion about the Bill among people with and without K-3 children. In addition, I found a statistically significant difference among individuals who believe the Bill is beneficial and also believe that it could potentially increase suicide rates among LGBTQ+ youths. My results give further insight into the controversy of Florida's Parental Rights in Education Bill and show that there is a widespread prejudice and bias against LGBTQ+ individuals; however, more research should be done to further understand the impact of these differences in the long run.

Abstract Name: **Inversion of In-Group Favoritism in Adversarial Conditions**

Introduction: In-group favoritism (Sumner, 1906; Taijfel & Turner, 1986) is the phenomenon of giving preferential treatment towards individuals within the same perceived social group (e.g., age, race, gender).
Purpose: To experimentally assess whether in-group effects will negate and even invert when one party exhibits actions / demands that exceed the boundaries of a normal in-group association.
Procedure: See Appendix. We created a workplace scenario where the participant assumes the role of a co-worker. In the first segment, the participant is assigned to work with Mary, who requests some minor favors (baseline condition), and responds to the five assessment items shown in the Appendix. In the second segment, Brittany joins the workgroup, and does things that should go beyond in-group boundaries (inversion condition), and then the participant responds to the same five items.
Hypotheses: (1) sum of the five ratings will be significantly lower in the inversion (I) condition relative to the baseline (B); (2) participants who are around the same age as the scenario models will show a stronger inversion difference relative to those who are not; (3) because of its nurturing facets, the Big Five trait agreeableness will moderate the effect such that more agreeable participants will be less affected by the inversion effect.
Participants: 63 total from convenience and classroom samples, age ranging from 16 to 62. Results:Hypothesis 1: Baseline (mean=17.4, sd=3.0), Inversion (mean=10.8, sd=3.3), t=14.82 ($p<.00001$) Hypothesis 2: Same age (B-I mean=3.94, sd=3.6), different age (5.1 / 2.9), t=2.09 Hypothesis 3: Correlation Agreeableness vs B-I difference $r = -.24$ ($p<.05$) Discussion: H1 was supported, H2 was significant but in the wrong direction (non-matching aged participants showed a larger inversion effect), H3 was supported (more agreeable, smaller B-I difference). Follow-up research suggested for H2.

Abstract Name: **How do Black Congressional Members Frame the Issue of Gun Violence? An Analysis of Black Congress Members, Black Constituents and Gun Violence**

Black Americans are disproportionately affected by gun violence. In fact, in 2022 Black Americans were projected to be ten times more likely than white Americans to die by gun homicide. As outlined by the United States Constitution, one of the responsibilities of Congress is to represent people within their district by developing and voting on legislation that protects constituents by making their communities safer. It is the responsibility of Congress to address the issue of gun violence because it is an issue that jeopardizes the safety of many American communities, as there are roughly 100,000 victims of gun violence each year. Research has shown that the race of a Congressional member impacts how they frame issues that constituents face in their districts, especially issues that disproportionately affect minority groups. Most scholarship focuses on whether minority Congressional officials are more concerned with minority issues. Through researching Black Congressional members' communication surrounding gun violence, this thesis will fill a gap in the literature by focusing on how Black Congressional members specifically frame the issue of gun violence, an issue that disproportionately affects Black American citizens. This thesis asks the question of how members of the 117th Congress, who identify as Black, frame the issue of gun violence. Using content analysis, this thesis will analyze speeches, press releases, and social media of Black members of the 117th Congress. This thesis will contribute to the literature about how racial identity affects how elected officials frame issues, specifically issues that pose more of a threat to people of color.

Abstract Name: Systematics of the Southwest Desert Genus Hebecarpa (Polygalaceae)

Phylogenetic analyses of poorly known groups of plants using molecular markers can provide insight into into species limits and biogeography, which in turn have conservation implications. Native to the Southwest U.S. and Mexico, plants in the genus Hebecarpa are small, perennial herbs with ornate flowers and winged fruits. The level of variability in form within species with disjunct distributions in the southwest have led to some taxonomic uncertainties. Phylogenetic studies recently separated Hebecarpa from Polygala s.l. however not much is known about the intrageneric evolutionary history of the group. This research aims to describe some phylogenetic relationships within Hebecarpa and to test hypotheses of species limits in the genus using molecular data. Field collections were made of several species in the genus, some from disjunct populations of with widespread distribution. DNA was extracted for PCR and sequencing of the nrDNA ITS and cpDNA trnL-rpl32 region. Phylogenetic analyses using Maximum Likelihood and Bayesian methods were used to analyze the molecular data. The results of this study provide evidence that there is genetic divergence between disjunct populations of H. barbeyana, indicating potentially disparate evolutionary lineages and the presence of cryptic speciation across disjunct populations. Polygala magdalenae was found to be nested within Hebecarpa, supporting its taxonomic status within Hebecarpa. These results will be used to inform taxonomic revisions, species delimitation and further studies using genomic data with a more comprehensive sampling of species from the genus.

Abstract Name: Waveform Play Space

One major purpose of this group is to form a collaboration between Music and Visual Arts at UWEC. A group of 4 students from Music, Photography, Graphic Communications, Illustration, Painting and Drawing will work with faculty mentors over the summer to translate sounds from nature that create interesting visual patterns in real time. The vibratons from those sounds will be the basis for developing an interactive installation envirment between Visual Arts and Music; Theater Arts. The resulting installation will be displayed publicly in the Haas Fine Arts Center Lobby in October 2022. This student/faculty team will work for approximately 10 hours per week during the summer and early fall to complete the project. Faculty includes Professor Jyl Kelley from Art; Design, Professor Gary Don from Music Theory, and Assistant Professor Mykola Haleta.

Abstract Name: **Analyzing Interdisciplinary Teaching on Utilization of Math and Health Children's Books to Support Diverse K-8 Children?s Math Learning in Urban Classrooms**

This project aimed at 1) analyzing pre-service teachers' interdisciplinary teaching using math and health children's books and 2) identifying difficulties and challenges in a diverse learning environment with this interdisciplinary approach in urban K-8 classrooms in Southern California. About 78 pre-service participants from three math method classes participated in this study. Data collection includes pre- and post-questionnaires that assess their disposition and knowledge of interdisciplinary teaching, their creation of math and health children's books, and their reports of fieldwork teaching from the children's books. Data analysis includes both quantitative and qualitative methods. Quantitative methods were used to analyze the differences in pre-service teachers' disposition, knowledge of interdisciplinary teaching, children's math skills, health awareness and their disposition toward STEAM learning. Qualitative methods were used to analyze the approaches of interdisciplinary teaching used by the pre-service teachers, and to analyze the difficulties and challenges in a diverse learning environment. The preliminary analysis shows that the pre-service teachers were able to use a variety of ways in teaching math and health children's books in their fieldwork, and, as a result, their knowledge of interdisciplinary teaching and disposition were improved. There are some difficulties and challenges in children's learning: suggestions were identified for more effective interdisciplinary teaching, such as using manipulatives and teaching vocabularies before reading.

