Abstract Name: **Synthesis and Characterization of a Doxorubicin-Human Serum Albumin Drug Conjugate Via Traceless Cobalt Coordination Chemistry**

The use of nanotechnology-based drug delivery systems in the context of cancer treatments has the potential to help target drug chemotherapeutics to tumor cells more precisely while simultaneously reducing off-target toxicity. One of the most prescribed chemotherapeutics, doxorubicin, is an anthracyclines drug that is effective in treating cancer; however, the drug exhibits dose-limiting cardiotoxicity. Dox intercalates DNA, resulting in the deterioration of DNA strands and the ultimate inhibition of DNA and RNA synthesis. Doxorubicin's chemical structure contains a primary amine group that can be used to crosslink it to a protein. This project focuses on using cobalt coordination chemistry as a novel crosslinking strategy to synthesize conjugates of Dox bound to human serum albumin (HSA). The synthesis of conjugates of DOX with HSA will be discussed along with methods for characterization via HPLC that allow the number of Dox molecules bound per protein molecule to be determined.

Abstract Name: **America's Black Maternal Mortality Rate**

Being that standard medical practice and practitioners are prone to dismiss the role of social determinants that contribute to an individual's state of health, Black women are at a particular disadvantage when seeking any sort of medical treatment. The lack of representation of Black women in the medical field is an overlooked pitfall of the medical community. Specifically, medical textbooks and medical school training cater more to the care of non Black patients. Textbooks and training focus more on white anatomy which leads to the exclusion of other minority groups including Black women and causes increased levels of discrimintation and mistreatment in their pre and postnatal care. Historically, the majority of leadership roles in the medical profession are fulfilled by white males. Issues then arise in effectively treating patients of all demographics, when the only reference physicians have to base treatment plans on is white patients. Furthermore, the health equality among Black women in hospital settings in the United States is statistically appalling. Systemic racism is compromising the health of Black women. Due to the lack of race and gender representation in the medical field, the racial bias health practitioners have towards Black women causes racial health disparities that have negative long term effects on the mother giving birth or her newborn. The purpose of this research paper is to bring light to the power imbalance that Black women face in these environments at such a vulnerable and life changing time. These inequalities are a reflection of our social and economic progress today. There is currently inadequate research on this topic which is evident in the continuous neglect that Black women still face in U.S. hospitals.

Abstract Name: **Counting Co-cultured Cells with Convolutional Neural Networks**

Recent developments in convolutional neural networks (CNNs) have produced significant advances in image analysis applications. By automating the feature-learning process during image analysis, CNN models can minimize development time to create results more efficiently. CNNs have been prominently used for regression tasks, such as calculating the distance, size, or count of objects. In this paper, we discuss the utilization of CNN models in cell counting algorithms, with specimens that have been collected and digitized using fluorescence microscopy. We present this in the collection of two types of biological cells: astrocytes and adult hippocampal progenitor cells (AHPCs).Astrocytes and AHPCs are two distinct types of cells that are found in the central nervous system. Astrocytes are star-shaped glial cells that have the major purpose of maintaining brain homeostasis and neuronal metabolism. Meanwhile, AHPCs have the task of proliferating and differentiating into new specialized cells like astrocytes. Cellular differentiation is a process in which stem and progenitor cells can divide into new specialized cells with distinct functions. Both cell types could be visualized using DAPI staining, which is a nuclear stain commonly used for quantifying the total number of cells present in an image. This research aims to create a CNN model that can quantify the number of astrocytes and AHPCs in an image.Unlike the traditional, restricted approach of using CNN models to count all cells in an image, we have developed a solution that can predict the number of cells of a specified type. The motivation for this was to be able to work with image datasets that contain multiple types of cells. We have named it CellCounter, a CNN model which can enumerate the amount of both astrocytes and AHPCs by using multi-output regression. The model's accuracy and speed make it ideal for counting tasks.

Abstract Name: **Three-State Biaryl Lactone Molecular Switches with Amine donors**

Our research is focused on the synthesis of four bridged biphenyl molecules with amine donors.These three-state biphenyl molecules, due to their chemical properties, will find applications as nanoscale fluorescent sensors and molecular mechanical devices. Biphenyl molecules have known dihedral angles, leading to differing optical and conducting properties when manipulated. By using a lactone-bridge we can force the molecule into and out of planarity; at low pH the molecule takes a planar conformation ("ON"), while at high pH it's non-planar ("OFF"). Research from previous groupshas shown similar two-state molecules' effectiveness at readily switching conformations when exposed to different chemical environments. We are researching the addition of diethylamine and diphenylamine donor groups. By combining cyano and nitro acceptors used previously and differing amino donors within biphenyl molecules, we can enhance optical properties and pH sensitivity. This pH sensitivity will be more precise with the addition of a third "OFF" of the molecule. At low pH, the amino group should become protonated, leading to the second "OFF" state and giving the molecule a narrow "ON" state. The "ON" state would result in visible color differences than the "OFF" state of the molecule. These characteristics would improve the usefulness of these molecules as pH sensors. We have successfully synthesized two of our target molecules, one molecule is a cyano acceptor group with diethylamine donor group and the other is a nitro acceptor group and diethylamine donor group. We will be continuing this work to synthesize the other two molecular switches.

Abstract Name: Design and Evaluation of a novel binder protein for SARS-CoV-2 using the game Foldit

Severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2), the virus causing COVID-19, infects human cells when the receptor binding domain (RBD) of the viral spike protein binds to the human angiotensin converting enzyme 2 (ACE2). Monoclonal antibodies targeting the spike protein have been shown to block RBD-ACE2 interaction effectively and have been used for the treatment of COVID-19; however, antibodies cannot be delivered intranasally to treat early stages of infection due to their large molecular size and instability. Therefore, there is a need for small proteins that can bind with high affinity to the spike and prevent its interaction with ACE2. De novo protein design using current automated methods is difficult due to the exponential number of possible structures that would need to be searched and the imperfect prediction of a protein's native conformation. The online citizen science game Foldit provides a potential solution to these challenges by combining human spatial reasoning skills with the Rosetta algorithm into an effective platform for protein design. Here, we present a novel SARS-CoV-2 binder protein that was designed using Foldit. Three metrics were used to evaluate the proposed protein's binding affinity with the coronavirus target: ΔΔG, buried unsatisfied polar atoms (BUNS) quantification, and contact surface area. The proposed binder protein consists of 92 residues and uses a three-helix bundle fragment from the ACE2 receptor. Hydrophobic packing and hydrogen bonding were incorporated at the RBD-binder protein interface to optimize target binding. The computer-generated protein provides a candidate for SARS-CoV-2 therapeutics. Laboratory testing will need to determine the folding, stability, and neutralizing capability of the proposed binder protein.

Abstract Name: 3D Models as a Tool for Learning Dogfish Shark Anatomy: An Analysis of Student Satisfaction

3D-printed models are being increasingly utilized as learning aids in medical and comparative anatomy education. Evidence that 3D models can significantly improve student accuracy in recognizing important anatomical landmarks and provide a low-cost alternative to more expensive, difficult-to-obtain, or fragile specimens has furthered their prevalence (1, 2). Additionally, 3D models provide a unique interactive experience with structures that may otherwise be difficult to observe in preserved specimens. This is particularly relevant with the chondrocranium and brain of the dogfish shark (Squalus acanthias). The chondrocranium is a cartilaginous structure that can be difficult to dissect and handle, and both brain and chondrocranium are fragile, prone to damage by undergraduate students unfamiliar with proper dissection techniques. This project addresses these issues by developing a novel, interactive-based 3D-printed model that allows students to understand the S. acanthias chondrocranium and brain in situ. The S. acanthias chondrocranium was modeled based on photogrammetry data developed by Thomas et al. (2). The brain was modeled using anatomic texts and preserved specimens as reference. A user study will be conducted in January 2023 to evaluate student satisfaction and perceived utility of these 3D models for learning in the comparative chordate anatomy lab at Iowa State University. Students will respond to survey statements using a 5-point Likert scale and will have an opportunity to provide qualitative long-form responses regarding their experience interacting with the physical models. Results from the survey will be presented in April 2023 and will inform the design process and production of improved 3D models for S. acanthias and other anatomic specimens, and may encourage the use of 3D-printed anatomical models more broadly in other educational settings as the availability of 3D technology increases.

Abstract Name: Genetic Codes Represented as Multivariate Data and Visualized as Chernoff Faces

Genetic codes can be thought of as the rules that govern the process carried out inside the living cells to transform genetic information into proteins. To date, there are seventeen mutations of the original genetic code; however, there is scarce information about the causes of these mutations and what the main differences among them are. Attempting to shed some light on this matter, we develop a mathematical model that enables us to represent a genetic code as list of numerical observations that can be used statistical and computational methods as well as to visualize the difference between them. At a primary stage, genetic codes can be mathematically regarded as block-21 partitions of the set of 64 codons. Using this representation as a starting point, we transform genetic codes into multivariable data in the form of vectors in a Euclidean space (i.e., a list of numerical observations) using a metric between codons to conduct the measurement of the determined variables. Such a metric considers both the chemical compositionand thestructure of codons as strings of characters. Our next goal is to use this vectorial representation to visualize the genetic codes in such a way that the differences among them become apparent. However, the number of observed variables (i.e., the dimension of the Euclidean space) is quite large, specifically 264-1. To overcome this issue, we proceed with the execution of a selection of variables method based on testor theory, that enables us to reduce the number of variables to near 10. Finally, we rely on the data visualization method known as Chernoff faces to exhibit genetic codes as human faces. We conclude with an comparative analysis of the similarities and differences among genetic codes and some biological implication derived from it.

Abstract Name: Defining driving performance measures and statistics for on and off road vehicles

This project aims to define the driving terms, measures, and statistics that are often used in vehicular research for on and off road vehicles. In different bodies of transportation research, driving terms are often defined in various ways and are occasionally not defined at all. This can result in making research difficult to compare across studies. Previously, research had been done to define driving performance measures and statistics in the standard J2944 “Operational Definitions of Driving Performance Measures and Statistics”; however, this research did not include off road vehicles. The project first requires an in-depth literature review, finding ways in which studies define driving terms, measures, and statistics. This data is then compiled into the final document, and terms that have not been previously specified are newly defined. The standard will also include diagrams to further clarify definitions of terms, measures, and statistics. This document will make these previously inapplicable studies more comparable and easier to gather information from, organizing different definitions of common terms with distinct titles so that researchers can actively choose which definition to use for their work. With the newly defined driving terms, previously uncorrelated studies have become applicable to one another. This research, when effectively utilized by future studies, will make these studies relatable by having a concrete and accessible set of definitions, and can additionally contribute to future studies comparing on and off road vehicles and vehicle testing.

Abstract Name: **Mechanism of Action of Antifungal Peptoids**

Due to the rise of drug resistant strains of fungal pathogens such as Cryptococcus neoformans and Candida albicans, there has been a need to identify new antifungal agents. In comparison to naturally produced antifungal peptides, antifungal peptoids mainly differ in structure, which prevents protease recognition giving higher bioavailability. Previous studies have shown that peptoids are effective fungicides. RMG8-8 and RMG9-11, two peptoids recently discovered in the Bicker Lab, have proven to be effective antifungal agents against C. neoformans and C. albicans, respectively. Reported here will be studies to determine the mechanism of action and other vital therapeutic properties of RMG8-8 and RMG9-11 using various biochemical and microbiological assays. Preliminary results of critical micelle concentration testing indicate that RMG8-8 as well as RMG9-11 do not exist as micelles at their minimum inhibitory concentrations, but rather function unimolecularly. Using a parallel artificial membrane permeability assay, it was found that RMG8-8 is likely unable to penetrate the blood brain barrier. However, RMG9-11 demonstrated good permeability, indicating that it may be able to penetrate the blood brain barrier to treat dangerous neurological infections of fungi. Subsequently, assays will be conducted in order to further understand the mechanism of action of both peptoid compounds to address the rising concern of drug resistant strains of fungal pathogens.

Abstract Name: **Looking into the Online Representation of Carceral Spaces via "PrisonTok"**

For many decades, the portrayal of prison in entertainment media has been the center of many TV shows, films, and literature. Often these narratives are dramatized, inaccurate, or highly censored. These media forms affect perceptions of formerly or currently incarcerated individuals into being reduced as violent, untrustworthy, and undeserving of a second chance. When the mainstream media is not heavily censored or edited, viewers are able to see the reality of inhumane conditions that take place within the prison industrial complex. When incarcerated communities began to control and contribute to their own representation, former and currently incarcerated individuals showed their lives through their own perspective. The popular social media app 'TikTok' allows these individuals to control their narratives. The app has a growing community of incarcerated creators, which is mainly known as "#PrisonTok". To gain a better understanding of PrisonTok's influence on how formerly or current incarcerated individuals are perceived and affected, an analysis of five users and around fifty videos all together is done. The analysis will be about the aesthetics of a video, engagement of online user interactions, and what the individuals affected by the justice system are trying to communicate. This research demonstrates a reflection of determination, hope, and the need for connection with the aim ofopening and facilitating a dialogue about abolition.

Abstract Name: Impact of Caffeine Combined with Resistance Training on Post-Exercise Arterial Stiffness in Habitual Caffeine Consumers

Background/Purpose: Increased arterial stiffness has been shown as a marker of cardiovascular-related events. Previous research has revealed resistance training and caffeine consumption leads to increases in arterial stiffness independently. Therefore, the purpose of this study was to determine the residual effect of combining resistance training and caffeine on arterial stiffness in resistance trained females. Methods: This experimental study was conducted on 18 participants between the age of 18 and 23 years who were resistance trained in accordance to ACSM resistance training guidelines. All participants were habitual caffeine drinkers as defined by consumption of at least 200 mg/day, 5 days/wk. Pre-trial evaluation of 10-rep max was performed to determine individual training load for each exercise session. Subjects completed both caffeine and placebo conditions in a counterbalance fashion to avoid an order effect. Caffeine was administered during each trial a dose equal to 3 mg/kg body weight. Each condition was followed by an exercise intervention consisting of a full-body superset resistance training protocol. Measurements of arterial stiffness (pulse wave velocity, pulse wave analysis, and pulse pressure) were obtained using the SphygmoCor® system at 4 different time points (baseline, post-exercis, 10min post-, 20min post-, and 40min post-exercise). Results: A two-way repeated measure analysis of variance (within-subjects) did not indicate a significant difference in measurements of arterial stiffness between placebo and caffeine trials, but a time effect was revealed to be significant within both trials ($p = 0.008$). Conclusion: The results did not indicate a summative increase in measurements of arterial stiffness due to the combination of resistance training and caffeine consumption.

Abstract Name: Virtual (and Hybrid) Summer Experience for Early Research (VSEER) Program: A Pandemic Collaboration to Broaden Participation

The VSEER program (Virtual and hybrid Summer Experience for Early Researchers),was first offered in summer 2020 in response to the pandemic. VSEER is acollaborative effortover several years, was developed and implemented by a team of campus directors across institutions in Iowa, Illinois, and Nebraska, and was adapted each summer to address the needs of students and objectives of the IINSPIRE LSAMP Alliance www.iinspirelsamp.org.The goals of the VSEER program are to provide early research training for studentsin a flexible environment across two and four year institutions, provide exposure to a variety of research approaches across disciplines, and create an environment where research may be understood in the context of culture. VSEER also aims to build community among program participants and mentors, develop participant STEM identity in the context of student intersectionality, and deepen student understanding of the purpose of LSAMP. The program is intended to increase the number of students from underrepresented minority groups that enter and thrive in STEM research fields.VSEER is an 8-week program in which students receive stipends for participating in an array of required and optional program activities. The core program consists of three components: an Introduction to Research course, lab tours, and community building. The core components are led by campus leaders and delivered synchronously via Zoom. The Introduction to Research course is delivered through Canvas Learning Management System. All students write a reflection and present a poster at the end of the program. Students have the option to be paired with a research mentor and engage in a research experience for an additional stipend. Students take pre and post STEM identity development surveys, receive a personal profile from the survey, and discuss the profiles with researchers.

Abstract Name: **Continued Studies of the Medium Effects on the Structures of Pyridine-Silicon Tetrafluoride Complexes**

We suspect that pyridine-silicon tetrafluoride complexes will exhibit structural changes in response to their surrounding environments, specifically, that the N-Si bond distance will contract in response to chemical medium. This study explores these structural changes caused by fluorine substitution on the pyridine and subsequently, solvation in low-temperature solid samples of inert gases (nitrogen, argon, and neon). These structural changes will be assessed through theoretical models of the bonding and experimental low-temperature IR spectroscopy. The models provide detailed structural information (e.g, precise N-Si bond distances), in addition to bond vibrational frequencies, bond energies, and bond potential energy curves. The low-temperature IR spectra provide measured values of key bond frequencies that correlate to structure in the inert media. Previous research was inconclusive because the models used were deficient and the extent of the medium effects were unclear. Now, we are reevaluating the structural results of C6H5N-SiF4, 3-FC6H5N-SiF4, 3,5-FC6H5N-SiF4, and 3,4,5-FC6H5N-SiF4 with a more sophisticated series of models. Interestinglywe have found that results are very sensitive to model choice, which highlights the need for experimental data on these systems. In turn, the predicted frequencies from the model results will be compared to infrared spectra from solid neon and solid argon. These comparisons convey the extent of structural change between the gas phase and the inert environments. Currently, experiments are in progress for 3,4,5-FC6H5N-SiF4 and these data will be discussed as well. in addition, we are mapping the N-Si bond potentials of these systems in the gas phase and in low-dielectric media. Comparisons of these data provide mechanistic insight into the observed and predicted structural changes.

Abstract Name: **Beyond a binary: Investigating criteria of insiderness in peacebuilding**

Peace building efforts around the world often struggle to achieve their aims, yet alone become self-sustaining initiatives that maintain societies transformed from cycles of conflict. These struggles may be related to the limited investigation, understanding, and support of insiders working to affect peace within their own communities. While existing literature has begun investigation of the unique roles of insider peace builders, there has not yet been sufficient theoretical analysis to understand the nuances of insider dynamics as a spectrum. Addressing this gap, this research project explores a) which criteria determine an individual's “insiderness” within conflict contexts and b) how these insider criteria interact with conflict dynamics to contribute towards peacebuilding practices. Through open-coding and thematic analysis of 14 sources addressing the nexus of “insider” and “peacebuilding”, two key areas of findings were identified: a) criteria of insiderness (e.g. trust with communities, geographical association, traditional knowledge or customs, etc.) and b) the abilities needed to utilize this insiderness for peacebuilding processes (e.g. maintaining trust, improving information flows, integrating traditional practices, cultivating peer networks, etc.). Identifying and evaluating these criteria can enable practitioners to better understand their roles in a peacebuilding process and their proximity to the conflict can be mapped according to salient criteria of insiderness in their specific context. Ultimately, this increased awareness of insiderness dynamics can contribute to more effective peacebuilding practices which champion local agency, overcome shortfalls of existing peacebuilding frameworks, and foster sustainable conflict transformation.

Abstract Name: Marginalization, Intersectionality, and Oklahoma Medical Cannabis Patients: An Exploratory Focus Group Study

In 37 states, cannabis' status as an illegal drug has shifted due to the process of medicalization. Oklahoma's medical cannabis program (OMMA) has gained national recognition as the only state with no qualifying conditions required to obtain a medical cannabis license. Oklahomans must receive discretion from one recommending physician who "certifies" that their medical condition(s) "qualify" for participation in the state's medical cannabis program. After obtaining OMMA patient status, patients must self-prescribe and rely on their lived bodily experiences as they access thousands of Oklahoma licensed cannabis dispensaries with little to no guidance of cannabis medicines. National health agencies recognize Oklahoma's particularly medically vulnerable socio-demographic profile, yet only one quantitative survey has accounted for socio-demographics of OMMA patients. In the last four years, there have only been two focus group studies exclusively for registered cannabis patients. Remarkably, no one has conducted a focus group study with registered medical cannabis patients to investigate the experiences of Oklahoma patients' with intersecting identities. Oklahoma's distinctive environment warrants the use of an intersectional, qualitative methodology. As such, the goal of this focus group study is to explore the interconnectedness of race, ethnicity, class, gender, and sexual orientation of Oklahoma patients. Particularly, the ways in which they navigate and/or negotiate their status as patient and a member of a historically marginalized community. The findings of this semi-structured exploratory study provide insight about Oklahoma's medical cannabis landscape, intersectional minority stress, and the perceptions of registered cannabis patients holding intersecting identities.

Abstract Name: DNA G-quadrupexes for Visual Signal Readouts in Bioanalysis

Nucleic acid scaffolds can fold into catalytically active conformations known as DNAzymes. Thus, DNA G-quadruplexes are notorious for enhancing the catalytic activity of hemin. The ability of nucleic acids to change conformation into the catalytically active form upon a target recognition has been engineered into a range of molecular diagnostic platforms. In this research project, we develop a system for visual signal transduction in biomarker detection. The new detection platform is based on an artificial activatable catalase enzyme. It is based on an oligonucleotide scaffold that binds and activates hemin to catalyse the decomposition of hydrogen peroxide. Hydrogen peroxide decomposition yields oxygen that is released in the form of bubbles. Bubbles can be detected either through the naked eye or under a microscope. When done by the naked eye, which is the visualization technique used in this project, it is a straightforward and easy-to-interpret route towards instrument-free visualization, and no scientific training is required. Thus, we work to develop an inexpensive and instrument-free platform for detecting clinically meaningful biomarkers such as antibodies and nucleic acids. The catalytic system consists of oligonucleotides that fold into G-quadruplex structure. G-quadruplexes are nucleic acid tetraplexes consisting of guanine-rich sequences. We will develop a scheme where a biomarker detection event results in folding of G-quadruplex into an active enzyme conformation.

Abstract Name: **The African Cost of Sustainability: Impact of Environmental, Social, and Governance (ESG) performance on sovereign risk in Africa**

Africa may be on the cusp of a seismic sovereign debt crisis as sovereign debt burdens skyrocket across the continent. In 2021, more than 20 low-income African countries were in debt distress as their prices plummeted and yields ballooned. Consequently, subsequent sovereign African debt issuances—particularly in the international capital markets—will have to offer higher yields to compensate investors for their higher risk profile. Unfortunately, offering higher yields will exacerbate the continent's debt woes. However, we posit that the potential cure for Africa's debt challenges may come from an unlikely source — ESG.

Adelman, Daniel

Abstract Name: **Sustainable Waste Management in Foreign Military Bases**

Today's financial markets are dominated by environmentally and socially conscious investors allocating capital to entities demonstrating a long-term commitment to sustainability. Similarly, we hypothesize that these ESG-centric investors may be willing to lend to African nations at a lower interest rate if they strengthen their ESG performance. Capelle-Blancard et al. (2019); Martellini & Vallée, 2021: Crifo et al., 2017; Semet et al., 2021 find a negative, statistically significant relationship between overall ESG performance and sovereign borrowing costs. However, none of these papers focuses exclusively on Africa, and this paper seeks to fill this gap. Firstly, this paper explores the relationship between ESG performance and sovereign bond yields. Secondly, it aims to identify the pillars of ESG that have had the most significant impact on sovereign risk.

Abstract Name: **Spilanthol alters the consumption of, and taste reactivity behaviors elicited by, NaCl solutions in male Wistar rats**

NaCl is an essential nutrient that humans and mammals consume to maintain cellular homeostasis. Humans add salt to food for the resulting pleasing taste. However, as the amount of NaCl consumption increases the mortality of patients with cardiovascular disease and ischemic heart disease increases (Adler et al., 2014; Yang et al., 2011). Compounds that can enhance the taste of NaCl could help reduce NaCl consumption without sacrificing perceived saltiness. Spilanthol is a bioactive compound that induces tingling and numbing in the mouth and enhances the sensitivity of taste receptors to salt (Xu et al., 2019). In the current study, the effect of spilanthol on the consumption of, and taste reactivity (TR) behaviors to, NaCl solutions in male Wistar rats (n=8) was evaluated. Suggesting that spilanthol enhances the sensitivity to NaCl, 6μM, spilanthol increased the consumption of a dilute (0.1M) NaCl solution (n=4, $p < 0.002$) and decreased the consumption of a higher concentration (0.25M) of NaCl (n= 4, $p = 0.05$). TR behaviors are the immediate oromotor responses to intra-oral infusion of solutions and reflect the palatability of the solution in the mouth (Spector et al., 1988). TR behaviors are classified as ingestive (indicating palatable) and aversive (indicating non-palatable). Rats tend to respond to low concentrations of NaCl with ingestive responses and perform aversive reactions to high concentrations of salt. In the current study, spilanthol increased the ingestive TR responses (n=4, $p< 0.02$) while not altering aversive responses (n=4, p=0.19) to a 0.1M NaCl solution. However, spilanthol alone decreased ingestive behaviors compared to water ($p<0.01$). We conclude that spilanthol is a salt flavor enhancer that alters NaCl perception and consumption. Currently, we are investigating the neural mechanisms underlying the behavioral responses observed using immunohistochemistry to the Fos protein which is expressed in active neurons.

Abstract Name: Using Enzyme-Linked Immunosorbent Assays (ELISA) to Understand Insulin-Degrading Enzyme (IDE)-Phosphatidylinositol Phosphate (PIP) Lipid Interactions

Insulin-degrading enzyme (IDE) has been linked to Alzheimer's Disease and Type II Diabetes due to its function in degrading insulin and the amyloid-beta peptide. IDE is, therefore, a potential therapeutic target for these diseases. This research aims to identify how IDE produced in the cell cytosol accesses its substrates, which are likely cleaved within the cellular endosomal system. It is hypothesized that some IDE localizes to endosomes by initially binding to phosphatidylinositol phosphate (PIP) lipids located in the endosome membranes. Computational docking studies suggested a site on IDE that might mediate an interaction with PIP lipid head groups. An enzyme-linked immunosorbent assay (ELISA) was used to evaluate whether mutations in this putative binding site disrupt interactions with artificial liposome membranes doped with PIP lipids. Results show that the mutations do affect PIP binding, with the variants IDE R824A,H885A,R892A and IDE Q813A,N821A,H885A having reduced or no detectable interaction with liposomes bearing phosphatidylinositol 4,5-bisphosphate (PI(4,5)). This loss or reduction of PIP interaction supports the hypothesis that IDE interacts specifically with PIP head groups and that this interaction is mediated by the proposed binding site. Improved understanding of this mechanism could someday enable the development of therapeutics for AD and/or diabetes mellitus and explain why these diseases are frequent comorbidities. While studying IDE-PIP interactions it was also observed that PIP lipids can bind in the inner chamber of the clamshell-like IDE molecule. The lab previously obtained a crystal structure detailing this binding interaction. Future work will investigate the possibility of IDE having a second function as a lipid transfer protein, which the lab is beginning to explore using a liposome-based lipid transfer assay.

Abstract Name: A New Generation of Farmers: Dynamics of Change?

With an aging farmer population set to retire in the next few decades, ambitions to change our agricultural system lie now with the next generation. Without dismantling the larger social structures that have kept current farmers from adopting conservation practices, however, the trends of soil and water degradation, consolidation, and pressure to reform are likely to remain the same. This project examines the factors that influence environmental change on a local level, and what supports are needed for farms to transition to sustainable practices. By doing semi-structured interviews of agricultural, environmental, and policy professionals in the Red Cedar Watershed, as well as attending local events related to these themes, I was able to observe the power dynamics that exist in the agricultural sphere. Qualitative findings suggest that most barriers to adoption are social and/or risk-based. Because of the high barriers to entry in agriculture, most younger farmers are tied to existing family operations and there is pressure to succeed, continue familiar practices, and consolidate for more financial stability. Additionally, farmers often rely on informal networks for knowledge sharing and many are hesitant or unaware of government programs that could provide aid. Fluctuating markets and increasing extreme weather events make it difficult, maybe impossible, for agriculture to continue its current path. Thus, I conclude by suggesting several policy and community-led programs that would aid younger farmers in a sustainable transition including financial support for new farmers to offset land, healthcare, and student debt expenses; greater support of local food and cooperatives; and expanded community education programs related to conservation agriculture.

Abstract Name: Exploring the attitudes, knowledge and beliefs regarding hospice care amongst racial and ethnic minorities

Hospice care is depicted to make the end of life comfortable and satisfactory. This research project explores the attitudes, knowledge, and beliefs regarding hospice and end of life care among racial and ethnic minorities. It is hypothesized that racial and ethnic minorities do not utilize hospice care as much as they could because of language barriers, less knowledge about the process of admission to hospice care and what it can offer them, cultural and religious beliefs, difficulties regarding health insurances and financial status. A lot of previous research has focused on exploring how socioeconomic status and Medicare claims contribute to employing hospice care. This research will be conducted using a convenience sample of 200 which will include Brooklyn College students and members of the larger Brooklyn Community. A survey approved by the IRB will be used to collect data. It is expected that there will be negative attitudes and beliefs and limited knowledge regarding hospice care amongst racial and ethnic minorities as compared to the white population. The unavailability of information to racial and ethnic minorities creates barriers to reaching out for end of life care. This calls for exposing these minorities to both educational and socioeconomic resources which could lead to positive beliefs and attitudes regarding hospice care.

Abstract Name: Food As Medicine Program Analysis

The relationship one has with food is directly correlated with one's health. Our current health system has a severe issue with individuals with chronic illnesses who face issues of affordability and accessibility to food. This has led food pantries across the country to develop food as medicine programs which can consist of medically tailored meals, medically tailored packages, and nutritious food referrals. Ultimately, the goal of these food intervention programs is to help create a better lifestyle and improve the health of individuals with food insecurity and chronic illnesses. This presentation will focus on an analysis of the Food as Medicine program at the Food Pantries for the Capital District. Our hypothesis is that Food as Medicine intervention programs improve the health of individuals with chronic illnesses which is evident through the changes in their A1C levels, BMI, number of hospitalizations, and blood pressure.

Abstract Name: MATLAB Image Processing for 2D Traversing Plasma Device designed for Wound Healing and Sterilization

Non-thermal Dielectric Barrier Discharge plasma jets find applications in plasma medicine. In practice, these incident plasma jets are exposed to skin wounds; therefore, an effective scanning of the wound surface is required. In the current research, a plasma scanning system was developed and tested. Various wound images were provided for the system to scan with a plasma jet. For this purpose, a Logitech camera connected to a Raspberry Pi was used to capture the required artificial wound (printed on a piece of paper) image area. This information was relayed to a 2D scanning device that held the plasma jet to scan the targeted area. A MATLAB based algorithm was used to identify the wound area by isolating red color pixels by using a specified threshold value. Inbuilt MATLAB functions were used to identify the minimum and maximum x- and y-values of the wound pixels to generate a bounding box. The developed program rotates the image and regenerates this bounding box at 1- degree intervals, and minimizes the area. The developed software was tested to identify a leg wound image (1.4in x7.3in). The pixel color contrasts were used to mark the boundary around the wound that ended up as a rectangle (1.3in x 7.4in). This was within an accuracy of 94% of the targeted area. To identify the limitations of the imaging software, different wound images (oblong, square, irregular, circular) were tested. Low color contrast between the skin and the wound surface appeared as the main limitation for the software. This presentation will include discussion on the scanning software development, the DBD plasma jet generation, and the functioning of the 2D traversing device which was employed to scan wound surfaces.

Abstract Name: Spray Integration in the Cooling of High Heat Flux Electronics

Spray cooling is an efficient cooling technique for high heat flux applications like metal forming and electronic cooling. However, without fundamental knowledge of fluid mechanics in these applications, spray cooling can be ineffective due to dry-out at low spray rates, or excessive liquid accumulation at high spray rates. In electronics like computer chips, these errors can cause crucial and expensive failures. The purpose of this research is to further understand the fluid mechanics and heat transfer processes behind spray cooling, enhance the ability of the process, and develop a phase diagram of collected data. The first technique researched was single droplet impingement. To obtain data, a high-speed camera was used to take detailed videos of microdroplets produced from a piezoelectric nozzle. Microdroplets of various liquids, including ethanol, isobutanol, and isopropanol, were dropped onto a heated copper surface, with the surface temperature ranging from 60 to 200 degrees Celsius. Droplet diameter, velocity, and resident time were tracked, as well as the associated behavior of evaporation, boiling, or leidenfrost, and the rate at which this occurred. These results contribute to the understanding of mechanical properties of microdroplets, discovering which combinations of droplet diameter, velocity, and liquid properties will improve their function in spray cooling. Another aspect researched was the ability of multi-droplet sprays to cool a heated surface via impingement and evaporation. An experimental setup was developed and assembled consisting of a pressurized air and water supply connected to an ultrasonic atomizer nozzle, heated plate, and thermocouples that relayed results to a data acquisition system. Preliminary results determined that cycling nozzle operation yielded similar cooling results to continuous spray, while saving up to 70% of fluid consumed. Future variables to explore include recycling atomized vapor, determining optimal timing of cycles, and testing additional liquids.

Abstract Name: Characterizing an Exoskeleton Device for Leg Muscles Rehabilitation

Stroke patients very often suffer from disability and are unable to walk freely. To regain their mobility, they need rehabilitation exercises. Commercial exoskeleton devices are availble but these are either very expensive or do not fulfill the patient's particular exercise requirements. An ongoing project at the San Jose State university is engaged in designing and developing an exoskeleton knee brace that will be cheap and will be user friendly [IMECE 2020, 2021, 2022, SCCUR-2022]. This knee brace relies on the fluidic muscles (Festo Corp) that use air pressure to mimic the leg muscles movement. The device consists of two parts, an upper brace for the front of the thigh holding the fluidic muscles and a lower brace behind the calf. The operating system includes a central control box that contains multiple solenoids and valves that are controlled by a central microprocessor (Arduino). The central system was activated by EEG sensors that were mounted on a human leg to activate the exoskeleton device. The EEG sensors' response was further processed for the noise reduction and was amplified by using an amplifier. Five fluidic muscles were characterized and calibrated before mounting them on a mannequin leg. Further experiments helped to optimize the knee brace design to mount it on a human leg. Experiments were performed to characterize the device operation by measuring the average leg rotation time and the maximum rotation angle as a function of applied pressure. Experiments show that the average time to reach the maximum rotation angle varied from 18 to 36 degrees where the rotation time varied from 1.58 to 1.23 seconds as the pressure increased from 30 to 60 psi. The presentation will detail the design and the operation of the exoskeleton device and will also describe the experimental results in a greater detail.

Abstract Name: Stress on elementary school teachers during COVID-19(2020-2022).

From December 2019 to 2022-present COVID-10 almost stopped the education system. How we teach our younger children can have a great impact on future generations if both the teachers and students are stressed trying to learn new online learning methods in times of a pandemic. Trying to figure out the stress factors of teaching during COVID-19 consisted of bad communication with both caregivers and faculty. Stress trying to teach children who don't have access to technology or are not in great family situations can both affect the teachers in not being able to help the students and students not having the time away from bad family situations and having a healthy place to learn. The current research addressed these issues throughout how teachers felt during th first couple months and the problems they encountered and how they decided to adapt and dhcange to give the most effective way to teach the children. Each school district had their own set of rule and regulations depending on the state they taught in.

Abstract Name: Factors Predicting Anxiety and Depression Among International Students

Anxiety and depression are common problems that interfere with functioning. There is very little research to understand what factors predict anxiety and depression in international students attending universities in the United States compared to the broader student population. One possible factor could be acculturation, the process by which an individual or a group adopts cultural practices and values while maintaining their own culture. Acculturation has been found to be linked with an increased odds of having a lifetime psychological disorder. Thus, research on acculturation and symptoms of anxiety and depression in international students is needed to better understand the mental health risks, namely loneliness and rumination, faced by international students. Our research examines the association between acculturation and internalizing symptoms (i.e., anxiety and depression) in a sample of international students who are participating in study abroad programs. Two hypotheses guide this investigation. First, we hypothesize that acculturation will be positively associated with later anxiety and depression symptoms. Second, we hypothesize that the associations of loneliness, rumination, discrimination and identity with later depression and anxiety will depend on acculturation, such that the associations will be stronger at higher levels of acculturation. We are testing these hypotheses with hierarchical regression. One model includes anxiety symptom severity as the outcome, and the other treats depression symptom severity as the outcome. In each model, loneliness, rumination, discrimination, identity, and acculturation are predictors in step 1. In step 2, the interaction of acculturation with each of these variables is added to the model. The data are still being collected and that results will be presented at the conference.

Abstract Name: Digital Financial Literacy and Small Business Performance in the Post-Pandemic Era

Financial Literacy (FL) has long been a topic of interest due to its many proven benefits (Ouachani et al., 2020). Rapid digitalization of firms - including financial service providers - has introduced a new strand in this field known as Digital Financial Literacy (DFL) which assesses the bridge between FL and basic digital skills. The pandemic forced businesses to adopt digital financial services (DFS) which most probably affected their business performance. This study aims to investigate the relationship between DFL and the performance of small businesses in Ghana after the COVID-19 pandemic. Modifying Lyons and Kass-Hanna (2021)'s framework to suit local conditions, this study will use surveys to measure DFL of business owners. Firm performance will be evaluated using growth in sales, revenue, and number of employees. A regression analysis would determine the nature of the relationship between these two variables. Most likely, there will be a strong positive relationship since efficient use of DFS, among others, cuts down the cost of making and receiving payments. This will indicate the need to integrate DFS in operations. Providers of financial services, informed by the results of this research will then be able to design better-suited DFS for small businesses. Services tailored to the unique operations of small businesses in Ghana would boost performance even more. The first of its kind in Ghana, this study opens up a new strand of literature within the context of Africa. Further research based on this study can explore how DFL affects other firm fundamentals like efficiency and resilience.

Abstract Name: Contribution of Infection with Cytomegalovirus (CMV) to the Production of Amyloid Precursor Protein (APP) and Alzheimer?s Disease-associated Beta Amyloid

With more than 6 million people in the United States living with Alzheimer's disease, the disorder is the most common cause of neurodegeneration and dementia. Persons infected with cytomegalovirus (CMV) are more than twice as likely to develop Alzheimer's disease and have faster cognitive decline after diagnosis. Alzheimer's disease is characterized by the formation of tau-based neurofibrillary tangles commonly seen in other neurodegenerative conditions, and the formation of extracellular β-amyloid plaques, a pathology unique to Alzheimer's disease. We hypothesize that CMV infection will promote increases in pathological markers of Alzheimer's disease. To test our hypothesis we are infecting CMV permissive cell types with murine CMV (MCMV) and measuring changes in pathological markers of Alzheimer's disease. Using western blotting, we have determined that MCMV infection increases phosphorylation and the accumulation of high molecular weight isoforms of tau in fibroblasts, neuroblastoma cells, and primary cultures of rat cortical neurons. While preliminary experiments did not show a decrease in the amount of amyloid precursor protein in MCMV-infected cells, we are more finely assessing production of intra- and extracellular β-amyloid levels using western analysis, immunocytochemistry, and enzyme-linked immunosorbent assays (ELISAs). Conducting these experiments will provide a comprehensive view on the contribution of MCMV infection to Alzheimer's disease pathology, addressing the mechanisms through which CMV infection might increase the risk of developing this neurodegenerative disorder, potentially identifying novel therapeutic targets.
Supported by Texas Woman's University (TWU) Division of Biology, a TWU Center for Student Research grant (to P.H.M), and a National Science Foundation (NSF) Promoting Research and Innovation in Methodologies for Evaluation grant (supporting AA, #1953448) from the TWU Research Enhancement Program (to DLH).

Abstract Name: Automated Temperature Control of a DBD Plasma Jet Through Feedback Loop

Low temperature, non-thermal Dielectric Barrier Discharge (DBD) plasmas find wide applications in plasma medicine. Due to their low gas temperatures, along with numerous radicals such as Nitrogen and Oxygen reactive species, plasmas are able to heal and sterilize wounds. A plasma jet is formed when voltage (~5-10 kV, 20-40 kHz) is applied to a Helium gas (~10-20 slpm). During medical application, it is important to limit the temperature of the plasma jet to avoid any damage to the exposed cells. For practical purposes, the control of plasma gas temperatures in real time is required. In this study, an automated system has been designed using stepper motors, a power supply, a K-type thermocouple, motor controllers, and an Arduino microprocessor. The system is designed to constantly read the plasma jet temperatures, light the green or red LED indicating the safe temperature zone, and controlling the power supply through a feedback loop control by adjusting the power knob of the power supply in an automated fashion. The optimum operating temperature was fixed at 30 degrees centigrade (obtained from literature for safe plasma operation) and the system was activated as soon as the temperature deviated from this targeted value. In this study both a helium plasma jet and a helium plasma sheet were scanned by a thermocouple to obtain two-dimensional temperature distribution with and without the automated system. Experimental results show that the feed back control system was able to control the temperature by adjusting the power supply in a correct manner. The plasma temperatures near the exit of the plasma device were found lot higher than 30 degrees Centigrade. The plasma jet exhibited lower temperatures as it propagated throughthe air. The presentation will describe the automation process in a greater detail and will discuss the experimental results from biomedical application perspective.

Abstract Name: **Investigation of Ventilation and Air Quality in Classrooms**

The transmission of the coronavirus can be greatly impacted by indoor ventilation and air purifiers according to the U.S. Environmental Protection Agency and other public and private institutions and researchers. The concentration of aerosols in the air that contain the virus can be reduced by proper ventilation systems, which circulate and filter the air for increased quality. Aerosols with a diameter of2.5µm or lessare a possible carrier of SARS-CoV-2. PM 2.5 pollution may also increase the cellular expression of ACE2, associated with greater viral susceptibility. Ventilation to reduce PM 2.5 levels addresses both risks. Tests using incense as an indicator before, during, and after burning were used to see how quickly the ventilation in the rooms was able to remove excess PM 2.5. A calibrated DustTrak II monitor was used to record particulate matter, then Honeywell HEPA air purifiers were emplaced to see if further purification would aid in ventilation compared to only an HVAC system. Room air exchange rates (ACH, hr-1) were calculated using a spreadsheet by Jimenez at UC-Boulder. ACH rates in a small (15 person) meeting room were 5.88 hr-1 with HVAC alone and 16 hr-1 with two added air purifiers. Corresponding rates in an average (35 person) classroom were 9.62 hr-1 and 12.0 hr-1 with a single purifier. In this case, HVAC and air purifier coverage was 1.25–2.72 times as efficient as just HVAC coverage. Results for local weightlifting rooms are currently being investigated and will be included. A limitation of this research was the occasional pooling of incense smoke near the opening of the air monitor leading to a temporary spike in PM 2.5 levels. Use offans can address this issue. HEPA air purifiers reduce PM 2.5 levels and in turn may help lessen transmission risk of SARS-CoV-2 aerosols and airborne viruses.

Abstract Name: **What are the Drug-to-Drug Interactions Between Xanax and Synthetic Cannabinoids?**

During the COVID-19 pandemic, depression, anxiety, and isolation caused by lockdowns and economic hardships drove substance abuse of both illicit and prescribed drugs to record high levels. Xanax, more commonly referred to as alprazolam, is an anti-anxiety benzodiazepine commonly prescribed to treat short term anxiety. According to figures from the United States Drug Enforcement Administration, alprazolam is amongst the top three prescription drugs diverted to the black market. Overdoses caused by alprazolam often may occur when combined with illicit drugs such as synthetic cannabinoids. Synthetic cannabinoids are commonly known as K2 and spice, and induce a “high” similar to cannabis but cause significant adverse side effects, such as cardiovascular and gastric issues. Synthetic cannabinoid account for a third of all new drugs of abuse on the market. Those suffering from substance use disorders are likely to mix alprazolam with synthetic cannabinoids which could lead to death due to drug-to-drug interactions. This possibility is supported by autopsy and clinical reports. Nevertheless, there is no research on the impact of these drug combinations on metabolism and subsequent parent drug levels that could cause adverse drug effects. In response, this project was designed to study drug-to-drug interactions of the synthetic cannabinoid 5F-APINACA and alprazolam in humans based on steady-state kinetics studies using human liver microsomes. Previous work done in the lab has identified the kinetics of 5F-APINACA in human liver microsomes. We will be comparing the previous kinetic data of 5F-APINACA to the kinetic data after adding alprazolam to 5F-APINACA in kinetic assays using human liver microsomes. Preliminary results show that alprazolam is a mixed inhibitor of 5F-APINACA, but futher experiments are still required. The metabolic kinetics in this study will be key to having a better understanding of the metabolic effects caused when substance abuse users mix alprazolam and synthetic cannabinoids.