Abstract Name: **The Impact of Ontological Security on Political Territorial Disputes**

This research focused on investigating how ontological security impacts and causes conflict between various nation-states. The study extended previous research conducted by the authors, examiningontological security in Russia and Ukraine, to the conflict between Hong Kong and China. Specifically, this study investigated how the creation and rupture of ontological security within citizens of disrupted countries potentially lead to political disputes between nation-states over sovereign territories. A qualitative content analysis (QCA) was performed on sources relating to ongoing events, such as Mainland China's aggression towards Hong Kong and the significance of the national and individual identities of the Hong Kong people. In this study, behaviors, associations with identities, and emotions experienced by Hong Kong people were extracted from 31 academic sources. The study's findingssuggest that strengthening ontological security through culture and religion was the most prevalent within our data set. When comparing these findings to previous research performed, both similarities and differences in ontological security between Ukraine and China, two distinctly different nation-states, were found. The observations discussed in this study can be used to understand better how to engage in conflict resolution for territorial disputes from a diplomatic, peace-keeping perspective.

Abstract Name: **Machine Learning for Diagnosis of Traumatic Brain injury and Developing tools for Educating the General Public**

Identifying brain injuries in the preliminary stages through machine learning is important to avoid more complex situations in the brain. Long-term effects of brain injury can be associated with an elevated incidence of Alzheimer's disease and chronic traumatic encephalopathy. Machine learning is important and useful in avoiding the late realization of fatal brain injuries. The increased diagnostic accuracy of MRI (magnetic resonance imaging) technique reduces patient exposure to radiation by reduction of required scans. The goal of this research is to use machine learning techniques to detect traumatic brain injuries from MRI datasets using classification and clustering approaches. The preliminary stages involve importing the labelled dataset using python programming language and visualizing the topographical images. The next step is to convert the image data into numerical data. Then we will build a machine learning model for classifying the images either as normal or abnormal (indicates brain traumatic injury). The final step is to evaluate the accuracy of the model and calculate model's accuracy. We will present the results obtained so far.

Abstract Name: **Quantification and Stability Studies of Citrus Fruits- An Undergraduate Pilot Studies for Antioxidant Assay**

Antioxidants are oxidation-preventing agents that exert protective effect on important biological molecules through preserving function and promoting physiological balance. For the course-embedded general chemistry undergraduate research, citrus fruits with ascorbic acid (vitamin C) content were selected due to their notable antioxidant property. The primary aim is to quantify ascorbic acid (vitamin C) using select citrus fruits via acid-base and redox titration techniques. Instructor-guided proof of concept (POC) and pilot experiments will comprise 20% of coursework. Successful completion of the POC level qualifies for advancement to the pilot studies. Heat and time-based stability will be determined by groups of students as teammates in the class. Having learned the theoretical principles, a measure of achievement will base on ability to design and execute experiment according to set criteria, having quantified the ascorbic acid content and piloted the stability studies for the of the citrus fruits. The quantification result will guide classification as good, excellent or exceptional, based on FDA recommended daily allowance (RDA). The stability study outcome will inform advisory on storage -based potency of select citrus fruits at the various storage conditions. The reaction kinetics will of ascorbic acid degradation will also be elucidated. This serve as preliminary studies for the functional antioxidant assay.

Abstract Name: Unconscious Bias or Trainable Attitudes? Training Implicit Biases That May Be Detected in the Implicit Association Test

Implicit Association Tests (IAT) are intended to measure beliefs that people are unable to admit (Project Implicit).Architects of the IAT acknowledge that results are onlyweakly correlated with measurable behaviors. The purpose of the current research was to determine whether a neutral implicit association could be trained into participants and subsequently be detected on an IAT. Participants were trained to associate negative words with angular shapes, and positive words with rounded shapes. Training sessions presented angular or rounded shapes, followed bypositive or negative words. Participants had to press “correct” or “incorrect” buttons depending on the shape and word association shown. After completing all training sessions, participants were given an IAT to determine whether they showed an implicit preference for rounded shapes. The IAT was created using the experimental design utilized by the IAT Website according to the methodological designs provided by the authors (Project Implicit) and replication studies (Jain et al, 2022). Data collection is currently ongoing.During the training session, trainees’ reaction times were tracked to measure the strength of the associations being developed between shapes and positive and negative stimuli.After completing the IAT, trainees’ scores on the rounded/angular shape IAT will be analyzed using the standard chi-squared analyses to identify the presence and strength of implicit associations.Additionally, using a X2 test of independence, trainees’ IAT scores will be compared to scores of untrained participants who complete the same IAT.If results indicate that trainees exhibit implicit associations between rounded shapes/positive words, and angular shapes/negative words, and do so to a greater extent than control participants, this will suggest that implicit associations detectable by IATs can be formed quickly, and with relatively few exposures to previously nonexistent associations.These findings hold implications for understanding implicit associations and contribute to conversations on developing bias awareness training.

Abstract Name: How Social Media Discourses Shape Gendered Stereotypes of Women in Entrepreneurship

There is much evidence that entrepreneurship tends to be a male-dominated industry and that social media contributes to stereotype formation. This project uses content analysis of 34 various Instagram pages from women entrepreneurs. The analysis highlights what linguistic choices women entrepreneurs use in their social media posts. The captions are also classified based on their framing of women's entrepreneurship. Recent studies on women entrepreneurship have found that the Meso/Macro environment plays a role in the growth and development of women entrepreneurs. Taking an analytical gaze on these linguistic and visual choices may open a space to understand the gendering stereotypes of women in entrepreneurship. Additionally, may reveal the gender subtext that exists in the linguistic choices of women entrepreneurs. In this paper, I ask: what are the dominant social media discourses around women in entrepreneurship and how do the linguistic choices of female entrepreneurs reinforce or dismantle existing gendered stereotypes? For the woman entrepreneur, this analysis may highlight certain discursive practices that contribute to bias and inequality in the entrepreneurial space. For the linguist and philosopher of language, this analysis can reveal how discourse plays a role in stereotype formation in a given historically excluded group.

Abstract Name: The Wining Game

The glorification of winning in intercollegiate sports over the years has taken an unhealthy turn. The National Collegiate Athletic Association (NCAA) has slowly shifted from a governance system based on enforcing its stance on amateurism to one that covertly endorses its slow shift into commercialism. This switch has directly affected the perception of collegiate sports, putting a significant amount of pressure on the coaches to produce winning seasons; thus creating a demand for athletes with high mental toughness. The objective of this study is to research the emphasis on mental toughness in athletes as the win-at-all-cost mentality continues to prevail within the intercollegiate sporting scene. Drawing from pre-existing literature to enhance our understanding of mental toughness. We will be able to determine what programs focused on supporting collegiate athletes will be beneficial, what should be included and how to properly tailor them to combat the negative implications established by a fixation on mental toughness.

Abstract Name: Synthesis of Non-natural Amino Acid Catalysts

Catalysts are integral to improving the sustainability of chemical synthesis through the maximization of yields and subsequent minimization of reactant and energy consumption. Traditionally, transition metals have been utilized; however, concerns of toxicity, cost, and waste management have led to the development of organocatalysts. Mimicking proteins in biochemical systems, amino acids serve as a suitable scaffold for the synthesis of organocatalysts. With the decrease in toxicity from transition metals to amino acids comes an increased susceptibility to degradation; therefore, the synthesis of non-natural amino acids, specifically beta and gamma-amino acids with additional carbon atoms inthe peptide backbone, are of particular interest due to their decreased susceptibility to hydrolytic degradation. The additional carbon atoms in the peptide backbone also makes the synthesis of multifunctional monomers possible through the presence of multiple chiral centers. Here, a novel triamino acid monomer possessing an alpha, beta, and gamma-amino acid was synthesized in five steps.The activity of similar monomers in the catalysis of the Michael addition of aldehydes to nitroalkenes has been previously established in this lab. The future directions of this work are focused on the synthesis of dipeptides by coupling the triamino acid monomers and establishing whether enhanced catalytic activity is observed.

Abstract Name: **Identification and Annotation of Chico and Foxo Orthologs in Drosophila Species to Understand the Insulin/Tor Pathway Evolution**

The Insulin/Tor (IT) pathway is a crucial signaling pathway responsible for metabolism and glucose uptake, and has influence on longevity, fat/protein metabolism, and cell growth. Inaccurate regulation of this multi-functional pathway plays a key role in many well known human diseases, from diabetes to cancer. Chico– a gene involved in the IT pathway– encodes for a substrate responsible for positive regulation of the insulin receptor's (InR's) binding activity. Past research on network architecture has found that a gene's constraint level is affected by its connectivity and position in the pathway. Ponce et. all showed that IT pathway genes closer to the membrane evolve faster than downstream counterparts. We hypothesized that, due to its involvement in the crucial IT pathway, chico's orthologs are conserved in the target species D. elegans, D. ficusphila, D. miranda, and D. hydei, and their protein identities would decrease according to phylogenetic distance from the reference species D. melanogaster. However, we predicted that chico's selective constraint will be weaker than other pathway elements (i.e. FOXO) because of its upstream position. Chico's putative orthologs were annotated in all four target species and modeled with tools from the Genomics Education Partnership (GEP) pipeline, including the UCSC Genome Browser, tBlastn and Blastp searches, the Gene Record Finder, and the Gene Model Checker. The target species' protein alignments were examined, roughly spanning 45%-80% similarity to the reference species. The average protein identity percent was lower than FOXO's, supporting our hypothesis that position in the pathway is inversely related to selective constraint. Additional species genomes have been recently added to the GEP pipeline. Future studies across those genomes will strengthen our findings.

Abstract Name: **Engineering a Biological Habitat for real-time monitoring of plastic consumption in a Microgravity Environment Onboard the International Space Station**

Low-density polyethylene (LDPE) is a widely used thermoplastic polymer, with applications ranging from packaging to radiation shielding. LDPE is substantially less recyclable than other common plastics, such as polyethylene terephthalate (PET), high-density polyethylene (HDPE), and polypropylene (PP), with a <5% EPA-reported recycle rate. Therefore, LDPE disposal is an imminent and growing environmental challenge on Earth, and similarly affects future needs for waste disposal during long-term space travel. Recently, Galleria mellonella, commonly known as the waxworm, was shown to degrade LDPE into ethylene glycol in offering a sustainable approach for plastic use and disposal. In July 2022, Arkansas State University sent an experiment to the International Space Station (ISS) to test if waxworms can degrade LDPE in a microgravity environment as a part of the NASA Student Payload Opportunity with Citizen Science (SPOCS) program. The engineering challenge required designing an instrumented waxworm habitat, that met NASA's operational constraints for ISS experiments, capable of maintaining waxworms during a ~30 day flight while monitoring their mortality, overall health, and LDPE consumption. Constraints included a standardized form factor, maximum power at 900mA/5V, and full environmental containment. The final module (10x10x15 cm) was instrumented with cameras for observing waxworm behavior during flight, as well as temperature sensors and humidity sensors, all controlled by a Raspberry Pi Zero microcontroller. A rapid design and testing approach was used during the design phase, utilizing 3D printing to quickly test and validate designs. This approach resulted in the build of an autonomously operated module to capture images and log temperature and humidity data. Real-time imaging capabilities confirmed the hypothesis that waxworms can survive microgravity stress and validated food and plastic consumption patterns and behaviors similar to earth controls. These results may enable new strategies in the future for improving sustainability and waste efficiency during long-term space travel.

Abstract Name: Teaching The California Genocide

This presentation covers a nine-day Project-Based Learning unit plan for twelfth graders on the California Native American Genocide of 1846 to 1873. The unit plan sequentially scaffolds the students' learning, allowing them to construct meaning as they interact with content in various learning tasks requiring critical High Order Thinking (Jigsaw activity, research, public presentations, etc.). Along with inculcating virtue to prevent future genocides, the desired outcome of the unit is for students to extrapolate what they know about the California Genocide into the modern day to take a stand as informed citizens on the current Native American reparations debate.

Abstract Name: Assessment of thread microgrooving and nanofiber coating's impact on stainless steel bone anchors' immediate biomechanical and microstructural performance in vitro

Bone anchors are often used implants in orthopedic surgery on both humans and animals. Our research is now concentrating on increasing the longevity of orthopedic implants by surface treatment of implants with the goal of delivering facilitative molecules to the bone-implant contact. In the current work, we want to ascertain how the device's acute biomechanical and microstructural performance are impacted by microgrooving and nanofiber coating. Bone Anchor Unmodified (BA), Bone Anchor Micro-Grooved (MG), and Bone Anchor Micro Grooved with Nanofiber Coating (NF) are the three treatment groups that will participate in the trial. The study's parameters included histomorphometric and biomechanical measurements. Total microcrack area was calculated by adding together related and disconnected regions; measurements were compared to calculate microcrack area as a percentage of bone area in the ROI. Microcracked area has decreased significantly in Group samples of microgrooved and microgrooved- nanofiber mesh anchors compare to the intreated group. In general, bones with larger trabeculae thickness, lower structural model index (SMI), and higher bone mineral density (BMD) have higher pullout strengths. Despite this, due to their simplicity of application, less surgical exposure, and low morbidity, bone anchors are often employed in all bone areas in both human and animal patients. While cancellous bone and metaphyseal bone share some of these characteristics, cortical diaphyseal bone does not. The observed results indicate that Microgrooved and microgrooved Nanofiber mesh anchor groups have a prospective value. By showing an increase in total surface area contact at the bone-implant interface and a decrease in microcracked bone area, increased frictional forces resisting pull out should be expected.