Abstract Name: The Intersection of Foster Care, Substance Use, and Incarceration

According to the National Conference of State Legislatures, up to 80 percent of children in foster care have significant mental health issues, compared to approximately 18 to 22 percent of youth in the general population. The American Academy of Pediatrics, "Healthy Foster Care American Initiative", identifies mental and behavioral health as the two "greatest unmet health needs for children and teens in foster care." Traumatic experiences that a large percentage of foster youth report, combined with the fact that the general population of adolescents begins drinking anywhere from age 13 until 17, increase the likelihood of substance use disorders in foster youth. Another study conducted by National Household Survey on Drug abuse found that 40 percent of adolescents who had resided in various foster care placements were likely to use alcohol compared to 30 percent of youth in the general population, and they were twice as likely to use drugs. In addition, close to one-fifth of the U.S. prison population are former foster children. This study examines the prevalence of substance abuse in foster care youth whose voices are silenced. Through a meta-analysis of current literature, we create a policy and advocacy resource that educators, policymakers, and advocates can use. While some counties and cities in the US provide services in an attempt to support youth, the quality and quantity of programs offered vary considerably, due to limited available funding, lack of education, awareness, and/or staffing. More preventative services for substance use disorders need to be made available, and there needs to be a focus on providing better quality mental health services. In addition, foster parents should be required to complete in-person trainings that are more in-depth and more frequent.

Abstract Name: The Role of Spanish-language Press in the United States in the First Half of the Nineteenth Century

The cultural perspective of having different ethnicities and races contributing to their unique history establishes mass progress following the creation of American Studies in the middle of the 20th century. My research focuses on the perspective of Hispanic, Spanish-speaking American news-press starting in the 19th century concerning its origin and how the Spanish-language press covered black and African Americans. Explicitly, I am attempting to establish a shared history between Hispanic Spanish-speaking Americans in their attitudes and coverage of black and African Americans in Spanish-language newspapers from 1808 to the Civil War. The purpose of my research is to decern that Spanish can be used as a tool to examine the collective shared American history of all ethnicities and races. The cultural lens of American and other ethnic studies can be utilized to investigate other groups of Americans that existed at the same time. The purpose of using newspapers is to establish a primary source account of the direct voice of the individuals who produced news, advertisements, and other various forms of commentary. Researching Spanish-language newspapers has uncovered several discrepancies from the expectations I presumed of the 19th century, including the owning of enslaved people and how I predicted enslaved and black Americans to be discussed in the 19th century were deterred in my findings. While Spanish-language press has been addressed by other scholars in the past, especially in Southwestern communities, my research is explicitly focused on utilizing the Spanish-language press as a means to add a Hispanic lens that could add to the overall perspective of American history as currently documented.

Abstract Name: **In-Air Sonar System for High-Speed Drone Flight Through Cluttered Environments and Poor Environmental Conditions**

State-of-the-art in-air sonar systems fall far short of enabling the phenomenal perceptive detail and flight performance exhibited by the echolocating Microchiropteran bats. As the Microchiroptera demonstrate, collision-free flight navigation through cluttered environments and poor environmental conditions can be performed reliably at high speeds while exclusively using in-air sonar. We hypothesize that drones can achieve this performance by mimicking the ultrasonic emission capabilities of the Microchiroptera and by inferring flight trajectories using a deep neural network (DNN) trained in a simulation that fully models the acoustic phenomena used by echolocating animals. A novel phased array architecture based on capacitive micromachined ultrasonic transducer (CMUT) technology has the potential to fully mimic the transmissions of the Microchiroptera by generating large-amplitude, wideband ultrasonic waves with variable direction and beamwidth. To receive the echoes with high directional determinability, a large array of tiny micromachined digital microphones can be directly interfaced to an FPGA for processing. A deep neural network (DNN) model that uses convolutional layers to detect features in the microphone data across the time dimension can output collision-free flight trajectories to reach a desired destination at a given trajectory. To train the DNN, a novel finite volume method (FVM) is proposed to enable the efficient simulation of the nonlinear interactions between acoustic waves and provide a physically accurate virtual environment for drone flight with sonar. This research has the potential to enable a large range of technological developments and integrations due to the unique advantages that in-air sonar has over other spatial sensing technologies (e.g., computer vision). Additionally, the described DNN model could be trained to enable a wide range of complex tasks beyond drone flight, such as detecting objects that are not in line-of-sight of the sensor and identifying objects based on their acoustic signatures.

Abstract Name: **Investigating the Mechanism of nanoparticle toxicity by tracking H202 production with electrochemical techniques**

Nanoparticles are increasingly being applied to new technologies as their unique size-dependent properties contribute to more efficient systems. However, the use of nanoparticles hasn't come without a cost. Studies show that these engineered nanomaterials can lead to toxic effects on the life present in the environment by producing reactive oxygen species like hydrogen peroxide (H2O2). H2O2 is a powerful oxidizer that remains relatively stable in abiotic environments. However, H2O2 also has the capacity to rapidly kill cells via hydroxyl radical generation. Lithium Cobalt Oxide (LCO) and lithium nickel manganese cobalt oxide (NMC), both nanoparticles used in the fabrication of lithium-ion batteries, were tested for the generation of H2O2. Using the electrochemical techniques amperometry and cyclic voltammetry, the voltage and current of the LCO and NMC solutions were compared with a background solution of 0.1M potassium nitrate (KNO3), in order to track the production of H2O2 from these material in solution over 26 hours. Findings suggested that LCO leaked H2O2 into the solution overtime, with the most H2O2 being released in the first 30 minutes. H2O2 emanated from these nanoparticles could explain the mechanism for their toxicity in the environment, informing the creation of safer nanomaterials in the future.

Abstract Name: **Effect of Guanidinium Content on the Anion Binding Capacity of Polyallylamine-Based Polymer Networks**

Crosslinked polymer networks have essential uses as sponges that remove unwanted or excess compounds from water. For example, a crosslinked network of polyallylamine, known as sevelamer, is a drug used to treat hyperphosphatemia, a disorder involving excess phosphate in the body. It works by binding dietary phosphate in the digestive tract, thereby preventing excess absorption by the body. In this research, we built on what is known about sevelamer, replaced the amino group in polyallylamine with guanidine, and studied the effect on binding to different classes of anionic molecules. Previous studies from our group found that increasing the amount of guanidine decreased the binding capacity of the networks for inorganic phosphate. Here, we study the binding capacity of different polymer compositions to glyphosate and bile acids. Polymer networks were prepared from polyallylamine hydrochloride (PAA), which was converted to polyallyguanidine-polyallylamine (PAG-PAA) copolymers with different amounts of a guanylating reagent. These copolymers were crosslinked with epichlorohydrin to create three networks: PAA (sevelamer), 25%, and 50% PAG-PAA. These networks were incubated with glyphosate, and the binding capacity was assessed by the change in glyphosate concentration, which was determined using both ascorbic acid malachite green assays. Our results suggest that glyphosate capacity increases with increasing guanidinium content. A colorimetric enzyme-based assay is being used to study bile acid absorption by the polymers, but the project is ongoing regarding bile acids. Overall these results will inform the future design of polymer resins for the treatment of medical conditions and environmental remediation.

Abstract Name: **Effect of acute oxytocin administration on social behavior in male and female mice**

Oxytocin is a neurotransmitter and hormone with a well-established role in prosocial behaviors in animals and humans. It is currently being tested in clinical trials for the treatment of social symptoms associated with autism spectrum disorders. However, the behavioral effects of oxytocin treatment have been variable with both prosocial (increased empathy) and antisocial (increased competitiveness) behaviors resulting in humans. Previous studies in our lab have shown increased anxiety-like behaviors in mice treated chronically with oxytocin (1 12 ug dose per day for 14 consecutive days, data unpublished). The current study aims to see the effect of acute oxytocin administration on social behavior in male and female mice to determine if the schedule of oxytocin administration affects behavioral outcomes. Adult C57BL/6J mice will be acutely pretreated with saline or oxytocin (12 µg) an hour before the behavior tests. Saline or oxytocin will be administered either intranasally (i.n., 12 ug in 12 uL, 6 uL per nostril) or intraperitoneally (i.p., 12 ug in 120uL). Mice will complete a battery of behavioral tests including the elevated plus maze (EPM), three-chamber sociability task (3C), and free dyadic social interaction (FDSI) after drug administration to determine changes in social behavior and anxiety-like behavior. Noldus EthoVision XT and human coders will code anxiety-like behaviors, social preference, and social novelty. I expect to find that acute oxytocin administration will increase sociability as measured by the 3C and FDSI tasks while avoiding increases in anxiety-like behaviors, as measured by the EPM task, associated with chronic administration.

Abstract Name: The Excellence Capsule (NExT)

Transformational leadership is a leadership style that can inform our high-impact educational practices by serving as a better capacity builder for students. Inspiring positive changes in those who follow, transformational leaders are generally energetic, enthusiastic, and passionate. Not only are these leaders concerned and involved in the process, but they are also focused on helping every member of the group succeed. The Nonprofit Excellence and Transformation (NExT) Program makes for a great capacity-building opportunity by focusing on the progression of professional development. We hypothesize that the NExT program serves as an excellence capsule not only for the non-profit organizations that they partner with but for the student by expanding their knowledge, professional skills, and cultural awareness, through a gradual process that prepares them for their next step in the real world.

Abstract Name: Conformity and Friendship Satisfaction Among University Students

The rhetoric around one's role in a friendship or relationship is largely shaping up to promote a lack of conformity. Adolescents and young adults are now regularly told to "stand out" and perhaps that fitting in isn't always the best option. This, however, prompts the question of what role conformity plays in impacting friendship satisfaction. This paper explores whether there's a correlation between an individual's level of conformity and their level of friendship satisfaction. Gender and relationship status are explored as potential mediators in this relationship. The participants' level of conformity was measured using the Elevator experiment, where participants enter an elevator and find 4 other people facing the rear end of the elevator. Participants accordingly make one of three decisions, they either turn and face the rear end (conformity), continue standing the same way (non-conformity), or hesitate (mid-level conformity). Participants then completed a questionnaire that assesses their level of platonic friendship satisfaction across three scales. This process was completed 75 times by participants, with 25 students conforming, 25 not conforming, and 25 mid. Results of the Anova show that there is no significant correlation between conformity and friendship satisfaction; however, there was a significant correlation between gender and friendship satisfaction, which indicated that girls are overall more content with their friendships. This opens lots of areas for future research, as it can be worthwhile to explore some of the other factors that result in girls being more satisfied with their friendships at this specific age.

Abstract Name: **Identifying Disparities in Elementary Education**

Multivariate data from several sources on the New York City Public School students was mined and analyzed by several factors including gender, race, household income, and community income. These data illustrate the achievement gap in the New York City schools among various socio-economic groups and racial and ethnic groups. Analysis of the aggregate data showed that students from families classified as low-income had lower levels of proficiency on a third grade math assessment than students from households not classified as low-income. Further analysis revealed that scores were not, in fact, tied to the income level of students' household, but rather associated with the socio-economic status of the school community. This presentation will describe the process of mining and analyzing the multivariate data set as well as the findings of the analysis.

Abstract Name: **Harvesting the Sun and Wind for Portable Microgrid Applications**

Globally, it is understood that reducing carbon dioxide (CO2) emissions is a high priority. As such, 137 countries have pledged to reach carbon neutrality, of which 90% are targeting to complete this by 2050. Advances in renewable energy are required to facilitate these goals, with significant focus on contributions from wind and solar. Mobile microgrids featuring renewable resources are an essential milestone toward these goals. The American Society of Mechanical Engineers (ASME) is hosting a microgrid competition in the form of solar and/or wind powered remote controlled vehicles. The vehicle is required to transport weight from a charging station to an unloading area over a 10-minute time frame. Ideation methods were used to prepare conceptual designs. Upon finalizing the concept design, the detail designs were completed and a prototype was built to harness both wind and solar energy while storing it in a supercapacitor array. Size constraints and scoring bonuses for minimized size fostered unique arrangements of solar panels with minimized projected area and foldable wind turbines to minimize total package volume. The energy harvesting, storing, and size minimizing design applications considered for the final design can be applied to small, portable microgrids for low energy harvesting applications in emergency response situations.

Abstract Name: Effects of saccadic and smooth pursuit eye movements on whole body postural responses during upright perturbed reaching movements.

During daily activities, such as a simple reaching task, motor control and coordination of the upper and lower limbs are essential for successful completion of the task. This coordination is done through anticipatory and feedback responses in the upper and lower limbs, which includes corrections to center of pressure (the point where the force due to pressure passes through the body) ensuring balance is maintained throughout the task. Anticipatory and feedback responses occur when upper and lower limb muscles activate before any movement is initiated, which helps maintain balance and posture during the task. There is already evidence that mechanical perturbations applied to the upper limb elicit rapid responses in lower limbs; however, it is unclear if different eye movements (smooth pursuits and saccades) affect upper and lower limb coordination, specifically during mechanical perturbations. The study aims to identify the potential differences in muscle activity during perturbed and unperturbed reaching movements when different eye movements are utilized. The experiment includes two tasks: a reaching and visuomotor tracking task. Reaching movements to peripheral targets requires saccadic eye movements, while the tracking task requires smooth pursuit eye movements. The preliminary results indicate that there is a clear shift in center of pressure along the medio-lateral axis occurring approximately 80-100ms before the reaching movement is initiated in both conditions, indicating a possible anticipatory response. Upon further analysis, we anticipate seeing differences in EMG muscle activation during perturbed trials for the two conditions with specific interest in the long latency reflex period occurring 75-120ms after force onset in lower limbs and 75-105ms after force onset in upper limbs. We will quantify how different types of eye movements would affect anticipatory and feedback response. We will also identify if saccades and smooth pursuits provide feedback for anticipatory and feedback responses in upper and lower limbs.

Abstract Name: Male Participation in Parent Education

The student researchers seek to create an environment that motivates fathers to attend ;parent education courses by exploring the factors involved in the participation of males in parent education. The student researchers targeted a sample size of 78 fathers while utilizing a mixed methodology survey with an emphasis on quantitative. The students distributed this survey through online platforms and local grocery stores. The student researchers collected data during a three-week-long period. The survey contained five demographic questions regarding age, race/ethnicity, marital status, number of female children, and number of male children. The majority of respondents were ages 41 to 50, (28.2%; n=22), 20.5% (n=16) were ages 31 to 40, 16.7% (n=13) were ages 20 to 30, 12.8% (n=10) were ages 51 to 60, 10.3% (n=8) were ages 61 to 70, 7.7% (n=6) were ages 71 to 80, and 2.6% (n=2) were 81 to 90 years of age. Regarding race/ethnicity 85.4% (n=51) of respondents were White/Caucasian, 28.2% (n=22) were Hispanic, 2.6% (n=2) were American Indian/Alaskan Native, 2.6% (n=2) were Black/African American, and 1.3% (n=1) were Asian/Pacific Islander.The student researchers created a code sheet using Google sheets, which consisted of converting the survey questions into a code. The student researchers used the Statistical Package for Social Sciences (SPSS) to analyze data collected. The student researchers utilized the Hahn's Coding Process to analyze the qualitative data. The themes: Work, Family, Time, and Disability consist of responses that reveal obstacles within the father'slives that would interfere with their attendance toparent education classes. Conducting this research provides information to include programs specifically for males to become more involved in parent education.By gaining insight from fathers in the community, the researchers will brainstorm ideas on how to make it easier for fathers to be able to attend parent education classes.

Abstract Name: **Biocatalytic Upcycling**

Nature has evolved a variety of enzymes capable of breaking down chemical waste products to generate carbon source fuel for survival. Non-heme iron ring cleaving dioxygenases (RCDs) are a class of biocatalysts that break down aromatic chemical waste products to generate important organic building blocks, such as muconic acids and muconic semialdehydes. While these enzymes have been explored for their potential as bioremediation catalysts, there are relatively few examples of their use in preparative scale synthesis. We envision that these enzymes will enable upcycling of waste products to produce useful quantities of valuable organic building blocks. In these studies, we are analyzing the ability of an extradiol dioxygenase, BphC, to produce muconic semialdehydes and conjugated ketones under preparative scale conditions. Existing research on BphC has been limited to reactions with catechols at low substrate concentrations. Our work utilizes UV-vis spectroscopy to analyze reaction progress while optimizing conditions such as reaction temperature, time, pH and buffer composition. Initial studies confirm that the isolated BphC catalyst is active and is capable of generating structurally diverse semi-aldehydes and ketones. This data will be used to develop a preparative scale reaction platform for synthesis, isolation and characterization of reaction products.

Abstract Name: **Empathetic Portrayals of Homelessness and PTSD in Home and Stories from the Shadows**

The realistic views of resignation in Home, Toni Morrison's historic fictional work, combined with the resiliency of individuals in Stories from the Shadows, present an accurate depiction of the human experience regarding homelessness, PTSD, and other hardships. Homelessness is a pervasive problem in U.S. society, and both books demonstrate that acknowledgment and understanding are the only way to improve the lives of those who struggle with it. These works also illustrate the difficulties those living with PTSD face. Home follows the journey of Frank Money, a Korean War veteran, as he discovers who he is and where he belongs. The ideas and theories of individuals presented in this novel are supported by the real-life stories Dr. Jim O'Connell recounts in Stories from the Shadows. The combination of these two works depicts an American society that fails to protect its people and alienates those who struggle. Together, the works create an acknowledgment of the undeniable strength that these individuals hold and maintain. Morrison and O'Connell's advocacy for those suffering from homelessness or PTSD invites compassion and empathy. Although those living in adverse conditions may have resigned themselves to a lifetime of failure and tribulation, they are not to be further condemned by individuals unwilling to lend a helping hand. Home and Stories from the Shadows engage readers so that they might discover what it is like to live in distress on the outskirts of society.

Abstract Name: COVID-19-Related Disruptions on Relationships and Their Effects on Older Adults' Depressive Symptoms: Perceived Mattering As A Moderator

Older adults faced unique challenges during COVID-19 lockdowns, including restricted contact with loved ones. As a vulnerable group during the pandemic, the risks of exposure carried heavier consequences leading to most older adults and their caregivers placing great importance on adhering to isolation guidelines. The disruptions caused by COVID-19 on relationships posed negative consequences on the mental well-being of older adults, however, few studies explore the possible moderating effects of individual differences. Past studies have observed that how important an older adult feels to others can significantly influence their mental well-being. The current study therefore focuses on the degree to which COVID-related disruptions were associated with older adults' depressive symptoms while also examining the moderating role of perceived mattering, or how important one feels they are to others. Data were collected through online surveys from a convenience sample of 137 older adults (Mage = 67.77, SD = 10.38) who completed surveys regarding disruptions in their relationships due to COVID-19 (e.g. separation from loved ones), depressive symptoms, and perceived mattering. Preliminary findings suggest that disruptions to relationships due to COVID-19 were positively associated with depressive symptoms ($r = .354$, $p < .001$), whereas perceived mattering was negatively associated with depressive symptoms at the level of a trend ($r = -.210$, $p < .001$). Our next steps are to: (1) include control variables (e.g., race, gender, work status) and (2) test the interaction between disruptions and perceived mattering. Furthermore, we will utilize a subset of qualitative data to examine differences in how COVID-19 affected relationships for older adults who reported high versus low perceived mattering. Findings from this study have the potential to aid in the understanding of how specific subgroups of older adults may be more susceptible to the negative effects of disruption to relationships than others.

Abstract Name: Student Organizations as a Means to Effectively Develop Safety Culture Within Undergraduate Chemistry

Safety education for college-level chemistry labs can be adequate for minor incidents of broken glass and small spills, but the chemical industry and graduate programs are often under the scrutiny of environmental health and safety departments that have far more stringent requirements than an average undergraduate student will encounter. Students who graduate with a bachelor's in chemistry often find themselves with a job where chemical hygiene is practiced at a level they aren't used to. Considering the professional and personal implications that poor adherence to chemical safety can have, more could be done at the undergraduate level to develop the skills and mindset associated with chemical safety. The Chemistry Student Safety Team (CSST) is a student-led, mindset-focused organization working to foster a safety culture at UWEC. The CSST is mentored by UWEC faculty and the UMN-Twin Cities Joint Safety Team (JST). The CSST uses safety demonstrations, awareness campaigns, PPE sales, and safety themed merchandise to promote safety culture. To track attitudes in the UWEC department of chemistry, the CSST uses an annual safety survey along with a system to report near miss incidents anonymously. Student safety organizations at an undergraduate level are an innovative way to promote safety-culture through peer education. With faculty support, student-led safety organizations such as the CSST can be an integral part of disseminating safety information to other students within undergraduate chemistry programs. Involving students in education and safety initiatives at an undergraduate level can lead to more effective researchers, more productive employees, lower organizational costs, and a more safe and equitable learning environment.

Abstract Name: Improving the Classification Performance on Small-Sized and Imbalanced Datasets

Predicting rare but high-impact events is critical in many medical applications, such as health risk prediction and disease diagnosis. While sensor technology has improved rapidly in the last decade, machine learning (ML) techniques for the prediction of rare events lag behind general prediction models. Most optimization techniques used to train ML models implicitly assume a balanced distribution of events in training data. This research focuses on improving the performance of classifiers on imbalanced and small-sized individual asthma patient datasets using oversampling techniques, as these issues significantly affect medical datasets in healthcare applications. Imbalanced data causes the classifier to be biased toward the class with more data samples (the majority class), reducing its accuracy for minority class data. The class imbalance problem is particularly challenging in the medical domain because the goal is to predict whether a patient is at risk for a particular disease. However, these cases are often in the minority class. Moreover, machine learning-based classifiers require a large amount of data to be adequately trained. Therefore, having a small-sized training dataset is also an obstacle because it hinders the classifier's performance. To improve the performance of prediction models on imbalanced and small-sized asthma patient data, we first investigated existing synthetic minority oversampling technique (SMOTE) variants at the data level. SMOTE variants solve the class imbalance problem by generating synthetic data samples and adding them to the minority class data until the classes are balanced. We proposed three new minority oversampling techniques: Incremental K-Means Clustering (IKC), SMOTEBoost and SMOTEBoost with Control Coefficient (SMOTEBoost and SMOTEBoostCC), and Average Neighbor Vector Oversampling (ANVO). We evaluated the effectiveness of the proposed techniques compared to the existing SMOTE variants. The evaluation results show that the proposed methods are comparable with state-of-the-art oversampling methods.

Abstract Name: Pre-Code Versus Contemporary Female Screenwriters: Working Towards More Authentic Depictions of Women on Screen

Even in the 21st century, movies have remained an integral part of American pop culture, and while methods of consumption have changed, millions of Americans still flock to theaters every year. So why is it that, even in 2022, Americans are not proportionally represented in film? In today's world, there is a lack of adequate representation of women in film. While there may be more characters who are women than there were in the past, the depictions of women are not always the most accurate. The solution to this ever-present issue in the industry is hiring more women as directors, executive producers, producers, and/or writers, as this increases the likelihood of films portraying women more authentically. Although there were few in number, pre-Code female screenwriters such as Lorna Moon and Dorothy Howell wrote films with daring and realistic depictions of women during a time that was characterized by male dominance. This change from the status quo for female characters sent a ripple through the film industry that can be seen even in films today. Contemporary screenwriters such as Phoebe Waller-Bridge and Diablo Cody carry on the legacies of both Moon and Howell in that they too write more authentic female characters and challenge how society views women today. Although the stories in contemporary films may be different than pre-Code films, the women written by these female screenwriters are very similar and act as lifelines for young girls who are used to seeing the same stereotypical woman in every film they see. Although film has evolved greatly over time, unfortunately, the industry still struggles with its representations of women. However, it's screenwriters like Waller-Bridge and Cody who are trying to change this and are working upon the foundations the pre-Code female screenwriters built in the early Hollywood era.

Abstract Name: Assessing College Food Security Status and Perceptions of Student-Led Weekly Meal Program Attendees during the COVID-19 Pandemic

The COVID-19 pandemic initially disrupted food access across the U.S., leading to increased food insecurity in many at-risk groups. College students particularly have faced a disproportionate risk of inadequate food access while 40% of edible food is wasted annually. Since 2018, the Campus Kitchen at the University of Kentucky, a student service organization that addresses food waste and food insecurity issues, has developed a model program, Farm to Fork (F2F), to serve healthy weekly lunches using recovered food and provide educational resources to college students. F2F attendance was tracked at every meal and attendees were invited every semester to complete an anonymous online survey that assessed food security (FS) status of students utilizing the program, categorized as high/marginal, low, very low FS groups through the validated USDA six-item FS Survey, and determined attendees' perceptions of F2F using the 18-item Likert program evaluation scale. Chi-square test was used to compare differences in FS status between the 2020-2021 academic year during which COVID-19 mandates were heavily enforced on campus and the 2021-2022 academic year in which COVID-19 mandates were lightened. Since inception, F2F has served over 7,000 meals to at least 1,500 students. Of the survey respondents during two academic years, 61.69% (n= 207) were classified as food insecure. FS status categories between the 2020-2021 (32.88% very low FS, 27.4% low FS, and 39.73% high/marginal FS) and 2021-2022 academic years (27.16% very low FS, 35.8% low FS, and 37.04% high/marginal FS) did not differ significantly (p=0.51). Over 75% of respondents agreed that F2F "improved access healthful foods", "increased fruit and vegetable intake", and "met dietary needs". These findings highlight the positive perceptions that survey respondents had of F2F and this student-led program's capability and resilience to serve the college community throughout the pandemic.

Abstract Name: To Probe the Conformational Fluidity of the Intrinsically Disordered Protein GTPase HRas using Molecular Dynamics Simulation

GTPase HRas is an enzyme that is linked to bladder and thyroid cancers. It belongs to the group of intrinsically disordered protein, which lacks definite protein structure. Their conformational fluidity allows them to adopt various structural forms making them efficient biomolecules. However, their three-dimensional structure is difficult to ascertain because the disorder prevents an ordered crystalline structure to form. Therefore, the role of their folding-unfolding dynamics on function, especially the effects of other biomolecules, has remained poorly understood. In the present study, the conformational changes of GTPase HRas have been investigated in the presence and absence of crowders using classical mechanics-based molecular dynamics simulations. Protein data was acquired from Alphafold - the artificial intelligence-aided protein structure database. Subsequently, the atomic coordinates of the protein were used to prepare five different simulation systems: water as a control, ethylene glycol, and three types of polyethylene glycol crowders of varying molecular weights ~ 600 Da, 8 kDa, and 20 kDa. Results will include 50 ns molecular dynamics simulation data, used for illustrating the effects of these crowders on the conformational dynamics and energetics of the GTPase HRas protein.

Abstract Name: **Title: Identification of miR-135-3p as an Epigenetic Mediator of NR3C1 Silencing in Stress**

The epigenetic role of microRNAs (miRNAs) is crucial in understanding the psychological and neurobiological abnormalities underlying numerous psychiatric illnesses. Aberrant miRNA expression and their regulation are often associated with stress related psychopathologies including major depressive disorder (MDD) and suicidal behavior. Recent observations show the impacts of specific miRNAs in inducing maladaptive changes in the hypothalamic-pituitary-adrenal (HPA) axis by targeting many stress related genes. In this study, we utilized a restraint rodent model to pinpoint the role of stress-related genes and their regulation by miRNAs in developing depression-like behavior. Of various stress-related genes (NR3C1, CRH, CRH1, CRH2, BDNF, FKBP5, and TRKB), we found that mRNA expression of the NR3C1 gene was significantly down-regulated by 45% (p=0.042) in the prefrontal cortex (PFC) of restraint rats compared with handled controls. Our in-silico prediction analysis showed interaction of miR-124, miR-504, miR-137-5p, 132-5p, miR-34a-5p, miR-425-3p, miR-20b-3p, miR-29a-3p, miR-34c-5p, miR-200a-3p, miR-18a-3p, miR-18a-5p, miR-125b-1-3p, miR-130b-5p, miR-15a-3p, and miR-135 3p with the NR3C1 gene with high confidence scores. qPCR-based expression analysis revealed significantly upregulated levels of miR-135-3p by 160% (p=.044) in the PFC of restraint rats, suggesting that miR-135-3p is involved in the post transcriptional silencing of the NR3C1 gene. The study is currently in progress using various in-vitro (miR oligo-based gain and loss of function), in-vivo (Ago2-based immunoprecipitation), RNA-induced silencing complex, and methylated DNA immunoprecipitation techniques to gain further insights into the epigenetic regulation of the NR3C1 gene by miR-135-3p to put forth their potential contributions in developing stress-related mental disorders.

Abstract Name: **Pothole Detection System using Deep Learning**

Asphalt roads have monopolized the streets of America since its founding, but one problem persists, potholes. Americans pay nearly $3 billion a year to repair damage caused by potholes, and this number looks to only increase over the years due to the increase in vehicles. The objective of this research is centered around creating a quick and efficient way to accurately detect potholes, in addition to making it simpler to find the areas where recurring potholes need to be reinforced with asphalt. The model is deployed over Google Street View and detects potholes over a set route making the previous way of dealing with potholes obsolete. The model implemented in this project was the SSDmobilenet. SSDmobilenet was used because it has a speed of 19 m/s with a mean average precision of 20.2 which is used to measure the recall of the model. This was slightly more accurate than the YOLO (You Only Look Once) model. For accurate results, 436 images were hand-picked out of a Kaggle dataset in order to ensure there were no images that would cause false positives in the training set. These images were then trained using the SSD model for 120,000 epochs.
When the completed model was able to accurately detect potholes on Google Street view over multiple given routes, the model reached an accuracy of 81% over a 5 -hour training period. Additionally, the detection of potholes is only a small piece of what this model is capable of. Additionally, we look into taking the detections made on Google Street View and plotting them on a Google Maps API. This will help alert drivers to where potholes are and help them choose the best route. Overall, Pothole Detection could lead to a major breakthrough in road health and safety.

Abstract Name: Perception of Social and Physical Environmental Risk Factors Affecting Women Experiencing Homelessness: A Mixed Method Study

Homeless people in general confront many difficulties that make their lives very challenging. However, when it comes to women experiencing homelessness, those challenges can threaten their own well-being by increasing the risk of victimization and decreasing the levels of personal safety. This research project has three aims: first, to better understand the link between victimization and social and physical environment as it relates to homeless women; second, to recognize which aspects of the social and physical environment homeless women find threatening and difficult to overcome; and third, to examine the areas of conflict within the coexistence of homeless women in a mixed-gender transitional shelter. This study is based on a mixed-method approach. The data are drawn from fivein-depth interviews and from secondary survey data collected by Ozanam Manor, a faith-based agency. The qualitative analysis uses a naturalistic perspective to study homeless women in their own living settings in a transitional shelter and provides a rich, contextualized understanding of homeless women's perception of risk. We also analyze secondary survey data collected by Ozanam Manor and use correlation analyses to understand the relationship between social environments and respondents' safety perceptions.Our research goes a step further by assisting Ozanam Manor in identifying and comprehending areas for improvements, such as security and staffing, in order to better accommodate and meet the needs of the individuals of their institution, as communicated by the women in our study.

Abstract Name: "Probation was a great way to go": Exploring Community Corrections Officers' Professional Perceptions and Orientations

Probation/parole officer orientation has been studied in professional decision-making, but few studies have explored officers' perception of their jobs. Moreover, no research has considered how these perspectives may be connected with officers' professional orientation. Findings from this mixed method study suggest that officers value probation/parole as both a helping and law enforcement profession. Additionally, significant differences exist between why officers entered the field and which job duties they find rewarding based on their professional orientation. These findings have implications for probation/parole departments, specifically regarding recruitment and training approaches, and larger criminal justice reform efforts.

Abstract Name: The Lord's Novel: A Narratological Analysis and Interpretation of the Bible as Story

Biblical and literary scholars cooperatively examine the Bible as literature through an integration of Biblical studies and literary criticism that has grown in depth and reach. Yet most scholarship divides the Biblical text into its component parts (Alter, Ryken, Andersson) while overlooking what the whole text accomplishes as a cohesive narrative (Greenstein). This project attempts to reconcile existing scholarship on the Bible as literature with the field of narratology through analysis of the whole Bible as story. By researching and applying Biblical narratology, it traces a single, unified narrative arc through the Bible and interprets meaning from that arc. It defends the argument that the Bible has meaning as a restoration narrative when the entire text becomes a single story. Additionally, it demonstrates how this message can be missed when the text is parsed into the sum of its parts. This project argues for the beauty of the Bible's meaning as story while adding new perspective to scholarly conversations of the Bible as literature.

Abstract Name: Monitoring Kelly Creek Health During and After Restoration

We implemented a short-term, two-year research project to measure the water quality of an urban creek undergoing restoration. We hypothesized that restoring the creek would positively impact the health of the stream by improving the macroinvertebrate abundance, water column characteristics, nutrients, and chlorophyll a.
The study contained three sites along Kelly Creek in South Beloit, IL. Site 1 and site 2 were within the restoration area of the creek. In these areas, efforts were made throughout the duration of the study to pick up trash, clean out muck, and install limestone outcroppings to increase public accessibility. Site 3 remained untreated. Data were collected in 2021 and 2022 from early May to late August approximately every two weeks. Macroinvertebrate abundance, temperature, dissolved oxygen, total phosphorous, and chlorophyll a were collected during each sampling period. Richness, diversity, and the Hilsenhoff Biotic Index (HBI) were calculated.
Preliminary results suggest that Chironomidae and Amphipoda abundance differ significantly by site. Chironomidae have a greater abundance in sites 1 and 2, the restoration area, while Amphipoda have a greater abundance in the non-restoration area. Chironomidae have a high HBI Index value, therefore their presence indicates significantly polluted water in the restoration area. Amphipoda have a lower HBI index value, which indicates that the non-restoration area has better water quality. The overall HBI index value varies significantly between sites, with site 2 showing the poorest water quality. Sites 1 and 2 contained sandy substrate which Chironomidae prefer, while site 3 contained rocky substrate which Amphipoda prefer. The process of restoration may also have temporarily disrupted the macroinvertebrate community, which may take time to recover. This study will help to aid further study and improvement of Kelly Creek and gain insight into the short-term impact of ecological restoration in polluted areas.

Abstract Name: More than one victim: The mediating role of envy in the impostor phenomenon-workplace deviance relationship

Those who experience the impostor phenomenon (IP; Clance; Imes, 1978) believe they have tricked others into believing they are more competent than they believe themselves to be, and they fear being exposed, despite impressive records of achievement. While most research presents those who experience IP as victims to be pitied, little research has considered the dark side of IP and the lengths those who experience it will go to avoid discovery. The purpose of this study is to fill this gap and examine the dark side of IP.HypothesisDrawing on conservation of resources theory (COR; Hobfoll, 1989), we hypothesize that IP is positively related to both episodic envy (EE; Duffy at al.,2021) and interpersonal workplace deviance (IWD; Bennett; Robinson, 2000). Next, we hypothesize that EE is positively related to IWD. Finally, building on our previous hypotheses, we expect IP to have an indirect, positive effect on IWD through EE.MethodWe collected survey data across three time periods utilizing Amazon's Mechanical Turk (MTurk; Burhmester et al., 2011), with IP and control variables (gender, age, race, and ethnicity) collected at Time 1, EE at Time 2, and IWD at Time 3. There was a minimum of 14 days between each wave of collection, and our final matched sample included 119 participants.FindingsUtilizing Preacher and Hayes' (2008) mediation procedure, our results provide support for our hypothesized positive relationships between IP and EE (B = 0.9699, .001) and between EE and IWD (B = 0.4283, .001). We found no direct effect of IP on IWD, however, we did find a significant indirect effect of IP on IWD through EE (b = .4154, SE = .1113, 95% CI [.2005, .6403]), suggesting full mediation and providing broad support for our hypothesized model.

Abstract Name: Statistical Analysis of Kinematic Measurements on Signatures for Forgery Detection

Can we tell whether a digitally-captured signature is authentic or forged? To address this question, data is obtained with a software called MovAlyzeR® to capture the "on-line" movement and pressure aspects of a signature as it is written on a digital signature pad. This technological aspect makes the MovAlyzeR® system critical as more signatures are written electronically over time and as more electronic signature pad owners decide to store its data. The MovAlyzeR® system records various information about a signature as it is written. The signatures are decomposed into strokes, and each stroke's qualities are analyzed. The variables collected include size, duration, velocity, jerk, and pressure. A multivariate statistical method called the Hotelling's T-Squared Statistical Test is used to compute test statistics for pairs of genuine and forged signature exemplars. The resulting score is a metric for predicting forgery that can be interpreted as a dissimilarity score because it will be large when the pair represents a forgery and small when the pair represents a genuine comparison. The corresponding test statistic scores for the known genuine comparisons are used to approximate the known-match score distribution via kernel density estimation and similarly for the non-known-match distribution under each forgery condition. Then, the test statistic is computed and compared to each reference distribution for each new comparison. The ratio of these two values is the score-based likelihood ratio, which is a statistically based objective method for assessing the value of evidence towards forgery. It can be used independently or to supplement other objective or subjective questioned document examination methods.

Abstract Name: Soil Moisture Sensor

Indoor self-watering systems make it easy to have an indoor garden with low maintenance. The main goal of the self-watering system was broken into three parts: the moisture sensor, data processing, and triggering the water pump. The goal of the soil moisture sensor component of this research project was to design a working sensor to test soil humidity of an indoor house plant. The project was built using six jumper cables, a soil moisture sensor, a relay board, and an Arduino Uno. The soil moisture sensor was chosen after extensive research pertaining to soil moisture sensors and self-watering systems. Multiple professors were consulted to ensure that the Arduino was programmed correctly and to ensure that the soil moisture sensor was set up successfully. When the components from the original planned design were unavailable, the design team became innovative to acquire usable components and modify the design to still meet the goals of the project. Some of the testing that was done to see if the soil moisture sensor worked included comparing results when the soil moisture sensor is wrapped in a wet napkin versus when the soil moisture sensor is laying on top of a dry napkin. The moisture value of the soil is mapped to a scale of 0-100% based on the extremes recorded from the napkin tests. The sensor was also tested on a Jade plant, Moonstone plant, and a Curry Jade plant. When the sensor was first placed in the soil, it read between 27 and 28%. 50ml of water was placed in the soil and after 5 minutes the sensor read between 50 and 63% depending on where the sensor is placed in the soil. The device worked as expected and the subsystem is ready to integrate into the overall system design.

Abstract Name: Exploring Trisha Brown's Methodical Approaches to Choreography

When it comes to Trisha Brown, most people in the modern dance community know who she is, or they know of her because of how iconic she was when exploring new movement ideas in modern dance. She seemed to lead the evolution of modern dance for decades throughout her career, and almost every new work she presented was ground-breaking. The question is then, what about Brown's approaches made her outcomes so successful at each point in her career? To name a few of her approaches, Brown used internal rhythms, postmodernism, accumulations, Locus (her famous cube), and intense examination of musical scores to create her works. Brown created her own choreographic devices and combined them with improvisation and trial and error to create her works. Oftentimes, she had to write down or draw her new concept on a piece of paper before being able to translate that idea into her dancers' bodies. Although each of her approaches was unique and different from the next, I primarily used an interview I conducted with one of Brown's dancers, Mariah Maloney to uncover Brown's recipe for success. This interview, coupled with primary and secondary information from books, performance reviews, and peer-reviewed articles, led me to find one prominent theme between all of Brown's processes. Brown always kept her dancers' abilities in mind when creating a new work, which brought a sense of comfortability that showed from her dancers. Through this research, I hope to help other choreographers utilize Brown's way of working to find success in their own processes.

Abstract Name: **The Use Of Social Media During The Pandemic**

Nowadays billion of people use social media platforms as a way to keep in touch with family and friends, fill spare time, find content, find inspiration for things to do and buy, share and discuss opinions with others, and the list goes on. This project focused and investigated on the use of social media during the years, in particular during quarantine/lockdown. Utilizing the public source data, I explored several research questions including how many hours people spent on social media, the popularity of social media apps, as well as what age group uses social media platforms (teenagers, young adults, adults). After data cleaning, the data visualization followed, and multiple dashboards were created using Tableau; the data analysis was mainly completed in R. The findings and analysis results were also presented in this research.

Abstract Name: **Education Students' Understanding of Scale and Geometric Space of the Earth, Moon, Sun System and Cause of Moon Phases**

This sequential explanatory mixed methods study examined how well pre-service teachers and education students understand the Earth/Moon/Sun scale, motion, and orbital geometry necessary to observe various lunar phases from an Earth-based perspective. Research has shown that students have great difficulty understanding the cause of lunar phases with many incorrectly explaining the phases are caused by the Earth's shadow, the Sun's shadow, or an object blocking the Sun's light (Wilhelm et al. 2018; Plummer et al. 2010). The research question investigated was: What understandings do students have about the Moon and its phases, and how do their lunar conceptions relate to their spatial ability? This question was explored with undergraduate education students from two institutions in the south-central United States. Quantitative data consisted of 72 participants completing a modified Lunar Phases Concept Inventory (LPCI; Lindel, 2002) with 25 multiple-choice questions. To better understand students' lunar-related spatial-scientific thinking, we followed the quantitative data collection with select student interviews (high, low LPCI scorers) using a semi-structured protocol concerning Earth/Moon/Sun geometry, lunar motion, and why the Moon appears different at different times. The LPCI findings showed that approximately 59.3% of students held the Earth-shadow misconception, 9.4% had an object-blocking explanation, 3.1% had the Sun-shadow explanation, while 28.2% had the scientific explanation when describing the cause of phases. We also found that 18.8% of students did not correctly understand the scale of the Earth/Moon/Sun system (e.g., distance between Earth and Moon) with many believing the Moon to be much closer to Earth than it is, which could be a possible reason students tend to hold shadow and blocking notions. Similar to the LPCI, interview results showed general misunderstandings of why lunar phases occur, with some participants not able to correctly sketch various phases, nor accurately explain the Earth/Moon/Sun geometry for particular phases.

Abstract Name: **The relationship between personality and problematic binge-watching behaviors in college students.**

Purpose: Relationships between Big Five personality traits and problematic binge-watching behaviors were investigated. Binge-watching TV may be potentially addictive, causing problematic watching behaviors (Flayelle et al., 2019). Introverted people are more likely to excessively use media (Kircaburun et al., 2018). Increased social media usage occurs with high introversion and neuroticism; as well as low openness, conscientiousness, and agreeableness (Sindermann et al., 2020). These relationships are useful to infer a similar relationship between personality traits and problematic binge-watching behaviors. Escape from negative stimuli is the strongest motivating factor to binge-watched television (Starosta et al., 2020). Based on evidence from Kircaburun et al. (2018), Sindermann et al. (2020), and Starosta et al. (2020), I hypothesize 1) those who are high on introversion and neuroticism will have more problematic binge-watching behaviors, and 2) those who are high on agreeableness, conscientiousness, and openness will have less problematic binge-watching behaviors.
Procedure: The preliminary sample consisting of 32 college students completed the following scales: Binge-Watching Addiction Questionnaire (Forte et al., 2021), Big Five Inventory (John & Srivastava, 1999).
Results: Pearson product-moment correlation procedure was used to examine the relationship between the personality traits and binge-watching scales. Negative significant relationships between conscientiousness and binge-watching dependency, (r (31) = -.425, p = .014), and between agreeableness and binge-watching dependency (r (31) = -.388, p = .026) were found. No other relationships were significant.
Conclusions and implications: Hypothesis 1 was not supported, contrary to the findings of Kircaburun et al. (2018). Hypothesis 2 was supported, where conscientiousness and agreeableness were negatively related to binge-watching, similar to the findings of Sindermann et al. (2020), but openness was not. These findings are important for children as they continue to use social media and streaming services to watch television. Future studies should examine the cause of problematic binge-watching behaviors.