Abstract Name: 3D Printed Segmental Bone Defect Treatment with Bioabsorbable Interlocked Nails

A segmental or long bone defect is a bone void or hollow that will not heal without treatment. Distraction osteogenesis, induced membrane, and vascularized fibular transplantation are some of the additional therapy possibilities. Another treatment method employs halo-type equipment to gradually shorten the limb until the ends of the segmental bone defect are close enough together for the body to mend the defect. The goal of this project is to test 3D printed polycaprolactone (PCL) bone scaffolds in vitro with agar-collagen hydrogel and magnesium (Mg) embedded PCL (Mg-PCL) intramedullary nail systems. The proposed technique for healing a rabbit tibial segmental bone defect is to integrate two biomedical systems: a bone scaffold implant and an interlocking nail system. Both the scaffold and the intramedullary nail were made of a bioabsorbable material that degraded slowly over time, allowing bone cells to fill in the gaps left by the implants. The scaffold implant was produced from polycaprolactone and was fabricated utilizing 3D printing techniques (PCL). The scaffold was subjected to a mechanical test to evaluate the stress and strain. A cell viability test was done using stem cells on agar-treated scaffold. We chose BMSCs for this experiment because of their ability to adhere to scaffolds for in vitro growth as well as differentiate into committed progenitor cells and expand. The interlocking nail adds stability. The scaffold reduces healing time. Load carrying throughout the recovery period due to the scaffold. This research addresses the technological challenge of manufacturing osteoconductive bone replacements paired with osteogenic cells and/or bioactive substances, as well as a progressively biodegradable interlocked nail system for critical size bone deficiencies.

Abstract Name: The Repatriation of Cultural Heritage: The Idea of Ownership

Ownership is the fundamental tension surrounding the repatriation of cultural heritage, though the context of ownership has shifted throughout the history of cultural heritage. Cultural heritage is innately complex, with various international and national laws regarding cultural heritage. To add a further layer of complexity and confusion, each case of repatriation of cultural heritage has its issues and surrounding circumstances that make it challenging to create enforceable and universally applicable guidelines on how to repatriate cultural heritage. Overall, The first section is an overview of cultural heritage and repatriation efforts.Besides a basic overview, this section will also review the historical development of the idea of ownership as it relatesto the repatriation of cultural heritage. Furthermore, the second section of the paper will discuss the legal framework of the repatriation of cultural heritage by looking at the international agreements and laws meant to protect and regulate the movement and the acquisition of cultural heritage. The third section of this paper will provide case studies or examples of the repatriation of cultural heritage. In the same vein as the analysis of the case studies, the paper's final section will detail a few possible solutions to make repatriation a less divisive issue internationally, as well as answers to make repatriation overall easier.

Abstract Name: Pandemic Experiences of Utah College Students Collected Through Oral Histories

COVID-19 is a global health crisis; the impacts will likely be seen for decades. It has led to technological and medical advancements. It has shown a lack of learning from previous infectious diseases and demonstrated profound political and cultural divides in the US. The COVID-19 pandemic affected the life of every individual around the world. Whether through contracting the virus, changing how they learned or worked, experiencing isolation, or feeling the economic impacts.This experience has separated people physically but allowed people to create connections through a collective experience. People, companies, and schools have found ways to adapt to the uncertainty associated with the pandemic. These methods include video conference calls, masks, and social distancing. Even though it was a universal experience, some individuals and communities felt disparate impacts. Through a series of oral histories collected from college students throughout Utah, I have explored what life was like throughout the pandemic for a variety of people. Oral histories allow people to tell their stories and share what is important to them. The pandemic impacted media and technology usage, interpersonal connections, and individual beliefs. Stories showed political unrest and polarization, mental health struggles, and isolation. The changing beliefs surrounding social distancing, masks, and vaccines were revealed in the stories collected. The oral histories have been transcribed and coded for these themes.This research is essential because it establishes some of the pandemic's impacts and how those are consistent throughout the population. It helps create an understanding of the unseen impacts of the pandemic and show how it will impact our individual life and our society in the foreseeable future.

Abstract Name: Minority Status and Mental Health

Discriminatory behaviors live throughout society today and all generations of the past. How do these behaviors impact groups with minority status? The aim of this study is to research how chronic stress expereinced by people with minortity status impact mental health. There will be multiple angles applied to this study. The first area of interest is how social media either contributes to or gives a community for discriminatory behaviors or does social media allow for an outlet for those with minority status to build support and community. The second area of interest is how does stress related to choronic discrimination exposure contribute to the mental health of individuals with minority status. Previous research has shown disparities in mental health, substance use, and other factors related to mental health among groups with minority status when compared to the same age group of majority status individuals. This study will identify factors associated with positive and negative mental helath development across multiple minority status groups through a survey implemented and analyzed in the spring semester of 2023.

Abstract Name: **Charge radius and mass distribution of deuteron quark-gluon plasma**

Contemporary nuclear models do not describe or explain mass distributions inside of atomic nuclei. Established particle physics is unable to precisely calculate any of the fundamental particle masses or mass ratios. Precise calculations of nuclear charge radii have been difficult to obtain using established nuclear models. A deuteron is a proton fused with a neutron. This project assumes that deuteron decoherence into a quark-gluon plasma involves the quarks and gluons losing their identities and merging together. It is also assumed that this decoherence involves charge completely dissociating from mass. A novel approach to calculating a deuteron quark-gluon plasma's charge radius and mass distribution is developed. A deuteron quark-gluon plasma is modeled as two interacting oppositely-charged surfaces. The positively charged surface is an hourglass shell. The negatively charged surface is a torus shell wrapped around the hourglass neck. The hourglass shell will be assumed to be inflated by standing waves. These standing waves are proposed to be virtual photons explained by quantum electrodynamics. A curious relationship between muon mass and the deuteron's torus shell mass is used as a starting assumption. This proposed deuteron model is an extension of a recently published proton model based on the circular Unruh effect, zitterbewegung effect, quantum electrodynamics, classical electromagnetism, and quantum chromodynamics. This project involves algebra and calculus that can be understood by undergraduate physics students. The long term goal is to apply this method to modeling larger nuclear structures.

Abstract Name: **Analysis of PHYB Mutations Identified in a Genetic Enhancer Screen in Arabidopsis thaliana**

The plant Arabidopsis thaliana contains the genes LRB1 and LRB2 (Light-Response BTB 1 and 2) that encode proteins functioning as target adaptors in complexes that initiate degradation of the phytochrome red/far-red-light receptors. Plants containing mutations of both the LRB1 and 2 genes are hypersensitive to red-light, because there are increased levels of the phytochromes in these lines. Genetic screens were conducted in the Gingerich lab to identify mutations that increased the red-light hypersensitivity of LRB1 and LRB2 double mutant plants. Such mutations might occur in additional genes involved in red light responses. In several of the lines the putative "enhancer" mutations were found to be within the PHYB gene, which encodes the phytochrome acting as the major red-light receptor in Arabidopsis. Recent work has focused specifically on two of the enhancer mutant lines, each of which has a point mutation in the PHYB coding region which is predicted to change a single amino acid in the encoded phytochrome B protein. We believe these forms of phytochrome with the single amino acid change may have increased activity and we have been characterizing the effects of these mutations on light responses and phytochrome action. One of enhancer mutant lines also has a blue-light hypersensitive phenotype, and we have conducted genotype/phenotype co-segregation experiments to determine if the PHYB mutation in that line may also be responsible for that phenotype. Progress on these projects will be presented.

Abstract Name: **X-Ray Fluorescence Analysis of Elemental Composition of Rattlesnake Venom**

Snake venoms are complex biochemical mixtures, largely consisting of proteins and peptides, and have been the primary focus of studies on venom composition aimed at producing more effective antivenoms and discovering potential therapeutics. However, venoms also contain a variety of smaller organic compounds, metal ions and carbohydrates.Relatively little is known about these components. Venom can bequite distinct, havingvariation within the same species due to geographic location, diet, age, or sex. Few studies considerdiversity and relative abundance of inorganic compounds likemetals, asmany components are metalloenzymes. In the present work, X-ray fluorescence spectroscopy was used to analyze venom from over 100 Prairie Rattlesnakes (Crotalus viridis viridis) in a single population on the eastern plains of Colorado and compare levels between age groupsand sexes. Additionally, venoms from other speciesin western Colorado were also characterized to determine levels of variation within and between species. High concentrations of sulfur were found in the venoms, particularly among male neonates C. v. viridis. Many proteins and peptides in the venoms contain multiple disulfide linkages, which is likely the reason for high sulfur levels. Calcium and zinc showed no sex-related differences, and both were more concentrated in neonate venoms. In particular, potassium levels were high in both male and female neonatesbutfound at 1-2 orders of magnitude lower concentrations in adultvenoms. The differences in element concentration within species, between species and between age classes may be linked to age-related changes in diet. This work is providing novel results thatis settingdirections for future research into larger questions concerning differences in elemental composition of snake venoms globally. The use of X-ray fluorescence (XRF) spectroscopy canquantify numerous elemental concentrations in microgram amounts of venom, providing a versatile and convenient analytical method to compare withinand between species variation.

Abstract Name: **The Sardonic Destruction of Seduction: Examining the Beguiling Behavior Against Literature's Fallen Women**

The scandalous women portrayed in nineteenth-century literature are represented in simple societal constructs, yet the author's approach to these concepts makes the stories controversial and irrational. The presentation of misbehaving women holds many complexities, but only a few do it so analytically engaging: Gustave Flaubert's Madame Bovary; Leo Tolstoy's Anna Karenina; Thomas Hardy's Tess of the d'Urbervilles; and Edith Wharton's The Age of Innocence. Nevertheless, the author's gender seems to play a role in presenting the female portrait and psyche. The aforementioned male authors illustrate their infamous women as too vulnerable, naïve, and possessing a propensity of hysteria during their fall from grace. The male gaze places these titular characters in compromising situations that lead them to be seduced. As a result, they are affected by the temptations surrounding them, which ultimately morph their selfhood around the dominance of men. In contrast, Edith Wharton features passionate and determined women who discover their autonomy. Wharton, unlike her male counterparts, focuses less on female sexuality and more on female empowerment, allowing her women to manifest their individuality without a man's influence. Correspondingly, the characters are not the villains of their stories, even though they are implied as such because of their improper lifestyles. The real culprit of all the travesties is the authors, shown in the negative motif in which they write their female characters. These novels, which were all written within seventy years of each other, prove that time alters the perspective of society and gender theory. As time progresses, the philosophy of authors seems to shift; their characters – especially the female ones – are represented in a more inclusive viewpoint that allows for a more progressive projection of women.

Abstract Name: **Modeling Allee Effect in an Aggregated Eco-epidemiological Model**

A continuous predator-prey model subject to the Allee effect, prey aggregation, and infectious disease in the prey population will be presented during this talk. We assume that the prey population grows logistically in the absence of predator species. We split the total prey population into two distinct classes: infected prey and susceptible prey. Mathematical preliminaries such as positivity and boundedness are investigated. The analysis of the dynamical behaviors of the proposed model centers on the numerical simulations in which the Allee threshold and disease transmission rate of the prey are the primary parameters. The biologically feasible equilibrium points are analyzed. We will discuss our findings with emphasis on the potential applications in conservation biology.

Abstract Name: **"Where On the Soles of Your Feet May Tread": An Analysis of Fumi-e and the Repression of Christianity by the Tokugawa Shogunate**

This research focuses on the appropriation of religious symbols of the Other. More specifically, the significance Japanese art, such asfumi-e,and the appropriation of Buddhist iconography by Japanese Christians in 17th century Japan will be examined. In this study, I argue that the use offumi-ein the ritualistic profanation of Christian icons conducted by officials of the Tokugawa Shogunate was to maintain social order in the face of the Jesuits' infiltration of Japanese society. While the Japanese political elites transformed Christian icons into objects of scorn, underground Japanese Christiansappropriated Buddhist icons to conceal Christian worship.First, a brief summary of 16thcentury warring states period, which divided the country into numerous competing factions, will be provided. Second, the effects of the Jesuits' presence and their conversion of severalDaimyo, or feudal lords, will be examined.Third, I will discuss the initial repression of Christianity, during which the missionaries were expelled from the country, and demonstrate the significance of the spectacular profanation of Christianity throughfumi-ein maintaining social stability under the Tokugawa Shogunate. Fourth, the use of Buddhist iconography, specifically Maria-Kannon statues,in clandestine Christian worship by underground Christian sectswill be addressed.This research makes use of scholarship on the social significance of public spectacles, and art historical literature.The importance of this study is that it demonstrates the fluidity of religious icons generated by specific political and social contexts.