Abstract Name: **Design of a Novel Decoy FGF2 with Increased Stability and Cell Proliferation Activity**

FGF2 is a multifunctional growth factor, part of the highly conserved superfamily of fibroblast growth factors. In particular, FGF2, found in embryonic and adult cell types, plays a significant role in the development and function of multiple organ systems. Furthermore, FGF2 plays roles in angiogenesis (blood vessel formation) and wound healing, which show promise in medical applications and tissue engineering. Although promising in its potential, wild-type FGF2 itself poses issues of inherent instability, which affect its overall function. By generating a recombinant protein, consensus, or "decoy" FGF2, the problem of instability in wild-type FGF2 can be solved. Consensus FGF2 can help in creating a more stable protein, thus improving function over time, as structure correlates to effectiveness in function. By eradicating this issue, a higher stability in FGF2 can be applied to biochemical and medical industries, to name a few. For example, thermal instability wouldn't be an issue with a more stable FGF2 protein when considering external factors, such as the supply chain when transporting for further biochemical research and medical applications. Thermal stability, as found in preliminary results, also indicates a longer shelf life, if used in potential medical applications. Overall, the aim of this project is to improve the stability of wild-type FGF2, a potent but unstable fibroblast growth factor, thus improving its function via experimentative methods of small-scale and large-scale expression, purification, and characterization of structure and stability. In short, the goal of the experimental design is to compare cell proliferation activity of wild-type FGF2 and consensus FGF2 with analyses of structure and function. The ability to solve the problem of instability, which was already suggested via initial findings, in FGF2 by fabricating a more stable and functional growth factor can open new doors for further research and breakthroughs in the fields of biochemistry and medicine.

Abstract Name: Determination of Nickel's Effects on Wisconsin Fast Plant

Nickel (Ni) is an important nutrient for plants that plays a role in urease activity, an enzyme essential for the metabolism of nitrogen. The uptake of N and carbon (C) during leaf development is also interfered with by a lack of Ni. Previous work demonstrated that Ni water solution between 0.1ppm and 10ppm promoted Wisconsin Fast Plant growth versus control water and had a positive impact on plant health. The current study continued this study using seeds, rather than established plants, and combined chemical and biological methods to examine plant growth. The experiment was conducted in our on-campus greenhouse. Five standard concentration solutions of Ni were produced, 0.1-ppm, 1-ppm, 5-ppm, 10-ppm, and 12-ppm and added to the plant seeds. Each concentration and a control containing 0 ppm of Ni, was watered on 24 seed samples. Seeds were watered every 3 days, and containers were filled by appropriate water twice a week. The third procedure used FLAME Atomic Absorption Spectrometry (FLAA) to demonstrate the concentration of Nickel in the soil measured at 0.02 ppm. Plant growth was measured using plant height, the rate of growth, the number of blooms and the number of leaves. The results show that the control group grew tallest, and the 5-ppm group grew slowly. However, the 5-ppm had the most bloom number, and the 0.1 ppm had the lowest number of blooms. The 12-ppm had the most leaves number, and the lowest number was for 10 ppm. In conclusion, Ni did not demonstrate consistency in growth rate, number of leaves, or number of blooms, on the Fast Plant as expected. In the future, the effect of Ni on plants from a store or using a Ni solution spray will be explored.

Abstract Name: Music and Emotions: The Effect of Computer-Generated and Commercially Available Music on Human Emotions

The use of background music while completing mentally stimulating tasks has recently gained popularity. What gives music its potential to improve learning outcomes has to do with characteristics like tempo and tone. This research investigated the changes in EEG signals under numerous experimental conditions: silence, 3 ascending tempos of commercially available music, and 3 ascending tempos of computer-generated music with two different genres: classic and modern. The order in which music was played was randomized for each participant. The first three trials used commercially available classical music across 3 tempos: slow, moderate, and fast. The other six trials used computer-generated music to test each of the following modern and classic music genres: calm, stimulus, and focus. During testing, brainwave activity and heart rate were measured by the means of electroencephalography (EEG) and electrocardiography (ECG) respectively. The Muse 2 headband from InteraXon was used to measure alpha, beta, theta, delta, and gamma waves using four different channels. The E4 Empatica wristband measured heart rate throughout the different music tests as a parameter to indicate if spikes in brain activity can have a direct effect on heart rate. The results indicated that different types of commercially available music had an overall higher power spectral density than that of computer-generated music. This suggests that brain activity was stronger when listening to commercially available music. With the computer-generated music, all the Muse 2 channels were synchronized with one another in terms of brain activity. This indicates that computer-generated music has the effect of causing identical activity in terms of power spectral density, while showing spikes at frequencies in the front and back areas of the right and left hemispheres of the brain. The testing of computer-generated music was used to examine the frequencies to see if the music piece evokes the intended emotion.

Abstract Name: **Testing the M-? correlation for determining the black hole mass in Type II Active Galactic Nuclei**

According to General Relativity, all the information about a black hole can be derived from just the mass and its angular momentum (charge as well but we assume it is electrically neutral). It is therefore important to have accurate measurements of the black hole mass. In this research project we investigated the masses of black holes within Type II (i.e., obscured) Active Galactic Nuclei (AGN) calculated using the M- σ relation, a correlation between the black hole mass and the galaxy bulge frequently used when direct dynamical methods are not available. We started from a sample of AGN selected from the hard X-ray sky survey done by the Neil Gehrels Swift Observatory, restricting it to X-ray sources with luminosity greater than 1042erg/s and within 40 Mpc. These filters brought our sources down to 20 AGN. From the literature, we collected the black hole mass values obtained with dynamical methods (Maser, Virial Theorem, Stellar/Gas Dynamics) and compared them to the values measured using the M- σ relation. Our preliminary results suggest a substantial discrepancy between the black hole mass values measured with M- σ and the ones inferred with more direct measurements, indicating that the use of the M- σ relation for Type II AGN may be problematic and must be treated with caution.

Abstract Name: **Impact of Provider Demographics, Previous Training, and Consultation on Provider Perceptions of a Parent Coaching Intervention Delivered in the Medicaid System**

Background: Little is known about factors that influence providers' perception of evidence-based practices.
Objectives: Investigate how provider demographics, training experiences, time, and consultation impact perceptions of Project ImPACT, a parent-coaching intervention for autism.
Methods: 16 providers received consultation about Project ImPACT. Two-level multilevel models examined the effects of provider demographics and training experiences on perceptions of Project ImPACT over time and with consultation. Providers completed the Perceived Characteristics of Intervention Scale weekly.
Results:
Relative advantage (RA). For those who had taken a course related to parent-coaching, average baseline (BL) RA ratings were 1.15 points lower in consultation period than BL, $t(7.66) = -3.56$, $p = .007$. There was a significant association between observing parent-coaching outside of practicum and ratings of RA, $t(8.96) = 2.44$, $p = .04$; clinicians with that training rated Project ImPACT as .67 points more effective than other therapies from BL to consultation period. There was also a significant interaction between time and condition, $t(251.98) = 2.95$, $p = .01$. Ratings increased during the BL by .03 points each week, $t(249.94) = 4.98$, $p < .001$. Ratings in consultation period did not significantly change.
Compatibility. The association between taking a course in parent-coaching and ratings of compatibility was similar to results for RA (see Table 1). Overall, ratings decreased each week by .05 points, $t(259) = -2.48$, $p = .01$. The interaction of time X condition was also significant, $t(257.84) = 3.38$, $p < .001$. Ratings in the BL period increased each week by .02 points, $t(252.41) = 2.96$, $p < .003$. Ratings in consultation period decreased by .05 points each week, $t(259) = -2.48$, $p = .01$.
Conclusions: Taking a course and observing parent coaching affected clinician ratings from BL to consultation period. Consultants should consider this when supporting clinicians to use a new intervention.

Abstract Name: **Who bit Smilodon? A tale of attempted murder at Rancho La Brea**

Direct evidence for interaction among extinct species is difficult to obtain because the animals no longer interact. Fossil specimens are often incomplete because most soft tissues have been lost, or show damage. Therefore, conclusions regarding what any animal did may be impossible to determine. A proxy for interpreting behavior can be achieved, however, if it is possible to identify physical traces left by animals interacting while they were still alive. There are many different types of traces. These include skin and organ impressions, tracks, scratch and other kinds of marks from claws or teeth left in impressionable substrates and scars in skeletal elements of fossils. These latter are often attributed to bites from other animals, whether conspecifics or not. This study identifies which species interacted with the Smilodon fatalis individual represented by the skull found at Rancho La Brea, the tar pit in Los Angeles. This individual shows a hole in the outer surface of the frontal bone on the left side that could be a bite mark. To determine whether this is correct we examined the other species found in the same location. Taxa that could have bitten our specimen include Arctodus simus, the short-faced bear, other Smilodons, Canis dirus, the dire wolf, and Panthera atrox, the American jaguar. For each of these species we examined the overall size, length, degree of anterior and posterior curvature and anteroposterior and mediolateral thickness of the canine teeth. The goal was to determine which, if any of these teeth, fit the hole in the skull.
We discovered that only a moderately worn upper right canine tooth of an individual of P. atrox fit the defect in the skull well. This tooth matched the diameter and shape of the opening perfectly. We therefore are able to conclude that an American jaguar bit Smilodon.

Abstract Name: **Education System Vs. Undocumented Students**

The American education system is made to provide students access to a bright future; however, for undocumented students that is not the case. The research below will show that the system has limited their ability to experience a system that those who are documented have access to. Due to this, undocumented students face issues related to their mental health, emotional well-being, lack of access to resources, racial injustice, and effects on household. The lack of solutions has led to an unequal education system; however, there is nothing being done to come up with solutions. Although there are holes in education, teachers and those of higher power are not taking the time to understand all that these students face. Undocumented students are left to face these struggles on their own, ultimately setting them up for failure. While some students have the help of DACA, Deferred Action for Childhood Arrivals,they are still limited when receiving an education. Limitations should not exist when it comes to an education that will be their door to an unlimited future. Their fear of getting deported leads to unattended emotional and mental issues (Lad, 2013). Their fear of an incomplete household leads to an unfocused school career (Rangel, 2022). Their lack of resources leads to unreachable goals (Terriquez, 2015). The struggles of others' stereotypes lead to an unfair pathway to success (Lopez,2018). While many think there is only one pathway of education, that pathway comes with many obstacles for undocumented students. The education system has given undocumented students opposition, which is why we decided to bring light to this issue.

Abstract Name: The Associations Between Early Adversity, Recent Life Stress, and Disordered Eating Habits

Research has shown stress can have extremely adverse effects on a both mental and physical health as seen with a wide array of illnesses such as depression, anxiety, cardiovascular disease, and autoimmune disorders. Compared to the aforementioned disorders, however, relatively little work has examined how stress might detrimentally affect eating behaviors which can in and of itself contribute and coincide with a myriad of health issues such as obesity (which often leads to its own slew of health ailments) and eating disorders (including but not limited to anorexia nervosa and bulimia). This study analyzes whether early adversity stress exposure and recent life stress exposure additively or interactively relate to disordered eating behaviors in a sample consisting of 260 male and female college-aged participants. This was done using multiple self-reported measures; such measures include the Eating Attitudes Test (EAT), the Dutch Eating Behaviors Questionnaire (DEBQ), and the Stress and Adversity Inventory for adults (STRAIN). These measures were then be analyzed to determine whether any sort of significant association could be established between eating behaviors and early adversity and recent life stress through potentially additive or interactive relationships. Contrary to original belief, early adversity and recent life stress worked interactively to constitute a correlation with certain eating behaviors. This finding will perhaps prove useful as discussions on potential treatment plans for the aforementioned ailments that are often spurred by disordered eating behaviors continue.

Abstract Name: Refining the Timeline of Indigenous Occupations at Frog Bay Tribal National Park

The Middle Archaic period in Wisconsin (5,000 years ago) was a time of warming climate, new technologies, and changing lifeways. On the shore of Lake Superior there sits an archaeological site (47BA60) at Frog Bay Tribal National Park in Red Cliff, Wisconsin. This site gives us a glimpse into the past to understand what life was like for the Indigenous people of that time. By acquiring and analyzing new radiocarbon dates from this site my research works to refine and understand the timeline of occupations there and expand our knowledge of the Middle Archaic period in Northern Wisconsin. The results of this radiocarbon analysis also provide a greater understanding of Anishinaabe cultural history and past lifeways on the land that is now the Red Cliff reservation. All information gathered for this research is done in collaboration with the Red Cliff Nation and will be provided to their Tribal Historic Preservation Office so that it may be used to educate the public and inform future archaeological investigations. By working directly with the tribe, indigenous knowledge and input plays a major role in the research. This method called Collaborative Archaeology prioritizes tribal resources and wishes to do arcaheology as culturally responsibly as possible.

Abstract Name: **Investigating the Effects of Mutations R130E and D132N in the Catalytic Activity of Malate Dehydrogenase**

Malate dehydrogenase (MDH) is an enzyme that plays an important role in several metabolic pathways such as the tricarboxylic acid cycle (TCA) cycle. The TCA cycle is the primary source of cellular energy and it plays a critical role in aerobic respiration. This research looks at the reversible redox reaction catalyzed by MDH where malate is oxidized and NAD+ is reduced to form oxaloacetate and NADH. The purpose of this research is to investigate the effects of MDH mutations D132N and R130E and observe how those mutations might affect the catalytic activity of this enzyme. We hypothesized that these mutations would lower MDH's specific activity due to the changes in the overall net charge of the amino acids which could impact interactions with the substrate at the active site. To test the hypothesis, the wild-type and mutant enzymes were purified using His-tag affinity chromatography. Enzyme activity was monitored with a spectrophotometric assay that follows the disappearance of NADH at 340 nm. The results showed that the mutation at position 130 (R130E) abolished enzyme activity. In contrast, the D132N mutation had a 33% reduction in activity compared to the wild type. These findings suggest that the arginine and aspartate residues at positions 130 and 132 in the MDH loop play an important role in substrate stabilization and catalysis. Future work will focus on studying the effects of the R130E and D132N on MDH substrate binding (Km) and specificity.

Abstract Name: **Analysis of Stellar and Exoplanetary Attributes to Determine the Feasibility of Carbon Based Life in Exoplanets**

Over the past few decades, the search for a counterpart to Earth has only increased in prominence, with reliable data from satellites such as Gaia and datasets like the NASA Exoplanet Archive providing more possibilities for habitability than ever before. Searching for habitable exoplanets is crucial because it gives us insight into the early history of our solar system and potential theories of primitive life formation on Earth. The main criterion for an exoplanet's habitability is its ability to host liquid water. This depends on many characteristics unique to each exoplanet and its host star, all of which must work together to create an environment capable of sustaining carbon-based life as we know it. Our research aimed to analyze the habitability of the exoplanets in the NASA Exoplanet Archive by determining if the exoplanets resided within their host stars' circumstellar habitable zone (CHZ). To accomplish this, we first removed entries considered controversial or redundant to ensure accuracy in our data. We then calculated each host star's bolometric luminosity to determine the inner and outer bounds of its CHZ and see if its exoplanet was within the region. We hypothesized that all of the exoplanets we found to be habitable would have eccentricities less than or equal to 0.4 and host stars with surface temperatures less than or equal to 7500 K. Based on our results, all of the exoplanets we deemed habitable had host stars with temperatures less than or equal to 7500 K; however, some had eccentricities greater than 0.4, thus disproving our hypothesis. We then compared our data with the NASA Planetary Habitability Laboratory (PHL) Dataset and found three exoplanets in common: Kepler-1649c, Kepler-174d, and Kepler-62f. Furthermore, our results yielded an extra 50 exoplanets as potential contenders for habitability in addition to NASA's findings.

Abstract Name: Do You See Your Bias? An Accent Perception Study

Accents are an important social stimulus that influence how we form groups and interact with others. The purpose of our study is to identify variables that influence accent perception. Meltem et al. (2019) found that demographic categories such as gender, skin color, and physical features can influence accent perception. English speakers listened to recordings from non-native English speakers presented with different images and rated their accent in a Qualtrics survey on a scale from 0-10 (following Cal State LA and the University of Wisconsin-Whitewater's IRB guidelines). They answered demographic and language background questions. A one-way repeated measures analysis of variance was conducted to identify differences between the ratings for each image. A statistical significant difference between conditions was found. The results indicate that visual stimuli have an effect on accent perception; foreign accent ratings were higher when a Latinx person was presented with the audio. These results show how physical traits influence accent perception, therefore accent should be understood as a bidirectional relationship between the speaker and listener.

Abstract Name: Analyzing Interdisciplinary Teaching on Utilization of Math and Health Children's Books to Support Diverse K-8 Children?s Math Learning in Urban Classrooms

This project aimed at 1) analyzing pre-service teachers' interdisciplinary teaching using math and health children's books and 2) identifying difficulties and challenges in a diverse learning environment with this interdisciplinary approach in urban K-8 classrooms in Southern California. About 78 pre-service participants from three math method classes participated in this study. Data collection includes pre- and post-questionnaires that assess their disposition and knowledge of interdisciplinary teaching, their creation of math and health children's books, and their reports of fieldwork teaching from the children's books. Data analysis includes both quantitative and qualitative methods. Quantitative methods were used to analyze the differences in pre-service teachers' disposition, knowledge of interdisciplinary teaching, children's math skills, health awareness and their disposition toward STEAM learning. Qualitative methods were used to analyze the approaches of interdisciplinary teaching used by the pre-service teachers, and to analyze the difficulties and challenges in a diverse learning environment. The preliminary analysis shows that the pre-service teachers were able to use a variety of ways in teaching math and health children's books in their fieldwork, and, as a result, their knowledge of interdisciplinary teaching and disposition were improved. There are some difficulties and challenges in children's learning: suggestions were identified for more effective interdisciplinary teaching, such as using manipulatives and teaching vocabularies before reading.

Abstract Name: **Relationships Between Insomnia, Stress, and Perceived Daytime Impairment**

The life of a college student is one filled with assignments, tests, work, and a social life squeezed in. During this time, sleep is often neglected as a necessity or even unattainable for some students. Students do not realize how much of an effect sleep can have on their perceived daytime impairment. Stress also seems to have a large correlation with recurring lack of sleep. After completing literary research, a variety of hypotheses concerning insomnia and other sleep issues, stress, and perceived daytime impairment were made. It is hypothesized that insomnia scores will be positively correlated with stress scores; that perceived daytime impairment scores will be positively correlated with stress scores; and that insomnia scores will be positively correlated with perceived daytime impairment scores. One hundred and seven undergraduate students at a small, private university in the southeast participated in a survey to study the correlation between these three variables. The following instruments were administered: Bergen Insomnia Scale, Sleep Related Impairment Measure, and the College Student Stress Scale. It was determined that all three hypotheses were supported with significant moderate, positive correlations. These findings were consistent with existing literature. Recommendations, implications, and limitations will be presented.

Abstract Name: **The regulation of cold inducible RNA binding protein and hormonally upregulated neu-associated kinase in Anolis carolinensis lizards**

The green anole lizard (Anolis carolinensis) is a seasonally breeding animal. These lizards change physically and behaviorally due to a variety of genes that are regulated differently across seasons and affect why these lizards undergo changes during the different seasons. Cold inducible RNA binding protein (CIRBP) and hormonally upregulated neu-associated kinase (HUNK) are the two genes that we selected to look into their role in regulation in these lizards. HUNK contributes to phosphorylation and the upkeep of homeostasis.CIRBP is a cold-shock and stress response protein that can be induced after exposure to particular conditions that include hypothermic conditions. Based on our findings, we predicted CIRBP would be upregulated during the nonbreeding season and HUNK would be upregulated during the breeding season. We hypothesized that both genes would not vary in female and male lizards. First, we designed primers for our genes and checked these primers were then amplifying the correct PCR amplicons, by performing PCR and gel electrophoresis. DNA was then sequenced and RNA was isolated from brain tissues. We then used this isolated RNA to create cDNA to use in a qPCR. We created a standard curve that allowed us to analyze the data for both genes. We have successfully retrieved the qPCR data for CIRBP, HUNK, and beta-actin as a control group. We will be able to analyze our results and determine whether either gene is differentially expressed. This will allow us to understand the roles CIRBP and HUNK have in changes throughout the different seasons.

Abstract Name: Political Divide

The current political climate in teh US is more than contentious. The current state of the us verses them attitude divided along the political lines is ever worsening. What information is fact and what is political rhetoric? How can the divide be bridged? What are the potential dangers of such a divide in a powerful country? This research is designed to study how the political attitudes across the US are shaped by unfriendly dialog and news media bias. The goal is to understand how the varying forces around the political disconnect predict the perspective of adults in the US. This research will focus on political knowledge, willingness to connect with people of differing views, commitment to current political views, and news seeking behaviors when identifying underlying reasons for the unwillingeness to accept others with different viewpoints and what can be done to mediate the negative behaviors creating an even wider divide between the groups. How does having friends with widely different political views impact inter-political discourse? What communication skill sets can be cultivated to foster necessary listening and dialogue techniques? Data analysis will be completed in the spring semester of 2023.

Abstract Name: We Need You to Look not Look Away: A biopic of the lived experience of primary progressive aphasia.

This video biopic highlights the lived experience of a couple in our Eau Claire, Wisconsin community living with Primary Progressive Aphasia (PPA). While understanding of PPA is growing, this degenerative neurological condition remains poorly understood. This biopic was collaboratively created to increase understanding of PPA through the lens of the lived experience. Aphasia, which occurs most commonly due to stroke, refers to a loss or disruption of language. Primary Progressive Aphasia is a degenerative neurological condition that begins as subtle changes in language. However, as the disease progresses, not only do language difficulties become more frequent, but cognition declines as well. This video biopic was used as part of the course curriculum of an online graduate Aphasia course in the Communication Sciences and Disorders department at the University of Wisconsin – Eau Claire. While students typically are exposed to aphasia and related conditions through a combination of textbook and journal article readings, as well as clinical video examples, first-person lived experience videos are much less available. The video medium provided an opportunity to blend the science of the neurologic condition with the art of the video lens, providing viewers with a unique, first-person glimpse with personal video footage to enhance understanding of PPA. Students watched the video, and completed a survey developed by the research team. The survey assessed impact of the biopic, changes in knowledge of PPA, and how the video may have emulated key areas of best practice in services to individuals with PPA. Students reported significant changes in pre- versus post-knowledge of PPA. Additionally, they were able to identify examples of best practices evident in the video biopic. We conclude that the biopic medium is useful as a primary or supplementary medium to enhance students' understanding of PPA and the perspective of those living with it.

Abstract Name: Examining the Experiences of STEM Students in Linked-Learning Communities

Women, students of color, and students of low socioeconomic status are historically underrepresented in science, technology, engineering, and mathematics (STEM) programs. While women are half of the population, they only make up 34% of STEM workers in the United States. African Americans, Latinx individuals, and Alaska Natives make up 23% of the STEM workforce, despite being 30% of the population (National Science Foundation, 2021). Disparities in representation for minority groups perpetuate stereotypes about who belongs in STEM (Brockman, 2021; McGee et al., 2017), while also limiting the voices and contributions of a broader population. Interventions, such as linked-learning communities (Goldman, 2012), diversity programs (Burt et al., 2020), and mentoring programs (Apriceno, 2020) have been introduced in STEM programs to combat underrepresentation; however, the research thus far is predominantly quantitative. While providing useful insight, quantitative data does not reflect unique individual experiences, so qualitative research would better allow for understanding of student experiences. The College of Math and Science at Bridgewater State University is conducting a randomized control trial on linked-learning communities of first- year STEM students. In these linked-learning communities, students take three classes together to build community and sense of belonging. As part of the larger study, this research will examine the role of linked-learning communities among STEM students with varying social identities and backgrounds. Students will answer open-ended questions regarding their experiences in the college, in their major, with peers and faculty, and their personal identities during semi-structured interviews. Data will be analyzed using thematic analysis to identify patterns (Braun; Clark, 2020). We anticipate that students will highlight connections with peers that were supported through the linked- learning communities. This examination of student experiences will increase our understanding of student success and belonging in STEM, particularly for traditionally underrepresented students.

Abstract Name: Oppression in Xinjiang: Rhetorical Parallels to the Causal Mechanisms

This paper focuses on the framings of ethnic conflict compared to expectations of political science explanations of the causes of such conflict. I used the example of Uyghur Muslims and Han Chinese in Xinjiang as narrated by Chinese and U.S. news media. Framings are statements used to portray the who, what, and why of an issue through the emphasis or exclusion of information to create a specific agenda. The theoretical expectation from social science is that ethnic conflict is a result of a commitment problem, which is where the two parties in the conflict cannot credibly guarantee the protection of the other. I performed a comparative content analysis to uncover the framings that both internal and external actors are using, the differences between them, and their congruence with universal expectations from political science analyses of ethnic conflict. Findings of incongruence help us interpret narratives surrounding issues of ethnic conflict and respond to them more effectively through policy as there may be a mismatch between the rhetoric surrounding these issues and what is at the root of the conflict.

Danae Anderson

Abstract Name: The role of response format in assessing the impact of increased video playback speed on comprehension

The use of asynchronous video lectures as a means of content delivery has become a common feature of college courses. This is obviously true of online courses; however, the steady growth of asynchronous learning approaches in face-to-face classes has accelerated rapidly in response to the COVID-19 pandemic (Lee, 2020). This requires students to play a more active role in self-regulating their learning; however, this also allows students greater flexibility in choosing how they engage with lecture content. Consequently, students often watch online content at accelerated speeds. To date, research findings have been mixed as to whether this negatively impacts comprehension (Lang et al., 2020; Murphy et al., 2021). Performance discrepancies among studies may be partly explained by differences in the response formats used to assess comprehension (Collins et al., 2020). The current study aims to describe the role of response format (i.e., open-ended vs. multiple choice questions) in evaluating the impacts of increased media playback speed on comprehension. Methods: Thirty-five college-aged students watched three 15-minute researcher-created video lectures relating to cognitive psychology, each presented at a different playback speed (i.e., 1x, 1.5x, 2x). After watching each lecture, participants answered ten multiple-choice and ten open-ended questions to assess comprehension. Each question set had two versions with identical question stems but different response formats. Videos and question sets were counterbalanced across participants to reduce ordering effects. Analyses have not yet been completed. We expect higher scores on multiple-choice questions and slower playback speeds. We also expect the open-ended questions at 2x speed to be disproportionately harder than other conditions. The application of findings to pedagogy and student study strategies will be discussed.

Abstract Name: Isolation and structural analysis of new and possibly medicinal alkaloids from Hyoscyamus niger

The use of plants as medicine is an ancient practice that is still widespread today. Over half of modern medicines are derived from or inspired by natural products. There has not been extensive inquiry, however, into the constituents of many medicinal plants, so there are likely many more medicines to be found. The goals of the research to be completed in December 2022-May 2023 are to isolate and confirm the structures proposed for new, unreported alkaloids from the medicinal nightshade Hyoscyamus niger so that we may test their bioactivity. These new compounds, a series of tropane alkaloids named hyorhamnosines A-C, were discovered in June 2022 during liquid chromatography-tandem mass spectrometry (LC-MS/MS)-based profiling of young H. niger seedlings. The structures proposed from the mass spectra are not reported in the literature and these compounds could have medicinal activity. The most abundant hyorhamnosine alkaloids will be extracted from the plant and purified via semi-preparative high-performance liquid chromatography (HPLC) fractionation using an automated fraction collector. The structure of the pure alkaloids will be confirmed via nuclear magnetic resonance (NMR) spectroscopy, and the pure alkaloids will be sent to our collaborators for bioactivity assays. The isolation of novel plant molecules followed by their bioassay is a common route for discovery and development of drug candidates of plant origin.

Anderson, Jessica

Institution: *MN - Gustavus Adolphus College*

Author/Contributors:
Jessica Anderson, Lauren McQuade

Abstract Name: **Acute Fluid Intake and its Effects on College Students' Body Mass Index**

Background. Body Mass Index (BMI) is a value derived from height (m) and mass (kg) measurements. BMI is broadly used to categorize individuals based on their tissue mass and height for purposes of medical screening, health information, and policy-making. A multitude of variables (e.g., race, gender, muscle mass, exercise, nutrient intake) can affect an individual's mass which alters their BMI. Individuals preparing for body fat screenings, including BMI measurements, are typically advised to abstain from drinking fluids four hours prior to testing to avoid inaccurate measurements. Few studies look at the effects of acute intakes of different types of beverages on BMI during a testing period. Statement of Purpose. The purpose of this study is to 1) examine the effects of acute fluid intake on college students' body mass index, and 2) investigate the relationship between beverage type and body mass index. Methods. Participants will be instructed to fluid-fast for twelve hours prior to testing. Participants will be randomly assigned into three groups: Water Intake (WI), Gatorade Intake (GI), or Control (C). Height will be measured prior to the ingestion of fluids. Participants will then consume their assigned beverage every thirty minutes for a total of three times. The amount of liquid ingested will be determined by their assigned sex at birth (Female: 75 mL/round; Male: 100 mL/round). The BMI formula, kg/m^2 = BMI, will be used. Data Analysis. Statistical analyses will be performed with SPSS Statistics 27.0.1.0. Descriptive statistics will capture critical patient characteristics. The BMI values will be compared using an ANOVA. Discussion. The researchers anticipate the GI will have significantly larger changes in BMI throughout the study compared to the WI and C groups.

Abstract Name: **Estimating Settlement of Strip Footings on Soft Clay Stabilized with a Granular Trench**

Research on foundation systems has brought increasing opportunity in the building construction sector for greater efficiency and accuracy in design. Available research development shows exploratory opportunity with a focus on quantifying the improvement offered by ground reinforcement through granular trench support in clay soils. Settlement analyses will be performed for a continuous strip footing placed on soft clay soil stabilized with a granular trench. The analysis software PLAXIS and LimitState:Geo will be used to develop models for evaluation and provide ultimate bearing capacity the along with settlement for considered configurations. Results from the theoretically developed model will be compared with published research for physical modeling and numerical method results in literature. The results will help the engineer to estimate the settlement when considering the inclusion of a granular trench beneath the strip footing. Design parameters such as trench depth, trench width, footing width, and friction angle of the granular material in the trench will be varied in this study to investigate their influence on the foundation settlement. Phase 1 of this research, which focused on quantifying the ultimate bearing capacity, was completed and concluded that these design parameters influence the design significantly. The current research (Phase 2) continues the investigation efforts of the various design loading parameters based on a set settlement. The models being used in the settlement evaluated used ratios of trench width to foundation width and then increasing the trench depth to width until the loading needed shows a plateau. With the addition of settlement, the engineer will be able to create a comprehensive foundation design for the problems in hand by addressing the main design constraints: strength and settlement. As an available resource, the results will provide progression in ability to accurately design reinforced foundation supports in building projects.

Rory Anderson

Abstract Name: ?Hoped and Wished My Life Would Feel Enchanted?: Queer Worldbuilding Within The Little Mermaid

This project examines the significance of queer theory and cultural production by analyzing the impact of The Little Mermaid fairytale, as well as its movie and musical adaptations, on the queer community. The literary and lyrical influence, themes of transformation, and queer folks' cultural interpretations/nostalgia constitute The Little Mermaid as a form of queer coming of age and worldmaking. The author of the original fairytale (1836), Hans Christian Andersen, wrote of unrequited love to express his own forbidden queer desire at the time. Likewise, Howard Ashman, the film's lyricist, expressed his experiences as a gay man living during the HIV/AIDS epidemic through his creative choices in the movie (1989). Besides the original context of the story and adaptations being produced as allegories for queer love, modern queer theories demonstrate the positive impact the tale has had on generations of queer folk, who have found self-acceptance through the story. Queer worldbuilding shows how parallels between Ariel's fictional world and common queer experiences are long-lasting and significant to creating a safe space for the community at large. In addition, the heroine's perseverance in the face of unaccepting family and prejudice offers a vision of queer futurity, whereas pop culture adoration of Ursula demonstrates the trans monstrosity theory. My research focuses on how transgender folks in particular connect to the story, and mermaids in general. The symbolism of the mythical creature in transfeminine communities has been discussed at length in academic spheres, but little research has been done on how the themes resonate with transmasculine and gender nonconforming individuals. Our community has an innate ability to find themselves in arts, music, and literature because they can convey emotions that are too complex or powerful to articulate independently, and queering The Little Mermaid is a brilliant example of that.

Anderson, Tyler

Institution: ***PA - Slippery Rock University of Pennsylvania***

Discipline: Theatre and Dance

Author/Contributors:
Tyler Anderson

Abstract Name: An Investigation of Race, Gender, and Queer Theories in Numerous Variations of Tchaikovsky's Swan Lake

As Western concert dance has evolved to include progressive ideas, bodies of color, Queer bodies, and not-fully-abled bodies, there are still historic structural barriers in place that restrict these bodies from being shown on a proscenium stage. Be it due to a person's race/ethnicity, gender expression, sexual orientation, or disability status, certain individuals have continued to face discrimination in a discipline that promotes self-expression as White, heteronormative, abled bodies have often hoarded the spotlight and program notes. There are, however, various organizations, such as Les Ballets Trockadero de Monte Carlo and Ballez that actively combat this discrimination by highlighting underrepresented bodies on stage. Analyzing dance through the lens of Gender Theory shines to light the ways in which political ideologies and beliefs held off stage affect what is presented on stage and those presenting it. In my essay, I will introduce the concepts of intersectional discrimination and oppression and apply them to historical and contemporary choreographic works such as Pyotr Ilyich Tchaikovsky's Swan Lake to support my claim that historically dance has been a segregated and patriarchal field, yet that has not stopped individuals with marginalized identities from creating, producing, and distributing works to various audiences. Inspirations from the time periods in which the works were created, such as during the Civil Rights Movement and HIV/AIDS epidemic, will also be dissected to attest to the motivations behind the works and choreographers. I will also examine the various stigma management tools utilized by these companies, such as using humor or conventionally attractive bodies to make their works palatable, and further examine who, ultimately, these decisions favor. This synthesis of discriminations faced by performers and choreographers alike will expose the various ways discriminatory behaviors creep into dance settings, the effect they have on those involved, and the audiences' responses to them.

Abstract Name: **Determining Interactions between Neurotransmitters and DNA Sequences Associated with Neurodegenerative Diseases**

The interaction of various neurotransmitters with G-rich DNA sequences was analyzed to understand its role in the associated neurodegenerative disease. The neurotransmitter may promote or inhibit the formation of quadruplex DNA in G-rich sequences, which may affect disease pathology. Additionally, the binding of the neurotransmitter may be concentration dependent or dependent on the presence of a monovalent cation. The interaction of four DNA sequences, NOP56 5'-(GCG CTG)-3', CSTB promoter 1 5'-(CGG GGC GGG GCG)-3', PRNP 5'-(CCT CAT GGT GGT GGC TGG GGG CAG)-3' and c-myc 5'-(TGA GGG TGG GTA GGG TGG GTA)-3'were separately studied with the neurotransmitters tryptophol, melatonin, serotonin, and dopamine. Fluorescence spectroscopy, DNA melting, molecular docking and surface enhanced Raman spectroscopy (SERS) were used to study the interactions. Dopamine promoted the formation of quadruplex in CSTB and c-myc but inhibited it in NOP56. The DNA sequences NOP56 and CSTB only formed quadruplex with melatonin in the presence of potassium ions. Melatonin promoted quadruplex formation with c-myc. Serotonin promoted the formation of quadruplex DNA in NOP56, CSTB, and c-myc. Tryptophol inhibited the formation of quadruplex DNA in NOP56 and CSTB samples, but c-myc formed quadruplex with or without tryptophol and potassium ions. PRNP did not form quadruplex even after the addition of each neurotransmitter. The SERS data showed a vibrational signature, that was dependent on DNA concentration. Further analysis will be completed to determine how these disscovered interactions can affect the progression and characteristics of the respective diseases.

Andrews, Annaya

Dr. George Ude

Abstract Name: **Longitudinal Study of Seasonal Effects on Soil Microbial Communities at Bowie State University Campus Using Metagenomics Approach**

Metagenomics is the application of metabarcoding technique to the study of communities of microbial organisms directly in their natural environments, which bypasses the need for isolation and lab cultivation of individual species. Soil microbiome is one of the world's largest collection of biodiversity and the microorganisms play critical roles in the regulation of soil fertility, carbon cycle, nitrogen fixation, etc., yet a vast majority of soil microorganisms is still unknown. Using the metagenomic approach, soil microbial communities from three locations (Henry Circle Fountain, Loop Road Lake, and Loop Road Stream) on Bowie State University's (BSU) campus were analyzed across all seasons (Fall 2019, Spring 2020, Summer 2020, Winter 2021, and Fall 2021). The aim of this research was to determine the impact of seasonal change on the diversity of BSU's soil bacteria ecosystem and to identify its microbial diversity by season and location. DNA extraction was performed, followed by polymerase chain reaction (PCR) using 16S index primers, and gel electrophoresis to determine successful amplification of PCR samples. Samples were sequenced and analyzed using DNA Subway's Purple line. This line is designated for metabarcoding anaysis and was used to identify microbial taxa and genetic variations within BSU's microbial community. Season specific microbial groups as well as common soil microbial groups were identified. Results determined Proteobacteria as the most abundant phyla across all seasons and locations. Other abundant phyla identified were Bacteroidetes, Acidobacteria, Verrucomicrobia, Cyanobacteria and Chloroflexi. Analysis also identified more diverse taxa during Fall and Spring seasons than in Winter and Summer seasons.

Abstract Name: **Using Structured Video Chat To Improve Relationships Between Young Children And Remote Grandparents**

We hope to add to the existing literature about understanding the cognitive and social developmental challenges of video chat in order to support its use with children. Previous studies showed that video chats can be challenging for everyone, especially for children (Myers & McKenney, 2019). Importantly, more families used video chat during COVID-19, but only 28% of grandparents video chatted with their grandchildren (Duflos & Ferrand, 2020). Increasing this percentage could significantly improve grandparent-grandchild relationships because video chat frequency is a strong predictor of grandparents' closeness to their grandchild (McClure & Barr, 2017). Our research directly compares two approaches to facilitating video chats between grandparents and young grandchildren (18-72 months of age): structured reading, structured play, and an unstructured control group. Both structured approaches have three sets of instructions that involve varying the location in which the activities take place: in the grandparent's environment (Grandparent-led Reading and Show and Tell), in both the grandparent and child's environment (Reading with Matching books and Imitation with Common Objects), or on the screen (On-screen ebooks and Drawing). Families receive instructions about which activity to try, and use video chat on their own without the researchers being present. Parent-child-grandparent triads (n=180; the largest multi-session observational study of young children and video chat to date) will record 10 video chats each. We expect that structured reading and structured play will increase children's engagement and joint attention, defined as shared gaze on an object with the grandparent (primary outcome measures), as well as grandparents' enjoyment of video chat and closeness with their grandchild (secondary outcome measures). Data collection is currently ongoing, and preliminary results from a subset of the sample will be available by the time of the conference. We expect that structured video chat will facilitate more positive social interactions between grandparent and grandchild.

Abstract Name: **Keep Sweet: a rhetorical criticism of the ideographs within the FLDS religious sect that built the hegemonic society lead by Warren Jeffs**

This article is a rhetorical criticism of the "keep sweet" ideology that contributes to the hegemonic society of the FLDS religious sect led by Warren Jeffs. The Fundamentalists of the Church of Jesus Christ of Latter-day Saints are a cult that practices polygamy and communalism. According to McGee, Humans are not conditioned directly to beliefs but to a vocabulary of concepts, called ideographs, that function as guides, excuses for behavior, and act as building blocks for an ideology. Three ideographs will be analyzed: perfection, obedience, and loyalty. I analyze these ideographs' diachronic and synchronic structures and their relationships by comparing revelations given by Warren Jeffs from prison in 2011 and in 2022. This analysis demonstrates how the FLDS constructed these ideographs through rhetorical documents with set standards that construct the "keep sweet" ideology of the FLDS church. Keep sweet, no matter what; the term reminds members to do as ordered, not question, not cause conflict, and to strive for perfection. In this rhetorical analysis, I argue that these ideographs developed to exert control over the behavior and beliefs of the FLDS members, persuading them to obey the patriarchy without question. The ideological criticism reveals why the "keep sweet" ideology has such a transcendent effect on generations of people.

Abstract Name: **The Path of Matrimony: A Comparative Analysis of Indian Arranged Marriages and American Love Marriages**

From a Western perspective, Indian arranged marriages tend to look like an oppressive practice as individuals see the arrangement process as a complete loss of choice. Due to the individualistic nature of American culture, the courtship process of arranged marriages is considered taboo in the Western world since arranged marriages are not founded on intimacy and connection, which tends to be the groundwork for American marriages, creating a negative attitude around the practice. However, the marriages from each culture have shown themselves to be very similar in nature through their foundational components, despite their vast differences in the path to their relationship. My research bridges the gap between Indian Arranged marriages and American Love marriages by identifying how the diverse cultural mindsets affect the concept of marriage in each culture but can still lead to the same feelings and attitudes in both marriages. Using Sternberg's Triangular Theory of Love, I breakdown down the overall concept of marriage into three different components, love, intimacy, and compassion to discuss how each culture chooses to prioritize each component in their individual understanding of marriage. The research discusses how the individualistic nature of American society and the collectivist nature of Indian societies create the different ratios of each component in each type of marriage, but the project ultimately highlights how each marriage shows that there is significant overlap in the feelings and attitudes that each kind of couples has towards their relationship. Through an intense review of journals discussing the psychological aspects behind each relationship, interviews of couples from each type of marriage, statistics behind relational attitudes, and a deep analysis of different religious and social characteristics of each culture, I my research explains how each relationship can lead to the same outcomes despite their different pathways.

Abstract Name: **A Non-Negative Matrix Factorization Approach to Computing ?Fingerprints? in Spectra of Nuclear Materials and Novel Statistical Proof**

In nuclear reactors, tracking and predicting the amount and type of plutonium present is essential to prevent build-ups that can lead to nuclear meltdowns. When different wavelengths (from 0-1650) are run through 110 separate nitric acid solutions for ten repetitions, the resulting data matrix is 1650 x 1100. To predict the plutonium present and the nitric acid used, the dimensions of the matrix must first be reduced. In this paper, we proposed a novel application to reduce the dimensions using a Non-Negative Matrix Factorization. The method currently used to reduce the dimensions is Principal Component Analysis. However, multiple reduction techniques should be implored to check the prediction when dealing with a potentially catastrophic element. In this research, the first attempt to reduce the dimensions of plutonium data using a non-negative matrix factorization approach was utilized. The results proved to be more explainable and often more accurate than principal component analysis showing that if implored instead of PCA or in addition to PCA, this novel NMF approach can help prevent nuclear meltdowns. Additionally, this article is aided with a novel supplemental proof conveying that minimizing reconstruction error is equivalent to maximizing variance in principal component analysis.

Abstract Name: Avoidance Expression of Wistar-Kyoto and Sprague-Dawley Rats Following Overnight Fast

Interoceptive feedback to the brain about the physiological internal state of the body plays an important role in guiding behavior. A single overnight fast can reduce anxiety-like behavior in rats, as assessed in the elevated plus-maze, open field tests, and acoustic startle and light-enhanced startle responses in rats. This reduction in anxiety appears to be an adaptive response to negative energy balance as it promotes exploratory and food seeking behaviors thus increasing the likelihood of body energy repletion. However, very little is understood about the biological and behavioral mechanisms through which physiological state influences behavior in the Wistar-Kyoto (WKY) rat, a model for stress vulnerability. The WKY rat exhibits behavioral inhibition (BI), a temperament characteristic associated with increased vulnerability to stress when compared to Sprague-Dawley (SD) rats, which serve as non-behaviorally inhibited (NBI) controls. Previous research has demonstrated that WKY rats exhibit superior avoidance performance in a signaled lever press avoidance task in which a tone conditioned stimulus (CS) signals a foot shock unconditioned stimulus (US) relative to NBI controls. The current study tested the hypothesis that an overnight fast affects lever press avoidance responding. We tested this by examining the effect of an overnight fast in female WKY (n = 8) and SD (n = 8) rats on signaled lever press avoidance. While the overnight fast did not impact avoidance behavior in WKY rats, fasting significantly increased avoidance performance in SD rats. However, total lever presses during the avoidance period was significantly increased in both WKY and SD rats following overnight fast. Our results support the view that physiological state plays an important role in influencing behavior and is the first demonstration that a single overnight fast can enhance avoidance responses in non-behaviorally inhibited SD rats to the level of avoidance demonstrated by behaviorally inhibited WKY rats.

Marshall Apps

Abstract Name: Improving Patient Outcomes for Cancerous Tumor Removal

Advancements in tumor ablation through use of biocompatible foam will allow for an optimized procedure, leading to decreased postoperative pain. Ablation involves using medical imaging, such as ultrasound and CT-tomography, to remove cancerous tumors in the liver, kidney, and lung. Targeted microwave energy is used to kill and remove cancerous cells. There is risk of thermal damage to neighboring healthy tissues, which can lead to potential complications to nearby organs and blood vessels, as well as unnecessary postoperative distress. There are current techniques to displace tissues and provide a buffer between the target tissue and its surroundings. Saline or CO2 can be used to separate the tissues, but are not always effective due to gravity. Saline tends to pool at the bottom of the cavity and CO2 rises, making both inadequate displacement agents. Creation of a biocompatible foam was completed, through a collaboration with Mayo Clinic Health Systems-Eau Claire and UW-Eau Claire, to replace current methods. The stiffness and stability of the foam displaces tissues for the duration of the procedure, and eventually dissipates. The foam provides thermal insulation during the procedure and prevents thermal damage from the ablative process. Such properties of the foam were quantified using agar hydrogel tissue mimics with a series of ablation trials. The hydrogels were embedded with thermochromic dyes that change color at a given temperature, and each temperature change represented the extent of tissue damage. Photos captured during the ablation allowed analysis of the color change in individual pixels to map to temperature to determine the insulative foam properties during the duration of the procedure. Through manipulation of biocompatible materials, an enhanced foam properly separates and insulates tissues. This will prevent extensive discomfort during and after the ablation procedure to remove the cancerous tissue and protect the healthy tissue, thus improving patient outcomes.

Abstract Name: Hyperbaric Oxygen Therapy: Non-Healing Chronic Wounds

Hyperbaric Oxygen Therapy is the center of relief for non-healing diabetic wounds, compromised skin grafts, osteoradionecrosis, soft tissue radio necrosis, gas gangrene, and chronic osteomyelitis. Generally processing diseases and pressurizing the chamber up to 2 or 3 atmospheres on top of the patient (500 mm Hg). Studies show that patients will show progression after 40-60 treatments. While solely focusing on the lower limbs and dealing with an ulcer diabetic foot, research shows that it'llsignificantly increase the stem cells, mobilization, blood flow, and vasculature to the designated area. All the while producing peripheral axonal regeneration it will also focus on improving neuropathy. While we acknowledge that this non-healing wound comes with its risks such as losing all sense of pain and ultimately goes in correlation with affecting systematic effects. Importantly, these data will be collected over a period of time allowing effects of HBOT to be examinedon the changing community of bacteria present in DFI. Hypothesis: HBOT effects non-healing wounds by accelerating the healing process and interacting with bacterial species in wound, causing a change in the virulence potential furthermore interacting/altering multispecies. The hypothesis was tested by utilizing microbiome analysis on sequential samples that isolate adult patients who experience uncomplicated HBOT without antibiotics. Results: Data indicated the MIC of most antibiotics were lower versus normoxic growth. Bacteria undergoing alternate gene regulation and respond to hyperoxia and pressure generated in HBOT. Biofilm studies showed that bacteria S. aureus reduced greatly under HBOT. Conclusions:Research can better help to identify the many existing mutualistic symbioses it'll then help the healing process of HBOT and minimize the diversity of microbial populations. Such mutualistic symbioses are identified, then targeted antimicrobial therapy could be used togenerate a shift in the microbial populations allowing for faster healingof thesechronic wounds

Abstract Name: 3D Printed Positive Electrodes for Lithium-Ion Batteries

Constantly evolving technology demands equally advanced subcomponents. Commercial lithium-ion batteries, fundamental in all electronics, are composed of opposed layers arranged in a single pile, promoting a two-dimensional diffusion of lithium ions to generate energy. Multi-material additive manufacturing (AM), or 3D printing, can potentially revolutionize the production of these lithium-ion batteries. It is possible to improve their electrochemical performance through an improved mechanical design, made possible by computer-aided design programs and the newest advances in AM. Reconfiguring batteries' structures to promote three-dimensional ion diffusion will maximize energy efficiency and reduce futile weight and volume. The first step towards reconfiguring batteries is to produce each individual component. This research project focuses on the development and 3D printing of a novel photosensitive material loaded with lithium cobalt oxide (LiCoO2) electroactive active material and a conductive additive that will act as the positive electrode. The Vat Photopolymerization (VPP) printing technique was employed to print this new resin due to its wide range of adjustable parameters and resolution. Printing challenges related to the resin's properties were overcome by optimizing the printing parameters including exposure times, layer height, temperature, and UV light intensity. The prints were subjected to thermal post-processing to obtain better electrochemical performances while maintaining adequate mechanical integrity. The results obtained through this research pave the way towards newly designed 3D printed batteries promising better performance. In the future, efforts will be focused on the design and printing of complex battery components with the ultimate goal of developing batteries as non-obtrusive components of electronics by conforming their shapes to the specific design of each application.

Abstract Name: **"A bird with a broken wing": Disability and Normality in Kate Chopin's The Awakening**

Kate Chopin's "The Awakening" depicts Edna Pontellier, a married woman attempting to cast off the disciplinary shackles of the nineteenth century through a personal rebirth. As theorized by the French philosopher Michel Foucault, discipline is more than controlling behavior; it is about optimization of the body. The three pillars of discipline – hierarchical observation, normalizing judgment, and examination – contribute to a view of the body as "a site of normalization." Renowned disability studies specialist Lennard J. Davis theorizes that in any novel can be found "a kind of surveying of the terrain of the body, an attention to difference." In "The Awakening," Chopin often describes Edna's bodily experiences, from exhaustion to passion to boredom. The language surrounding Edna's awakening is marked by disability metaphors that frame her as a disabled body and polarize her from the moral norm. Often, scholarly conversations about "The Awakening" are centered on its feminist or naturalist themes, but the lens of disability studies can provide a fresh perspective on Edna's transformation, revealing how constant monitoring characterizes her struggle as one against normalization, not just expectation. Applying Foucault's three pillars of discipline and Davis' reflections on normality and disability, I plan to show that Edna's position outside the norm is exaggerated by the disability-coded language used to describe her body and behavior, and that it is not so much the societal expectations themselves against which Edna rebels, but rather the suffocating standards of discipline and normality that surround them. Anticipated audience takeaways will include an understanding of the relationship between disability and normality and an increased awareness of the subtle presence of disability metaphors in early feminist literature.

Abstract Name: **Understanding the Role of Glut3 in Huntington's Disease using Mouse Models**

Our brains make up 2% of our total body weight. Despite its size it uses up 20% of the total energy in our body. This energy is in the form of glucose. Normally, glucose is delivered into the neurons in the brain by a protein called GLUT3. In individuals suffering from HD, there is less of this protein being expressed. As a movement disorder Huntington's disease symptoms include problems with coordination and loss of muscle strength. Past studies have shown that loss of Glut3 in fruit flies was associated with worse HD symptoms and earlier onset. The same study showed that increasing Glut3 delayed the onset and ameliorated some of the symptoms. Together these focus points help form our hypothesis in which we say that deletion of glut3 will exacerbate and accelerate HD symptoms while overexpression of Glut3 will delay and improve the HD phenotype. This was tested through both breeding, which provides us with these mice models, and behavioral analysis that allow us to examine the severity of phenotypes. Our behavioral analyses include rotarod and open field in which we expect to see that the mice who are missing glut3 fall earlier and have trouble keeping up compared to the WT mice (normal mice). When we create these mice who overexpress glut3, we expect them to perform better than the knockout mice and at the same level as the WT mice. From the open field we expect that glut3 levels will affect other behavioral traits. When mice have glut3 knocked out they would explore less meaning they mainly stay in one spot, and when they do move they move at a slower pace. Overall glut3 levels determine the severity of symptoms in HD which in this case we focus on motor coordination.

Abstract Name: Perceptions of Social Media's Educational Value in Relation to Evidence Based Practice

This project evaluates the educational value of social media platforms including TikTok, Instagram, and Twitter as course-based learning supports in an online graduate-level aphasia course. Components of evidence-based practice (EBP) in each of the three social media platforms are analyzed against student posts. These components include client perspectives, clinical expertise, and internal/external evidence (ASHA, n.d.). Additionally, student perceptions regarding the utilization of social media in course-based assignments are analyzed. Individually, TikTok (Escamilla-Fajardo et al., 2021), Instagram (Carpenter et al., 2020), and Twitter (Hull Dodd, 2015) indicate a positive response among students and faculty in higher education. Social media in a classroom setting can help co-create knowledge, facilitate different learning styles, promote experiential learning, and enhance collaborative skills (Stathopoulou, 2019). Though each of the platforms are continuously rising in popularity, there is a substantial absence of conducted research studies that evaluate them holistically. A course-based assignment requiring use of each of the three social media platforms was assigned to 24 graduate students in an online aphasia-related course. Six prompts were presented every two weeks, and students used their assigned social media platforms to explore and develop answers to the prompts. Platforms were rotated across all students, so each student used each platform twice. The social media relics submitted by students were categorized based on the three components of the EBP triangle. Frequency counts for the presence of EBP domains within submissions for each platform will be presented. Additionally, student perceptions of each platform, their learning benefits, and their comparative value to the other course assignments will be discussed. Results will be discussed and applied to potential course-based pedagogical applications using social media platforms.

Abstract Name: Determining the functional role of the GOX1969 protein in Gluconobacter oxydans

Acetic acid bacteria are used in many industrial processes (vinegar, vitamin C, antidiabetic drug miglitol production, etc.). These industrially important reactions are mainly done by an arsenal of membrane-bound dehydrogenases that shuttle electrons directly into the respiratory chain. Among these dehydrogenases, GOX1969 in Gluconobacter oxydans was predicted to be a PQQ-dependent dehydrogenase of unknown function. However, dehydrogenase activity has not been detected after multiple analyses by a number of labs. Reanalysis of the protein sequence reveals similarities to the BamB protein that functions as a subunit of the-barrel assembly machine (BAM) complex that is responsible for the assembly of-barrels in the outer membrane of gram-negative bacteria. To test if the actual physiological function of GOX1969 is as the BamB subunit of the BAM complex, we introduced the gox 1969 gene into an Escherichia coli K12 mutant that lacks BamB. Growth deficiencies in the mutant lacking BamB were restored when gox 1969 was expressed on the plasmid pBamB. This provides the first evidence that GOX1969 is functionally acting as a BamB in G. oxydans. Functional information of uncharacterized genes will provide new insights that will allow a more accurate modeling of metabolism and more rational strain design.

Abstract Name: Education Incentives for Vocational Schools in the Northern Midwest

As students graduate from high school, they are expected to choose their future educational path. The options for students consist primarily of attending a four-year university or a two-year vocational school. In the US, four-year schools continue to enroll significantly more students than vocational schools, which has implications for the labor market. This research examines the reasons that students attend higher education, and if the incentives that they face disproportionately favor four-year universities. To answer my research question, I conducted interviews and administered a survey of students at a four-year university and students at a technical college. I looked at motivators such as the cost of attendance, “translatability” or the ability to take what you learn in school and apply it to the workplace, and “personal achievement” or the perception of a student’s ability to complete the program. Comparing survey responses to in-depth interviews, I find that the decision to attend university or technical school is the result of several factors. Most important, for both groups, is program options. Since many programs are offered exclusively at the university level or at trade school, if a student knows what program they want to pursue, this has a great deal of influence on their choice. Surprisingly, personal connection and community is a primary motivating factor for university students. Regarding incentives, such as financial aid, nearly half of four-year students are given some incentive to attend school. However, the overwhelming majority of technical college students (>80%) did not receive any incentive to pursue their program of choice. These results are important because they show that incentives disproportionately benefit four-year universities. To better prepare students to enter the labor market that demands certain types of skills, the same kinds of incentives should be provided for students to attend two-year schools.

Abstract Name: Fabrication of Micromodels for Analysis of Drying and Multiphase Flow in Porous Media

Drying and multiphase flow in porous media is central to a broad range of natural and engineering applications, including oil recovery, CO2 storage, and critical zone science. In many scenarios, these porous solid matrices display multi-scale variability in pore structure and physical properties such as porosity and permeability. For instance, in critical zone, soil is often viewed as a hierarchical organization: primary particles of a few micrometers in size form microaggregates of hundreds of micrometers in size, which in turn form macroaggregates, effectively leading to dual porosity in the porous media. The resultant multi-scale flow dynamics and inter-/intra-aggregate interaction in this system are recognized to control numerous processes, such as water and gaseous transport. However, the underlying physics including fluid mechanics and thermodynamics, is not well understood. In this study, we fabricated surrogate porous media called micromodels employing microfabrication techniques. The fabrication process includes HMDS oven exposure, photolithography, plasma etching in an Oxford ICP machine, and anodic bonding. The new micromodels are unique in that they are in a glass-silicon-glass bond. Previous micromodels use one glass wafer per silicon wafer and are analyzed from the glass side of the micromodel. These new double glass micromodels allow for an innovative approach for flow measurements as two microscopes are used. The new micromodels provide solutions to more efficient analysis of multiphase flow. Analysis includes velocimetry, drying process of water in porous media, and water-air interface behavior through porous media, which will provide valuable insight into the underlying physics during drying of porous media.

Abstract Name: Effects of External Shocks on the labor dynamics of Refugees and Locales: Similar or Varied?

Refugee displacement is one of the significant drivers of global migration in the 21st century. It is also responsible for various economic and political shifts in countries across the world. One such economic shift identified is the imbalance in labor supply and wage caused by migration in the countries and regions that host the refugees. The recent mass migration of the Rohingya refugees, caused due to forcible displacement by the Myanmar government, to the southernmost part of Bangladesh has impacted the local labor market dynamics. However, to date, the impact is relatively unknown. The COVID-19 Pandemic further exacerbated the issue and created greater imbalances in the local labor dynamics. Previous studies conducted on mass migration including the Mariel Boatlift study, conducted following the arrival of Cuban migrants to Miami that increased the Miami labor force by 7%, showed virtually no effect of the migration on the local labor markets. The labor markets in developing countries tend to be different from developed countries and hence mass migration in emerging countries, alongside the presence of external labor shocks, can have adverse effects on their labor markets. Using available panel data (Cox's Bazar Panel Survey - 2019 & 2020/2021) on the Rohingya refugee and local population labor conditions, this study intends to investigate how the pandemic has impacted the refugee and local labor wages through difference-in-difference analysis to compare the labor markets of areas affected by refugee migration to less/non-affected local regions and intends to show plausible and significant effects on these labor metrics within the local region.

Abstract Name: Viability of Trypanosoma cruzi in RBCs at cold storage temperatures

Chagas disease (American Trypanosomiasis) is caused by the protozoa Trypanosma cruzi. Chagas disease affects approximately 10 million people in Latin America, manifesting in pyrexia, malaise, splenomegaly, and cardiomyopathies. T. cruzi is commonly spread through the infected feces of the 'kissing' bug. After insect bites, blood transfusion is the second most frequent mode of transmission. The Center of Disease Control (CDC) estimates in the US, around 300,000 individuals are infected with T. cruzi, causing a considerable disease burden. The goal of this research will be to study the viability of T. cruzi in packed red cell aliquots stored at various cold temperatures to study parasitemia. If successful, storage of packed red cells in cold temperatures will show reduced viability of infectious T. cruzi; creating a simple adjustment to current prevention methodologies furthering the reduction of transfusion-transmitted American trypanosomiasis. Warming temperatures can shift the distribution of triatomine insects, allowing the spread of the disease to non-endemic areas such as the United States as climates become more favorable. Pollution, insecticide resistance, and tourism are additional factors that may contribute to this threat. Means to prevent trypanosomiasis from blood products will become pertinent with this change. Routine screening of blood-donors using a questionnaire has reduced the incidence of contracting trypanosomiasis in non-endemic areas. Serological testing is not mandatory outside endemic areas because it is suspected that the number of T. cruzi-infected donors is small, and screening each donor would not be cost-effective. Although the questionnaire has been effective, it fails to screen asymptomatic carriers resulting in transfusion-transmitted infections. To mimic organ-donor tissue, cultures stored at low temperatures have shown a reduction of trypanosomes. Past research has explored cold storage on the viability of Babesia in blood bags. Minimal research has been conducted on the viability of T. cruzi in blood stored at cold temperatures.

Abstract Name: **Investigating the Potential of Gut Bacteria to Metabolize Metformin**

Originating from galegine, found in goat's rue, metformin became the most prescribed pharmaceutical for type 2 diabetes due to its capabilities to control blood sugar levels without causing hypoglycemia. Aside from maintaining blood sugar levels, metformin has been used to treat heart failure, polycystic ovary syndrome, weight loss, inflammation, and can help decrease the risk of a stroke. With the widespread use of metformin, about 30% of users have reported side effects of nausea, vomiting, diarrhea, stomach aches, loss of appetite, or a metallic taste in their mouth. This project investigates the potential of gut bacteria to metabolize metformin. Growth studies were performed with two different brands of probiotics and metformin as the nitrogen source. Results show that probiotics have limited capability to degrade metformin, however, the absence of known metabolic intermediates suggests that the drug is not fully metabolized. Total genomic DNA was isolated from commercial probiotic cultures and used to conduct polymerase chain reaction assays (PCR). Primers were designed to amplify metformin degrading genes, previously identified in the metformin degradation pathway. This was followed by gel electrophoresis and DNA sequencing to determine if the probiotics contained genes similar to the ones encoding metformin degrading enzymes. The results show that a gene homologous to cytD was present in both probiotics. Probiotic B also contains a hypAB homolog. Using BLAST, results show that the DNA fragment amplified with cytD primers was identical to a gene encoding an ABC transporter for Lacticaseibacillus rhamnosus, which is a prominent bacterium in both probiotic cultures. The limited metformin degradation observed in commercial probiotic cultures suggest that gut bacteria do not metabolize this drug under aerobic conditions. Future work will focus on studying metformin degradation under anaerobic conditions and using bacteria from human feces capsules to mimic the gut microbiome.

Karina Diaz Rios

Abstract Name: **Dietary Patterns in Mexican-origin Adults in the U.S.**

Mexican-origin adults in the U.S. have the highest prevalence of diabetes (14.4%) in comparison to other Hispanic subgroups like Puerto Ricans (12.4%) and Central/South Americans (8.3%). Improving diet quality in Mexican-origin populations can help reduce their risk of diet-related chronic diseases, including diabetes. This study aims to describe the state of evidence on dietary patterns of Mexican-origin adult populations in the U.S. A systematic review was conducted with searches in four databases (i.e., Google Scholar, PubMed, Web of Science, and ProQuest) following the Preferred Reporting Items for Systematic Reviews and Meta-Analyses guidelines. Articles were included if their primary focus was diet quality among Mexican-origin populations in the U.S. Findings of peer-reviewed articles focusing on Mexican-origin adults were systematically extracted and narratively summarized by 2 researchers. The initial search rendered a total of 1,383 articles. After title and abstract review, 91 articles were included; 22 articles were retained and summarized upon full-text review. Findings revealed that Mexican origin populations have a poor diet quality. Specifically, Mexican-origin individuals consume more refined grains and sodium and do not meet the recommended amount of unsaturated fat. U.S.- born Mexicans who are the most acculturated consume more sodium, saturated fats, and sugars, than Mexicans who are the least acculturated. This research provides insight into the dietary patterns of Mexican-origin populations that may contribute to an increase in the risk of chronic diseases such as diabetes. Given the increased risk of diet-related chronic diseases among individuals of Mexican origin, the poor diet quality of this group unveiled in this study indicates a critical need for interventions to improve eating choices, particularly around limiting the consumption of refined grains, sodium, and saturated fat, with a targeted focus among those who are more acculturated

Abstract Name: Gun Violence in Schools

Gun violence has become a huge problem, especially when it comes to our schools. Just this year, as of October 31, 2022, there have been forty school shootings, twenty-eight of the victims were students and the other six were staff members. According to SIERP (Stanford Institute for economic policy Research) more than a hundred thousand students between 2018-2019 were involved in school shootings. School shootings have a major effect on students' mental health, academic performance, and enrollment ((Dodson, 2021,). School should be a place where children want to go to learn, make new friends, and a place where they can feel safe and secure. Sensible Gun laws need to be implemented in addition to school based interventions that address problems before shootings occur. One solution that has been tossed around and will not help this situation is arming teachers with guns. This literature review looks at the effects and impact of gun violence on students and offers some research-based approaches for creating safer schools and communities (McMillan, Jordan; Bernstein, 2022).

Abstract Name: The Future of Prosthetics: Prosthetics and how 3D printing will shape its future

The term "prosthetic limb abandonment," is used to describe an anomaly in which people need or use prosthetics and are given the opportunity and money to acquire one, but still deny the prosthetic. This anomaly can be caused by different factors like the social perspective of prosthetics, or just the look and feel of these artificial limbs. With the use of 3d printing people can design custom prosthetics that fit, feel, and look good. Therefore, 3D printing might decrease the amount of people who are under the umbrella of prosthetic limb abandonment.. A systematic review was performed to gather information on 3D printing and prosthetics such as prices of prosthetics, 3D printing implemented into prosthetics, the transition into cybernetics, and the look of prosthetics. Articles were analyzed to collect information on the advancements that have been made in the past few decades. Based on the data gathered, 3D printing does reduce the cost of manufacturing an artificial limb because of the reduction in time needed to make the prosthetics and the variety of possible material that can be used to create the prosthetic. Not only can 3D printing be used as a prosthetic cover, but it can also be used to 3D scan and print a mold of someone's ear to help create soft tissue prosthetics also known as the SPPC process. The transition into cybernetics has been a slow process, however engineers in Hiroshima, Japan have managed to create a prosthetic that takes its input from ultrasonic sensors, it also possesses an impressive range of motion. The purpose of this paper is to broaden the reader's view on the field of prosthetics and help people realize the potential this industry has in the near future. Keywords : Prosthetics, 3D printing, myoelectric, cybernetics, prosthetic limb abandonment.

Abstract Name: Fabrication of MEMS Filters for Applications in Rapid Prototyping and Biotechnology

Effective techniques for the separation and spatial manipulation of shaped microscopic particles are vital to applications in fields ranging from biotechnology to manufacturing. For instance, shape-specific separation can be used to isolate microbes and biomolecules. Printers used for rapid prototyping from composite materials could benefit from a device that constrains the orientation of microscale filler materials such as metals, glass or carbon fibers. The separation and alignment of shaped particles is generally challenging, since nonspherical particles can freely rotate and present different faces during motion. In this presentation, we describe the fabrication of lithographically patterned and anisotropically etched microscale pores in a single crystal silicon substrate, that are designed to overcome these difficulties. We present data on the engineering limitations and outcomes of this fabrication process and preliminary results from flow testing. These precision-engineering pathways show promise for both the shape-based separation of non-spherical particles as well as in controlling their spatial orientations.

Abstract Name: Impact of Metformin on Cocaine Sensitization in GLT-1 and AMPK Phosphorylation in the Medial Prefrontal Cortex and Striatum

Cocaine is an addictive stimulant, with over one million people suffering from cocaine use disorder. Cocaine sensitization, an enhanced motor response to repeated, intermittent cocaine administration, impacts various protein levels in the corticostriatal reward circuit. In this circuit, the medial prefrontal cortex (mPFC) communicates with the Nucleus Accumbens (NAc) via glutamatergic projections which help regulate reward-seeking behavior. Cocaine self-administration downregulates glutamate transporter 1 (GLT1) gene expression, disrupting this communication. Another protein impacted by cocaine is Adenosine monophosphate-activated protein kinase (AMPK), which maintains cellular energy homeostasis. Cocaine sensitization reduces phosphorylated AMPK (pAMPK) in the dorsal striatum (dStr) and increases pAMPK in the PFC. Pain research suggests AMPK activation can regulate GLT-1 function in spinal cord, so we aimed to probe that relationship in the brain and determine if cocaine impacts AMPK GLT1 in the mPFC, NAc, and dStr. We have shown that introducing metformin to the NAc core decreases cue-induced cocaine seeking in rats. In this study, rats were given cocaine (15 mg/kg) or saline injections for six days and a challenge injection on the seventh day. They were divided into groups based on the initial and challenge injections they received: cocaine; cocaine (c-c; n=13), cocaine; saline (c-s; n=12), saline; cocaine (s-c, n=10), saline; saline (s-s, n=12). The locomotion of rats was tracked for forty-five minutes following daily injections. Brain tissue was extracted from the regions of interest and pAMPK and GLT1 levels were quantified using western blots. Results showed significantly higher pAMPK levels in the mPFC of the c-s group. Next, we aimed to determine if metformin pre-treatment could prevent cocaine sensitization and associated protein changes. This experiment will inform research into the impact of cocaine sensitization and the development of relevant pharmacotherapies.

Abstract Name: **Designing a user-centric public transportation app for Chicago suburban trains**

Public Transportation in America has a poor reputation for a long list of reasons including Traffic Management, Large Fleet Costs, Long Commutes, etc. Users need a reliable system to convey real-time events as they travel. Current applications on the market do not provide users with the vital information that they need for their travels. I hope to explore these issues and create an application that allows user information contributions and provides exact timing notifications to identify city traffic and disruptions. User Experience Design is a design process that involves integrating and testing the interaction between human users and a product or website. In my UX case study, I will conduct several interviews and surveys of public transportation users. With these concerns in mind, I will build and design an interactive prototype of my own public transportation app. The questions I will study in this project are: What opinions or ideas does the public have regarding the use of the public transportation system of city trains? What do users believe could enhance the quality of these platform apps to aid their travels? This is why, from my self-conducted research as well as my readings on the matter, I am creating a new app dedicated to the public transportation of the Metra train line. I will fill in the gaps that the Ventra(a transit app for CTA, Pace, and Metra transportation) application is missing, and I will incorporate my own features and designs to fulfill the user's needs. I am building identity (the combination of visual and content choices that represent a company's personality) for the user experience through a UX case study (which includes user personas, empathy maps, site maps, low-fidelity wireframes, and an interactive high-fidelity prototype). Giving insight into the issues of users and tackling them meticulously and systematically.

Abstract Name: **Creation and Characterisation of Lipodystrophic Mutant Mouse Models with Lmna Variants**

Familial Partial Lipodystrophy 2 (FPLD2) is the most common form of lipodystrophy, a disease that has symptoms of selective loss, redistribution, and dysfunction of adipose tissues (fat). FPLD2 is caused by mutations in (lamin A/C), which encodes nuclear lamina proteins that are important for nuclear function and essential to control gene expression, but its role in adipocyte homeostasis is insufficiently understood. Mutations in lamin A/C cause several diseases (laminopathies) including lipodystrophy and progeria. Using CRISPR-CAS9 technology, our lab created mutant mouse models to imitate human FPLD2 disease and consequently gain a deeper understanding of the mechanism of adipocyte loss in FPLD2. We created 7 different mutant mouse models that were characterized by which exon in Lmna had been mutated- Exon 1 (T101), Exon 8, (R482Q, P485R, K486N), and Exon 11 (S573L , N582H, R584H). These are all mutations that are known to cause FPLD2 in humans, however, we had to verify if the same applied to mice. The phenotypes for mutant mice that we expected were lipodystrophy, cardiomyopathy, spinal/bone deformities, stunted growth, muscular dystrophy, arthropathy and progeria because these are phenotypes shown by human patients of FPLD2. We processed and compared the body weights and fat mass, collected serum, and dissected and weighed specific organs including the liver, hearts and adipose tissue. Analysis of the adipose tissue from the different groups of mice by histology gave us insight on the relationship between each specific mutation and adipocyte cell loss. We hypothesize that the mice that have adipocytes with mutant Lmna have significantly less adipose tissue and potentially more health problems as compared to the control group. These mice may develop abnormalities which mimic the pathology of FPLD2, which will help completely understand the mechanism of adipocyte loss in FPLD2 and discover a therapeutic target to help affected patients.

Abstract Name: Farewell Privet, hello Salem: Decolonization and language reform in Kazakhstan

This research project will analyze the role of language in the decolonization of Kazakhstan and the attitudes young Kazakhs hold in relation to language policies. While USSR might not have appeared to be a colonizing power because of the communistic regime, the division into the centerand periphery and the unequal relationships between the two support the idea of a colonizing empire. The Central Asian countries continue decolonizing education and history while attempting to build an identity independent of the Soviet citizen. Scholars attempted to analyze decolonization from a Western perspective, yet the experiences of Central Asian countries show the importance of inviting local voices into the discourse to expand on the different forms decolonization can take,including derussification, Islamization, and Turkification. This project will include in-depth interviews with Kazakh students at KU and a survey young Kazakhs will access on Twitter. The project will then utilize thematic coding and statistical analyses to explore trends in regard to language policy, use, and decolonization. The expected result is a positive relationship between the preferred use of the Kazakh language and condoning of the USSR. Central Asia is a geopolitically important area due to the strategic location between Russia and China, and understanding the region is vital to peacekeeping in Asia.

Abstract Name: Virtual reconstruction of 2000-year-old Herculaneum Scrolls

The city of Herculaneum was buried by mount Vesuvius in 79 A.D. alongside Pompeii. Because of the way the city was buried by the pyroclastic flow, organic material was better preserved than in Pompeii and notably thousands of carbonized scrolls were found inthe famous library at the Villa dei Papiri. Most of these scrolls are damaged beyond recongnition and are too fragile to be read by traditional methods. Our research aims to improve and build upon methods to digitally study these scrolls without inflictingfurther damage on the artifacts. For the scrolls that were opened in the 1800s and now find themselves mostly broken into multiple fragments called 'Pezzi', multispectral photographs were taken by our team in Naples, England, and Paris. We have improved the process of image registration and blending for these multispectral images. As for the scrolls that remain closed, the Herculaneum project aims to CT Scan themand apply our virtal unwrapping pipeline to virtually unroll these scrolls, in a process similar to the virtual unrolling of the En Gedi scroll lead by Dr. Seales in 2015. The complexity of the Herculaneum scrolls, however, requires a new approach in segmentation and ink identification. We have developed a new tool to carry out preliminary segmentations of the scrolls and tested our algorithm. The research prospectus includes the application of the machine learning algorithm for carbon ink identification developed by Parkeret al. 2019 to our newly obtained segmented fragments in order to reveal the content of the two-thousand-year-old scrolls.

Abstract Name: Theory of Mind Development in Late Talkers

Theory of mind (ToM) is a basic cognitive skill defined as the ability to attribute mental states of oneself and of others.This concept that the thoughts in someone else's head might bedifferentfrom our own is brand new in developing brains and typically starts to form around ages 4-5 years old. Theory of mind is called a theory because we as people are just theorizing at what others could be thinking, we don't know if that is necessarily true. A child with the capacity to express someone's belief (or mistaken belief) can then guess what could happen next or the reasoning behind that belief.Every minute of every day we are taking in information about people, for example, the way someone acts or the things they say, and combining it with what we already know about their personalities to form our own theories about those around us. Theory of mind is important to Speech-Language Pathologists (SLPs) because a child first begins communicating to express emotion and explain behavior. Children who have late-talking development are missing out on that expressive social communication.The purpose of this study is to see if these children who might have delayed speech and language skills also have delayed development of theory of mind. I will construct 3 false-belief tasks to assess ToM in the children participating and see how the children with communication disorders compare to their on-level peers. SLPs could use this information to help integrate theory of mind tasks into therapy, so the child is getting those similar social-emotional interactions as their peers.

Abstract Name: Disney Movies Released for Children Aged 5-12 between the 1990s and 2020s: The Evolution of the Princess of Color

Girls between the ages of 3 and 5 years watch an average of one Disney Princess movie per week. According to Bandura's Social Cognition Theory, the media children intake greatly impacts how children interpret societal roles and how they may approach them. This study examines the representation of culture and femininity in Disney movies, with both princesses and non-princesses, and how these representations might impact how young girls perceive their roles as women and how that would look in the world around them. In this comprehensive review, covering literature from 2008 to 2021, I explored the representation of culture and gender, and how young girls may replicate what they watch in Disney movies in their behaviors. Through reviewing this research and Disney princess movies, a correlation was made between the representation of various cultures and femininity in Disney movies and how young kids perceive and mirror those representations. The findings of the study included the following: Disney princess movies in the 90s leaned heavily on stereotypes of the new cultures they were portraying; culturally diverse princesses are perceived as less feminine, and therefore, less princessly; young girls portray characteristics of materialism, physical beauty, and princess-like posture; and young girls associate long, clean hair, rosy lips, big eyes, and a slim figure with beauty. Further research on the importance of media, specifically Disney movies, is needed to determine the next steps for protecting young girls from poor representation, and thus, protecting girls from replicating behaviors that restrict them professionally, socially, or in relationships.

Abstract Name: A Comprehensive Survey of Android Malware Detection using Deep Learning Techniques

Among smartphones, Android is the most famous and widely used operating system with around 3 billion users worldwide which is three times more than iOS users. Android attracts not only users and application developers but also hackers and malware developers. Consequently, this can negatively affect many people, for example, by invading their privacy, stealing their credentials, or even acquiring sensitive information to ask the victim later for a ransom. It has become crucial to take necessary countermeasures against this rapidly growing android malware trend. Many research papers were conducted to discuss different algorithms used for analyzing and detecting these malicious attacks. Some showed superior performance than others; Nevertheless, this survey focuses mainly on Deep Learning techniques used in Android Malware Detection. Thus, we aim to present a comprehensive analysis of the recent research using Deep Learning techniques to analyze their strengths and limitations, commonly used datasets, and contrast it to other traditional methods used in the past. Also, we refer to some of the challenges in this emerging field, provide our perspective on future opportunities and directions and relate its effects to individuals and society.

Abstract Name: Drug screening using Bioinformatics based tools to identify lead compounds against Naegleria Fowleri

Naegleria fowleri, also known as the brain-eating amoeba, causes primary amoebic meningoencephalitis (PAM), that affects the central nervous system (CNS). Patients with N. fowleri infection are unresponsive to current treatments with a survival rate of only 3%. Thus, it is essential to identify novel pharmacological targets and screen drugs. Naegleria fowleri protein library was explored to identify potential drug targets that have least similarity to any known human protein. Nfa1 (Uniprot: Q9NH76) was identified as one of the potential targets because it has no human homolog. Amoebae have cell surface features called feeding cups that are used to consume food, including host nerve cell membranes. Food cups are created during phagocytosis which includes the Nfa1 protein facilitating absorption through the cup-like structure. Nfa1 protein is involved in the formation of food vacuoles, locomotion, and importantly, also serves as an oxygen-binding protein. It is hypothesized that Nfa1 inhibition would arrest locomotion and restrict their foraging capacity, starving the amoeba to death. Based on the hypothesis, Nfa1 structure was predicted using Alphafold and the protein structure was minimized prior to docking. The minimized structure was validated using the Ramchandran plot. The Molprobity score was 0.83 with 2.5% of outliers towards C-terminal of the protein. Using various bioinformatic tools, binding pockets of Nfa1 were predicted. Drug library was screened after docking in Pyrx. Potential ligands that showed strong binding affinity and good pharmacokinetic properties were selected. Ligands were validated based on the blood brain barrier crossing, good GI absorption, ADME analysis, toxicity, and bioactivity profiling. The top compounds showed high binding affinities ranging from -7 kcal/mol to -9 kcal/mol. Selected compounds will be validated using toxicity assays against Naegleria and human cell lines for future studies.

Abstract Name: The Cardiorespiratory Response while Nordic Walking vs. Regular Walking Among Middle-Aged to Older Adults

Background/Purpose: Around 60-80% of waking hours for adults are spent in sedentary behavior while physical inactivity accounts for 9% of all deaths worldwide. Furthermore, there is a strong dose-response relationship between physical inactivity and all-cause mortality, cardiovascular health, and metabolic health. Recently, Nordic walking (NW) has been introduced as a superior mode of exercise where one can increase energy expenditure due to increased engagement of upper body musculature while walking at a moderate intensity pace. NW is like regular walking except for using walking poles. Within established findings, most work has been done in a laboratory which can interrupt natural NW mechanics. Therefore, the purpose of this study was to measure the cardiorespiratory and energy expenditure differences in Nordic walking and regular walking in a field setting. Methods: Twenty middle-aged and older adults participated in this study. Each participant's initial session included Nordic walking familiarization, 10-m gait speed test, and a peak oxygen uptake (VO2peak) test. The two exercise sessions consisted of either NW or regular walking on an indoor track for 30 minutes. All metabolic variables were measured via the COSMED K5. Results: A paired-sample t-test revealed a significant difference between NW and regular walking for %VO2peak values ($p = .008$), kcal·min-1 ($p = .005$), and total kcal expenditure ($p = .001$). No significant difference was found for preferred gait speed ($p = .485$) between NW and regular walking. Conclusion: NW is superior to regular walking in eliciting a higher %VO2peak despite similar walking speeds, a higher kcal·min-1, and greater total kcal expenditure. In turn, these data agree with previous research and supports the use of NW to increase energy expenditure to potentially prevent the risk of one's metabolic and cardiovascular risk.

Abstract Name: Adolescent social isolation stress enhances nicotine conditioned place preference and disrupts stress coping behavior.

Adolescence is a sensitive period in brain development that is marked by increased susceptibility to the effects of chronic stress, which may enhance vulnerability to neuropsychiatric conditions such as depression and substance use disorders. In the present study, we used an animal model to examine the effect of adolescent social isolation stress on coping behavior and nicotine reward. During the adolescent period from postnatal day (P)35-P49, male and female C57BL/6J mice were exposed to either social isolation (SI) stress or standard rearing (SR) conditions, as well as nicotine exposure (0.35mg/kg) four times between P35-P49 during a nicotine conditioned place preference (CPP) procedure. On approximately P50, stress-coping behavior was examined following a 6-minute forced-swim test (FST). Our behavioral results show that both male and female SI mice more rapidly develop nicotine CPP compared to SR mice, that SI mice exhibit increased levels of immobility in the FST, and that prior nicotine exposure during social isolation decreases immobility in the FST. These results suggest that adolescent social isolation stress enhances the rewarding effects of nicotine and negatively impacts stress-coping behavior. To determine whether adolescence is a sensitive period for these effects, ongoing research efforts are aimed at comparing these results to adult social isolation and nicotine exposure. Furthermore, we are examining stress-induced functional (c-fos expression) differences in the brains of SI versus SR mice in response to the FST via immunohistochemistry of the dorsal raphe ascending serotonergic system. Collectively, these analyses will help determine neurological correlates of adolescent susceptibility to the negative effects of chronic social isolation stress and inform our understanding of adolescent brain development and vulnerability.

Abstract Name: Electrostatic Capture of Forensic Evidentiary Residues Using a Children's Toy

Crime labs currently rely on plastic swabs or chemical extractions to collect and analyze drug residues from surfaces. These methods require direct contact with the sample and can ruin important underlying evidence such as fingerprints and touch DNA. I am working on a non-contact sampling method; a sampling device that samples residues while being held over the surface of the evidence. Microscopic particles from residues on evidence are lifted using an inexpensive toy, a Fun Fly Stick, and a glass-sheathed metal needle. This device can also be coupled with a mass spectrometer for analysis with the electrified capillary held in front of the inlet to the mass spectrometer.A Fun Fly Stick has ~27kV of voltage with a negligible current that is applied to a metal needle. The metal needle is covered with a glass capillary, which is held 2mm over a surface for 30 seconds to capture solid particles from residues. The tip of the capillary is placed 4mm from the inlet of the mass spectrometer (Thermo LTQ XL). A voltage is then applied to the tip to generate an aerosol that ionizes captured analytes.Cocaine, methamphetamine, MDMA, alprazolam, caffeine, procaine, benzocaine, diphenhydramine, and hydrocodone were used for the initial tests. At microscopic levels of drug residue, there was a strong detection of signal with this technique of collection. My current work is focused on perfecting this safer, more effective, non-contact method of collection of these drug residues. This will allow for field work at crime scenes to be faster and not jeopardize any evidence left behind by criminals.

Abstract Name: Studying antibiotic resistance in Enterococcus with a One Health approach

One health is the connection between animals, humans, and the environment. Our study uses this concept to understand community-acquired antibiotic resistance using Enterococcus as a model. In an urban environment, animals have a great potential to be a reservoir for antibiotic resistance genes (ARG). Urban environments also contain a great deal of pollution from businesses and transit, leading to metal contamination of the nearby environment, seeping into soils, waters, and groundwater. This metal pollution places pressure on bacteria, leading to the development of metal resistance genes (MRG) and ARG. Our hypothesis is that wildlife exposure and MRG in an urban environment have a strong correlation with community-acquired antibiotic resistance. Enterococcus is a gram-positive bacteria found in the gut of humans and animals and has a high potential to transfer between these populations. Our study uses wildlife sampling, MRG, and ARG identification as well as the comparison of antibiotic-resistant Enterococcus strains of human and wildlife origin collected in metro Detroit. A total of 140 rodent and bird fecal samples were collected, giving 269 positive Enterococcus isolates. Eighty-one clinical isolates were recovered from outpatients at the Henry Ford Hospital. Antimicrobial Susceptibility Testing (AST) was performed for 16 antibiotics using Sensititre plates. Only 7 samples showed no antibiotic resistance. Multidrug resistance was demonstrated by 17% of isolates. The samples had the most resistance to lincomycin (89.55%), followed by quinupristin/dalfopristin (32.84%) and nitrofurantoin (17.54%). This study suggests the prevalence of antibiotic-resistant Enterococcus in the urban environment and the clinical importance of the findings. Further analysis is underway to compare animal and human isolates on Enterococcal species distribution and molecular subtypes.

Abstract Name: **Environmental Variables Regulate the Patterns of Root Colonization Fungal Endophytes in Guinea Grass (Megathyrsus Maximus)**

Dark Septate Endophytes (DSE) and Arbuscular Mycorrhizal Fungi (AMF) are two endophytic fungi which have a mutually beneficial relationship with plants. DSE is an endophytic fungus that colonizesin primarily nitrogen-rich environments, but it is also known to colonize roots in nitrogen-limited areas. Similarly, AMF colonizes plant roots and flourishes in low resource environments. Both AMF and DSE optimize nutrient and water efficiency in plants while receiving sugars from the host plant. This relationship is influenced by environmental factors such as soil moisture, pH, organic matter, salinity, soil nutrients, and land use. In this study we analyzed the relationship between a forage grass Megathyrsus maximus (Guinea grass) and the two endophytes and the influence of environmental variables. Megathyrsus maximus is an invasive African forage grass species that escaped from its original confinement ofgrazing land and made its way into untended areas where it dominated over native species. Guinea grass can endure a variety of environmental and soil conditions; however, it is reported that the probability of their expansion increases linearly with soil moisture and nitrogen.Our analysis of roots and soil samples collected from 150 locations in South Texas Plains ecoregion show that the plant is heavily colonized by the endophytes both AMF and DSE and this relationship is influenced by soil moisture levels. AMF had a positive relationship with soil moisture while DSE had a negative relationship with soil moisture. Roots samples collected from areas with higher soil moisture had higher AMF colonization while roots from drier soils had higher DSE colonization. Our results show that Megathyrsus maximus can potentially outcompete the native grasses with its positive association with AMF and DSE. Thus, land managers looking to manage this plant should prioritize the plant-soil feedback in their management plan.