Abstract Name: **Facultative interactions between ants, aphids, and black-eyed pea**

This study is the first exploration of ecological relationships between ants, aphids, and black-eyed pea (Vigna unguiculata).Black-eyed pea produces nectar in extrafloral nectaries (EFNs), on stems and leaves. EFNs attract ants that consume EFN nectar and protect plants from herbivores. This ant-plant facultative mutualism can be disrupted when aphids are present. Aphids are phloem-sucking herbivores that provide sugar to ants by excreting “honeydew”. Aphids can parasitize the ant-plant mutualism by stealing the plant’s sugar and stealing protection from the ant “bodyguards”. Aphids colonized plants during the preparation of the field plot, but initial population size was low. After ants (Camponotus spp.) established themselves on plants in the field plot, aphid numbers increased very rapidly, and we observed aphid-tending behavior by ants. In addition to herbivores, the abundant aphid population attracted a variety of predatory insects. Presence of ants had a negative effect on shoot and fruit weight; means for ant exclusion treatments were higher than the ant inclusion treatments. Adverse outcomes for plants with ants likely relate to high costs of ant-tended aphids removing sugar from the plants. The lowest plant growth and reproduction was seen in plants with ants and sealed EFNs. Aggressive aphid tending behavior is likely on these plants since ants received no EFN-nectar. Interaction between ants and nectar effects on shoot and fruit weight showed a trend for less severe negative effects of ants when nectar was available. More research is needed to understand how interactions shift as ecological communities change because ants can be allies or enemies to EFN-bearing plants. Vigna unguiculata is a critical source of global food security in the face of climate change threats.This study may provide ecological insights for ways to employ agroecological approaches to increase yields of black-eyed pea in the future.

Abstract Name: **How can ponderosa pine seedlings be propagated to improve drought resistance in the field?**

Ponderosa pine, a widespread species in the western US, is a valuable species economically and environmentally. The preservation of this species is important for the ecological health of many forests due to increased temperatures, drought, and frequency of forest fires. Reforestation efforts following fire and timber removal often fail because seedlings propagated in greenhouses are not resilient to stressful field conditions. To increase seedling field survivorship, drought resistance, and to decrease mortality rates, we implemented a number of treatments in the greenhouse during the initial propagation. The treatments were a manipulation of water supply and different types of fertilizer, tested with seeds collected from varied elevations. After threemonths of growth in the greenhouse under these treatments, we measured height and both shoot and root biomass of the seedlings. We also measured days to mortality on a subset of the seedlings. Seedlings subjected to drought treatment and amino fertilizer grew shorter but survived longer. These seedlings allocated more biomass below ground, which likely contributed to their longer survivorship in the days to mortality test. However, despite the potential benefits these treatments conferred to seedlings in the greenhouse, all seedlings experienced nearly 99% mortality after they were outplanted to a nearby field site. We suspect that most of this mortality was due to frost-heaving, a process whereby seedlings can be pushed out of the ground during frost-thaw cycles that occur in soils in the winter, and is exacerbated by the creation of bare patches of soil around the seedling during planting.

Abstract Name: **Identifying breast cancer education message preferences among Black college students using conjoint analysis.**

Black women have excessively high breast cancer mortality rates. This disparity is due in part to the higher incidence of aggressive breast cancer among Black women under the age of 40. Early-detection and early treatment lead to significantly lower mortality rates. However, sociocultural barriers, such as lack of perceived risk for breast cancer, impede adherence to breast cancer screening guidelines for young many Black women. Cancer education interventions that are focused on increasing knowledge about breast cancer, breast cancer risk, and breast cancer screening methods have been shown to be effective at increasing breast cancer screening rates. The purpose of study is to determine the most effective way to deliver culturally-relevant breast cancer education messages to young Black women via social media. Culturally-relevant breast cancer education messages in the form of social media posts were developed using the Intervention Mapping Framework. The messages are based on the constructs of the Health Belief Model, and previous qualitative research with the target population. Conjoint analysis will be conducted with a sample of Black college-aged women. We will assess the participants preference for message frame (gain frame vs. loss frame), message format (illustration vs. photo), and message source (Black female peer vs. Black female healthcare provider vs. healthcare provider of another race and gender). Regression Analysis will be performed to determine the most desirable elements of the messages. The results of this study will be used to finalize the cancer education messages. The messages will be disseminated via social media sights.

Abstract Name: **The effects of restoration projects on phosphorus concentrations throughout Manitowoc County streams and Lake Michigan**

Phosphorus poses an ongoing challenge to Lake Michigan. Excess levels cause algae blooms resulting in degraded water quality in near-shore waters. As local tributaries serve as important phosphorus sources to Lake Michigan, we analyzed phosphorus levels in two streams in Manitowoc County, WI—Centerville Creek and the Little Manitowoc River.These streams have historically exceeded Wisconsin DNR surface water phosphorus standards of 0.075 mg/l phosphorus. Each stream has undergone restoration near where they enter Lake Michigan in order to slow stream flow and reduce phosphorus loading into Lake Michigan.Each creek showed a different trend in phosphorus concentration along its length.Centerville Creek showed lower phosphorus concentrations within the restoration area compared to the upstream branches, although all significantly exceeded the WDNR threshold. North branch averaged 0.510 mg/L phosphorus, and the south branch averaged 0.430 mg/L.Sites within the restoration project averaged 0.307 mg/L. In contrast, no difference in phosphorus concentration was noted between the upstream and restoration sites in the Little Manitowoc River.This may be because this restoration was more recently completed (2020 vs 2012), or due to the surrounding land use as the Little Manitowoc River runs through the city of Manitowoc, while Centerville Creek goes through agricultural land. However, overall concentrations across the Little Manitowoc River were lower than any of the Centerville sites, with an average concentration of 0.071 mg/L, below the WDNR threshold, and rain events did not increase phosphorus as much as in Centerville Creek. Future work will focus on identifying future sources as well as continued monitoring to evaluate the success of these restorations and inform land use decision-making.

Abstract Name: **A Pilot Study Investigating Veteran Identity Using the Photovoice Technique in a Qualitative, Community-Based Participatory Action Research Framework**

Veteran identity has been defined as a Veteran's self-concept that derives from their military experience within a sociohistorical context. Reintegration into civilian life can be difficult, experiencing a "reverse culture shock" that can negatively impact many interpersonal relationships and result in experiencing negative feelings such as helplessness, isolation, and emotional disconnection. Understanding how Veterans define themselves in their civilian lives can give us insight that could bridge the gaps between them and their available support systems. We utilized a qualitative, community-based participatory action research (CbPAR) model where Veterans are empowered to use their voices to tell their stories and researchers serve to help communicate their stories to the community. We are using the photovoice technique where Veterans take pictures that represent the answer to the following prompt: What does being a Veteran mean to you? This study is part of a larger project using photovoice and lyric analysis to help define the "sights and sounds" of Veteran identity. Our Veterans will then be interviewed individually where they are asked questions to help the researchers understand the symbolism of the images relating to the prompt for them. Transcripts of the interviews are being analyzed to uncover common themes and elements that represent a definition of Veteran identity. Preliminary results of these analyses will be discussed after completion of our member-checking process, which helps establish external validity within the community. Our next aim is to present the images and our results in an immersive, interactive gallery experience to allow for the Veterans' stories to be told. We argue that without more emphasis on qualitative, CbPAR methodologies, research with special and/or marginalized populations, like Veterans, will continue to be more exploitative than beneficial and will further reinforce the distrust in scientists and clinicians already experienced by many in these populations.