Abstract Name: **Increased Intake of Alpha-Linolenic Acid is Associated with Higher Exam Scores**

Roughly 60% of the human brain is fat. Essential fatty acids (EFAs) Linoleic and alpha-linolenic acids are critical for building the brain's structure, synthesis of neurotransmitters, and developing the visual cortex, among other important functions.This study investigates how EFAs intake may affect brain function, and if these effects are reflected in student exam performance. We hypothesize that increased consumption EFAs will be associated with higher test scores. An analysis of cognitive function based on exam scores was conducted on 602 student participants attending Weber State University. Two-day diet records were collected. Grams as well as percentages of recommendation consumed based on required calories of linoleic and alpha-linolenic EFAs were calculated from the diet record using Diet and Wellness Plus software. The data analysis was completed using RStudio. Models were created using linear regression and variables were removed based on p-value using backward elimination. The best model created included the following variables: LinoleicCal% (the fraction of the total calories required provided by linoleic fatty acid), α-LinolenicCal% (the fraction of the total calories required provided by alpha-linolenic fatty acid), and the interaction between the previous two variables. Exam scores increased by 5.43 times, for each additional α-LinolenicCal% percentage increase ($p = 0.01$). For each percentage increase on both LinoleicCal% and α-LinolenicCal%, exam scores decreased by 0.27 times ($p = 0.02$).Our results show that it is not only the amount but also the ratio in which these two fatty acids are consumed that influences exam score performance. This is in accordance with previous studies showing that intake of omega-3 polyunsaturated fatty acids are inversely related with risk of impaired memory and flexibility in middle aged adults.

Laquinton Chun

Abstract Name: Self-Guided Historic Tour of University of West Georgia Campus

Augmented reality (AR) opens the door to novel ways of conveying content in its physical context. This project explores the potential of AR to showcase the history of the campus of the University of West Georgia, and gives recognition to lesser known portions of its history. We have designed and implemented a mobile application that serves as a self-guided tour through the university's historic front campus. The application was built in Unity and uses Vuforia Engine for the augmented reality component. Three-dimensional models were built in Autodesk Maya. A campus map displays the user's current location and points of interest. Each point of interest can be tapped to learn more about it. The featured information includes pictures, a textual description, audio, and a three-dimensional model of a former building and historic objects. The historical objects were provided by the History department in an interdisciplinary collaboration to ensure accuracy and a diversification of perspectives. For the AR component, the application employs image targets that, once scanned, showcase historic information in its physical context. For example, an academic building that does not exist any more is displayed at its former location. Since the application is heavily user-interface driven, it is designed using event-driven architecture to ensure strong usability for the user. Additionally, our application uses the Singleton design pattern for our application data pertaining to the points of interest. For a demonstration, we have a representative building that has athree-dimensional model, audio recording of a description,and images of the interior of the building. While AR is used already in education, training, and commercially, it has relatively little use in historic campus tours. Our application can serve as a framework for other historical campus tours that may benefit from augmented reality.

Abstract Name: Does Correcting Errors Improve Graduate Students' Ability to Write Accurate Stuttering Treatment Plans?

For the past few decades, speech-language pathologists and graduate students have continued to report feeling under-prepared and having low self-efficacy in regard to working with adolescents who stutter. In an effort to increase self-efficacy and preparedness, two groups of graduate students participated in a class activity where they worked in teams to identify, explain, and correct unambiguous errors in case studies involving adolescents who stutter. The errors could be goals and activities that do not align with client values or goals that do not align with treatment protocol (e.g., stuttering modification, fluency shaping or a combination approach). To measure progress, students completed a knowledge and self-efficacy self-assessment and designed a treatment plan for an adolescent who stutters at two different times. Once before the error-correcting activity and again after the activity. Self-assessments were designed to measure the students' self-perceived knowledge and self-efficacy of their ability to provide treatment to people who stutter. Treatment plans were completed so that the researchers could assess the students' understanding of treating stuttering. Treatment plans were scored by a rubric that examined internal consistency, appreciation of client values and rationale. The research team reached consensus during scoring. Differences in survey ratings and treatment plan scores pre-activity and post-activity were analyzed after the course was completed, to maintain anonymity.Data analysis is ongoing. Our preliminary research findings show that there are 10 domains where the students' knowledge increased from pre-assessment to post-assessment. These domains include: reducing frequency, reducing severity, reducing tension, identifying disfluencies, speech goals, thought goals, emotion goals, bullying assertiveness, and social goals. Students also reported to have better self-efficacy in regard to working with children who stutter after the error-correcting activity. We are presently in the midst of analyzing the treatment plans. Data analysis will be complete by the end of the semester.

Abstract Name: Predicting Malware attacks with the help of Machine Learning

Malware has become a more widespread problem alongside the fast growth of technology. Malware is any unwanted software placed in the system without knowledge or consent for performing malicious activities. Despite the widespread adoption of novel preventative procedures, the number of malware attacks steadily rises yearly. These attacks can spread through networks and disrupt any operation, leading to many cyber thefts, leaked or destroyed data, and, most often than not, ransom. Unfortunately, many of the anti-malware systems that are available today are only able to defend the system from malware that is already known. To address this problem as part of this research, we constructed a model that uses the predictive power of machine learning algorithms to estimate the likelihood that a computer will become infected with malicious software. Data from Microsoft Defender, a built-in antivirus solution for Windows, was utilized to compile the publicly available dataset used in this research, which includes information about hardware and system software installed on Windows machines. We envision that with the assistance of our machine learning models application, we will be able to reduce the number of compromised systems significantly.

Abstract Name: Queer Places and Hierarchies in the Book of Strangers by pseudo-I?fah?n?

In pseudo-Iṣfāhānī's Book of Strangers (Adab al-ghurabāʾ), a 10th-century collection of graffiti-poems and stories about feeling out of place, the narrator intentionally selects a specific story of his intimate relationship with a young man of high status. I offer a close reading of this text with sensitivity to space and status in order to show how the protagonists queer the private-public divide and the power dynamics between them. Two moments of crisis take place in this story. The first occurs when the narrator, who often waits by the young man's place, broadcasts his love in a poem written on the wall outside. In this moment of tension, we observe the narrator queering the space they share by choosing to out their private intimacy. The young man's rebuke reveals the resilience of the well-established and socially enforced hierarchy that separates them. The final crisis is the imprisonment of the young man's father. This incident causes the young man to take refuge with the narrator at his house where they exist unexpectedly as equals. In this moment of reversal, the protagonists create a queer space where they reject the well-established social hierarchy. By showing that space and social status are queered by acts of individual and group resistance, I draw attention to the limits of the acts vs identities paradigm as a frame for understanding Classical Arabic cultural representations of same-sex love and desire.

Abstract Name: **Development of Pectin Microspheres for Pulmonary Drug Delivery**

The delivery of drugs to the lungs through inhalation is a relatively complex process due to the natural defensive mechanisms of the respiratory tract having the ability to remove or inactivate them. Size plays a substantial role in the fate of inhaled particulates: large ones are deposited in the upper respiratory tract and small ones are simply exhaled. This study aims to develop biocompatible microspheres that are 3 μm in diameter and can encapsulate pulmonary drugs to allow for their delivery to deep portions of the lungs. Pectin, a polysaccharide polymer derived from citrus and apple peels, was chosen as the microsphere material due to its biocompatibility and degradability in solutions replicating physiological environments. Electrospray was used to develop the pectin microspheres with parameters such as voltage, feed rate, gauge size of syringe tips, and distance between syringe tip and collection sheet being defined as significant contributors to the resulting size of the microspheres. Other parameters such as the ratio of pectin: PEO solution significantly affected the uniformity and morphology of the resulting pectin microspheres. The rate of pectin microsphere degradation can be altered through coating with polymers, such as chitosan or gelatin. Microspheres were modified by coating with either of these materials in order to improve the stability of microspheres in physiological conditions.

Abstract Name: **Low Cost Filter Media for the Removal of Phosphorus in Agricultural Runoff Treatment Systems (ARTS)**

Seasonal hypoxia of lakes in the Midwest, Gulf of Mexico, and surface waters around the world as a result of excessive algal production, has a detrimental effect on the local aquatic species, environment, and recreation. Despite investments in point source reductions, seasonal hypoxia is persistent, in part due to non-point agricultural sources of phosphorus (P) (35% of total P load to Lake Michigan). Agricultural runoff treatment systems (ARTS), consisting of sedimentation basins and phosphorus removal structures, are an effective field treatment to reduce nutrient pollution. Numerous media (80) for phosphorus removal structures have been investigated for their P removal potential and the hydraulic conductivity; Ca, Fe, Mg and Al content of media are important factors. Reactive media derived from waste products would create a product from waste, extending time prior to disposal, supporting a circular economy. Waste residuals (e.g. drinking water treatment residuals, wood waste, vegetative waste) will be modified (through metal additions, heat treatment, pelletizing, and binder addition) for and evaluated for dissolved P removal from agricultural runoff.. Treatment potential of modified waste media will be measured using flow through lab scale reactors constructed out of 0.75-inch diameter PVC pipe. Columns will be completed in triplicate for each media. Influent and effluent samples will be collected every 5 to 10 hours until effluent P is 50% of influent P. Ortho-phosphorus will be measured in collected samples using a discrete analyzer (Seal AQ300) at UWGB. Media will be designed to maximize P sorption capacity, hydraulic conductivity, mechanical strength, efficacy in high flow systems (10 min retention times), and reuse potential; minimize toxic side effects, energy consumption, and cost, critical to adoption. Results from flow through analysis will guide selection of reactive media deployed for field evaluation.

Abstract Name: Assessment of Hardware Obfuscation for Hardware Oriented Security

Due to the various threats in the globalized semiconductor supply chain, the security of integrated circuits (IC) has become a serious concern. Among the well-recognized security threats, the growing hardware intellectual property (IP) piracy and reverse engineering challenge the traditional chip design and fabrication. Obfuscation is a technique that makes comprehending and reverse-engineering a design difficult and is a promising solution for securing hardware IP against various attacks, such as reverse engineering, piracy, and tampering. This work utilizes the four most popular obfuscation - random logic locking, strong logic locking, anti-SAT logic cone, and cyclic obfuscation techniques. We implement these obfuscation techniques with different key sizes ranging from 32 to 128 bits using Xilinx Vivado and Artix-7 FPGA board to analyze the area and power consumption. Further, we compare the attack resilience of these techniques against powerful SATand key sensitization attacks. Our results show that the anti-SAT technique consumes the most area and power because of extra key input; however, the anti-SAT method is the most resilient against SAT and key sensitization attacks.

Abstract Name: Composite Material Modeling Using a Modified Finite Element approach to Characterize the Mesoscale Properties of Statistical Volume Elements

In homogeneous and isotropic materials, the constitutive matrix [C] which represents mechanical properties of a material in elastic region can be determined using Young's modulus and Poisson ratio. However, the constitutive matrix [C] of composite materials can be a computational, and even an experimental challenge because most composite materials have heterogeneity and anisotropy, which means their mechanical properties depend on the location and direction of measurement. Although finding composite materials' mechanical property [C] is very hard in mesoscale composite materials, the composite materials are widely used in industries because they are often lighter, stronger, and cheaper than simple materials. One method to address the multiscale problem is to use Representative Volume Elements (RVE) to find the smallest material volume that can represent the whole material. The composite's heterogeneity is "homogenized" (essentially averaged or made "smooth") by the RVE. However, some material behaviors, such as fracture, are very sensitive to regional anisotropic and heterogeneous material behaviors and cannot be described effectively by RVE. To overcome this problem, researchers have tried to assign anisotropic and heterogeneous material properties at an intermediate, mesoscale. One of the methods of analyzing mesoscale composite material is the Statistical Volume Element (SVE) method, which can be used to determine a statistical representation of the constitutive matrix [C].This research approached SVE analysis via the reduced stiffness matrix to improve efficiency on simulation. The stiffness matrix is generated through Abaqus, a commercial finite element analysis software, then, all information from Abaqus such as boundary node numbering, coordination of nodes, and reduced stiffness matrix are output. Strain-displacement mappings are calculated using successive perturbation of boundary node coordinates. To approximate the constitutive matrix of each SVE, the energy equation can be solved using various boundary conditions simultaneously. These approximated constitutive matrices form a statistical

Abstract Name: Pathways to Seeking Mental Health Services Among Muslim Americans.

What are the pathways that Muslim Americans have taken to utilize mental health services? What factors impact Muslim Americans' help-seeking behaviors? The research surrounding this topic found that acculturation to Muslim versus American values affected the likelihood of Muslim Americans reaching out to mental health services (Haque et al., 2019). The research demonstrates how Muslims who are less likely to seek help found services like group therapy, therapists of similar/same background, and therapy through imams and/or mosques the most approachable (McLaughlin, Ahmad, Weisman de Mamani, 2022). The major gap in the literature is the lack of research on the populations that have successfully sought out mental health services and the pathways in which they did so. This study aims to fill that gap in the literature. The data will be collected using a survey distributed through Qualtrics online. Muslim Americans who are 18 years or older and have used some form of mental health services are our target audience and will be recruited through digital and print flyers and social media. The study's expected findings will be that those of the younger generations and those who are more acculturated will have utilized mental health services more than those of the older generation who are not as acculturated. Expected findings also see religiosity impacting the individual's likelihood of using mental health services. The survey will be distributed and data collection will occur in the winter 2022-2023. The data will then be analyzed in early Spring of 2023.

Abstract Name: Identifying Cognate RNA Sequences of Non-Structural Protein 9 in SARS-CoV-2

As an RNA+ virus, SARS-CoV-2 infection (COVID 19) leads to direct translation of viral RNA to produce non-structural proteins (Nsp) responsible for viral replication. For example, Nsp 7 and 8 are thought to act as a helicase, Nsp 9 as a single stranded RNA binding protein and Nsp 12 as the replicase essential to the proliferation of the virus. Studies of homologous, Nsp 9 proteins in HSV, MERS, and SARS-CoV-1 indicate this protein binds both DNA and RNA sequences. In SARS-CoV-2, Nsp 9 contains an unusual OB, greek key motif thought to keep RNA single stranded for efficient replication in other viruses. Together these results suggest, Nsp 9 may function in SARS-CoV-2 to keep the viral RNA linear for replication by Nsp 12; however, little is known about the RNA binding requirements or structural contacts and interactions in this protein-RNA complex. Tryptophan fluorescent studies of Nsp 9 have been developed to identify cognate RNA binding sequences and structures. Initial studies indicate binding of an RNA pseudoknot structure in the 3'-untranslated region of the viral RNA. Further analysis of RNA structural requirements for stable Nsp 9 binding will be important in further deciphering the role of Nsp 9 in SARS-CoV-2 as pseudoknot structures in the 5' and 3'-UTR have served as a switch from viral RNA translation to replication and may serve as a handle for control of this ever infecting and mutating virus.

Abstract Name: Submitting to Memory in "The Night Porter": Memory Work as Disruption of Natural Attitude

This paper synthesizes the existing scholarship on Liliana Cavani's 1974 film The Night Porter with the existentialist and phenomenological ethics of Simone de Beauvoir and memory studies to analyze how the film implicates our natural attitude toward women's submission via Lucia's submissive situation. The film begins when Lucia (Charlotte Rampling), a death camp survivor, and Max (Dirk Bogarde), a former SS officer, bump into each other by chance in 1957 Vienna. The two begin to replay the sadomasochistic sexual relationship they had during Lucia's internment, revealed through a series of flashbacks throughout the film in which their dominant/submissive dynamic plays out. Specifically taking up Beauvoir's existentialist position that we are always subjects for ourselves and objects for others, and that submission appears as a destiny to women, as understood by philosopher Manon Garcia, I analyze Lucia's relationship with memory in the film as similarly ambiguous to this relationship with Beauvoirian subjectivity. I argue that women's (via Lucia's) recognition of the ambiguity of memory, which comes from their necessitated recognition of ambiguity in subjectivity, is essential in performing Annette Kuhn's idea of "memory work," which the film asks us to perform by calling into question the historical situation of women's submission. Finally, I consider how Kuhn's memory work is related to the disruption of Husserlian natural attitude, and how Cavani's film requires this disruption of natural attitude toward our memory of women's submission to appreciate the film as moving us toward a future feminist situation for all women.

Abstract Name: The Role of Inhibition in Convergent and Divergent Thinking

Creativity is a valuable skill that is cherished in nearly every domain of life. Research in neuroscience and psychology has attempted to understand the physiological states and cognitive processes underlying creative thinking abilities, focusing primarily on divergent and convergent thinking. Divergent thinking (DT) involves the production of multiple possible solutions while convergent thinking (CT) requires finding the single, best answer to a problem. Prior research suggests a positive correlation between DT and depleted cognitive inhibition. However, considerably less attention has been given to the relationship between inhibition and CT. Although seemingly counterintuitive, inhibitory control could play a vital role in certain convergent tasks by suppressing salient, yet irrelevant, stimuli that may prevent generating novel ideas. For example, Sio et al. (2022) found that the number of strong, irrelevant associates predicted problem solving difficulty in Remote Associate Test (RAT) problems.In the current study, we explore how the depletion of inhibition affects both CT and DT problem solving. Participants will be randomly assigned to either a control or inhibition depletion condition. The latter will complete the computer-based Sustained Attention to Response Test (SART) to deplete inhibitory control. The controls will complete a similar, but non-inhibitory, computer-based task of simply pressing a button regardless of the stimuli. Participants will then complete both a DT and CT task, the Alternative Uses Test (AUT) and a set of RAT problems, respectively. The order of tasks will be counterbalanced across participants. We hypothesize that weakening inhibition will facilitate the generation of creative ideas in the DT task (AUT). In contrast, we predict that that solving RAT problems will be more challenging with depleted inhibition, particularly for RAT items with extensive irrelevant associates, as these may block retrieval of the right answer.

Abstract Name: **Glycomaterial Implants Facilitate the Recovery of Forelimb Motor Function after Severe Brain Injury**

Severe traumatic brain injuries (sTBIs) result from blunt force and penetrating brain trauma that cause long-term brain volume loss and functional impairments. There are currently no approved interventional therapies to prevent brain volume loss and dysfunction in sTBI patients. We hypothesized that acutely implanted 3D brain-mimetic constructs will prevent brain volume loss and facilitate recovery of reach and grasp function in rats. In order to test this hypothesis, we performed intracortical engineered chondroitin sulfate (eCS) hydrogel implantations acutely (48h) after sTBI lesions in rats. To mimic clinically relevant mass lesion evacuation procedures of contused tissue, we induced controlled cortical impact (CCI) injuries to the rostral forelimb area (RFA; M1/M2 cortex) followed by biopsy suction ablation (SA) of contused tissue at 48 h post-CCI. Forelimb reach and grasp function was evaluated on a skilled reach task (SRT) every week for five weeks post-CCI. At Week 5 after CCI, animals underwent retrograde axonal tracer (Fluorogold) injections for terminal axonal tracing studies. Our results from SRT demonstrated significant deficits in reach to grasp activity of TBI only (CCI + SA) groups compared to the Sham (craniotomy only) group at Week 4 and 5 post injury. Hydrogel treated animals (CCI-SA-eCS) showed significantly improved reach and grasp performance efficiency and a reduced assay duration when compared to TBI controls at 5 weeks post injury. Overall, these data demonstrate that eCS hydrogel implants induced recovery of forelimb motor function sub-acutely after sTBI. Ongoing work is focused on assessing neuronal activity and plasticity of reach and grasp circuitry.

Abstract Name: **A green chemistry project: catalytic reactions in supercritical carbon dioxide**

Green chemistry is a development and practice of environmentally friendly and safe ways to carry out chemical processes. “Greening” of the chemical industry can be achieved by adopting new alternative methods with less toxic materials involved, less wastes produced, less energy required, and altogether safe to humans and environment. One of the big challenges in the current chemical industry is the use of volatile organic solvents. Solvents are used to mix multiple reagents to react, and when the reaction is over, the solvent is removed by evaporation. This convenience comes with a price: the vapor easily escapes to the environment and causes air pollution. Furthermore, most volatile organic solvents are either flammable or toxic, or both, and is a hazard to workers. Supercritical carbon dioxide (scCO2) is a possible environmentally benign alternative to traditional organic solvents. ScCO2 is abundant in nature, non-toxic, and a renewable resource, unlike common organic solvents, which are mostly produced from non-renewable petroleum. CO2 is gas at a regular temperature and pressure, and a solid at a low temperature below -77 degrees Celsius (known as dry ice). When CO2 is placed under high pressure (1071 psi) and a moderate temperature above 31 degrees Celsius, it becomes a supercritical fluid. Supercritical fluid is dense like a liquid and can dissolve solutes, but it is also like a gas with low viscosity, which makes solutes move fast and collide to react efficiently. We are testing scCO2 as a reaction solvent for chemical reactions involving different types of catalysts: zeolites, immobilized enzymes, and homogeneous transition metal catalysts. We are examining whether the reactions catalyzed by these catalysts are as efficient in scCO2 as in traditional volatile organic solvents, or better, and whether scCO2 has effects on the selectivity of the reactions.

Abstract Name: **Community Health Workers: Training Course Design and Testing**

Background: Montana has seen an increase in the Latino population – as much as 189% in some locations in the last decade. The rapid growth of this monolingual, Spanish-speaking population means that many health needs are not being met. As many as 80% lack health insurance. Promotores de Salud, or Community Health Workers (CHWs), are members of the community who are specially trained to provide a bridge between individuals and the healthcare system, thus closing the gap between the communities and healthcare. Currently, the Montana Office of Rural Health offers virtual training in English. No program exists for the Spanish-speaking community.Methods: Working in a multi-disciplinary team and with a trained promotora, we created and tested a Spanish-language Montana-specific online training course for CHWs. The course is four modules and meets nationally-established training criteria for CHWs. Trained promotores evaluated the course for content, accuracy, and acceptability using an online survey.Results: Overall, responses were positive, and respondents ranked our course as “better” or “much better” than a nationally-recognized virtual training course. However, some feedback suggested further edits and language refinement. Therefore, we hired one of the promotoras, a native Spanish-speaker from Peru, to revise the final product.Conclusions: The creation of this course will have a drastic impact on the public health of the Latino community in Montana. We anticipate our course will strengthen the Spanish-language public health workforce by increasing the number of trained CHWs and thereby increasing access to health resources. We expect to publish and disseminate the course in winter 2023.

Abstract Name: **Introduction and Progression of Early Algebra in the Beast Academy Comprehensive Curriculum**

As students progress through elementary mathematics curricula, arithmetic is the main point of focus. However, a call for algebra to become a component of the elementary mathematics curriculum has gained momentum because implementing algebra in early elementary curricula increases student understanding of algebraic concepts and eases the transition to deductive algebra later in mathematics. The Beast Academy comprehensive curriculum was developed with a focus on problem solving through monster characters in a graphic novel who demonstrate different ways of mathematical thinking. Beast Academy incorporates problems where students engage with algebraic thinking earlier than suggested in the Common Core State Standards and continues to incorporate problems which emphasize algebraic thinking through practice problems in subsequent levels. This progression introduces students to algebraic language while enhancing their current learning. We are interested in the trajectory of problems which build algebraic thinking as well as problems in which students are doing algebra. We will present our findings on how this curriculum introduces algebra to students, and how current literature suggests this will impact student learning outcomes.

Abstract Name: **From Transitions to Catastrophes: UNICEF and the United Nations at Cross-Purposes**

With an alarming rate of global increase in armed conflicts, environmental disasters, poverty, and exploitation, all intensified by the COVID-19 pandemic, the need for emergency international humanitarian action is more important than ever. Organizations like UNICEF have been successful responding to and alleviating the effects of humanitarian crises and are in a unique position to provide aid to victims of humanitarian emergencies.Although UNICEF has made extraordinary accomplishments in its efforts to provide aid to countries experiencing national emergencies, the UN is not as effective in its efforts to physically intervene in other states via peacekeeping. The official purpose of UNICEF is to promote and protect the rights of children and women everywhere; however there is a dichotomy between the official rhetoric of UNICEF and the actions of the UN's peacekeepers. For example, in countries like the Central African Republic, UNICEF has provided substantial aid which helped many women and children since the violence that erupted in 2013, but the follow-up UN peacekeeping mission had the opposite effects of enabling violence against the same women and children, further exacerbating the exploitation of those whom UNICEF had pledged to protect.This paper explores the tensions between UNICEF and UN peacekeeping actions. To examine these cases, I will utilize UN, UNICEF, and peer-reviewed scholarly sources to consider their quantitative and qualitative evidence and evaluations. Overall, this project hopes to reveal the tension between UNICEF and UN actions and ways to resolve these tensions, so that I can shed light on how the UN may more effectively pursue its human rights and security goals. By examining different examples of UNICEF's successes and failures where UN peacekeepers were present, this paper seeks practical solutions to the UN's overall challenge of providing emergency aid while protecting the rights of children and women.

Abstract Name: **A Python Program for Visualizing and Determining the Forces in a Statically Determinant Truss**

Solving for the internal and support forces of three-dimensional statically determinant trusses is straightforward though time-consuming. The solution process is algorithmic and well-suited for a computational approach. Using VPython and Python's Numpy linear algebra package, wehave created a Python program to calculate the forces in the members of a statically determinant three-dimensional truss, the support forces on it, and visualize them.The program reads an input file that contains the location of the joints, the members connecting the joints, the support structures holding the truss in place, and the external forces on the truss. The truss is visualized using VPython's rendering tools allowing the user to easily change viewing perspective. The members are color coded to indicate whether they are in tension, compression, or are zero-force members, which enables a direct qualitative observation of the stresses on the truss. Numerical results are saved to an output file and can also be displayed on the rendering of the truss. The result of this computational approach is a coherent display of the truss and the relevant forces obtained in an efficient manner, a result that would be tedious to obtain by hand.

Abstract Name: **Quantifying the Relationship Between Arbuscular Mycorrhizal Fungi and a Native and Invasive Thistle**

Our research explored the relationship between arbuscular mycorrhizal (AM) fungi and two prairie plants – the native Pasture Thistle (Cirsium discolor) the invasive Canada Thistle (Cirsium arvense). AM fungi associate with the majority of plants and assist in mineral nutrient uptake. In return, they receive photosynthetically fixed carbon from host plants. Their relationship with plants can be quantified by assessing dependence upon and responsiveness to AM fungi. Dependence is defined as the plant's inability to grow without AM fungi while responsiveness is the growth difference between inoculated and non-inoculated plants. We hypothesized that Pasture Thistle would have a stronger responsiveness and dependence on AM fungi than Canada Thistle because of the degraded mutualism hypothesis, which states that invasive species do not associate with local mutualists as closely as native plants. To test this hypothesis, we grew plants with and without AM fungi at ten different soil phosphorus levels, with twelve replicates per treatment. We measured the longest leaf length and height weekly, and after 10 weeks of growth, determined overall root and shoot biomass. We found that Pasture Thistle and Canada Thistle could both grow without AM fungi. Pasture Thistle was more responsive to AM fungi, growing 37% better when inoculated than when not inoculated, while Canada Thistle, showed a negative responsiveness. These results support our hypothesis that the invasive species would have a degraded mutualism with AM fungi. It is likely Canada Thistle lacks a strong relationship with AM fungi because it grows in disturbed areas where there is a low AM fungal presence. We also found that Pasture Thistle was most responsive at a soil phosphorus level similar to that in its native range, suggesting that it likely has a shared evolutionary history with AM fungi.

Abstract Name: **Increasing Age and Hypothyroidism: Heightened Risk for Older Gujarati and Rajasthani Indian Vegetarian Women Due to Extended Exposure to Phytoestrogens**

Subclinical hypothyroidism is defined by an elevated Thyroid-Stimulating Hormone (TSH) with normal levels of free thyroxine (T4). 11% of the Indian population is affected by hypothyroidism, which is alarmingly high when compared with the prevalence in other countries such as 2% in the UK and 4.6% in the USA. Although many external factors, such as cyanogenic compounds and the unregulated use of pesticides, contribute to this high prevalence, one contributing factor may be India's large population of vegetarians. This review aims to explore how both a vegetarian diet and increased exposure to this diet may heighten the risk for hypothyroidism.Plant-based proteins are extremely common in a vegetarian diet; soybean, in specific, is a popular and high-quality source of plant-based protein. Due to soybean's affordability and high protein content, India ranked fourth in the domestic consumption of soybean worldwide in 2021. Soy and soy-based products are a major source of isoflavones, which are a specific class of phytoestrogens. After reviewing literature published by experts in the fields of public health, nutrition, and endocrinology, a link between the consumption of phytoestrogens and an increased risk for hypothyroidism was found. To illustrate, studies on isoflavones indicate that phytoestrogens increase estrogen levels in the body. In addition, studies on hypothyroidism have found a connection between increased estrogen levels and the onset of hypothyroidism.Based on the stated studies, this research proposes that an increased exposure to a soy-centric vegetarian diet, among other external factors, may cause older Indian vegetarian women to be more susceptible to hypothyroidism. Due to these findings, more options and research regarding a balanced vegetarian diet and other protein alternatives should be considered by nutritionists and physicians.

Abstract Name: **Myeloid Differentiation in stat3 Knockout Danio rerio**

A significant portion of the United States population is affected by blood-based cancers. The American Cancer Society estimates that there will be about 20,050 new cases of acute myeloid leukemia (AML) in the year 2022 (Key Statistics for AML). AML is the rapid production of immature myeloid cells by the bone marrow, which lacks the typical myeloid cell functions of clearing infections or promoting tissue repair. Macrophages and neutrophils differentiate form myleoid progenitor cells. The developmental pathway of macrophages and neutrophils has been researched to produce new therapies and more effective treatments for AML. In previous experiments, the inflammatory protein granulin has been identified as an inflammatory factor necessary for myeloid cell development. The grna gene is the zebrafish ortholog to mammalian Granulin (GRN). Using bulk RNA sequencing, it was indicated that grna expression results in an upregulation of stat3 expression. Previous data has shown that grna knockdown using a gene specific morpholino significantly reduced macrophage and neutrophil numbers (Campbell et at., 2021). We expect to validate the morphant data with a mutant stat3 zebrafish line. I will utilize whole-mount in situ hybridization (WISH) and fluorescently tagged transgenic zebrafish witha mutant stat3 to visualize the number of myeloid cells produced. Myeloid cell numbers are expected to decrease with the loss of functional Stat3 expression, similar to that seen in grna mutant zebrafish. Understanding the pathway of myeloid cell production could lead to improved AML therapeutics.

Abstract Name: **Impact of a Short-Term Virtual Exercise Program on Various Bouts of Sitting during Overnight and Non-overnight Weeks among Family Medicine Residents**

Study Purpose: The purpose of the study was to examine the impact of a three-week virtual exercise program on the varying bouts of sitting behavior during overnight shifts week and non-overnight shifts week among family medicine residents. Methods: Thirteen participants ages 30.75 ± 3.98years were recruited and were asked to wear an inclinometer device on the mid-thigh of the non-dominant leg for 14 consecutive days (one-week overnight shifts and another week of non-overnight shifts). After the baseline monitoring was complete, a virtual interview was conducted with each participant to gather information about the current exercise habits and perceived exercise barriers. Based on the feedback from the interview, a three-week tailored exercise program was developed, and videoclips demonstrating the exercises were prerecorded. Participants were encouraged to incorporate the exercise program at least two days a week during the three-week intervention period. During the second and third weeks of the intervention period, participants were again asked to wear the inclinometry device. Descriptive statistics and paired samples t-tests were employed to examine the changes in various bouts of sitting from baseline to during intervention. Results: One participant withdrew from the study due to injury; therefore, 12 participants were included in the analyses. Paired samples t tests revealed no significant differences in varying bouts of sitting behavior between overnight and non-overnight shifts weeks as well as between baseline and during intervention (p .05). Conclusion: The findings of the study suggest that longer intervention period may be needed to change prolonged sitting bouts (greater than 2 consecutive hours of sitting) from baseline to intervention among family medicine residents. Understanding the varying bouts of sitting behaviors will help to provide participants with specific exercise intervention program that is tailored to reduce the bouts or prolonged sitting, either in an occupational setting or during leisure-time.

Abstract Name: **The Impact of Far-Infrared Technology on Quality of Life in Older Adults**

Identifying various methods of pain amelioration to meet the unique demands of older adults (OA) may be crucial to increasing the quality of life (QOL) of this population. The purpose of this randomized, single-blinded study was to examine the effects of far-infrared heat (FIR) on pain management and QOL in OA. FIR utilizes a long light wavelength that simulates dry sauna-like conditions. Examining the relationship between FIR and pain is important due to the increased prevalence of chronic pain associated with aging and the corresponding impact it has on QOL and physical performance. Nine OA completed the study, eight of whom were women. Participants were randomly assigned to either a convective heat group (CON) or a convective and far-infrared heat (FIR) group, with convective heat set to 60℃/(140℉). Participants received six, 30-minute heat sessions over the course of three weeks. Pre- and post-assessments included physical measures such as range of motion, gait speed, timed up-and-go, and hand grip strength. Standardized questionnaires were used to determine pain severity and its interference with daily life, and the impact pain had on overall QOL, using a five-point scale. T-tests were used to compare the groups' pre- and post-assessment measures. Results indicated that pain severity was significantly reduced (from 3.31 to 2.5, 0.05) in the FIR group from pre-to-post, and that pain interference was significantly reduced (from 1.26 to 0.43, 0.05) in the CON group from pre-to-post testing. No other significant differences were found. Findings suggest that heat therapy was successful in reducing pain over time, but that FIR heat specifically, was not superior to that of convective heat alone. Our results couldn't discriminate between the independent effects of FIR and convective heat benefits. Further research is required to properly identify the relationship between QOL and the use of FIR.

Abstract Name: **?-decay strength function of 54,52 Co and 55,53 Ni**

P process is believed to be responsible for the formation of heavy proton-rich nuclei in the universe. Because p nuclei are short-lived, the specific properties of their reaction and decay paths are difficult to measure. This work deals with the decays of four nuclei, 52,54 Co and 53,55 Ni. β+ decays for each isotope were recorded with the Summing NaI(Tl) detector at the National Superconducting Cyclotron Laboratory. A preliminary β-decay Intensity Function was derived with Total Absorption Spectroscopy. Total energy spectra, individual γ energy spectra, and multiplicity spectra for decays to levels in the child nucleus were modeled with GEANT4 based on information from the National Nuclear Data Center. The measured spectra, when fit with the simulated spectra, give the probability that a particular child level is populated during decay. Refined results, when compared to theory, will provide insight into the formation of p-nuclei elements.

Abstract Name: Artifice in Arden: An Ecofeminist Study of Shakespeare's As You Like It

In this project, I will examine Shakespeare's As You Like It through an ecofeminist lens. Despite decades of scholarship on questions of gender and ecology in the play, scholars have failed to combine those two concerns into a single line of inquiry. Ecofeminist theory provides precisely this combined method by illuminating at once the exploitation of gender and the objectification of the natural world. Famously, the main character Rosalind is exiled from the court into the Forest of Arden, where her father has also been exiled by his usurping brother. Rosalind disguises herself as a young man named Ganymede and eventually encounters her "crush" Orlando, who is also exiled in the forest, and a melancholy man named Jacques. Only in the play's final scene does Rosalind remove her male disguise, and most of the cast makes a triumphant return to the court, leaving the forest behind. The title of the play itself does not lend to a straightforward interpretation, for Shakespeare implicitly encourages audiences to derive meaning through whichever interpretations they deem best: as you like it. My project seeks to understand how, in Shakespeare's most famous play about gender and nature, the two mutually reinforce and depend on each other.

Abstract Name: Vision Guided Drone Flight

Drones are increasingly being used for reconnaissance, tracking, and inspection of locations that are difficult to access. Our team's research is to create increased autonomy for drone flight in physically confined environments. Our team is currently using the Tello EDU drones which can be programmed using the Python programming language. It, allows us to utilize OpenCV in conjunction with the Tello drone's built-in camera. The OpenCV software library is an Open-Source Computer Vision software. Computer Vision (CV) is the area within Artificial Intelligence (AI) that builds algorithms for computing machines to be able to make autonomous decisions based on visual data. OpenCV has built-in functions for a wide range of visual intelligence tasks including object detection. We're making use of April Tags which allows us to visually tag locations in physical space. Current work is focused on developing software for the drone which will enable it to fly through a gate to enter a confined space without collisions. In our research so far we have found that using the AprilTags to identify the border of the gate opening is an effective approach for guiding the flight path of the drone so it can enter the gate collision free. We, have also found that it is possible to incorporate YOLO, which is a CV algorithm for object detection for being able to identify objects within the field of vision of the flying drone's camera. Potential future uses for vision guided drones is the ability to navigate through environments and around obstacles to find people or objects of interest. The Tello drone's ability to fly as a swarm allows it to communicate with other drones, run tasks in parallel, to speed up task completion. Future research efforts will be directed towards swarming and task parallelization.

Abstract Name: **'Childish Platform' or Universal Medium: Making sense of Gen Z's SnapChat Attitudes and Usage**

In 2022, 44.5% of young people between the ages of 8 and 23 are Snapchat users. Snapchat usage for this generation is higher than all other platforms according to Statistica.While the majority of Gen Z uses Snapchat daily, there is a lack of extant research concerning how Gen Z uses and is affected by their Snapchat usage. Most research into social media use focuses on Facebook and Instagram given they have been the most used platforms until present times (Auxier; Anderson, 2021). As digital natives, Gen Z is used to building and maintaining relationships online. To better understand how Gen Z uses the Snapchat app to build and maintain relationships, this study sought to answer the question, " Why do people use Snapchat." To answer this question, we conducted a series of semi-structured interviews with 14 members of Generation Z. We utilized thematic analysis techniques (Nowell, Norris, White; Moules, 2017)to analyze the interview transcripts. The findings indicate that individuals continue to use Snapchat because it has been gamified (e.g., snap streaks, snap scores, story views, and emojis to indicate friendship closeness). That gamification has worked in conjunction with a fear of missing out to keep users interacting daily. Additionally, the analysis revealed that Snapchat users express a desire to move on from the app as they age, but continue to use it daily as it's the easiest way to maintain connections.

Abstract Name: **Single Mothers in Sitcom History, 1950-2010: Reflections of a Changing America on the Small Screen**

Since the popularization and standardization of episodic television formats, the sitcom genre has been a staple for American audiences, and within it the nuances of family life are frequently a central focus. By providing comedic exaggerations to relatable characters and circumstances, sitcom programs are unique points of access and comfort within which many viewers see their own lives and concerns reflected. My research attempts to determine whether depictions of single-mother households from episodic American sitcom television historically underwent noticeably different treatment by writers or audiences than other household dynamics did, and what may have contributed to these differencesif so. The foundations of this researchlie in an exploration of multiple popular American sitcom programs and their content across those decades, as well as previous research conducted regarding relevant events in television and feminist history from America's past. Through an examination of tropes and common themes in popular single-parent American sitcoms from 1950 to 2010, this analysis discusseshow changes in the common model for these shows over time– shifting focus from single fathers in unique scenarios, to realistic single working mothers– appear to have correlated significantly with the rise of feminist social movements, as well as actual shifts in household demographics, impacting their audiences over this period. Additional research on this topic could provide crucial insight regarding the relationship between sociology and mass media– specifically, how negative societal attitudes regarding women and single parents may have been reinforced by situational comedies in American history.

Abstract Name: Intersectionality Between The Black Community and COVID-19 Testing

There is a long history of exploitation of minoritized communities, specifically the Black community, at the hands of the US Healthcare system which has led to medical mistrust in the Black community. COVID-19 has significantly highlighted these disparities between racial and ethnic groups. Black communities are especially susceptible to diseases which affect the heart, lungs, kidneys, and gastrointestinal tract, which are the organs which harbor the angiotensin converting enzyme 2 (ACE-2) receptor. This receptor is attacked by the COVID-19 virus making individuals who already have underlying conditions more likely to develop serious health consequences. The purpose of this study was to investigate the differences between different racial groups and their participation in a free COVID-19 testing site in a suburb of Oklahoma City. It was hypothesized that there would be a significant difference in the number of Black Americans who would choose to be tested because of distrust of healthcare systems. Demographic data were collected from the testing site, deindentified, and then aggregated by race and ethnicity to determine the racial makeup of patients within the sample. The hypothesis was not supported as the percentage of Black Americans who accessed the testing site (5.82) was larger than the percentage of Black Americans living in the surrounding community (4.5). The limitations of this study were that data were only collected at one site and the site did not specifically target Black Americans as participants. In conclusion, despite other research findings supporting Black American mistrust, this study found that Black Americans were willing to be tested for COVID-19. This opens the door for other studies to examine Black American attitudes toward healthcare as it relates to social well-being.

Abstract Name: The Impact of Genre on Electrical Responses during In vivo and In vitro experiments.

Music has been proven to elicit autonomic responses in human cells such as cell viability, cell motility, and skin conductivity. While numerous music-based studies are generalized and address the emotional response a person may exhibit, there is limited research addressing the effect of varying musical genres on the electrical activity of the human body. Our study aims to unveil the influential impact that musical selections may have on skin conductivity, cell viability, and cell growth in bovine brain artery endothelial cells (BBAECs). We hypothesize that musical genre and tempo will impact the body's electrical response, as well as cell viability and growth in BBAECs. To test our hypothesis, we developed a musical playlist of three songs within three distinct genres: classical, gospel and rock. Each song was played for 120 seconds, alternating with a 120-second quiet period at the beginning and end. For in vivo experiments, electrical activity was analyzed via skin conductivity using a Q-S222 galvanic skin response (GSR) sensor. For in vitro experiments cell viability and cell proliferation were determined based upon each genre. Our GSR results revealed that Rock was 2.43 ± 0.17 μS, Classical was 2.23 ± 0.18 μS and Gospel was 3.08 ± 0.51 μS. While one of the Gospel songs had the largest tempo, it did not demonstrate the greatest GSR. Regarding the BBAECs, the cell viability and growth was more significant in the presence of music as a whole. Understanding this information, we can elucidate how specific genres elicit electrical responses such as brain activity and cerebral brain flow.

Abstract Name: **Religious Counselors and Cultural Competence: When Beliefs Collide**

Individuals with a fundamentalist religious orientation respond defensively to challenges against their religious beliefs(Abeyta; Blake, 2020). Individuals who are intrinsically religiously oriented are internally focused and help others based on their own values, whereas quest-oriented religious individuals are altruistic and act based on the values of those they help, (Batson 1976, Batson et al., 1989). Researchers aim to understand the relationship between orientations of religiosity and counselors' perceived multicultural competence with clients. In this exploratory mixed-methods study, 35 counseling students and alumni from a small midwestern religiously affiliated college completed a survey with open-ended questions and scales. The short answer questions ask about faith, experiences in clinical training, and counseling practice. Participants completed the 12 Item Quest Scale (Batson; Schoenrade, 1991), Revised Religious Orientation Scale (Gorsuch; McPherson, 1989), Multidimensional Cultural Humility Scale (Gonzalez et al., 2021), Lesbian, Gay, Bisexual, and Transgender Development of Clinical Skills Scale (Bidell, 2017), and Fundamentalism Scale (McFarland, 1989). Researchers discovered participants who score themselves as fundamentally oriented and see religion intrinsically, score highly in self-awareness. Participants who score highly in quest orientation score highly in competence to work with LGBTQ+ clients. The results were: significant positive correlations between intrinsic and fundamentalist (N=29, r= 0.646, 0.000), fundamentalist and self-awareness (N=29, r= 0.416, 0.25), quest and LGBT DOCSL (N=35, r= 0.384, 0.04), as well as significant negative correlations between fundamentalist and quest orientations (N=29, r= -0.595, 0.001). Qualitative responses indicated that counselors who wrestle with their religious beliefs are more willing to engage clients' values. Conversely, religiously certain counselors displayed more internal conflict and less confidence when helping clients with differing beliefs. These initial results support Abeyta and Blake's (2020) findings that those who are more fundamentalist and intrinsically oriented help others according to personal values.