Abstract Name: **One Fish, Two Fish, Weird Fish, New Fish: Pycnodont Specimens from the Arlington Archosaur Site of Texas**

Pycnodonts are a group of extinct bony fish (Triassic to Eocene), with deep, narrow bodies and flat, bulbous crushing teeth. They lived mainly in shallow marine and freshwater environments. This study will focus on the teeth of Pycnodont fish collected at the Arlington Archosaur Site (AAS) from the Lewisville Formation of Texas (Late Cretaceous, 95 million years ago), which hosted a diverse assemblage of organisms as part of a deltaic ecosystem on the shoreline of the Western Interior Seaway. Three tooth plates, eight pharyngeal teeth, and about fifty individual dentary teeth were identified. The dentary teeth and tooth plates were cleaned with acetone and water and examined and photographed under a microscope at high magnification to identify different microwear features of the teeth. Microwear features are markings on the surface of the teeth such as scratches, gouges, or pits that allow for interpretation of diet in extinct species. The dentary teeth demonstrated several scratches in different orientations with relatively few gouges or pits observed. The purpose of this research was to describe the dental anatomy of the AAS pycnodont specimens and assess their likely dietary intake. The results described here further support previous interpretations of the environment and availability of hard-shelled or resistant prey.

Abstract Name: **Special collaborative murals project**

Little matters more to me than nature, mother nature, my nature, the nature of things hasalways captured my curiosity. Artists such as Wilhelm Theodor Nocken and Rebecca Livermore inspire my perspectives and embolden my artistic approach. Their work captures the scale and vibrant color usage, renewing me with a sense of wonder.I often start by creating inventive source photos and sculptures that are translated into a painted medium. While painting I employ a wet brush sketching method on the canvas to build a base layer that I methodically add onto, utilizing different brush sizes and texturing methods. Above all else I seek to feel connected with my paintings, occasionally using my hands as my utensils. My work incorporates raw emotions that become the closest to someone looking through my eyes, to understand my nature. Although my work primarily focuses on male mental health and the silent suffering we experience, I would be interested in collaborating on Equity/Diversity/Social Justice mural project. I would like to focus on the diversity of human existence and the endless possibilities to create beautiful murals with many perspectives and voices. I possess strong team-oriented skills, incorporating viewpoints and ideas of others to create a unique vision. I believe that I also possess leadership skills both from my role as a senior undergraduate student artist as well as qualifications as the Chief Music Director for WSKB which has me coordinating around two dozen DJs alongside the general manager to create a welcoming and diverse community. I look forward to this incredible opportunity.

Abstract Name: **Testing the Effectiveness of the Wisconsin Arch as a Barrier to Dispersal for Ordovician Gastropods in Southern Wisconsin.**

The Ordovician (485-444 million years) Platteville Formation crops out extensively across southern Wisconsin. The most fossiliferous Member is the Mifflin Member which has been the subject of several paleontologic publications for over a century. Recent collections in a previously unpublished quarry near the UW-Whitewater campus has revealed a unique gastropod fauna, including the ornate species Phragmolites triangularis, among at least six others. In order to test the effectiveness of the Wisconsin Arch (WA) as an undersea barrier to dispersal, this new faunal collection was compared quantitatively with 20+ other coeval quarries that also contain gastropod faunas. The Raup; Crick similarity index (0-1) was calculated for all sample pairs, with values greater than 0.95 indicating significant similarity and values less than 0.05 indicating significant dissimilarity. For a null hypothesis of no barrier effect for the WA, falsification would require significant dissimilarity index values of sample pairs across WA suggesting it was an effective barrier to dispersal. Values above 0.05 for any sample pair do not reach our rejection level and cannot falsify the null. Out of 350 possible comparisons, only 7 sample pairs are less than 0.05, thus the great majority of data suggests that the WA was not an effective barrier for the dispersal of gastropods, and that gastropods of the Ordovician has wide-dispersing planktotrophic larvae like those of today.

Abstract Name: **Media presentation of Psychedelics in Historical and Contemporary Print News**

The introduction of psychedelics in the American public consciousness started in the 1950s and has continued to evolve. [LT1] This research uses content analysis of print media found via internet databases to understand this change and see what the contemporary media is saying about psychedelics. Specifically, I compare coverage of psychedelics in LIFE magazine during the 1950s-1960s to coverage in New York Times magazine from January 2020 to November 2022. These sources were chosen because they were and are widely read publications in the US. For both publications, all articles containing the terms 'psychedelics' and 'LSD' were included. For LIFE, the articles could appear anywhere, and for the New York Times articles in both the opinion and health sections of the paper were included. The themes in the data show that, in the past, the interest in psychedelics focused on the cultural impact of psychedelics, fear around their use, and the evolving legal and social problems around them. The was a specific interest in Timothy Leary and his impact in the way psychedelics were used as well as on Watson's trip to Mexico. LIFE magazine wrote two cover stories about psychedelics in this time period, and these two articles articulate the change over 9 years most clearly, from curiosity to fear. Currently, there is interest in the medical use and mental health use of psychedelics. This interest relates to the increased number of studies being done on psychedelics and their use in the medical field. There is also concern and noticing of increasing use of psychedelics (and all recreational drugs) among young people in the US. In the opinion section, there is a discussion about how and when psychedelics should be used, with some authors being for and some against recreational use.

Abstract Name: **Using Survey Data to Report on Low-Income Household Experiences Shopping at the Eau Claire Downtown Farmers? Market**

Food insecurity is a significant issue facing many American households. The Supplemental Nutrition Assistance Program (SNAP) provides increased access to food for families in need. Additionally, fruit and vegetable (FV) consumption has been shown to improve health and reduce the risk of a variety of chronic diseases. However, poor nutrition among children and adults, including low FV intake have contributed to rising rates of obesity among US children which have been shown to persist into adulthood. It is particularly challenging for low-income households to purchase/eat the recommended amount of FV. Farmers' markets offer a wide variety of fresh, local and healthy foods, especially FV, but data show that low-income households are much less likely to shop at farmers' markets. The Eau Claire Downtown Farmers' Market (ECDFM) sponsors a Market Match Program (MMP) incentivizing SNAP households to shop at the market. Administrative data on program utilization suggests that most SNAP households shop at the ECDFM using the MMP relatively infrequently. This poster presents data from surveys of SNAP shoppers at the ECDFM in 2022 (N=349) to learn more about their experiences using the program including what limits their shopping at the market and what might increase their ability to shop at the market. Our results indicate that the most significant limitations to shopping at the ECDFM were the market location/hours, SNAP benefits running out and just not remembering. Correspondingly, the most mentioned things that would encourage more frequent shopping at the ECDFM were expanded market locations/hours, a larger match amount and also being reminded. Among our other key findings are that the ECDFM MMP provides many benefits including reducing food insecurity among EC SNAP households. This poster is connected to another submitted poster analyzing a variety of administrative data from recorded transactions of SNAP shoppers using the ECDFM MMP.

Abstract Name: **An die Freiheit: How Programmatic Interpretation intersects with Politics in Beethoven's 9th Symphony**

Ludwig van Beethoven's Symphony No. 9 in D minor, op. 125 has historically been associated with politics, being utilized by various political organizations and entities since its premier. Central to the work's political viability and utility is a focus on its programmatic messaging which espouses unity and brotherhood. In light of recent waves of criticism that focus upon classical music, and more specifically, Beethoven's music, as symbols of Eurocentrism and elitism, this paper attempts to critically evaluate the work's rhetorical argumentation, considering it within the context of its famous (and infamous) reputation. By analyzing aspects of harmony, melody, and the manipulation of Schiller's text, this paper examines how the finale evokes three differing musical settings, each being associated with a particular culture and/or religion. In the treatment, juxtaposition, and overlapping of these musical settings, this paper offers how two differing interpretations of the work are possible: One which centers on the work's humanistic ideals, and another which imagines Eurocentrism inherent to its model. By focusing upon the finale of Beethoven's 9thsymphony in particular, this paper hopes to contextualize the intersection between art, artistic interpretation, and politics, and how we, as listeners and performers, engage in that intersection.

Abstract Name: **Sustainability of Resources for College Food Pantries**

Over 40% of college students are food insecure. Students in need are 43% more likely to fall behind in classwork and drop out of college. Students with food insecurity are also more likely to develop severe mental health conditions like depression, anxiety, low self-esteem, and loneliness. This study seeks to explain what factors contribute to sustainability of resources in university food pantries. The purpose of sustainability research is to find new and efficient ways to meet the needs of students who are food insecure in college. The student researchers explore the issue of sustainability of resources within college settings and how it impacts the resources obtained by grants and donors. The student researchers developed the following question: What are the factors involved in the sustainability of resources within college food pantries? The student researchers used 16 scholarly journal articles to inform their research on the factors that contribute to the long-term sustainability of food pantries in institutions of higher learning. Researchers using purposive and snowball sampling to identify a minimum of 100 participants with the help of the public directories to complete the questionnaire.The student researchers identified three common concepts within articles: factors of sustainability of food pantries, barriers and obstacles to successful food pantry use, and pantry development. The information gathered from the articles assisted the student researchers in question development for their survey.This research aims to identify the factors in sustaining a college food pantry through increased use. This information is important in attaining the researchers' overall goal of aiding the Tarleton Purple Pantry in developing a plan to sustain resources through Tarleton State College's rapid growth in enrollment.

Abstract Name: **Deterministic Chaotic Behavior in Solar Radio Bursts.**

Solar radio bursts are an intense and sudden increase insolar radio emissions connected to solar flares. They are one of the extreme space weather events that eventually can affect the Earth's environment. The used data were solar bursts observed at radio frequencies recorded with the radio polarimeter of the INAF-Trieste Astronomical Observatory. Solar bursts observed at radio frequencies are classified depending mainly on their different phenomenology and often show fine pulsating temporal structures that involve a great variety of phenomena, including sinusoidal-like oscillations patterns, and repetitive outlines of fine structures such as train of drift bursts, which indicates a fragmentation process in the generating mechanism. The great diversity of such phenomena involves different explanations and theoretical modeling. In such systems, pure determinism is not expected due to a high dependence and interconnection of several parameters, making the evolution of these dynamical systems very sensitive to any variation in the initial conditions, which is the indication of a deterministic chaotic behavior. The aim of this contribution is to determine if the underlying process generating such events can be described as deterministic chaos. Consequently, we applied nonlinear dynamics theory and some of the fundamental tools of nonlinear analysis were used as the Lyapunov exponent, correlation dimension, local point-wise dimension, and Hurst exponent. In the analyzed data, nonlinearity is detected, and the dimension analysis gives some hints for a quantitative description of the time series associated with the selected radio bursts, which is the via to characterize the complexity of the related physical mechanisms generating such events.

Abstract Name: **Social Synchronization of Conditioned Fear Requires Ventral Hippocampus Input to Amygdala**

Social organisms synchronize behaviors as an evolutionary-conserved means for thriving. Synchronization under threat benefits survival and occurs across species, including humans, but the underlying mechanisms remain unknown, due to the scarcity of the relevant animal models. Here, we developed a rodent paradigm in which mice synchronize classically conditioned fear response and identified an underlying neuronal circuit using chemogenetic inactivation. Mice synchronized cued but not contextual fear and synchrony was higher in males than in females. Inactivation of the ventral but not dorsal hippocampus or dorsomedial prefrontal cortex abolished fear synchronization. Finally, the disconnection of the hippocampal-amygdala pathway diminished fear synchronization. The synchronized expression of conditioned fear relies on the ventral hippocampus-amygdala pathway, suggesting that the hippocampus transmits social information to the amygdala to synchronize threat response.

Abstract Name: An Exercise in Understanding the Research Process: What is the Greatest American Rock Band?

Most undergraduate students find the research process daunting and enter into any research project with great trepidation. Undergraduate preparation and instruction in the process of research varies across disciplines as does the nature of what constitutes research and scholarly work. Across multiple semesters I have used the following group-based research project as a way to introduce business students to "doing research." Students are asked to answer the research question "What is the greatest American rock band?" Typically, this is framed as a low stakes exercise focusing on process as opposed to outcome (e.g., there may be no right answer). It allows for as much (or as little) instruction in the research process as necessary. Groups are required to produce a scholarly paper and to make an in-class presentation. The exercise exposes the students to the rudiments of critical thinking and the scientific method. Specifically, they first need to define the research question (e.g., define "rock," define "American") and set boundary conditions. Then they need to articulate evaluation criteria. Next comes the important task of "finding materials" to use and evaluating their quality. Finally, they synthesize what they have found and attempt to answer the question. Generally, students enjoy the exercise and realize that they know more about doing research and writing in a formal manner than they originally thought. With this experience under their belts the students are in a better position to begin a project specific to their disciple. Although my use of this exercise with undergraduate students has been limited to business majors, it could be modified so as to introduce students in other disciplines to the process of "doing research," especially where a formal course sequence in research methodology may not exist.