Abstract Name: **The Impact of COVID-19 on the United States Household Activities**

This study examines (1) How household activities were affected by COVID-19, (2) How COVID-19 affected activities in a U.S. home by gender, and (3) How the U.S. home improvement was affected by the COVID-19 pandemic restrictions. Using data from publicly available secondary sources such as the U.S. Bureau of Labor Statistics and the U.S. Census Bureau; we find that lockdowns in response to the COVID-19 pandemic significantly impacted household activities and the home improvement market. Household activities increased by 12 percent in 2020, while work-related activities declined. Besides sleeping, the most common household activity was food preparation and cleanup which increased by 3 percent in 2020. Some of these activities were more common in specific genders. Men spent 54 percent more time on lawn and garden care, while women spent 11 percent more time on housework and 12 percent more time taking care of children within the household. When looking at married fathers and mothers, we find that married mothers had a 9 percent decrease in work-related activities, while married fathers had a 27 percent increase. Married mothers had a 40 percent increase in leisure and sports activity when compared to pre-pandemic levels, while fathers only had an 8 percent increase. However, changes in these household activities were temporary and reversed in 2021 to almost pre-pandemic levels. Do-it-yourself (DIY) projects surged in popularity from the lockdowns, and average retail sales of building materials and garden equipment increased by 12 percent in 2020. The sudden demand for these materials combined with a decreased supply caused by a global supply chain crisis, led to producer softwood lumber prices to increase by 121 percent in 2021.

Abstract Name: Role of Motivation on Academic Success

The collegiate world is constantly discussing how student motivation is related to student success. How true is this correlation? Does the motivation importance change with the specific course or the format the course is taught in? Can the institution or instructor impact the student motivation level by understanding intrinsic and extrinsic factors that motivate students? The aim of this study is to determine what motivation in education is and how it impacts the academic success of college students. Factors that will be studied include intrinsic and extrinsic motivation factors, academic performance, familial college experience (1st generation students vs non 1st generation students), and the role of the institution and faculty. The study will be completed through a survey with a battery of questions adressing all the key areas mentioned above. Demographics will also be collected to compare possible inter-group differences. Correlational analysis will be completed through data collection in the spring semester of 2023.

Abstract Name: IceAct Prototypes Toward an Imaging Air Cherenkov Telescope Array at the South Pole

IceAct is a proposed array of small and cost effective imaging air Cherenkov telescopes situated at the IceCube Neutrino Observatory at the South Pole. Since January 2019, two prototype IceAct telescopes have been taking data during the South Pole winters. Four years of data-taking experience has taught us much about how these telescopes perform in the harsh South Pole environment. Here we will detail the lessons-learned and ongoing research and development efforts to update these prototypes for future Polar seasons.

Abstract Name: **China's 1994 Tax Reform- Fiscal Re-centralization in a Post-Planned Economy**

The 1994 tax-sharing system, or fenshuizhi, helped propel China into a modern era of fiscal management. New policies that opened China's economy to the world allowed markets to thrive, but during a time of rapid growth, the central government was financially floundering. Previous administrations funded government budgets with highly centralized profit-turnover systems and inconsistent fiscal contract arrangements throughout the country, but the decentralization of China's economy left the central government unable to tap into the new economic growth. China's central government had a massive deficit and severe corruption. To avoid a financial crisis, a Tax Sharing Reform was introduced in 1994, providing new revenue sources and re-centralizing fiscal management.The 1994 reform separated local and central taxes, so each level of government could achieve better cooperation within its respective sector. This significantly reduced fraud and bias of income distribution that previously suffocated the central government. Furthermore, it provided both provinces and the central government with adequate revenue to fund essential expenditures. The tax-sharing reform resulted in a better-balanced distribution of government resources so the government and the people could benefit from the flourishing economy.

Abstract Name: **Discriminant Analysis of NSSI Characteristics and Risk Factors for Suicide**

Non suicidal Self Injury (NSSI; intentional injury to body tissue without suicide intent) is prevalent among college students. Many studies have supported a strong association between NSSI and suicidal behavior, above other common risk factors such as hopelessness and impulsivity. Current research is working to identify potential typologies of suicide risk to better inform prevention (Dhingra, et al 2016; Martin, et al 2020), but most focus only on cognitive risk factors and utilized self-reports. To best identify typologies, NSSI and behavioral measures of risk factors should be included. The purpose of the present study is to examine which combination of NSSI characteristics and known suicide risk factors best differentiates severity levels of suicidal behavior. The sample for the present study came from an archival dataset of a longitudinal study of NSSI and suicide risk in 420 college students with a history of self-injury (Mean age = 18.92, SD = 1.38yrs; 83.9% Female; 91.8% White). Assessments of attentional bias to suicide, NSSI characteristics, suicide ideation, suicide attempts, fearlessness about death, depression, hopelessness, and impulsivity were collected using online self-report and reaction time measures. Past year frequency of NSSI was 9.19 (SD = 16.40 acts), and 60.6% reported having made a suicide plan or attempted suicide (36.2%) in their lifetime. We will run a Discriminant Analysis to identify which combination of risk factors best differentiates those with severe to less severe risk for suicide ideation and attempts. We expect to find several clinically significant severity subgroups based on the risk factors analyzed (e.g. those with high NSSI frequency, hopelessness, and attentional bias to suicide will be in the attempt group vs. Ideation group). Results from the current study can be used to identify the most salient risk factors for clinical risk assessments, and to guide prevention/interventions.

Abstract Name: **Understanding the Contributions of Hormonal Contraceptives and Cortisol Levels to Fear Learning in Women**

Women who use hormonal contraceptives show heightened startle reactivity to a threatening stimulus. Previous results from our lab showed a significant increase in fear-potentiated startle (FPS) in women who were on hormonal contraceptives compared to women who were naturally cycling. These results stayed consistent throughout three acquisition trials. Others have shown that the use of OCPs (oral contraceptive pills) is related to the dysregulation of the HPA-axis and elevated circulating cortisol levels. Cortisol dysregulation is strongly associated with fear and anxiety, and individuals who have experienced stress and trauma often show dysregulation of the HPA-axis including cortisol abnormalities. The aim of the current study is to use the fear-potentiated startle (FPS) paradigm to examine the relationship among women's hormonal contraceptive use, cortisol levels, and fear learning. The FPS paradigm is well established as a noninvasive tool to measure amygdala activity and characterize biological correlates of fear learning. FPS measures startle amplitude (μV) in the presence of a reinforced conditioned stimulus (CS+) that is paired with an unconditioned stimulus (US), as well as during exposure to a non-reinforced conditioned stimulus (CS-) that is not paired with a US. In the current study, participants were divided by hormonal contraceptive use including women who were naturally cycling and women who were currently using hormonal contraceptives. Participants underwent three acquisition trials to measure their fear learning. Saliva was collected at baseline and after acquisition. Saliva samples were analyzed using ELISAs to measure cortisol levels at each time point. Data will be analyzed to determine the influence of cortisol on the established relationship between fear learning and contraceptive use. Results from this research have the potential to help identify the biological bases of pathological fear learning processes that contribute to an elevated risk of anxiety disorders in women.

Abstract Name: **Visualizing Utah Lake Nutrient Concentration using GIS-Remote Sensing Analyses**

Utah Lake, one of the largest freshwater lakes west of the Mississippi River, has been experiencing harmful algal blooms (HABs) in recent years. These blooms produce a cyanotoxin that poses a health risk to the ecosystems and people living near the lake. HABs have been linked to excessive nutrient loading in lakes and reservoirs. There are various nutrient sources in Utah Lake, including nutrients from tributaries, surface runoff, effluents, stormwater, groundwater, and atmospheric deposition. The objective of this study is to use nutrient measurements and remote sensing imagery to examine any potential correlations between nutrient concentration and HABs distribution in the lake and to visualize how the HABs vary spatiotemporally. Measurements of ammonia, nitrate, nitrite, and phosphate were conducted over the course of a 5-week period in the summer of 2022 as well as 1 week of on-lake sampling. The measurements were used to interpolate the nutrient concentration in the entire lake. The interpolation maps were then compared against a band ratio from Landsat satellite imagery which is a good indicator of levels of chlorophyll a, a pigment-protein within algal blooms. These interpolation maps were also compared against an interpolation map made of phycocyanin concentrations, another pigment-protein within algal blooms, measured at each sampling site. The preliminary results have shown the highest correlation between phosphate and nitrite concentrations to the algal blooms in Utah Lake. The highest concentration measured was 2.96 mg/L of phosphate at the Hobble Creek downstream sampling site, the next two highest at 2.29 and 2.17 mg/L were also phosphate measurements taken at downstream sites. The nutrient with the highest average concentration was nitrate with an average of 0.46 mg/L. Observations from this study could be beneficial for decision-makers to prioritize the areas for HABs management and establish in-lake nutrient standards to minimize HABs occurrence and frequency.

Abstract Name: Mental Health In Athletes

Athletes who are in higher education, collegiate athletes, are individuals who can struggle with addressing concerns related to their own mental health. Athletes can develop these ailments due to their environment: self-esteem stigmatization, sport-related injuries like concussions, influences from coaches, their view on social status, and even overtraining. This research examines the effectiveness in outreach programs and the outcomes from having a mental illness as well as correlational factor of stress. In an attempt to analyze athletes and their stressors, a survey was directed to those who participated in sports. The search for a correlation between coaches and causes of stress, questions were asked in a survey related to athlete stress and relationship with the coaching staff. The participants responded with 'probably yes' and 'probably not'. This showed that athletes were prone to facing stress at an average and above-average level. Stressors and rehabilitation in athletes are reported to have been extremely difficult. Results reported back that athletes definitely struggle to reach out to others. The group also searched for solution rates regarding outreach encouragement with peers and coaches. The report shows a vast majority responded that they weren't encouraged by others. The results showed that mental illness is potentially still a hidden topic across the sports world. This study aims to help support the research that collegiate athletes do experience mental ailments and that these ailments are caused by many factors: the responsibilities of training and overcoming challenges, the consequences of injuries, and advice from coaches or peers.

Abstract Name: The Role of the Urban Built Environment in Breast Cancer Mortality Health Disparities

Breast cancer is the second-leading cause of cancer-related death among women in the United States, but mortality rates vary across the population. Previous studies use individual and county level data to examine the association between breast cancer mortality and various socio-demographic and environmental variables. However, global regression models assume spatial stationarity meaning that associations between explanatory variables and breast cancer mortality are the same across geographic space and scales. Therefore, the objective of the study is to use county-level data that describes the social and built environment across the contiguous United States to explain breast cancer mortality rates, as reported in the Surveillance, Epidemiology, and End Results (SEER) database, using a multi-scale geographically weighted regression model (MGWR) that accounts for spatial heterogeneity. We compare our MGWR model with a baseline global linear regression model (OLS). The MGWR outperformed the global linear regression model with an adjusted R2 of 0.91, explaining about 43% more variance than the OLS. The R2 for each county is high in the western part of the US and decreases towards the east. In comparison to global linear regression, MGWR had the same overall trends in terms of relationships between explanatory variables and mortality. For example, as mammogram screenings, health food index, and primary healthcare physician ratio increased, breast cancer mortality decreased. However, MGWR reveals spatial heterogeneity associated with the magnitude and direction of each relationship across counties. Such an approach allows for greater consideration of where certain variables are most influential in breast cancer mortality allowing for location-specific interventions.

Abstract Name: Social Power Impacts The Decision of the Verdict; The Bobby Dunbar Case

The disappearance of Bobby Dunbar is an unsolved historical mystery. Bobby Dunbar was a child who went missing in August 1912. His parents, Lessie and Percy, searched for months and found a similar-looking child named Bruce Anderson. Bruce Anderson had moles and scars identical to Bobby Dunbar. Lessie and Percy Dunbar sued in court that Bruce Anderson was their child—that Bruce Anderson was Bobby Dunbar. The Dunbars were awarded custody of Bruce Anderson, who was removed from the home of his unmarried mother. This case provides evidence that social power and worth will sway a verdict toward the most powerful. This paper examines the literature on social justice in adoptionas well as on the relationship between poverty, child welfare, and adoption. Applying this research, this paper analysis newspaper accounts of the court proceeding to argue how the newspapers' reports influenced the outcome of the case by ruling in favor of the Dunbars. Newspaper articles portrayed the Dunbars as fit parents due to their money and social class, while portraying Julia Anderson as unfit due to the nature of her being in poverty. A close reading of these reports shows that the social class that you are put or born into becomes a part of your identity. This “identity” is how the world views you.

Barnes, Phoebe

Abstract Name: Transgender Patient Outcomes and Education

Transgender (trans) patient outcomes are some of the worst outcomes out of all patient populations. Current documentation shows that trans outcomes are especially low due a multitude of factors including but not limited to: transphobia, refusal of care, inadequate care, discrimination, and homelessness. While there are many studies covering trans mental and physical health outcomes and risks, there is little to no information regarding how trans patients can improve their health outcomes themselves. This proposal aims to improve trans patient outcomes by empowering them through means of education. This will be done by first evaluating trans participants baseline knowledge regarding trans health risks and care via a pre-presentation survey. The survey will also evaluate participants' confidence levels and concerns regarding seeking healthcare. Afterwards, participants will be provided an educational presentation containing information from this literature review in addition to information on how they can advocate for themselves and better navigate the healthcare system. Lastly, participants in this study will fill out a post-presentation survey which will evaluate how confident participants feel regarding navigating the healthcare system and their ability to advocate for themselves. Participants will also be provided an educational pamphlet that summarizes the presentation's information. Because this proposal primarily focuses on improving trans patient outcomes by means of education and self-advocacy, this proposal study will use a practice-based approach inspired by Petry et al. (2020) article as it provides information on how individuals can best advocate for themselves in everyday life.Keywords: Transgender outcomes, transgender, education, empowerment, self-advocasy, health outcomes

Abstract Name: **Engaging Undergraduate Students with Animal Assisted Therapy Activities, Outreach, and Research**

Animal Assisted Therapy (AAT) is a recent phenomenon in the research literature with the first reports appearing just over 20 years ago. The current and popular trend of embedding certified animals into the higher education system is based on the overwhelming popularity of the practice and on the positive outcomes of research endeavors related to the activity.
This presentation will be a discussion of how the AAT program at the University of Central Oklahoma Department of Nursing has been shown to be an effective strategy to improve the mental outlook and modify stress of students and faculty. Not only does AAT provide modify stress, it provides opportunities for students to engage in research, conduct independent research, and assist in the care and management of the dogs. This is hands-on approach is a very effective approach to teaching research methodologies, and helps students learn the importance of complementary and alternative health interventions.
Topics to be addressed in this talk include barriers to animals on campus as well as the expense associated with such programs. Although the dogs initially arrived on campus Fall of 2019, the pandemic prohibited the practice of AAT for the next 18 months. Once restrictions were lifted, the program began to develop quickly, with undergraduate research students given an option to do AAT research. Acquisition of grant funding to add a dog to the team led to a group of students who participated in training and socialization of the new dog. This spring will be the second-year students will be presenting evidence-based practice and/or research findings that involves the AAT Dogs.

Abstract Name: **How Historical Nuclear Energy Policy Differences Between France and Germany Connect with the Current Energy Crisis**

Nuclear energy will not be the optimal long-term sustainable alternative to coal or natural gas as an electricity source to reduce carbon-dioxide emissions unless it is tied with the improvement of other renewable energy sources. In this research, I assess the historical divergent nuclear energy policies found in France and Germany as a case study. Though both share similar resource and geographic positions, after World War II the European Steel and Coal Community was proposed to integrate Germany into the rest of Western Europe setting the two countries on very different paths regarding how they would ultimately choose to pursue nuclear energy policy. Moving to present day, I exploit the continued differences in nuclear policy due to the 2008 Financial crisis and the current Russian-Ukraine War to explain that the two countries' not integrating their nuclear policies benefits not only themselves but also the European Union, contrary to popular opinion. Current nuclear energy research exalts the electricity generation abilities of nuclear power plants and their environmental benefits for good reason, however, the existing and possible risks caused by nuclear power plants is extreme enough for a re-analysis to occur. These findings suggest that nuclear energy policies should remain a country-by-country decision and not focus on integration, but on the improvement, advancement, and accessibility of fully renewable energy sources such as wind, solar, or hydropower as well as maintaining nuclear resources.

Abstract Name: **Electroanalytical Performance of Antimony Modified Glassy Carbon Electrode in Detecting Lead and Cadmium**

Metals such as lead and cadmium are some of the most dangerous pollutants that can be found in the environment. Due to past human activity, lead had leaked into the environment from gasoline and lead-based paints. Lead poisoning can cause many adverse health effects in humans especially in the neurological development of children. The Environmental Protection Agency (EPA) has a set limit as to how much lead and cadmium are permitted in water sources, which are 15 and 5 ppb for lead and cadmium, respectively. The work that will be presented utilizes a glassy carbon electrode (GCE) modified by electrochemically depositing antimony (Sb) using chronoamperometry technique. In detecting lead and cadmium, the analytical performance of the modified electrode was evaluated using differential pulse anodic stripping voltammetry. The analytical performance of the modified electrode was evaluated in terms of linear dynamic range, sensitivity, response stability, and limit of detection. The developed method using the Sb modified GCE (Sb-GCE) exhibited good analytical performance, for example, the linear dynamic range was 0.1 – 100 ppb and 1 – 100 ppb for lead and cadmium, respectively. The limits of detection for lead and cadmium were 0.1 and 1 ppb, respectively, way below the EPA recommended levels. In future research, experiments will include ways to improve the response stability of the Sb-GCE surface which for lead is 7.3 % and that for cadmium is 5.4%. The developed method will be applied for real sample analysis of lead and cadmium in soil and water samples obtained locally.

Abstract Name: **The Narration of a Nation: Historiography, Literature, and the American Dream**

The American Dream is a narrative that acts as an intrinsic element to the development of the U.S. While it is an ever-present national ethos, little is understood about the history and background of the Dream, and why it was created. This project will examine the role of James Truslow Adams' idea of the "one eye shut" version of history -- ignoring the stories of the many in order to uphold the illusion of hard work as the only requirement for social and economic uplift-- and its role in the development of the American Dream. I investigate the impact of these narratives of the nation in the lives of those ignored, as these narratives emerge in the select texts of contemporary authors. This literature reveals the effects of the American Dream, and establishes that this national narrative is one that contributes to systems and cycles of oppression and exploitation. This project will not only reveal greater information about this national ethos and illuminate its troubled past, but also create a more comprehensive, "both-eyes-open" version of American history, literature, and the stories we live by.

Abstract Name: **Developing a Lesson Plan for Analyzing Sand Dunes Utilizing the Pythagorean Theorem and Estimating Vegetation Percentages**

High Needs School Districts (HNSDs) often have higher populations of low-income students who might have limited exposure or access to STEM compared to their non-HNSD counterparts. As a result, teachers in HNSDs need to make STEM more accessible to and equitable for their students. Citizen science has been found to be one such method to make science more accessible and inclusive. Thus, the purpose of this project was to develop a citizen science lesson plan that would make scientific content more relevant and accessible to high school students for two pre-service STEM teachers. This project was an interdisciplinary and collaborative effort between an Environmental Science Teaching major and a Mathematics Teaching major to develop a citizen science lesson plan on coastal dune topography and beach vegetation. The lesson plan integrated topics from Mathematics such as the Pythagorean Theorem, and topics from Environmental science such as coastal morphology and coastal marine botany. Prior to developing the lesson plan, the STEM teaching majors engaged in fieldwork on sand dunes in Pensacola Beach in Florida to help them frame the lesson and identify what specific activities students taking this lesson would be engaged in. The STEM teaching majors were able to develop a lesson plan in which students would use the Pythagorean theorem to plot the topography of sand dunes and would correlate the topography with their findings of different coastal vegetative species along the survey area of the dune based on knowledge of these species provided to them prior to the field experience. The primary objective of this project was to make STEM more inclusive by developing learners' understanding of coastal environments and the vital roles they play in our local communities using an interdisciplinary experiential approach.

Abstract Name: **Spokes On a Wheel: Activities of the UAW in a Time of Crisis**

During the late 1970s and early 1980s, the American automotive industry faced unprecedented competition from Japanese automotive companies. Companies such as Toyota and Nissan were importing automobiles into the country at ever-increasing numbers, while the Big Three car companies—Ford, GM, and Chrysler—tried in vain to bounce back from falling profits. Coupled with a larger economic context of inflation and increased oil prices, Japanese companies spent this period effectively dethroning the Big Three Detroit car companies that had enjoyed decades of superiority in the auto industry.While American car companies floundered, perhaps the biggest blow of the whole phenomenon was dealt to the American auto workers. Auto workers faced layoffsin increasing numbers, and as years passed with little employment opportunity in sight, they faced the serious threat of dried up unemployment benefits and eventual poverty. So, when corporate could not be called upon for aid, they turned instead to the labor union. The United Auto Workers union spent the entire periodin question, from about 1979to 1985, advocating for extendedaid for auto workers as well as for expanded support from the federal goverment. Two members of the UAW worth particular attention are Douglas A. Fraser and Donald Ephlin, President and Vice-President respectively of the UAW during this period. Both Fraser and Ephlin advocated for the support of auto workers during this period. From a cursory glance, however, it would seem as though Fraser and Ephlin were not on a united front—but they in fact were.Although Fraser and Ephlin pursued different, various tactics over this period, all of their efforts went towards the largergoal of supporting auto workers. This presentation will illuminate and analyze various endeavors undertaken by Fraser and Ephlin, looking at how they, though seemingly disparate,connect to each other and the UAW's larger goal.

Abstract Name: Subsurface Imaging of a Mass Grave: An Investigation within the Old Jewish Cemetery of Riga, Latvia

Over 6 million Jewish lives were lost due to the killing by Nazi authorities and their collaborators during World War II. More than 70,000 local and transported Jewish people from around Europe were executed in Latvia alone. The objective of the project is to locate the unmarked mass grave of 800 to 1000 Jewish prisoners. These prisoners were murdered by Einsatzgruppen members and Latvian collaborators in the streets of the Riga Ghetto, as they were on a forced death march to Rumbula, where they were to be executed on November 30, 1941. According to survivors' testimonies, the Old Jewish Cemetery is the place where Jewish prisoners that could not make it to Rumbula were killed. Based on electrical resistivity tomography (ERT) and ground penetrating radar (GPR) data collected earlier, anomalies were detected that could be interpreted as burial graves. Addition GPR data was collected to further solidify the interpretations. The GPR method sends electromagnetic pulses into the ground and records reflections off contrasts in the surface. A 10mx40m grid was laid down to examine the ground. A total of 160 lines 0.25m apart were collected with a Sensors and Sofware pulseEKKO Pro GPR system using an antennae frequency of 500 MHz with a step size of 0.02m triggered by an odometer wheel. The data was then process through pulseEKKO_Project 5 software. Collection of topography using the Topcon RL-H4C laser leveler and light detection and ranging (LiDAR) were used to examine the surface. The results of data collected by GPR indicates multiple subsurface disturbances in the location of the old wall, located in the corner of the park right next to Tejas and Virsaisu Streets, these subsurface disturbances are indicative of a mass grave. Further studies, such as aerial photography and additional GPR collections are suggested to determine an exact location.

Abstract Name: The Future for Assisted Suicide in the U.S

In the United States, 10 states have legalized physician assisted suicide for individuals diagnosed with a terminal illness. This prolongs constant debate between American's on whether physician assisted suicide should be a constitutional right in the United States or not which is a current and longtime controversy within the nation. The purpose of this study is to examine American's views on whether physician assisted suicide should be legal or illegal throughout the United States. I hypothesized that there is a difference in views regarding who is more accepting of physician assisted suicide as opposed to those who are against the process based on gender, age, and political party. To test this hypothesis, I conducted a 15-question survey and administered it using 'Survey Monkey' and 'Amazon MTurk'. My sample consists of 193 respondents in the United States over the age of 18. I found that there is a statistically significant difference in response regarding physician assisted suicide based on gender, party affiliation, and age. Specifically, I found that those who are 50 years old and over are more in favor of physician assisted suicide yet still believe it violates the ethical norms of the physician. I have also found that registered Democrats are more in favor of physician assisted suicide in comparison to registered Republicans, independents, or those affiliated with another political party. In conclusion, a vast majority of recipients support the idea of physician assisted suicide; therefore, policy makers should look to legalizing the process in more states throughout the country.

Abstract Name: Comparing the Association Between miR-181c, a Novel Population-Specific OncomiR, and Aggressive Tumor Biology in African American and European American Kidney Cancer Patients

Background: Renal cell carcinoma (RCC) is the most common type of kidney cancer (85%), and has the lowest survival compared to all other urologic cancers. There are three distinct RCC subtypes: clear cell (75%), papillary (15-20%), and chromophobe (5%). African American (AA) RCC patients have worse advanced-stage survival than European Americans (EAs), possibly due to aggressive tumor biology. microRNAs (miRs) and miR isoforms (isomiRs) silence mRNAs by preventing translation, and drive different mRNA expression signatures associated with invasiveness and metastasis. It is unknown if these transcriptomic signatures vary by race in RCC patients. Hypothesis: Population-specific isomiRs are associated with racial differences in aggressive tumor biology.Study Design: miR-seq, isomiR-seq, mRNA-seq, and clinical data were downloaded for AA and EA RCC patients in the pan-RCC TCGA discovery cohort (n = 121 AAs, n = 708 EAs). The PGS miR Expression Workflow, R, and cBioPortal were used to determine differentially expressed (DE) miRs, isomiRs, and mRNAs by race (P <0.05). isomiR expression inclusion criteria were ≥3 reads per million (1: low specificity and high sensitivity; 5: high specificity and low sensitivity) and abundant in ≥50% of patients (n = 415 patients). Results: miR-181c was significantly DE in AAs and EAs across all RCC subtypes (ccRCC: P = 1.01e-7, pRCC: P = 0.032, chRCC: P = 0.045). A total of 4/14 miR-181c isomiRs had significantly higher expression in AAs compared with EAs. High miR-181c-3p|5't-13,3'a-14| expression in AAs was associated with lower CDH1 expression. Low CDH1 expression is linked to EMT and poor RCC survival across subtypes. Conclusion: miR-181c-3p|5't-13,3'a-14| may be a novel oncogenic isomiR and biomarker of aggressive tumor biology in AA RCC patients. Clinical targeting via isomiR sponges would increase CDH1 expression and potentially reduce racial disparities in survival. Future Directions: Replicate these findings in pan-RCC patients in the CHTN/Geisinger validation cohort.

Abstract Name: The Wisconsin Council on Undergraduate Research: Working Together to Promote and Support Undergraduate Research, Scholarly and Creative Activities

Undergraduate research, scholarly, and creative activities (URSCA) have a long history in the University of Wisconsin System (UWS). Since 1999, various system campuses have hosted the UW System Symposium, an annual gathering modeled after the National Conference on Undergraduate Research. It brings together undergraduate researchers, their mentors, and program coordinators to showcase the accomplishments of and celebrate URSCA. With the support of a National Science Foundation grant awarded to the Council on Undergraduate Research to institutionalize undergraduate research at the system/consortium level, the Wisconsin Council on Undergraduate Research (WisCUR) was formally launched in 2013.The group initially consisted of URSCA program leaders and advocates from UWS institutions. Recently, its membership expanded to include private universities and technical colleges in Wisconsin. Its mission is to provide leadership to advance, enhance, and expand URSCA across the UWS and beyond in order to prepare graduates who can adapt and innovate for the challenges of the future. Since the inception of WisCUR, URSCA programs within the WisCUR network have made great strides. For example, three UWS schools (UW-Eau Claire, UW-La Crosse, and UW-Milwaukee) have won the Campus-Wide Award for Undergraduate Research Accomplishments (AURA). No other state system has received the honor of receiving multiple AURA awards. Partly due to its involvement with WisCUR, Concordia University developed an undergraduate research certificate program and Madison College created an undergraduate research program.Wisconsin higher education institutions have also faced a variety of challenges that require innovations and adaptations, and WisCUR has served as a resource and support in this area. In this presentation, we will share the organization and goals of WisCUR, typical activities (beyond UWS Symposium) we sponsor, and benefits of WisCUR to individual institutions and staff therein. We will provide suggestions on how to organize similar URSCA groups and invite attendees to share their experiences.

Abstract Name: **Liberty and Justice for All? Gender Differences in Emotional Reactions and Perceptions of Safety in Response to the Overturning of Roe v. Wade**

The recent, controversial overturning of Roe v. Wade has impacted the bodily autonomy and resources of American women. Previous studies identify negative emotional responses such as anxiety, fear, and anger in individuals impacted by laws that limit bodily autonomy, such as abortion restrictions and bans on gender-affirming care (Harris et al. 2014; Abreu et al. 2021). Though previous research has examined negative emotional responses to other laws restricting bodily autonomy, no research to date has investigated these responses in regard to the overturning of Roe v. Wade. Additionally, less is known about how gender influences individuals' emotional responses to this ruling or how laws restricting bodily autonomy impact college students. This study aims to compare perceived stress, anxiety, fear, anger, and feelings of safety between men and women in response to the overturning of Roe v. Wade. Participants will consist of 100-120 college students enrolled in psychology courses who will complete modified versions of questionnaires including the Perceived Stress Scale, Positive and Negative Affect Scale, Rosenberg Global Self-Esteem Scale, and a Likert-type measurement of safety perceptions after reading a description of the history of abortion rights and recent overturning of Roe v. Wade. The IRB has approved this study. Data collection is currently underway and will be completed by December 2022. T-tests will be used to examine differences between men and women. It is hypothesized that both men and women will express negative reactions, but women will express stronger negative reactions with the highest negative response to perceptions of safety. This research will increase understanding of college students' emotional responses to the overturning of Roe v. Wade and may be useful to college campuses as they reevaluate the quality and quantity of resources to support students affected by this ruling.

Abstract Name: **How Bemidji Area Businesses Attract and Retain Employees in a Job Loss Crisis**

The COVID-19 health crisis continues to have considerable economic and market consequences (Stuart, et. al., 2020), including for the Greater Bemidji Area. In this 30-mile radius encompassing the City of Bemidji, there are 3,859 businesses who collectively employee 39,257 people, and these businesses are struggling. Restaurants and other businesses have closed (Bemidji Pioneer, 2022) or modified open hours or offerings, primarily due to supply chain challenges, costs, and their ability to attract and retain quality employees (Kaori-Gurley, 2022). This has resulted in significant economic and market consequences for the Greater Bemidji Area and needs to be addressed. Specifically, the researcher proposes to investigate how Bemidji Area businesses attract and retain employees in a job loss crisis. This is critical, as the "two biggest concerns for employers are simply finding good workers and training them" (Robinson, 2000, p.X.). Example (La Venture, 2022, p. 7). You need to add the page number for the Robinson citation. The researcher will carry out an exploratory study using a non-probability convenience sampling method. A survey developed in Qualtrics will be distributed on social media to capture data from a minimum of 100 respondents 18 years of age or older, of any gender who reside in the Greater Bemidji Area. Data will be analyzed using descriptive statistics, cross tabulation, and triangulation to determine 1) how Bemidji Area businesses attract employees in a job loss crisis, 2) how Bemidji Area businesses retain employees in a job loss crisis, 3) the employment implications for Bemidji Area businesses resulting from the job loss crisis triggered by COVID-19, 4) identify employment (e.g., attraction and retention) solutions for Bemidji Area businesses, and 5) identify career readiness skills to increase employability by Bemidji Area Businesses.

Abstract Name: Characterization of METTL3 in Drosophila melanogaster Embryogenesis

METTL3 is an essential evolutionarily conserved gene that methylates mRNA on adenosine at the N6 position (m6A). METTL3 has been linked to numerous biological processes including spermatogenesis, neurogenesis, and embryogenesis. Although there have been several studies done to date on METTL3, none have been able to suggest a mechanism in a required process that clearly explains its essentiality. We aim to be the first lab to propose a mechanism in an essential process, embryogenesis. Our lab utilizes Drosophila melanogaster to investigate the role of METTL3.We are currently working to characterize METTL3 throughout embryogenesis. Using immunohistochemistry, we find that METTL3 and m6A have a prominent localization pattern in the CNS starting around stage 12 of the embryo. Our data corresponds with previous work that determined METTL3 mRNA localization pattern around those stages while we are looking at protein. We find in mutants that embryos never develop to larval stage. Additionally, in mutants F-actin appears to be disrupted evident by phalloidin staining. Lastly, using RT-qPCR we find abnormal regulation of genes required for F-actin regulation and subsequently normal embryo development. Our data suggest that METTL3 may be needed for embryogenesis by regulating the essential structural protein actin. Our findings may be the 1st to provide a direct essential mechanism for this important gene.

Abstract Name: Cybersecurity in Microgrid Environment

Today's electrical grid infrastructure reflects a trend towards the integration of computer network technology with traditional industrial control systems. This synthesis, often referred to as a "smart grid" would allow for more efficient transmission of electricity, reduced overhead costs for both producers and consumers, reduced peak demand, and more. However, it faces more critical cyber threats since it is the lifeblood of the nation's economy and vital to the health and safety of all residents. In June 2021, Colonial Pipeline paid roughly $5 million in ransom to hackers, and JBS paid $11 million ransom after a similar cyberattack. A report released by the Treasury Department found that around $590 million had been paid by victims of ransomware to their attackers in the first six months of 2021, as such attacks skyrocketed. Given the nature of computer network technology and the increasing prevalence of both state-sponsored cyberattacks and cyberterrorism, there is a clear need to harden such infrastructure to prevent its compromise. Our team in this cybersecurity microgrid testbed project is funded by the WiSys Ignite Grant, where we explore and study the possible cyberattacks against a microgrid. We first survey potential cybersecurity attacks, develop penetration techniques on a scaled-down version of a smart grid, and study the patterns of the successful cyberattacks. Referred to as a "smart microgrid", we attempt to infiltrate and disrupt it in order to better understand its weaknesses and the real-world implications of cyberattacks on critical industrial infrastructure and industrial protocols that are often overlooked.

Abstract Name: Thrust Measurements of a Coaxial Rotor Helicopter along with Flow Visualization Between Rotating Blades

A robust thrust stand was developed for thrust measurements of a coaxial rotor helicopter. Thrust measurements were used to gauge the effectiveness of the mounted rotor blades. The thrust stand consisted of a load cell and a sensor for rotational speed measurements. A Degraw (HX711-5kg) load cell with strain gauges and a preamplifier was employed. The strain gauge response was recorded by an Arduino based system to get real time thrust measurements. Before using it for the thrust measurements, the system was calibrated with known weights and a calibration curve was established for accurate thrust measurements. A coaxial rotor helicopter (SKY/Rover King) was mounted on the thrust stand where thrust was measured as a function of rotor rpm. In order to optimize the thrust, the design of the commercial helicopter was altered to vary the distance between the opposite rotating rotor blades. Experiments indicate that the thrust peaked around 3000 rpm to about 25 N as the rotor speed was varied from 0 to 4000 rpm. Similarly, the separation between the two rotors was altered and an optimized separation between the blades was found. In order to understand the flow structures between the two opposite rotating rotors, flow visualization was conducted. This was achieved by incorporating a smoke generator along with a helium neon laser sheet that was set at various angles between the rotating blades. A camera was used to capture the motion of the smoke particles within the rotating blades. Images reveal the existence of wake and flow instabilities that are currently under review. Final presentation will describe the thrust stand design along with the thrust measurements at various operating conditions. The discussion on the flow visualization and its impact on the thrust measurements as a function of the separation between the two rotors will be included.

Abstract Name: Microbial and Nutrient Analysis of Water Quality in a Metropolitan area of North Georgia

Introduction: The quality of water in Georgia has been affected by a vast number of contaminants entering bodies of freshwater. Water quality is determined by a diversity of characteristics. In Atlanta, many microbial species can be found in freshwater. The literature highlights various contaminants that are found in urban watershed areas. However, what is yet to be determined is how microbial communities vary in metropolitan Atlanta and how the diversity of microbial species affects the water quality in a given region. A rigorous assessment of urban water quality is necessary to understand the factors controlling safe water sources. Hypothesis: Our study sought to determine how microbial species affect the quality of water by collecting samples along Proctor Creek, a source known for having a high number of contamination sources. Methods: Our trend analysis encapsulated a four-prong approach using a Horiba U-50 machinery, IDEXX apparatus, metagenomic filtration, and nutrients analysis system. Results: After testing 6 sites, our findings showed that Proctor Creek had more pronounced cases of enterococci and Escherichia. coli compared to the control. Conclusion: These findings are important because of the impact they can have on food sources, water quality, and the health status of individuals who reside in this area. Further studies are needed to determine how these findings serve as a social determinant of health for individuals residing in these nearby communities.

Abstract Name: Neuroqueer: Post-Normal Possibilities and The Intersectionality of Neurodivergence and Queerness

Neuroqueer is an intersectional experience and identifierused by queer and neurodivergent individuals. Neuroqueer was coined by Nick Walker in 2008 while she was writing a paper for her graduate class. Walker received a large response to this term and recognized the power that it holds. As the LGBTQIA2S+ community grows and theuniversal understanding of intersectionality expands, the need to understand a variety of experiences is necessary. The Autistic, ADHD, OCD, BPD, and neurodivergent communities make up a significant amount of the LGBTQIA2S+ community and their experiences should be considered. Understanding neuroqueer identities can aid in a social and cultural shift to the neurodiversity paradigm. This paradigm recognizes that neurodivergence is natural and one of the many beautiful aspects of human experience. This cultural and social shift will help deconstruct and re-educate on topics of neurodivergence, queerness, neuronormativity,and heteronormativity. This will helpmoveaway from infantilizing, dehumanizing, and othering neuroqueer individuals along with changing society'sidea of what normal is. Together, we can engage in neuroqueering our communities and embodying neuroqueerness in our day to day lives.

Abstract Name: A Spatial Analysis of Cellular Signal Strength in Western Wisconsin

Across the United States, rural areas have lower levels of education, higher unemployment, and fewer economic opportunities compared to urban areas (Singh; Siahpush 2014). Rural residents have lower levels of access to health care and health services, and health insurance coverage rates are lower as well; as a result, the health of rural residents is poorer compared to their urban counterparts (Laditka et al. 2009).For Wisconsin, the disparities between urban and rural populations are stark. National estimates identify about 20 percent of the U.S. population as rural; in Wisconsin that number is even greater at 26 percent. The lack of healthcare providers, longer distances to healthcare, and lower economic status for rural populations places extra burdens for both providers and patients to meet and receive needed care. Telehealth, through synchronous and asynchronous remote appointments, provides health care providers opportunities to connect with patients outside of physical office visits, especially in rural areas.Coverage maps provided by major carriers are overall generalized, therefore the use of direct telehealth options using video cannot be properly assessed. This study will focus on measuring cellular telephone strength in rural areas through the direct collection of cellular phone strength for both AT&T and Verizon phones. Data will be used to interpolate strength for areas not along roads and a probability map will be generated using a Kriging method. Resulting maps will aid health care providers with more specific information to best provide patients the best possible telehealth option.

Abstract Name: **Discovery of a programmed frameshift in the tail assembly chaperone genes of the novel bacteriophage SeaWolves**

Bacteriophages are viral particles that specifically infect bacterial cells and have a potential use in the treatment of antibiotic resistant bacterial infections. The goal of this study was to characterize and annotate the genome of the novel bacteriophage SeaWolves that belongs to the EE bacteriophage cluster. Previously, we had discovered and annotated two other novel Actinobacteriophages of the EE cluster, Vanisius and Jannah, which we used for comparison in this study. EE cluster bacteriophages generally utilize the virulent lytic cycle and their genomes are relatively small in size with approximately 17,383 base pairs. The novel phages were isolated from soil samples using a known host, the soil-dwelling bacterium Microbacterium foliorum. Genome characterization and annotation were performed using PECAAN, Aragorn v1.2.38, tRNAscan-SE and DNAMaster annotation software tools. Our comparative genomic analysis demonstrated that SeaWolves and other EE cluster phages have a programmed translational frameshift in the tail assembly chaperone gene family. We identified and mapped the highly conserved slippery nucleotide sequence GGGAAAA within the tail assembly chaperone genes #10 and #11 by specifically searching for a slippery sequence motif across the 89 phage members of the EE cluster. The overlapping two open reading frames of these genes, resulting in production of two proteins, are flanked by the genes encoding the major structural components of the phage tail architecture. Further bioinformatics analysis showed the absence of the tRNA genes in the SeaWolves genome but generated strong evidence for strong conservation in the (-1) frameshifting site GGGAAAA. We conclude that such a consistent similarity in the EE cluster phages gene organization is not accidental, and that the programmed frameshift plays an important biological role, which has been conserved during phage evolution.

Abstract Name: **A Comparative Legal Analysis of Geico v M.O.: How Insurance Companies in Wisconsin can Better Avoid Litigation**

In contract law, the plain meaning of words is the primary tool for interpreting agreements, but often there is sufficient ambiguity as to the plain meaning, and that requires additional clarifying text. Highlighting this challenge, this project explores how the otherwise plain language phrase “use of vehicle” can present challenges to determining coverage under auto insurance policies, thus exposing insurance companies to unwanted litigation.This scenario is currently being litigated in Missouri where the plaintiff is alleging that the act of contracting an STD during sexual intercourse in the parked car is a covered “use of vehicle” subject to liability coverage under the policy. Since this is a question of state law, this project seeks to predict how the Missouri case would be adjudicated under Wisconsin law. By applying Wisconsin statutory and common law to the facts of the Missouri case, the analysis reveals that insurance companies operating within Wisconsin must use more precise language and explicit legal definitions tomitigate litigation risk presented by the uncertainty as to how judges and juries will understand the “plain meaning” of insurance coverage language.

Abstract Name: **Mascots in Graphic Design**

Mascots are often underrated and looked over, but their design often influences our decisions about the brand that they represent. Mascots come in many different shapes and sizes, and they are designed to represent and portray what the brand stands for. Mascots are also designed to capture the attention of the consumers. Mascots have been around for over 120 years, and they continue to change and evolve over time. New mascots are always being designed and old mascots are getting redone, but these fun characters will always be around to influence us and our decisions.

Abstract Name: **Assessment of soil physical health in an intensive corn production system integrated with perennial cover crops**

Minnesota alone produces about 9% of the nation's corn production and has become the 4th largest producer of corn in the U.S. The corn (Zea mays L.) production system in the U.S. Midwest is important because corn is used for livestock feed, agricultural exports, consumer products, and biofuel production. Despite the high yields, intensive corn production has caused negative impacts on soil and environmental health. These impacts are aggravated due to monocropping and a lack of actively growing rooting systems, leaving the soil exposed to wind and water erosion for more than half of each year. Hence, it would be essential to eliminate the extended periods of bare soil in the intensive corn production system. Thus, by increasing our understanding of soil physical health, we may improve root health, increase nutrient and water uptake through weed control, and increase the yield potential of MN farms. Previous studies have investigated the promising impact of annual cover crops on soil health between regular annual row crop production, but low adoption illustrates the need for alternatives. This study will evaluate the effects of perenneal cover crops (PCC) on soil health and corn yields in hopes to develop an innovative and sustainable corn production system with PCC. Evaluation is completed through various soil health indicators (Gravimetric soil moisture content, maximum water holding capacity, aggregate stability, bulk density). We expect corn grown with PCC (60 inches row width) will not cause a yield reduction but improve soil physical health compared to conventionally grown corn (30 inches row width) without PCC. Best soil health might be expected in grass and legume mixture with corn as the system will add more organic matter with diverse root biomass and exudates, thus creating better soil structure and aggregates.

Abstract Name: Botanical Composition, Yield, Horse Preference, and Forage Nutrient Value of Pasture Treated with Different Soil Amendments

Forage is the foundation of a horse's diet, therefore, pasture management is critical to improve horse health, nutrition, and pasture productivity. The objective of this study was to evaluate botanical composition, horse preference, yield, and forage nutrient value of pasture treated with horse manure, horse compost, commercial urea fertilizer, and a no product control. Plots were 3 x 6 m and soil amendments were applied at recommended or commonly used rates in May 2022. Sample collection and grazing periods occurred in May, June, July, August, and October, each over a two-day period. Botanical composition, average height, maturity, and yield of the pasture was taken on the day prior to grazing. The next day, horses were allowed to graze for four hours with preference visually assessed at two- and four-hours post-grazing based on percent removal. Data were analyzed as a randomized complete block design using PROC MIXED in SAS with significance set at P ≤ 0.05. Season-long yield ranged from 1.2 to 1.5 tons per acre and did not differ across treatments (P>0.05). Botanical composition differed across treatments with the control having the most weeds (32%) and the least grass (62%) while manure treatments had the most bare ground (11%; P ≤ 0.05). Forage nutrients did not differ across treatments (P>0.05). Horses did not prefer pasture treated with manure and only 15 and 33% of forage was consumed after two and four hours, respectively (P ≤ 0.001). All other treatments averaged 53 and 78% removal after two and four hours, respectively. Based on differences observed in botanical composition and preference, commercial fertilizer and compost appear to be the most beneficial soil amendments to be applied on horse pastures.

Abstract Name: Dressing the sky and stars: costume design for Silent Sky

What does it mean to leave a legacy you can't see? What does it mean to think past religious ideology? What does it mean to be a woman in the early 1900's, even more, a woman in science or a feminist fighting for justice? These are all substantial questions that the play Silent Sky by Lauren Gunderson delves into. This Fall 2022, Hope College's Theatre Department produced a production of Silent Sky directed by Rhett Luedtke. As the costume designer of this production, it was my responsibility to provide an intriguing and historically accurate set of costumes that best portray each characters' traits and a trackable visual of time and personality change throughout the play. Artistically, I had a pull towards exploring the roles that color, pattern, and silhouette play in each individual characters' appearance, however I also faced the additional challenge of providing historically accurate clothing for multiple periods of time. With the tools of artistic liberty and historical accuracy, I found creative ways to put together costumes fit for the time that also gave a visually appealing view of who each character was within the hour and a half you get to know them. An example would be how I put the character Annie in pants, as well as ties, as a means to show her fight against societal norms for women and her feminist morals. Using historical pictures and fashion plates, textual indication of characteristics, and weaving in the original and personal portrayal of the characters by their actors, I was able to finalize multiple costumes that best bring to light the director's vision for this production and show what it means to dress like powerful, smart, and righteous women.

Abstract Name: Personal Perception of Wisconsin FoodShare program and Effects on Food Insecurity

Food insecurity, defined as someone being unable to attain healthy or adequate amounts of food, is an issue that has affected around 12% of the US Population since 1996. Due to several factors, such as COVID-19, this number has recently increased to 18%. One of the groups most affected by food insecurity is college students, although this is often not incorporated in the larger dialogue to address the issue. As a result, estimates of college students experiencing food insecurity are roughly 46 to 50%. Because of perceptions about welfare programs, including Foodshare, students may not sign up for assistance despite showing the need for it. This study looks at the relationship between students' perceptions of welfare and food insecurity rates. Specifically, do these perceptions lead to students not signing up for Foodshare, which in turn leads to possibly higher rates of food insecurity on campus? To answer this question, I collect survey and interview data. I then analyze these data using quantitative and qualitative methods to find that many students do not have the proper knowledge of how to sign up for the Foodshare program, due to lack of or false information. Additionally, many students did not sign up for assistance because of political or personal rhetoric, even if that was against their better interest. Students stated that they often thought they were ineligible for the FoodShare program, or that the program wasn't for them because they had previously heard false information. The results of this study can be used to understand the various reasons, outside of a lack of physical access to food, that college students face food insecurity. Additionally, my results can be used to change Foodshare policy to ensure that the underserved population of college students are aided in obtaining food more efficiently.

Abstract Name: The effects of Time Poverty on Stress and Life Satisfaction in university students and workforce participants

In an increasingly connected world, where work and school are just a click away, work-life has integrated more and more into personal-life taking more of one's personal time. Advancements in telecommunication, telecommuting to work, has contributed to an 'always on' culture that values productivity and always being available. In light of this, there is limited research on perceived time poverty. This study examines perceived time poverty in conjunction with environmental demands and their effects on stress and life satisfaction in the context of university students and workforce participants. A survey using scales on time poverty, irritation, and environmental demands were used in a quantitative analysis to measure their effects on stress and life satisfaction.

Abstract Name: Charcoal Analysis of a Sediment Core from Mud Lake, WI

The Middle-Mississippian people settled in southern Wisconsin around A.D. 1050, near what is now Aztalan State Park. The site was occupied for two hundred years until it was abandoned around A.D. 1250, however little is known about why the Mississippian people chose to leave the site. A sediment core was collected from Mud Lake in Jefferson County, Wisconsin (43.05°N, 88.92°W) in January 2014 for the purpose of developing a climate record for the Aztalan site (43.08°N, 88.86°W). A charcoal record is currently being developed from the sediment core for the purpose of examining the links between climate, vegetation, fire, and anthropogenic activities in the region over the past 2,000 years. Different types of fires produce different forms of charcoal, and classification schemes exist to differentiate between the climate-driven and human-derived fires. Charcoal is analyzed in 1 cm increments and each centimeter of sediment is extracted from the core, treated with hydrogen peroxide and sodium hexametaphosphate, sieved through 125 µm mesh, and dried at 50°C for 48 hours. Samples are counted for the presence of charcoal using a stereomicroscope and 5-50x magnification. Dating of the sediment core combines radiocarbon and lead-210 dating techniques. Charcoal from the pre- and post-settlement of the Aztalan site will aid in differentiating between human and natural fires, and other geochemical analyses completed on the core will be presented to corroborate our interpretation. This will help us develop a better understanding of the role climate played in the abandonment of the Aztalan site.

Abstract Name: Tunable membrane-cloaked hydrogel nanoparticles for targeted delivery of senolytics to osteoarthritic joints

Introduction: Osteoarthritis (OA) is a common degenerative joint disease resulting in articular cartilage degradation, synovium inflammation, meniscal alterations, and chronic pain. Current therapies mainly address symptoms rather than the disease itself. Recent studies show that senescent cell accumulation in the articular cartilage and synovium significantly contributes to OA development. Senescent cells undergo irreversible cell cycle arrest resulting in an inflammatory phenotype negatively affecting adjacent healthy cells. Senoyltics are a new class of drugs that eliminates explicitly senescent cells. Here, we describe a strategy using membrane-cloaked hydrogel nanoparticles (McNPs) for sustained release of senolytics that specifically eliminates senescent cells to reduce cartilage damage and OA progression.Methods: McNPs were synthesized by encapsulating photocrosslinkable poly-ethylene glycol-vinysulphone (PEG-VS) hydrogels within lipid vesicles made from a mixture of 5.2 µmol DOPC, 4.5 µmol cholesterol, 0.3 µmol DSPE-PEG2000, and 0.015 µmol DSPE-PEG2000-maleimide.Results and Discussion: The extrusion of the lipid mixture yielded homogeneous vesicles with an average size of 145 ± 56 nm in diameter and a poly dispersive index (PDI) of 0.094. When PEG-VS monomers (5 wt.%) were added to the mixture, it yielded McNPs with crosslinked PEG hydrogel core. The properties of the core hydrogel can be tuned to sequester and release senolytics at a desirable rate. The McNPs (with 5% PEG) had a diameter of 185.5 ± 88.4 nm and PDI of 0.211, indicating stability. They remained stable for two weeks in PBS, maintaining their unilamellar structure. Compression testing on the core PEG hydrogel formulations showed that stiffnesses of 11.8 kPa to 42.3 kPa can be achieved by varying crosslinking density and monomer concentration. Currently, we are evaluating their in-vitro performance.Conclusions: Overall, we have synthesized McNPs that are homogenous, stable, and tunable. These are potent delivery vehicles that can be used as a disease-modifying therapy to reduce the burden of OA.

Abstract Name: **Heaven's Second Son: Crafting Legitimacy and Nationhood in the Taiping Rebellion**

The fourteen year period known in the West as the Taiping Rebellion is among the most significant conflicts in Chinese history, yet it is too often overlooked by Western academics in analysis of China's political modernization. Hong Xiuquan's Taiping Heavenly Kingdom (also known as Taiping Tianguo or Heavenly Kingdom of Great Peace) represents the first uprising to challenge Confucianism as the underpinning political philosophy and ideology of the imperial system; a threat to both the institutions that had governed China for millennia as well as reigning social and cultural forces of the Qing dynasty. As such the movement required radical recontextualization in order to claim legitimacy and gain ground among the lay population. The Taiping Rebellion attempted widespread appeal by utilizing a blended philosophy of Old Testament styled Christianity with elements of early Confucian ideologies as well as leaning into anti-Qing class and ethnic tensions. Hong Xiuquan crafted a unique political and religious framework that grafted a pared-down Christianity with heavy emphasis on the Ten Commandments onto a heritage of Chinese utopianism (datong 大同) from the Zhou Dynasty Book of Rites, Confucian familial order and its more egalitarian tenets, and co-opted the growing class and economic divide between Han peasantry and Manchu gentry in the Eight Banner system. By casting himself as a 'second son' of heaven, Hong was able to craft a unique bent on the established mandate of heaven narrative separate from state Confucianism that was still digestible to peasantry, one that gained further support from the grassroots by promising something akin to proto-communist land reform during a period of increased tax burden on peasantry.

Abstract Name: **Inversion of In-Group Favoritism in Adversarial Conditions**

Introduction: In-group favoritism (Sumner, 1906; Taijfel & Turner, 1986) is the phenomenon of giving preferential treatment towards individuals within the same perceived social group (e.g., age, race, gender).
Purpose: To experimentally assess whether in-group effects will negate and even invert when one party exhibits actions / demands that exceed the boundaries of a normal in-group association.
Procedure: See Appendix. We created a workplace scenario where the participant assumes the role of a co-worker. In the first segment, the participant is assigned to work with Mary, who requests some minor favors (baseline condition), and responds to the five assessment items shown in the Appendix. In the second segment, Brittany joins the workgroup, and does things that should go beyond in-group boundaries (inversion condition), and then the participant responds to the same five items.Hypotheses: (1) sum of the five ratings will be significantly lower in the inversion (I) condition relative to the baseline (B); (2) participants who are around the same age as the scenario models will show a stronger inversion difference relative to those who are not; (3) because of its nurturing facets, the Big Five trait agreeableness will moderate the effect such that more agreeable participants will be less affected by the inversion effect.
Participants: 63 total from convenience and classroom samples, age ranging from 16 to 62.Results:Hypothesis 1: Baseline (mean=17.4, sd=3.0), Inversion (mean=10.8, sd=3.3), t=14.82 (p<.00001)Hypothesis 2: Same age (B-I mean=3.94, sd=3.6), different age (5.1 / 2.9), t=2.09Hypothesis 3: Correlation Agreeableness vs B-I difference r = -.24 (p<.05)Discussion: H1 was supported, H2 was significant but in the wrong direction (non-matching aged participants showed a larger inversion effect), H3 was supported (more agreeable, smaller B-I difference). Follow-up research suggested for H2

Abstract Name: **The Influence of Glypicans on Glioblastoma Tumor Progression**

Glioblastoma (GBM), also termed grade IV astrocytoma, is a form of brain cancer with about 3 per 100,000 persons developing it either through de novo, or progressively from lower grade astrocytoma. Though this disease is rare, it is fatal with GBM patients typically having a 40% chance of survival the first year, and a 17% chance of survival the second year after diagnosis. GBM has no known cure and limited treatment options that consist of surgery followed by radiation and chemotherapy. One novel area to look at for treating glioblastoma is glypicans. Glypicans are receptors that reside on the cell surface and consist of a core protein with heparan sulfate chains, and a glycosylphosphatidylinositol (GPI) anchor. Glypicans in general play a role in tumor proliferation by regulating cell growth as well as cell signaling. In this study, we compared the difference in growth between GBM cell lines and CRISPR edited GBM cell lines that have a nonfunctional glypican-1. The glypican-1 knockout (KO) cells had reduced tumor growth compared to the unedited GBM cells. These results suggest that further investigation is needed on glypican-1 as a potential therapeutic target for treating GBM patients.

Abstract Name: **Role of Fear in an Eco-epidemiological Model with Species Aggregation**

In this talk, an eco-epidemiological model with species aggregation and disease in prey subject to fear of predators will be discussed. We assume that the reproduction of the susceptible class of the prey population is affected by fear induced by the predators. We present some basic mathematical results such as positivity, boundedness, and local stability. The coexistence of the species at the endemic state is possible for our proposed model via numerical simulations. This coexistence equilibrium can be destroyed by increasing the strength of fear of predators. We will show that the strength of fear can create and destroy the coexistence equilibrium. In some cases, we will show that the strength of fear can drive a stable endemic state into extinction in finite time. We will also present some interesting and rich bifurcation behaviors revealed by our model.

Abstract Name: **Small Modular Reactor Based Microgrid Cost Optimization**

The goal of this research is to develop case studies for clean microgrid systems (CMS) at selected test locations. The problem being faced is making CMS a reliable source that matches the required loads, as well as reducing the costs to make these energy systems affordable.Recently, an increase in generation ramp rates for small modular reactors (SMR) has been developed and there now exists a potential decrease in the cost of implementing and operating CMS.To design these case studies, load data was extractedfrom the New York Independent System Operator (NYISO) and the California IndependentSystem Operator (CAISO). Wind and solar data were collected from theMERRA-2 dataset from theNational Renewable Energy Laboratory(NREL). Power calculations were implemented through MATLAB and Excel to develop wind turbine power curve equations, and the NREL's System Advisory Model (SAM) software processed various solar panels to determinethe yearly renewable power resource.Often hybrid generation systems (HGS) require a battery storage system to offset demand peaks. In HGS, the battery storage is often one of the costliest components. In our HGS model, the NuScale SMR module was implemented with two different generation ramp rates. Sequentially, the effects on the overall cost of the system were analyzed. In all case studies executed, as ramp rates increase the batterycapacityrequired was reduced and nuclear capacity was increased by 35% on average.Then, withthe reduction or elimination of the battery,the Levelized Cost of Energy (LCOE) decreased by approximately 48%. This research suggests that an increase in ramp rates for SMRs, results in a significant cost reduction when implementing a clean HGS. Lowering of costs, positively influences the transition to clean power generation, which is crucial in lowering global carbon levels and decreasing the effects of global warming.

Abstract Name: **Racial/Ethnic Disparities in Kidney Transplant Rates Before and Throughout SARS-CoV-2 (hereafter referred to as COVID-19) in UNOS Region 4**

Background/Introduction: Between February and April 2020, the start of COVID-19, deceased and live-donor kidney transplants (KTs) decreased by 42.9%. KTs are already not performed equally across racial groups with the lowest rates of transplants being among American Indians/Alaska Natives and Blacks and the highest rates in Whites and Asians. This is particularly problematic because Black candidates are three times as likely to develop End-Stage Renal Disease (ESRD) as compared to non-Hispanic and White candidates but half as likely to receive a transplant, despite making up 30% of the United States (US) population and 13% of ESRD patients. The implementation of the Kidney Allocation System (KAS) in 2014 attempted to decrease these disparities, but the impact was limited.Purpose/Methods: A two-way Analysis of Variance (ANOVA) was conducted using data from the Organ Procurement and Transplantation Network (OPTN) to identify variance in the means of transplant rates across minoritized groups in UNOS Region 4 (Texas and Oklahoma) before and after the start of the COVID-19 pandemic. The two-way ANOVA was chosen over the one-way to determine the effect of COVID-19 on transplant rate recovery rates across racial/ethnic groups.Results/Limitations:There was no significant variance in the recovery of KT rates by race after the start of COVID-19 restrictions in the U.S. However, this analysis was limited to one UNOS Region over a 4-year period and excluded live-donor KTs and multiorgan transplants.Conclusions/Implications for Practice: These results challenge the argument that the KAS failed to decrease racial disparities in KTs. Even in a global health crisis, KT rates recovered equally across all racial groups. This suggests that progress has been made toward equitable access to KT. Further research is needed to determine if UNOS Region 4 was representative of the rest of the U.S.

Abstract Name: **Analytical Results of Commercial Cannabinoid-Infused Gummy Candies for CBD and THC**

Cannabis sativa is an annual plant that produces phytocannabinoids that have alleged medical benefits. A variety of dietary supplement products containing varying amounts of cannabidiol (CBD), tetrahydrocannbinol (THC), and other cannabinoids extracted from cannabis plants are now available. One of the most common dietary supplement product types with cannabinoids are gummy candies, which are made by combining gelatin, pectin, sugars, flavoring, and dyes with extracts from hemp or marijuana plants. Cannabinoid infused gummies have grown into a large market across the United States due to the legality of non-delta-9 -THC cannabinoids. These gummies are are not sold in state-run dispensaries and are not considered controlled substances. Consumersuse these infused products for medical purposes such as chronic pain, muscle soreness, and sleep problems. These gummies may have different amounts ofvarying cannabinoids that do not match label descriptions for mass levels per dose. We have been analyzing various gummy candy products to determine if manufacturer claims are reliable. State compliance testing is required for products marketed in dispensaries, but is not enforced for products sold in non-dispensary storefronts.Analysis of the gummies follows the state-compliance testing method for products sold in dispensaries. Analytical steps include dissolution in water and extraction by salting with acetonitrile. Ultimately, Ultra High-Performance Liquid Chromatography-Ultraviolet Detection (UHPLC-UV) calibrated with an eleven component standard was used for analyses. Results to date indicate that there is considerable difference between market claims and actual cannabinoid amounts in many gummy products sold outside of dispensaries.

Abstract Name: **Timing of Puberty in Mice Transgenic for CCL2**

Chemokines are a class of cytokines, which are small proteins involved in cell signaling. CCL2 is an inflammatory chemokine involved in immune response. Mice transgenic for the CCL2 chemokine under the regulation of human glial fibrillary protein (GFAP) promoter will overexpress CCL2 in glial cells of the brain. Specifically, these glial cells can affect the hypothalamus, which moderates hormone secretion in puberty. In addition, GFAP expression in the hypothalamus has been shown to be dependent on stage of the estrus cycle, thus, mice transgenic for over-expression of CCL2 can serve as a model for understanding how CCL2 impacts reproductive processes. Previous research in our laboratory found that pups born to females transgenic for over-expression of CCL2 weighed more than pups born to wild type females on 8 out of 12 post-natal days, and female pups born to transgenic dams went through puberty later than those born to wild type dams. However, proportion of time that adult females spent in each phase of estrus did not differ. We are now interested in examining timing to puberty in males and estrus cyclicity in peripubertal females. To determine if CCL2 has an effect on the rate of puberty of transgenic mice, we will be measuring and comparing timing to puberty in young transgenic and wild type mice. Following weening, we will be measuring the time until puberty by checking for vaginal opening in females and preputial separation in males. Once the females have gone through puberty, vaginal cytology will be conducted as a means of measuring estrus cycle length. We hypothesize overexpression of CCL2 in transgenic mice will influence timing of puberty in male mice and estrus cyclicity in peripubertal female mice. We have begun breeding and anticipate starting data collection on timing of puberty in 3 weeks.

Abstract Name: Species Identification Through Bioinformatics Techniques Helps Determines DNA Sequence Variation Present

Environmental DNA (eDNA) analysis from water samples using the metabarcoding approach is a rapidly developing tool to examine community assemblages and requires bioinformatic processing to recover and produce accurate results of species' genomes. With the implementation of new bioinformatics techniques in conservational biology, species identification from barcoding genes can further examine intraspecific haplotype diversity and supplement traditional field surveys with non-invasive methods. Here we develop a bioinformatic pipeline to identify freshwater fish species from Illumina MiSeq metabarcoding sequenced data of the mitochondrial COI gene recovered from field-collected water samples. In addition to providing accurate species-level identifications, we attempt to delineate intraspecific haplotype data for population analysis of the most common species. Reference files were created using the NCBI GenBank database and were implemented in blast searches to identify target species. The species list, however, is not exhaustive, and several different types of fish could match with the same barcode. We seek to find a more inclusive method of capturing species identity utilizing operational taxonomic units, OTUs, and overall gene alignment while relying less on reference lists. This work's results will help determine the genetic variation and population health of fish species in Buffalo Creek, Armstrong, and Butler Counties, in Southwestern Pennsylvania.

Abstract Name: Exploring the Contextual Interference Effect Using a Bimanual Coordination Task

Stroke, amyotrophic lateral sclerosis (ALS), and other movement disorders result in loss of upper limb function, thus impairing bimanual coordination. Motor imagery is an effective clinical intervention for accelerating recovery; however, the cognitive and neurophysiological parameters that inform effective strategies remain elusive. The study aims to explain the neural dynamics that underlie bimanual coordination during real and imagined movement. Healthy young adults (n=13) learned a visuomotor tracking task using either one or both hands in a single session. Two dials control the movement of an on-screen cursor. The left and right dials correspond to vertical and horizontal cursor movement. The participants were tasked with tracking a moving target using the left and right dials with the appropriate speed and direction. Before the session, each participant was fitted with a 40-channel EEG cap (Compumedics, Neuroscan). Two phases were tested: unimanual and bimanual control. The first phase consisted of unimanual control using the left hand to draw a vertical line and the right hand to draw a horizontal line. The second phase consisted of bimanual control in a 3:1 pattern followed by a 1:3 pattern. The pattern notation represents the ratio of left-hand turns to right-hand turns. Trials were 10 sec in duration, elapsed time from target origin to target endpoint; the intertrial interval (ITI) was 5 sec. Each trial block was followed by a mental imagery condition (MI) where participants were asked to imagine performing the task they had just completed with their eyes closed. Mental chronometric data were collected, and vividness ratings were assessed by self-report immediately after each trial block. The results indicated learning in a single secession; [$F(1,10)=19.43$, $p<.001$]. EEG analyses of active vs. rest conditions, and real vs. imagined conditions, are underway. These results may inform neurorehabilitation strategies for patients recovering from movement disorders (upper limbs).

Abstract Name: An Analysis of the Overlooked Value of Greatness

Greatness is a prevalent topic within philosophy of which many interpretations are offered, ranging from Aristotle's virtue-driven megalopsychos to Nietzsche's power-hungry übermensch. Humanity's persisting interest in the idea of greatness is undeniable– the desire for achievement can become obsessive, overwhelming and, for many, anxiety inducing. While there have been innumerable attempts to explain what greatness is, there is little to no scholarship on why we burden ourselves with the pursuit of greatness, consequently and uncharacteristically placing ourselves in a position of angst and vulnerability. The risk of failure and embarrassment loom menacingly behind displays of ambition, seemingly incompatible with the visceral desire for achievement many of us find so familiar.This paper attempts to primarily fill this absence and offer a conceptual analysis of greatness' value (why we feel the need to strive) while simultaneously remedying errors in the current philosophical concepts of greatness. Ideally, the concept of greatness and its value will offer solace and encouragement for those facing the anxiety and detriment that is all too often concomitant with the human desire for achievement. A coherent conception of greatness and its value will perhaps create an entry point to easing the variety of stresses and pressures that come with the pursuit of greatness. To accomplish this, the paper introduces multiple perspectives from prominent philosophers both of old (Plato, Aristotle, Saint Thomas Aquinas) and more contemporary (Nietzsche, Amy Allen, Virginia Held) through a critical lens. Using relatable, real world examples that promote interaction from a wide readership, a logical analysis and structural critique of each philosophy is conducted. Finally, a concept is offered and argued that finds both power and virtue are critical, even intrinsic, characteristics ofgreatness and its value.

Befus, Amanda

Abstract Name: The Foundations, Origins, and Scope of the Anti-CRT Movement

The purpose of this research is to understand the depth and scope of the recent anti-CRT criticism surrounding America's public-school history curriculums, to find explanations behind these criticisms, and to gain insight for how they will affect American public schools and educators in the future. The core methods of this research involved searching through digital, legislative, and tax documents. Through examining historical perspectives, this research pieces together the foundations of the current challenges facing public schools, as well as how they evolved to into the current anti-CRT movement. While researching historical examples such as Harold Rugg from World War II, and Gary B. Nash's National Social Studies Standards of the 1990's, it became clear that this is not the first time in which critical thinking in public-school history classrooms has been under scrutiny by conservative Americans. The second component of this research delves into the origination of this current movement. Christopher Rufo, a conservative journalist, twisted the term "critical race theory" as a controversial buzzword. In a country struggling through online schooling and reckoning over racially motivated police brutality, critical race theory took center stage in school board meetings and political debates as a contentious fight over the education of our racial history ensued, resulting in protests and legislative action. The results of these challenges lead to my final area of research, examining the implications for educators, legislators, and the future of America's public schools. The anti-CRT movement is a political movement that has successfully turned conservative Americans against the teaching of an accurate account of America's racist past, challenging Americans to learn about, reckon with, and come together to face the racial tensions that underly America's history and founding.

Abstract Name: **A Realistic Brain Phantom for Advanced NeuroImaging Quality Assurance**

Magnetic Resonance Imaging is a mainstay of medical diagnosis; its ability to non-invasively image a patients interior structures without the use of x-rays places it in position of great prominence in the field. Despite this prevalence, there is a noticeable lack of representative phantoms for MRI calibration. While phantoms for this purpose exist, they are, in general, non-representative and consist principally of a single-material, and as such cannot be used to monitor contrast differences, and instead are usually used to determine stability of the machine over time. The scope of this project was to construct and test a realistically shaped brain phantom using agar gel in order to better calibrate MRI machines. For this purpose, 3D printing had an attractive set of advantages; its ability to reproduce complex, organic shapes easily and quickly was utilized to reproduce the complex, organic shape of the human brain. First, a simplified, geometric phantom was created to verify the efficacy of the gel recipe, the effectiveness of several possible waterproofing materials, and to solidify the final process. This phantom was then evaluated for its geometry and longevity, as well as its accuracy in mimicking the relevant properties of the human brain, specifically the T1 and T2 relaxation times. The end goal is to evaluate this phantom for its effectiveness as a tool for calibrating MRI machinery.

Abstract Name: **An EEG Investigation of the Discrepancy Between Auditory and Visual Memory**

Previous research has indicated that visual recognition memory has a much larger capacity than auditory recognition memory. The purpose of this study was to investigate the disparity between the two memory systems by examining the neural circuitry involved in accurate recognition of visual and auditory stimuli, to examine the size of the discrepancy between auditory and visual memory across the lifespan, and to measure the relationship between working memory ability and recognition memory. In Experiment 1, participants completed a recognition memory task while neural responses were recorded with a 32-channel Brain Vision EEG system. Participants received a study phase with pictures/sounds, followed by an immediate recognition memory test. During the memory test, participants were presented with pictures/sounds that were old (presented during study), new (not presented during study), or exemplars that were variants of objects presented during the study phase. Participants were instructed to classify each picture/sound as “old” or “new” by pressing a corresponding key. In Experiment 2, participants ranging from 18 to 65 years of age completed a working memory assessment, followed by the recognition memory task from Experiment 1. The data analyses have the potential to indicate whether the discrepancy between visual and auditory memory is related to changes in gray matter density of the prefrontal cortex as we age. The results of this study will also improve our understanding of the connections between auditory memory, visual memory, and general cognitive ability and will allow a better understanding of the relationship between memory and general cognitive decline.

Abstract Name: **Synthesis of Nanofluidic Suspensions with High Solid Loading and Low Viscosity for Energy Storage and Conversion Applications**

Colloidal suspensions of nano-sized materials (or particles) in liquid media like water or alcohols have been historically investigated for their superior thermal properties. They are typically used as heat transfer fluids in industrial and automotive cooling applications. More recently, functional nanomaterial suspensions (referred to as nanofluids) have also been investigated as catalytic media for chemical reactions, solar harvesting applications, and electrochemical energy storage (battery) applications. Complex and novel behaviors exhibited by such fluids have resulted in many theories proposed to explain their thermophysical properties such as viscosity and thermal conductivity. Here, we report on the synthesis of nano-sized particles of Nickel (II) hydroxide (known to have stable redox chemistry) using a chemical precipitation method. Appropriate surfactants were used to effectively limit the diameter of the particles to less than 1 micron. Particle size, morphology, grain size, and crystallinity have been confirmed through various analytical methods such as electron microscopy (SEM), dynamic light scattering (DLS), and X-ray diffraction (XRD). Additionally, solid-state battery electrodes were produced, to test the redox activity of the particlesthrough repeated electrochemical cycling. Recent results include the preparation and testing of suspensions of these nanoparticles in water-based fluids to understand electrochemical activity in a flowable fluidized format.Additional properties of these fluids have been monitored as well, including stability (against sedimentation due to gravity) and viscosity as a function of solid content (0.1 to 50 wt.%). Preliminary designs of electrochemical cells to utilize these nanofluids for energy storage as well as conversion applications will also be discussed.

Abstract Name: **On the Effectiveness of Augmented Data Generation of Brain Tumors Using GAN based Techniques**

Deep learning models have shown promising results in the computer-assisted diagnosis of brain tumors from images. The training data should be sufficient with high quality and generalized characteristics to train the deep learning models accurately. However, in the medical domain, the training data is limited, as it is difficult to collect sufficient patient data because of the problem of patient recruitment, the burden of annotation of lesions by experts, and the invasion of patients' privacy.Researchers have developed different automated Data Augmentation (DA) techniques, such as scaling, cropping, flipping, and Affine transformation, to overcome the problem of limited data for training. Recently, Generative Adversarial Network (GAN) based DA techniques, such as TumorGAN, PCCGANs, and CPGGANs, have shown improved results in generating augmented data. However, the evaluations of the existing GAN-based DA techniques can be questioned as the experiments were conducted either on small-sized datasets or included only some of the available datasets. In this study, we conduct a rigorous investigation to determine the effectiveness of the GAN-based DA techniques by applying those in all the available Magnetic resonance imaging (MRI) datasets.

Abstract Name: Community College "CUREs" Engagement Deficits in Biology

Madison Area Technical College (Madison College) is a public technical and community college serving Madison, WI, and the twelve surrounding counties. Total enrollments exceeded 24,000 students in the 2021-22 academic year, with 42.2% of entering full-time students in Fall of 2020 continuing the following Fall. The Liberal Arts transfer program offers seven tailored pre-majors designed for transfer and satisfaction of the first two years of general studies at some institutions, with the University of Wisconsin-Madison serving as our largest transfer partner. A federally funded initiative to improve transferstudent success through the establishment of Course-Embedded Undergraduate Research Experiences (CUREs) was established in majors' biology courses beginning in Fall 2018. This project has resulted in over 500 students participating in skills-focused CUREsin biology courses, and is expandingbeyond the target courses to include related courses and programs. Prior to our CUREsimplementation, only 18% of students completed abiology majors course series within two semesters. After CUREsimplementation, 32% of students complete abiology majors course series within two semesters.Our panel will discuss this, and otheroutcomes of implementingCUREsin our biology courses, as well as the challenges and opportunities associated with implementing CUREsat a community college. Details about two of our collaborative CUREsinitiatives, including ourwork implementing Tiny Earth and Sea Phages across three different biology courses will be highlighted.

Abstract Name: A Rollercoaster of Emotions: How Non-Dancers Interpret Emotions Communicated through Dance Performances

This article explores the ability of non-dancers to interpret and understand emotions conveyed through dance movements and facial expressions. Dance and nonverbal communication work together to shape the human experience and contribute to the perception of the surrounding world. The art of dance breaks down communicative barriers and allows people to build deeper relationships with others and within themselves through nonverbal communication and emotional expression. Dance relies on the human body to convey messages because it is constantly serving as a medium for communication. The ability of the human body to be a communicative medium is a phenomenon often overlooked in a world consumed by media usage and other daily complexities. Natural and impulsive body gestures and movements have meanings that are interpreted and often universally recognized; they make people feel a certain way and understand things they otherwise may not. Dance is a form of movement that is filled with stories and meanings without using any verbal cues. This study draws conclusions based on nonverbal communicative patterns through dance movements and facial features. It will explore factors that may moderate the messages people receive when viewing dance performances including culture, age, sex, personality characteristics, and intelligence.By enacting the communication sensemaking theory, people make sense of nonverbal actions they see, including dance performances. The sensemaking theory guides people's development of an interpretation perceived from an observation by linking observed phenomena to past experiences. The ability to effectively apply this theorywill further be explored in this article. This article will investigateprocesses people use to decode meanings from body movements and presumptions of messages they understand.

Abstract Name: **Identification and Annotation of Chico and Foxo Orthologs in Drosophila Species to Understand the Insulin/Tor Pathway Evolution**

The Insulin/Tor (IT) pathway is a crucial signaling pathway responsible for metabolism and glucose uptake, and has influence on longevity, fat/protein metabolism, and cell growth. Inaccurate regulation of this multi-functional pathway plays a key role in many well known human diseases, from diabetes to cancer. Chico– a gene involved in the IT pathway– encodes for a substrate responsible for positive regulation of the insulin receptor's (InR's) binding activity. Past research on network architecture has found that a gene's constraint level is affected by its connectivity and position in the pathway. Ponce et. all showed that IT pathway genes closer to the membrane evolve faster than downstream counterparts. We hypothesized that, due to its involvement in the crucial IT pathway, chico's orthologs are conserved in the target species D. elegans, D. ficusphila, D. miranda, and D. hydei, and their protein identities would decrease according to phylogenetic distance from the reference species D. melanogaster. However, we predicted that chico's selective constraint will be weaker than other pathway elements (i.e. FOXO) because of its upstream position. Chico's putative orthologs were annotated in all four target species and modeled with tools from the Genomics Education Partnership (GEP) pipeline, including the UCSC Genome Browser, tBlastn and Blastp searches, the Gene Record Finder, and the Gene Model Checker. The target species' protein alignments were examined, roughly spanning 45%-80% similarity to the reference species. The average protein identity percent was lower than FOXO's, supporting our hypothesis that position in the pathway is inversely related to selective constraint. Additional species genomes have been recently added to the GEP pipeline. Future studies across those genomes will strengthen our findings.

Abstract Name: **Comparing Cave, Intermediate and Surface Astyanax mexicanus Swimming Speeds and Metabolic Oxygen Consumption**

The Mexican Tetra, Astyanax mexicanus, is a model organism for population genetics, circadian rhythms, and evolution thanks to their various populations. A. mexicanus has been classified in three unique factions: trogolomorphs, surface and recently introduced cave populations (intermediates) with populations of each throughout Mexico and Texas. With populations spread over different environments and geography, it was thought that the three factions are more genetically distinct. This is no longer the case, because cavefish face periodic flooding events, due to their cave environment and weather patterns. These flooding events require strong swimming abilities to navigate these higher velocities and wash cavefish into environments where they can interact with surface or intermediate fish. I hypothesize that cave fish will have a lower Ucritical or maximum sustained swimming speed than the intermediate and surface populations. Fish from cave, intermediate, and surface populations (n=8 for each population) were tested in a Loligo Swim-30 flow-through respirometer. Each trial included a one-hour acclimation time, ramp to 70% of the maximum speed and then stepping up by 0.2BL/s every 20 minutes (step test). Ucritical-values were calculated via dividing the time of the last step test before giving up, multiplying by the last unsuccessful step speed, and then adding to the last successful step speed. Cave populations had a lower Ucritical value (avg=6.0) than the intermediate (avg=11.2) and surface populations (avg=11.5), respectively. Metabolic oxygen data was collected by the swim tunnel oxygen probe during each trial. Surface fish have higher metabolic oxygen rates per flow speed than intermediate fish. This data aims to explains if intermediate Astyanax mexicanus are different from cave and surface morphs.

Abstract Name: **Nassau Street: A Case Study on the Housing Crisis, Floodplain Maps, and Environmental Justice**

Urbanizing regions across the United States face two major crises: housing and climate. The 'Nassau Street: A Case Study on the Housing Crisis, Floodplain Maps, and Environmental Justice' project focuses on the area of and surrounding Nassau Street, a river-adjacent street that is located in the predominantly low-middle income neighborhood of Belmont in Charlottesville, Virginia. The project seeks to analyze the intersectionality of both the housing and climate crises through the lens of a development ethics case in combination with applied anthropological techniques to produce community-based policy proposals.The story of Nassau Street begins with a case of unethical engineering and development practice that was perpetuated by the city's panic to resolve the housing crisis, authoritative disregard for climate change, and a violated partnership between the City of Charlottesville and the Federal Emergency Management Agency (FEMA). By working with the Nassau Street and greater Charlottesville communities, I engage with and better understand resident opinions, concerns, and experiences as they relate to the case study of interest. Through this, I consider how these local knowledge pools fit into a policy framework to address the case study issues and to prevent their future occurrences.The project collects, analyzes, digitizes, and reorganizes archival data related to Nassau Street and Charlottesville from regional libraries to reconstruct the extent of past flood events, project the severity of future climate-induced flooding, and to understand the fluxes of population demographics. Additionally, semi-structured interviews and focus groups are conducted to gain valuable, local insight and to ensure that community needs are met throughout the project process. The ultimate objective of the project is to provide a policy-based template that any locality may use to empower an active citizenry, protect communities from unethical development, prevent the occurrence of environmental injustice, and repair the relationship between localities and FEMA.

Abstract Name: **Female Resistance in the Biopic: Three Case Studies**

A common thread has permeated biopics about female whistleblowers as the genre has evolved over time: the lead actors often have established reputations in the romantic comedy genre. Casting in three such biopics makes this trend clear: Sally Field in Norma Rae (1979), Meryl Streep in Silkwood (1983), and Julia Roberts in Erin Brockovich (2000). All three biopics focus on antinomians, the term being used in a secular sense to refer to figures who rebel against the status quo despite the potential consequences. In these cases, subjects work to expose large corporations taking advantage of their workers. Without casting traditionally ingenuous, likable actors as the leads, the films' creators run the risk of audiences viewing the leads as overly abrasive. In all three case studies, female whistleblowers are "softened" through casting. In Norma Rae, the real Crystal Lee Sutton's personality is softened through Field's traditional femininity. In Silkwood, Streep's own charisma draws the audience to an otherwise less likable activist character. And in Erin Brockovich, the real-life Erin's brashness is made palatable through Roberts herself. This style of casting panders for box-office success, which does attract larger audiences to learn of these women's stories and success protecting the "little guys." However, no matter the actors' high-quality performances, this inherent character-softening still permeates the viewers' subconscious associations with the actors, devaluing the real-life whistleblowers' struggles and accomplishments against the Hollywood system's status quo. Ultimately, Sutton, Silkwood, and Brockovich (who, in reality, cared more about doing the right thing despite how it may hurt them than about others' perception of their likeability) are separated from their fictional counterparts through the choice of actors deeply associated with typical Hollywood feminine charisma, softening not only the women portrayed, but also the scope of their accomplishments.

Abstract Name: **Queer Monstrosity**

In Fall 2022, 18 students enrolled in an honor's course A Queer Lens, Representation Art, Photography and Film. Like the idea of queer theory itself, students were given the opportunity to dismantle the traditional assumptions about gender, sex, sexuality, heteronormativity, and more through a creative project. With the given prompt,create your own queer monster, each student could sculpt, draw or paint their concept. Students then applied their queer optic (Gopinath) of monster theory, queer artistic practices, and queer theory to realize their own aestheticThe creative process started with a rough sketch, pitched concepts to the class, and then consultationswith a monster making expert. If creating a sculpture then an armature was crafted for paper mâché clay application. Students will then take another week to finalize a queer monster by painting, dressing, adorning with different materials and textures.Within monster theory, beasts, demons, freaks, and fiends are symbolic expressions of cultural unease that pervade a society and shape its collective behavior. This aligns with queer theory because of the monsterization of queer characters in film and the queer coded monsters and ideasthatare usually prevalent in horror films. Taking the idea of monstrosity and refiguring it into a work of art, depictingand evokingsome sort of feeling (horror, longing, confusion, desire, etc.) was a goal for each student. In gathering all 18 works together we see the different interpretations of monstrosity. With this proposed exhibition, we envisioned monstrosity as a whole other level of what it means to be queer. Thus, each student will include a statement about their piece that explains their understanding of queer monstrosity.Final critique is taking place Decemeber 22nd, 2022. Images will be posted to Ellen Mahaffy's website shortly afterwords. (www.redcatphoto.com)

Abstract Name: **Purchasing Intent on Electric Vehicles**

With electric vehicles projected to make up 13% of all new car sales in 2022, they are said to be a revolutionary step in transitioning to a greener planet with less dependence on fossil fuels.However, there has been heavy debate on electric vehicles and whether they benefit the environment and the overall vehicle market. The purpose in creating my study is to understand the opinions of the customers, determining the state of the economy. The purpose of my paper is to see people's views on owning an electric vehicle and their reasoning for it. To do so, a survey was written through Survey Monkey, collected using Amazon MTurk with a total of 197 responses. The results show that 49% of those between 18 and 34 years old plan to purchase an electric vehicle in the next 5 years, while 42% of those 35-49 and 48% of those 50+ plan on purchasing in the next five years.Furthermore 67.2% of those between 18 and 34 years old drive electric vehicles for environmental purposes, 45.8 % of those between 35 and 49 years old drive them for environmental purposes, and 59.3% of those between 50+ drive them for environmental purposes. Understanding the driving factors of why people choose to purchase an electric vehicle is why we must determine if it could be a positive or negative trend to the saturation within the market, potentially impacting marketers, advertisers, and politicians on the forthcoming market saturation of electric vehicles.

Abstract Name: **Temporal Assessment of Detection Threshold Stability in Rodent Somatosensory Cortex Via Microelectrode Array Stimulation During Novel Operant Conditioning Paradigm**

Intracortical microelectrode arrays (MEAs) are capable of evoking various percepts through intracortical microstimulation (ICMS) in patients with paralysis and sensory loss. Our lab has developed a novel positive-reinforcement operant conditioning behavioral paradigm for assessing somatosensation in animal models without the use of pain aversion to quantify rodent perception thresholds in response to ICMS. Our goal is to develop a highly reproducible protocol for investigating the reliability of chronic ICMS and MEA longevity in vivo. All procedures were approved by the University of Texas at Dallas IACUC. Sprague Dawley rats were habituated and evaluated for proficiency in a nose-poking task prior to randomized assignment to either receive an implanted Microprobes platinum-iridium MEA device targeting the S1FL, or no implant, acting as a positive control group. The ICMS group was trained in a custom operant conditioning apparatus to nose-poke following an ICMS square biphasic pulse wave to receive a sugar pellet within a specified response window. After training, five baseline task-proficiency sessions were recorded followed by a behavioral task incorporating a randomized and adaptive up-down staircase psychophysical procedure used to determine detection thresholds of stimulation-evoked somatosensory percepts. ICMS parameters were as follows: charge balanced, biphasic waveform, 320 Hz frequency, 200 µs pulse width, 40 µs interphase interval, 650 ms train duration, 0-3 nC/phase charge (0-15 µA). The control group paralleled the same behavioral tasks with a 500 ms 6 kHz auditory tone that varied in amplitude for threshold detection sessions. A quantal stimulation dose-response curve with normalized responses and a variable slope was used to evaluate each groups' threshold detection progression. The results suggest that this paradigm can be used to assess the effects and performance of microelectrode array devices on chronic intracortical microstimulation sensitivity in the somatosensory cortex validating this paradigm as a tool for future perception detection studies.

Abstract Name: **Access to Unique Products From a Mechanochemical Synthesis**

Mechanochemistry is a synthetic method that utilizes grinding to initiate a chemical reaction by combining solid reactants, rather than dissolving them in solution. Advantages of this method include the absence of wasteful solvent and reduction in chemical hazards, which are key principles of Green Chemistry. This project focused on another unique feature of mechanochemistry, the possibility of accessing different products than those produced from solution synthetic methods. A Knoevenagel condensation reaction with four possible product structures was conducted using both solution and mechanochemical methods. Structural differences in the products obtained from the solution and mechanochemical reactions were characterized using nuclear magnetic resonance spectroscopy, and differences in bond vibrations were observed using infrared spectroscopy. Quantum mechanical calculations involving geometry optimizations were performed to understand the relative stabilities of the four possible product structures from this reaction. The single crystal x-ray structure of the product was obtained from the solution reaction method. Several mechanochemical variables were also investigated to determine the effect on the product(s) formed, including grinding time, amount of catalyst used, and stoichiometric ratio of reactants. The combined results of our experimental and computational studies provided strong evidence that mechanochemical methods produce different product structures than solution methods for this condensation reaction. This study demonstrates that mechanochemistry has important future implications in potential synthesis of products where either no solution method is currently available, or existing methods provide undesired products.

Abstract Name: **Characterization of Porous, Mineralized Collagen-Chitosan Scaffolds for use in a Bone-On-Chip Platform**

A primary component of bone-on-chip platforms is the development of a scaffold that mimics the cancellous bone microenvironment and provides support for cells. Cancellous bone is primarily composed of type I collagen and hydroxyapatite mineral. Porosity and protein mineralization are important components of cancellous bone, though previous studies primarily focused only on one. To address both properties, scaffolds were freeze-dried with both collagen and chitosan in weight % ratios of 10:0, 8:2, and 6:4. They were then carbodiimide-crosslinked for 8 hours to retain the porous structure, using 98% ethanol as solvent to prevent protein dissolution, and mineralized in either modified simulated body fluid (mSBF) or polymer-induced liquid precursor (PILP). Various mineralized scaffold properties were characterized with thermogravimetric analysis (TGA), Fourier-transform infrared spectroscopy (FTIR), energy dispersive spectroscopy (EDS), and scanning electron microscopy (SEM). TGA: Scaffolds had average mineral deposition of 20-40% in both mineralizing solutions, compared to 65% on average for bone, with PILP trending higher for 8:2 and 6:4 formulations. FTIR: Spectra of all scaffolds exhibited characteristic peaks for collagen (Amides I and II), and the C-H peak for chitosan was present for 8:2 and 6:4 formulations. EDS: Scaffolds were composed mainly of carbon, sodium, chloride, calcium, and phosphorus. Average Ca/P ratios, an indicator of bone apatite quality, were calculated for the different formulations and compared with a benchmark ratio of 1.67 for bone. Ratios were 1.00-2.38 for the different formulations, with mSBF-treated scaffolds having ratios above 2.00. SEM: Scaffold porosity ranged 40-55%; further optimization will hopefully increase porosity to the typical range of 70-80%. Next steps will be to finalize characterization and perform biocompatibility assays with osteoblast-lineage cells to assess the best formulation for the platform, which will be used to study changes in the bone microenvironment that may contribute to fractures following stroke.

Abstract Name: **COVID-19 VS. Higher Education: Understanding the Exigencies Through Students' Perspectives in Online Learning**

The Coronavirus Disease 2019 (COVID-19) pandemic has impacted how students learn. The sudden shift to the emergency remote learning format during the COVID-19 pandemic has impacted students' mental health, well-being, and educational resources. A survey conducted by Active Minds concluded that 38% of students reported difficulty focusing on their academics, and 74% found it challenging to stick to a regimen (COVID-19: Student Survey, 2021). The COVID-19 pandemic has influenced higher education to develop a framework that spans several learning formats. This study intends to highlight resources that aid students when academic courses in higher education are transformed from face-to-face to emergency remote learning, online learning, orhybrid learning format. The findings of this study will enhance academic faculty members' understanding of which course components are essential when navigating a pandemic in higher education. Students enrolled in AH 202: Nutrition for Health Care Professionals II completed a voluntary questionnaire regarding Northern Michigan University courses being converted to emergency remote online learning in the winter of 2020. Voluntary questionnaires were provided to students during the winter 2020, summer 2020, fall 2020, winter 2021, summer 2021, and winter 2022 semesters. In addition, students were also presented with a voluntary follow-up questionnaire at the end of each semester. The student responses from both; initial and follow-up surveys were compared to analyze the anticipated and actual challenges students experienced during emergency remote learning, online learning, and hybrid learning.With the results presenting an understanding of the limitations of the COVID-19 pandemic, this research study will provide knowledge and new perspectives from the student's point of view in higher education.

Abstract Name: **The Role of Energy Source on Mammary Gland Utilization of Plasma Amino Acids**

Animal agriculture is currently unsustainable with excess amounts of nitrogen polluting the environment, posing a threat to planetary and human health. Currently, an estimated 75% of the nitrogen consumed by a dairy cow is excreted in manure. The Arriola Apelo lab investigates nutritional strategies to stimulate signaling pathways that regulate milk protein synthesis directing nitrogen towards milk production, therefore reducing the amount of nitrogen waste entering the environment. The mTORC1 pathway shows promise as it coordinates nutrient and environmental cues to stimulate cellular anabolic processes, like protein and fat synthesis. Previously, our lab has demonstrated that insulin and amino acids (AA) synergistically stimulate mammary mTORC1 activity. We hypothesized that glucogenic energy, by stimulating insulin secretion, potentiate AA activation of mammary mTORC1 activity, thus increasing sequestration of AA for milk protein synthesis. To test our hypothesis, and as part of a larger study, 20 peak-lactation Holstein cows were used in a 4x4 repeated Latin square design with four 28-d periods and four treatments arranged as a 2x2 factorial. The two treatment factors were energy source: glucogenic (GE) or ketogenic (KE) and total metabolizable AA: 10% deficient (DAA) or sufficient (BAA). Blood samples were collected from coccygeal vessels (representing artery) and subcutaneous abdominal (mammary) vein at 6 timepoints during the last 2 days of each period. Plasma was isolated by centrifugations and mixed with isotopically labeled AA as internal standards for AA analysis by liquid chromatography-mass spectrometry. Mammary blood flow was calculated based on the Fick principle, using Phe+Tyr as non-metabolizable markers. Mammary extraction efficiency, uptake, and uptake to milk output ratio were calculated. Statistical analysis was performed in RStudio. Results from this study will contribute to a more sustainable dairy industry.

Abstract Name: **Role of Regulatory mRNA Structures in the Expression of Cancer-Related Genes**

Messenger RNA (mRNA) translation, the synthesis of proteins based on genetic code, is an essential process in gene expression. Translation is often inhibited when cells are under stress, but there are mechanisms that allow certain genes to bypass stress-induced inhibition. Prior studies have identified a list of genes that disregard stress signals to continue mRNA translation using regulatory RNA structures to hijack the translational machinery. We hypothesize that stress-signals must alter the RNA structure to trigger structure-mediated mRNA translation. Our target genes include oncogenes HIF1A, FGF2, and tumor-suppressor gene TP53. We aim to amplify regulatory mRNA regions previously reported for each gene from A549 lung carcinoma cell lines. Next, we will build and compare structure models for regulatory regions under three conditions: (a) cell-free, (b) in-cell unstressed, and (c) in-cell stressed. For structure modeling we use SHAPE-MaP, a chemical-probing strategy analyzed using next-generation sequencing (NGS). We have successfully extracted, probed, and amplified the target regions using gene-specific primers, reverse transcription (RT), and polymerase chain reaction (PCR). We analyzed PCR products using gel electrophoresis. Here we describe our experimental workflow along with data from NGS library preparation. Applying NGS using the Illumina MiSeq platform on target mRNAs, we will build RNA secondary structures with Shapemapper2 and SuperFold software packages. Our long-term goal is to describe structure-based mechanisms by which translation of cancer-causing mRNAs can be blocked, and how translation in cancer-fighting mRNAs can be reengaged.

Abstract Name: **Minimum Blockers of 123-Avoiding Permutation Matrices**

A blocker of n × n permutation matrices is a set of positions in an n × nmatrix that intersects each n × n permutation matrix at least once. A blocker is minimum if removing any position makes it no longer a blocker. The Hankel cyclic decomposition implies that each minimum blocker of 123-avoiding permutation matrices must have a cardinality of at least n, and minimum blockers containing exactly n positions are called minimal blockers. The well-known Frobenius-K¨onig theorem characterizes the minimal blockers of permutation matrices: any r × s submatrix is a minimal blocker of all permutation matrices if and only if r + s = n + 1.A permutation matrix A is 123-avoiding if it does not contain the 3 × 3 identity matrix as a submatrix. Recently, Brualdi and Cao characterized the minimal blockers of 123-avoiding permutation matrices. They showed that all minimal blockers of 123-avoiding permutation matrices must contain either the (1, n) or (n, 1) position and can be obtained by shifting some positions from an L-shaped blocker. We continue their study by defining flag-shaped blockers, which need not contain the (1, n) nor (n, 1) position and may have cardinality greater than n. We show that all flag-shaped blockers are minimum and all minimal blockers of 123-avoiding permutation matrices are special cases of flag-shaped blocker.

Abstract Name: **Neighborhood Effects: An Ethnographic Study of the South Loop, Pilsen, and Austin Neighborhoods in Chicago**

Place is more than just the physicality or location of something. It is also a product of buildings, streets, the people who surround it and occupy that space. Place cannot exist without the actors and the actors cannot exist without the place. Both play an essential function in understanding neighborhood effects and the necessary equipment for living. It is important that people develop the necessary knowledge and equipment for living to function and make the best of their daily interactions that take place in society. Chicago is composed of many different neighborhoods; however, each neighborhood poses different challenges with respect to the equipment for living or the practical routines individuals need to figure out and make their way through each community. This study draws upon first-hand observations, demographic analysis, and interviews to understand and compare these different routines in the South Loop, Pilsen, and Austin community areas of Chicago. Through this study it was found that these communities vary greatly in terms of access to clean and healthy food, relationship with the police and the community,diversity, homelessness, and access to everyday resources. These findings help to understand the importance of building a relationship with the community around you and why it is important for people to understand the daily equipment for living in these neighborhoods in Chicago.

Abstract Name: **Mindfulness Skills, Emotional Regulation, and Coping Mechanisms as Predictors of Academic Success and Wellbeing**

The goal of this research study was to determine the possible relationship between emotion regulation, coping, and three facets of mindfulness (acting with awareness, nonreactivity, and observing) in predicting perceived academic success and overall wellbeing. “Wellbeing" is a term that is often rated according to someone’s own perception of their mental and physical states. Academic success is determined by the individual’s own perception of what success should look like. Like Finkelstein-Fox et al. (2018) reported, “Understanding students’ intrapersonal resources that promote resilience and protect psychological well-being as they transition from high school to undergraduate life may provide useful directions for campus-based counseling interventions,” (2018, p. 639). Acquiring knowledge surrounding these variables and their relationship to individuals’ wellbeing could create pathways to decrease mental health issues in universities everywhere. The current study was conducted at a small, liberal arts university in the southeast. The Five Facet Mindfulness Questionnaire (FFMQ), a shortened form of the 60-item COPE scale called the Brief-COPE, The Emotion Regulation Questionnaire (ERQ), The Satisfaction with Life Scale (SWLS), and the Academic Self-Perception subscale were administered to 145 undergraduate students with a mean age of 19.52. The results were analyzed using a multiple regression analysis through SPSS. The results of this study revealed that acting with awareness was an overall predictor of overall wellbeing. A second multiple regression analysis revealed that the two variables of coping and acting with awareness were significant predictors of an individual's perception of their academic success. Emotion regulation and two facets of mindfulness (nonreactivity and observing) failed to significantly predict perceived academic success and overall wellbeing. Implications, limitations, and recommendations for future research were addressed.

Abstract Name: **The Mental Health Disparity Facing Sixty Years or Older Georgia Veterans in Rural Communities**

The VA predicts in the next two years, 77% of rural counties will have a shortage of mental healthcare providers. A majority of military recruitment is committed in these areas and in Georgia there are 630,000 military veterans, of those veterans 68.2 % served during or before the Gulf War. An increase in internet access is a must if we are to ever address the mental health crisis facing veterans living in rural Georgia. 29% of veterans in rural areas have reported ever receiving care for mental illness, while 22% of veterans in rural areas report suffering from mental illness. For perspective, 45% of veterans living in urban areas have received treatment. When the numbers are considered it becomes clear that rural veterans in America are at a disadvantage and in Georgia where 136 rural hospitals have closed, their resources will worsen. This raises the question: How can Georgia ensure that veterans aged sixty or older living in rural communities can receive sufficient evaluation and prescription of mental health medication? The answer is through an increase in internet access in rural Georgia, allowing for veterans to experience an increase in telehealth availability and quality.

Abstract Name: Smartphone Use on Well Being

How has Smartphone use impacted the general well-being of people today? The Smartphone usage has certainly increased over the past generation. The use is so prevalent that nearly everyone from 9-99 has one. Questions regarding how this intense Smartphone use is impacting the overall health and well-being of society has been discussed across many different aspects of research. This research intends to study how Smartphone use impacts the physical, psychological, cognitive, and social well-being of individuals across the generations. Previous research tendedto focus on one aspect or another of well-being, for example sleep or academic performance (cognitive functioning) or anxiety (psychological functioning). The research is lacking when looking at the global health of an individual and its association with Smartphone use. Thisstudy will also examine the specific ways individuals are using the Smartphones as well as how much of their daily life is consumed by the use. A correlational analysis will be completed in the spring semester of 2023 to determine what factors are impacted by Smartphone use.

Abstract Name: Adverse Childhood Experiences (ACES) and the Risk of Intimate Partner Violence (IPV)

The purpose of my research is to take a look at how trauma may or may not have an impact on couple relationships. This research is important due to the fact that one's previous negative and/or traumatic experiences have the ability to significantly impact their behavior and responses with their partner. Previous research has shown that one's previous occurrences do tend to influence one's trust, security, and anxiety in relationships. The target population for my extended literature review is for individuals who may be in environments with either perpetrators and/or survivors of IPV. The population also has to have had a previous relationship with this criteria or be in a current relationship with this criteria.If I were to conduct a study, amethod of evaluation would be outcome-based, in which I would have two different scales in the survey. One would be the ACEs test to evaluate the participant's adverse childhood experiences. The other would be the Conflict Tactics Scale that will evaluate different aspects of violence in their relationship. Since I am conducting an extended literature review, it will be broken down into themes such as: geographical components, diversity aspects, gender disparities, and other factors that are embedded in a literature review. I am confident that my findings from the extended literature review will show a strong correlation between these two aspects. My extended literature review will contribute to the field of knowledge by acknowledging the significant impact of negative childhood experiences. By seeing how it can affect couple relationships, we may be able to pinpoint certain relationship aspects and know how to improve the overall quality of relationships.

Abstract Name: **When Language Moves What Matters: Effects of Linguistic Framing on Endorsement of Black Lives Matter Tenets**

The Black Lives Matter (BLM) movement holds a mission to fight white supremacy and stop systematic, racially-motivated violence targeted towards Black communities (Black Lives Matter, 2013). Although the majority of U.S. adults in September 2021 reported that they support BLM, it can be helpful to learn more about why some people do not support the cause and factors that might alter support (Horowitz, 2021). One consideration is valence in linguistic framing, or the positive or negative feelings that certain words or phrases may automatically evoke (Avineri & Waygood, 2013). Framing is a low-effort way to affect attitudes without increasing knowledge and without need of rehearsal (Bizer & Petty, 2005). This study measured frame valence and how it shifts in independent versus combinatorial contexts by comparing the valence of statements on the BLM website's About page to the valence of the individual words out of context. Additionally, this study will see if statement and sub-phrase valence are related to ratings of support for the information in the statement or subphrase. In part one, the individual words from the statements were tested out of context to find the independent valences – positive, neutral, or negative. In part two, the full statements, as well as sub-phrase excerpts, were tested for valence as well as degree of support for the claim. Five-point Likert scales were used for both valence ratings (strongly negative to strongly positive) and support ratings (definitely not to definitely). Data collection is underway and results will be analyzed soon. The results of this study will hopefully have a positive impact on the Black Lives Matter organization by adding to our understanding of factors that can increase overall support.

Abstract Name: **A Comparative Analysis of the UK & US Police Forces and How the Media Shapes Public Perception**

This research investigated the public's perception of the police in the United Kingdom. Data is drawn from various newspapers published in London during the months of June and July 2022. Data showed that UK police are rarely included in the newspaper but when they are they are generally cast in a favorable light. Adversely other countries police forces are depicted in a negative perspective with most of their reporting aimed particularly at the US. Additionally, data was gathered from informal conversations with various members of the public living in or visiting England. I was able to gain the perspectives of seven persons of English background, two from Ireland, two from Sweden, one from France and a group of three police officers in London. Results showed that the UK police force are contending with issues of racism and xenophobia but they are typically regarded positively by the public. During the course of my research, I discovered that there are several startling laws surrounding the Internet, its dissemination of information, and the freedom of speech in the UK. The differences in the attitudes of the UK citizens regarding the government's involvement to withhold information from the public and impose limitations on what the citizens are allowed to say and share is a stark contrast to the attitudes of the average American citizen. A major finding in this study is that the British public and police perspective align around the belief that the U.S. could learn from the UK regarding confiscation of firearms. The citizens of the UK genuinely believe that if American citizens would just voluntarily turn over all of their firearms, then our citizens would have nothing to worry about when it comes to the police even when confronted with evidence of police brutality in their own country that bans guns.

Abstract Name: **Skill Assessment of Caregivers who Serve People with Intellectual and Developmental Disabilities**

This quantitative study assesses the knowledge and skill of caregivers who serve people with Intellectual and Developmental Disabilities (IDD) and explores the aspects of training they received prior and during their time serving the population. In order to test the skill of caregivers, studentresearchers created a survey with 15 qualitative and quantitative questions. There are 4 demographic questions that ask about age, gender, and ethnicity; and there are 11 questions that ask about prior experience, personal opinions of their training, and certifications. The collected data was received by sending out an electronic version of the survey to caregivers for people with IDD. Using 75 participants, this research aims to see how effective training is when used in practice. The research allows student researchers to explore solutions to maximize effectiveness. Once the data was received, it was entered into an excel codingsheet and copied into SPSS. This software provided student researchers with insight about their data based on correlations between prior training, certification and years of experience compared to their comfort level as caregivers. Student researchers used quantitative analysis such as Measures of Central Tendency, Chi-Square tests, and Correlations to find any statistical significance. The nonparametric testing that wasconducted for the research is the goodness of fit method. Student researchers thenran correlations between the variables of caregivers' age, gender, and education level.Overall, results indicate that participants felt the training they receive was beneficial, positive, and thorough (40%, n=30). The results also indicated that most of the participants had a high comfort level when it comes to caring for individuals with IDD (84%, n=63). The qualitative data is observed from open-ended questions. Student researchers intend to use these results to change training to maximize skillset and improve living conditions for people living with Intellectual and Developmental Disabilities.

Abstract Name: **A Computer-Based Model to Capture Gastric Electrophysiology Through Bio-Impedance Analysis**

The ability to monitor the bioelectrical activity of the gastrointestinal tract, in a non-invasive manner is essential for the diagnosis and management of functional gastrointestinal disorders. Electrical bio-impedance (Bio-Z) analysis is a promising method to acquire a wide range of human electrophysiological activities, through wearable electrodes. The Bio-Z sensing system consists of a four-electrode configuration on the body surface in which the two outer electrodes deliver a sinusoidal excitation signal transcutaneously, and the two inner electrodes acquire a differential potential which will be conditioned, processed, and mapped to the electrophysiology of interest.To this end, we developed a computer-based model of the human gastric system in COMSOL Multiphysics, a simulation platform based on the finite element method. Through the model, we simulated the Bio-Z analysis to capture the gastric electrophysiology, through the body surface. The objective of the project is to simulate the penetration depth of the Bio-Z analysis as a function of frequency and find the optimum frequency for the clinical data collection on human subjects. We developed the model of the abdomen through four layers of skin, fat, muscle, and peritoneum. Besides, we developed the model of the gastrointestinal tract through four layers of serosa, muscularis, submucosa, and mucosa. The model of four AgCl electrodes was added to the model of biological layers, too. The frequency-dependent permittivity and conductivity parameters were assigned to each biological layer for the simulation at each Bio-Z frequency. In COMSOL, we generated the electric fields resulting from the applied sinusoidal excitation signals at various frequencies in the range of 10 kHz to 250 kHz to the stomach, transcutaneously. Then, we plotted the power spectrums of the electric fields and compared them at the penetration level of the gastric tract.

Abstract Name: Investigation of Cancer Biomarkers Using SERS

Surface Enhanced Raman spectroscopy (SERS) can be used to detect changes in the composition of human saliva that may indicate the presence of cancer biomarkers. Cancer is a prevalent disease that affects many people. By using SERS with human saliva, a painless and possibly more effective way to detect cancer can be created. Like blood, saliva can show changes in proteins and concentrations of certain molecules that occur due to cancer. The method that our group will focus on is SERS which is an extremely sensitive spectrophotometric method. This is necessary when using saliva samples as many analytes are in very low concentrations. Our group is still in the preliminary stages of using the Raman spectrophotometer and optimizing SERS conditions. Moving forward, our group hopes to successfully run treated saliva samples on the Raman.

Abstract Name: Journalism Meets Performance: An Anthology of Ferocious Healing

Storytelling is the foundation for the fields of journalism and performance. While journalism is for truth-telling and performance offers empathy-building, the two can be merged to tell stories that leverage the strengths of both fields. A literature review and interviews with professionals supported the convergence of these fields to create more spaces to share and hear stories, including those less commonly sought after by storytellers and consumers of broadly marketed mainstream media. Based on this previous research, I produced a template that offers advice to social movements and groups when considering and developing work that combines journalism and performance. This template considers the topic, available time, content acquisition, storytelling method, and intended audience. To test this template, I created a performance, An Anthology of Ferocious Healing, which explored what healing and peace mean to young adults in a world that can be simultaneously complicated, frustrating, hopeless, beautiful, and joyous. These stories of respite were collected through interviews with individuals aged 18 to 25 years old in Minnesota, as well as adults in direct contact with the individuals, such as educators and parents. I included the unedited content that I gathered from these interviews in a resulting performance through various storytelling techniques. The performance was written in a gallery format that provided the audience with a self-paced, multimedia, and multisensory experience. This work blended practices of journalism, performance, theatre, ethnography, oral history, creative writing, and social justice to experiment with and expand the ways stories are told.

Abstract Name: Virtual Stories to Support Undergraduate Students in Developing Cultural Awareness

The Human Library project is working to connect "human books" (people with unique experiences and backgrounds) to "readers" (people who want to learn and grow) to challenge what they know. Inspired by events held by The Human Library, this research aims to create an opportunity for undergraduate communication sciences and disorders students to grow and learn from those whose backgrounds differ from their own and apply it to their professional development. In this research project, stories will be created and presented online by graduate students, alumni, or other professionals who self-identifyexperiences related to diversity in the field of communication sciences and disorders. These stories will create a virtual library for the undergraduate students enrolled in a senior-level course on serving diverse populations. Undergraduate students will choose to review and analyze a story, generating a shareable presentation for the class and a personal reflection on the experience. To measure the effectiveness of this project on diversifying student cultural perspectives, a survey based on the American Speech-Language-Hearing Association (ASHA) Cultural Competence Check-In: Self-Reflection, will be given to the students before and after the story analysis project. After that, change scores will be calculated for statistical significance. Reflections will be analyzed for general themes to further explain student learning. The results of this study will reveal whether this is an effective pedagogical method for diversifying student perspectives on culture within the scope of communication sciences and disorders.

Abstract Name: Papal Power vs. Secular Power: Renewed Interest in the Rule of Law in the Long Twelfth Century

Historians repeatedly trace the development of modern parliamentary democracy from Aristotle's Politics in the sixth century to Enlightenment thinkers like John Locke in the seventeenth century. Except for the Magna Carta, the long twelfth century is mistakenly considered a part of a "Dark Age" for democracy. The "Dark Ages" is a persistent misnomer created by Renaissance scholars to exaggerate the "light" of the Renaissance compared to the perceived "darkness" of the Middle Ages. However, many historians have debunked this assumption and proved the long twelfth century is rich with legal and political developments crucial to the structure and values of modern parliamentary democracy. When examining the medieval origins of democratic principles, many historians have overlooked the influence of the Roman Catholic Church in the rise of proto-democratic ideas and institutions in Western Europe. Some historians have emphasized the influence of ecclesiastical law as the foundation for these ideas but have not examined how ecclesiastical ideas were adopted by secular political communities. I will argue that secular-religious conflicts in the long twelfth century, starting with the Investiture Controversy, stimulated renewed interest in proto-democratic norms, such as the rule of law and political accountability. For instance, arguments in the long twelfth century over the independence of the church, especially church elections and courts, fueled the supporters of papal supremacy to insist on the rule of law and political accountability. Bishop John of Salisbury's Policraticus (1159) and Archbishop Stephen Langton's Magna Carta (1215) were two of the first influential examples of the rule of law and political accountability articulated in the Middle Ages. Additionally, advocates of secular supremacy, specifically Holy Roman Emperor Henry IV (1084-1105), inadvertently argued against tyranny, albeit, referring to popes.

Abstract Name: **Developing a Semiology Expert System for Pre-Surgical Localization of Seizures**

Introduction: Epilepsy is a neurological disorder caused by abnormal electrical brain activity and impacts 3.4 million people nationwide. Seizures have serious implications for patients and can cause a loss of control of movement, sensation, and awareness, and seizures can sometimes lead to death. When anti-seizure medications are insufficient, surgical resection of the seizure-causing regions of the brain is the standard of care. However, the techniques that localize seizure onset can be imprecise. Seizure semiology, which is the clinical progression of seizure symptoms, is initially used to build a testable hypothesis of where in the brain seizures originate. This hypothesis is then tested through imaging and electrographic studies. However, the usefulness of seizure semiology depends on the experience of the practitioner and varies across epilepsy centers. We have expanded on a computer expert system that helps identify which regions of the brain are likely to produce specific seizure semiologies.MethodsThe system is coded using MATLAB. Elements and timing of a patient's seizure semiology are inputs, and the output consists of images showing brain regions involved in the seizure. In the images, the timing of involvement is represented by the color of the brain region. The connection between seizure semiology and brain region was ascertained from literature review.System ValidationInitial validation consisted of comparing system output with expectations of an experienced epileptologist. Secondary validation tests planned include: 1) prospective comparison of maps produced by the expert system to maps produced by two epileptologists blinded to system output, 2) prospective comparison of seizure-freedom rates in patients in whom the earliest regions of involvement determined by the system were resected or to rates in patients in whom the regions were not resected. Surgical planning will not be based on the outputs of the expert system during validation.

Abstract Name: **Acute Effects of Intratumor DNA Electrotransfer**

Intratumor DNA electrotransfer (also known as electroporation) increases cell membrane permeability, allowing for transient and stable transfection of different cell types. This is characterized by changes in gene expression, which lends to its various immunotherapeutic effects. These are currently being explored via clinical trials in the United States. Specifically, this includes in vivo DNA electroporation to enhance the delivery of plasmid DNA in tumors. In this study, we aimed to determine the impact of intratumor electrotransfer of plasmid DNA on endogenous gene expression within a mouse model that is analogous to melanoma in humans. Results of the mouse studies were then confirmed by in vitro experiments conducted in B16-F10 mouse melanoma cells, allowing for a holistic view of its possible antitumor effects. Studies were conducted to determine the effects of plasmid DNA electrotransfer on mRNA expression after 4 hours via Affymetrix microarray analysis. The functional annotations tools on the DAVID v6.8 web server allowed for upregulated genes and their pathways to be identified. Further analysis revealed molecular functions involving cytoskeleton remodeling and pro-inflammatory signaling cascades. Cytoskeleton remodeling was validated through electrotransfer experiments at 4 hours, followed by F-actin staining via phalloidin. Inflammatory signaling was confirmed by the secretion of chemokines in electroporated cells and quantified via bead array analysis (MAGPIX System). These results indicate that pulse applications, with or without the introduction of DNA, can impact the therapeutic capabilities of DNA electrotransfer.

Abstract Name: **Development of Photocrosslinking Click Chemistry Probes to Investigate the Function of Falcilysin, an Essential Malarial Metalloprotease**

Human malaria is a parasitic disease caused by 6 different Plasmodium species, leading to approximately 600,000 annual deaths. All clinical symptoms of the disease result from the intraerythrocytic development of the parasite. During this part of the life cycle, the parasite expresses an array of proteases to carry out many essential processes, such as host cell protein degradation, host cell invasion, and parasite protein export. Falcilysin (FLN) is an essential metalloprotease expressed by the parasite during intraerythrocytic infection, and it is known to function in host hemoglobin degradation and in processing of apicoplast-targeted parasite proteins. Recent studies have identified FLN as a target of the clinical antimalarial drug chloroquine, and it appears likely that the protease carries out additional roles in the cell.We are developing chemical tools to enable further investigation of FLN biology and its potential as a chemotherapeutic target. Here we report our work to synthesize and evaluate a series of piperazine-based hydroxamic acids as inhibitors of FLN. As well as incorporating photocrosslinking and click chemistry moieties into the scaffold. These studies will provide the rationale for the development of increasingly potent FLN inhibitors while identifying possible off-targets in the cell.This work builds upon our previous research by further optimizing the N1 position on the piperazine core. We synthesized and tested a series of 10+ compounds with diverse substituents which were installed using a range of synthetic methodologies. In a subset of compounds we incorporated diazirine and alkyne moieties to enable identification of cellular targets using a combination of photocrosslinking and click chemistry. All compounds were tested against cultured parasites and purified FLN, and we identified additional structural requirements for potent inhibition of FLN. Multiple inhibitors were discovered with similar or improved potency relative to our previous lead compounds.

Abstract Name: **Community-Informed Process to Explore the Feasibility of Increasing Nutrition Education Capacity in a Rural Native American Community**

Health disparities with food insecurity and malnutrition affect many in rural California communities, especially in Native American youth, so increased access to services like health education may help to mitigate these issues. This project aims to determine the feasibility of connecting existing resources to improve nutrition-related preventive care capacity in these communities. A community participatory process was utilized to adapt traditional nutrition education offered by the Expanded Food and Nutrition Education Program to fit the cultural and contextual needs of the community. The classes were also adapted to be delivered remotely, via telehealth. The Tribal Board identified 3 community members to serve on the Community Advisory Board (CAB) for the project. Four monthly meetings were held with the CAB to discuss class logistics including telehealth delivery, schedule, space, equipment needs, and recipe selection. A partnership with the Outreach Department of the Indian Health Center was established to recruit participants into the classes. A community event was held to further explore recruitment and retention strategies with key informants within the community. A full series of 7 classes has been conducted to date. A total of 22 participants enrolled into the classes; 18 attended at least 4 classes. Dinner and take-home meal kits were provided each class. A local cafe prepared the meals for the classes and volunteers from the community helped with childcare. Participants provided feedback about the acceptability and appeal of the content and delivery mode by completing a survey at the end of each class and through a focus group interview after the last class of the series. Data is being compiled and organized using Excel spreadsheets for subsequent statistical and content analyses. Participants found the content useful to improve their eating practices at home and the telehealth format sufficiently engaging. A second series of classes will be conducted.

Abstract Name: **Resistance through Music in West Bengals Dalit Community**

For thousands of years, the caste system has had a stronghold on Indian society. Excluded from the four main castes, the Dalit, often referred to as “outcastes” and “untouchables,” are positioned at the bottom of the social hierarchy. In West Bengal, India, many individuals, often coming from upper castes, perpetuate the myth of the state’s supposed “casteless society.” However, the caste-based discrimination experienced by Dalit individuals reveals a different story. Dalit resistance dates back to Bengal’s colonial period, with efforts continuing in the post-independence era. Amidst nationwide Dalit activism and growing literary efforts in the 1960s, the Bangla Dalit Literary Movement soon followed in 1976, producing literary and musical works that persist today. In this paper, I investigate the role of music in Dalit resistance and the importance of storytelling within Dalit music. I analyze musical examples from Smritikana Howlader (b. 1960), a prominent Bengali Dalit singer-songwriter, poet, and political activist affiliated with efforts of the Bangla Dalit Literary Movement. Howlader’s music falls into the broader genre of Bengali modern music, influenced by folk traditions, Laghu Shastriya Sangeet (light Indian classical), and anti-British protest music. Her music, emblematic of her experiences as a Dalit woman, is rooted in her training in Hindustani classical music, often featuring a range of composed and improvised portions. In addition to her musical style, I focus on her songs’ lyrical content and performances. I investigate how Howlader’s songs reflect uniquely Dalit experiences through the mode of musical storytelling. Additionally, I explore how her performance has fostered a stronger sense of Dalit identity and belonging within the Bengali Dalit community. Ultimately, I argue that these musical and performative aspects of Howlader’s art serve to combat dominant caste ideologies and Dalit erasure, furthering the resistance efforts of Bengali Dalits.

Abstract Name: **Creative Ways of Broadening Participation in Undergraduate Research**

In this panel discussion, moderated by Prajukti (juk) Bhattacharyya (UW-Whitewater), three panelists will highlight innovative and effectivepractices for broadening participation in undergraduate research from the perspectives of faculty and administrators. These presentations will describe successful models of expanding participation from an administrator’s point of view, as well as highlight the roles of community engagement, mixed-age mentoring, and seminars designed to develop students’ identities as scholars.Catherine Chan from UW-Madison will highlight various barriers for expanding participation,and provide practical tools and effective collaboration strategies for overcoming those, based on her almost two decades of experience as a faculty mentor, grants administrator, program manager, and institutional administrator at different types of institutions.Angela Frey (co-author Jennifer Johanson) from Alverno College will showcase a mixed-age project where upper level students apply their STEM learnings to fulfill an unmet need of a community organization and disseminate their works through blog posts and presentations, while beginning students comment on those posts and personally reflect on the value of those projects conducted by upper-level projects. This presentation will focus on how the design of this project provides role models and leadership opportunities through community engagement, and ultimately leads to increased STEM identity and retention for students from underrepresented backgrounds.Alena Kubatova (co-authors Daphne Pedersen, Rebecca Simmons, Shaina Mattingly, Ka nishka Marasinghe, Gregory Vandeberg, Ryan Zerr) from University of North Dakota will describe a 1-credit science literacy seminar course paired with different curriculum-based research experiences (CURES) offered over the last three years. This presentation will focus on the impacts of these readings and discussions on beginning students on developing their STEM identities, interest in science topics, and formation of deep connections with faculty and peers.

Abstract Name: **The Neurocognitive Effects of Chemotherapeutic Drugs**

Chemotherapeutic treatments targeting rapid cell growth and tumorigenesis have prolonged the lives of cancer patients. However, many treatments have toxic off-target effects on normal tissue and organ systems, including the brain. Patients report persistent cognitive impairments including memory loss, anxiety, and fogged perception following treatment. Currently, there are no treatments against chemotherapy induced cognitive decline, and the underlying mechanisms remain unknown. In this study, we assessed the effects of common breast cancer chemotherapeutics cyclophosphamide, methotrexate, and 5-Fluorouracil (CMF) on cognitive function and immune-cell infiltration in mice. Here, we observed CMF created behavioral alterations in brain region dependent memory, anxiety-like behaviors, sociability, and locomotor function. Additionally, CMF treatment leads to alterations in resident and infiltrating immune cell populations throughout the brain. These findings give way to a more complete understanding of the neurocognitive impairments induced by off-target chemotherapeutic toxicity and provide a crucial first step towards understanding and improving the quality of life for cancer treatment survivors.

Abstract Name: **Dating Apps and Social Anxiety among Asian Undergraduate Students Post-COVID-19**

With the rise of dating apps, meeting new people has become increasingly convenient for young adults and individuals who prefer online communication. In this study, Social Compensation Theory will be used to analyze how socially anxious individuals try to compensate for their shortcomings in face-to-face interactions by using online dating apps. Previous research suggests there is an interdependent relationship between dating app usage and social anxiety. But this relationship is rarely examined within specific ethnic groups which unique cultural norms and practices may influence. This study investigates the relationship between social anxiety and dating app usage post-COVID-19 among Asian undergraduates at George Mason University. Participants (N = 200) will complete a survey through Qualtrics, a secure online survey platform. The survey will include a series of Likert-type questions. Social anxiety will be assessed using measures adapted from existing instruments such as the 18-item Social Phobia and Anxiety Index scale. Participants will be recruited through flyers and a campus engagement platform, George Mason University's Mason 360 portal. If the sample size is not fully achieved online, additional participants will be recruited on campus using in-person methods. Data collection will be completed by February 2023 and data analysis will be finalized by March 2023.

Bianco, Kristin

Abstract Name: **Rainwater Harvesting: A Lens into Sustainability Initiatives**

There have been numerous studies done researching the effectiveness of rainwater harvesting on a country's CO2 emissions and analyzing the best dimensions of collection barrels to optimize cost benefits, yet there has been minimal research on how a community can implement these types of programs to their constituents. Oftentimes, academia waits for research to "trickle down" to the general public. However, if there is no one to execute the findings of research, much of the work is for naught. Multiple cities have recently been attempting to reintroduce the practice of rainwater collection to conserve groundwater and instigate sustainability. The James River Basin Partnership, a nonprofit in southwest Missouri dedicated to protecting local waterways, has a program with the mission of promoting rainwater collection through a rain barrel rebate program funded through the state; however, they have been facing trouble in terms of participation. This paper proposes a study analyzing three different ways to introduce and market a rainwater harvesting system in three different neighborhoods in the JRPB region of Springfield, Missouri to maximize a nonprofit's abilities to best introduce sustainability initiatives into their community and follow through with the application of research done in academia. The works of Goldstein (2008) on water conservation have shown that social comparisons encourage residents to be more mindful of their water usage, and this proposed study will test this as well.

Abstract Name: **Pipeline to Success through Research and Community Connections for Underrepresented Women in STEM Majors**

Alverno College is the first Hispanic serving institution in Wisconsin with programs aimed to increase the population of STEM majors from underrepresented communities. In 2011, a pipeline was created with the Girls' Academy of Science and Mathematics program (GA) where high school girls work with the Natural Sciences, Mathematics, and Technology division (NSMT) faculty on Friday nights to participate in STEM activities, which encourages them to apply for undergraduate STEM programs. Since 2018, NSMT has increased its capacity to provide STEM undergraduates with on-campus summer research opportunities. Traditionally, these programs are designed for upper level students; however, Alverno's program is open to students of all grade levels. The main goal is to increase student self-efficacy in the laboratory, connect scientific research to the local community, and increase persistence in STEM majors. Alverno and the Milwaukee Riverkeeper has established a partnership in efforts to make a community-based connection and assist in water analyses researched each summer. Beginning-level students conduct water sample collection, analyses, and hypothesis building using chemistry and biology methods over a six week program. Upper-level students conduct more advanced water chemistry analyses, microbiological, and molecular biology research over eight weeks. Students attend weekly laboratory meetings and professional development sessions to learn about STEM careers, research/internship opportunities, and receive academic advising.GA has served over 730 students. The majority of participants are girls of color (96%) and those who qualify for free or reduced lunch (98%). Each year approximately 18-20 girls matriculate from GA to Alverno with about half majoring in STEM. The summer research program has supported 73 researchers (56 unique students), 65% who identify as women of color with a 95% persistence rate. A common themed found was an increase in personal identity as a scientist (self-efficacy). Furthermore, 54% of 2021 summer researchers applied for off-campus research opportunities.

Abstract Name: The effects of arbuscular mycorrhizal fungi on plant defense in Nicotiana rustica in response to simulated herbivory

Plants have evolved various techniques by which they protect themselves from herbivore damage. In developing these defense mechanisms, plants allocate resources away from growth to increase chances of survival. In an effort to compensate for this distribution of resources, studies have shown that plants can enlist the help of arbuscular mycorrhizal fungi (AMF), a mutualist that penetrates roots and exchangesinorganic nutrients for sugars. Prior research has indicated that under certain conditions both growth and defense increase inAMF-inoculated plants.Nicotiana rustica is one species that is associated with AMF. This tobacco species possesses both physical and chemical defenses, primarily in the form of trichomes and the alkaloid, nicotine. Through inoculation of this tobacco with AMF, we can investigate the mutualists effect on growth and defense mechanisms. In thisgreenhouse experiment, we will be looking at the effects of inoculation timing coupled with simulated physical herbivory. Plant mass measurements will betaken72 hours post herbivory. Nicotine levels and trichome density will be analyzed on select leaves of each treatment group. Based onprevious research, we expect to see increased defense in all herbivore damaged plants as well as heightened growth in all AMF inoculated plants. Higher levels of defense will be shown in all damaged inoculated plants, with the greatest levels seen in plants inoculated post germination.

Abstract Name: Yearly Survival and Growth Rates of Propagated Fatmuckets (Lampsilis siliquoidea) in Central Wisconsin

Freshwater mussels are key members of riverine ecosystems and are crucial for improving water quality. Mussels serve as valuable indicator species and suffer from many environmental disturbances, but despite their importance, large gaps remain in knowledge of freshwater mussels in Wisconsin. We measured the survival and growth of mussels exposed to ambient conditions in two streams in Central Wisconsin. Both selected streams included those that support diverse mussel assemblies. On October 29th, 2021, we received 120 Fat Muckets (Lampsilis siliquoidea) from the Genoa Fish Hatchery, measured, then released them into suitable areas on the Mill Creek; the Plover River Near Stevens Point, WI. Before release, mussels at the Mill Creek site averaged 1.853 cm in length, 1.03 cm in width, and 0.52 cm in thickness. At the Plover River site, mussels averaged 1.859 cm in length, 1.068 cm in width, and 0.546 cm in thickness. We utilized silos to encompass the 1.5-year-old mussels. Each site has 1 silo, containing 15 individuals per silo. Our objective is to determine seasonal survivorship and growth rates throughout our year-long study. Experimentation at these sites will provide an indication to determine which areas are suitable for future reintroductions. We expect 1) Mussel growth and survival will be significantly reduced in the winter months, compared to the summer months. 2) Mussel growth and survival will be significantly different between the two sites. These sites were measured monthly beginning April 21st and lastly October 21st, 2022. This is part of an ongoing study through the University of Wisconsin – Stevens Point's student chapter of The Wildlife Society.

Abstract Name: Social Media and Self-esteem

Social media, what did we do before it existed? Were we better off before or are we now? The debates around social media use are endless. There are strong viewpoints on both sides. Some believe it is literally the demise of human society, contributing to the delinquency of minors and providing negative information that molds the minds of the young. Others believe it is entertainment and provides no harm to society and has no impact to the changing world we live in. Still others are cautiously in the middle. While social media has been around for some time now, we still know very little about the potential long-term impact. The population most influenced is the young. This research study explores the association between age of beginning use of soical media and the impact on various aspects of development. The key areas of interest are mental health, self-esteem, sexualization, achievement and addiction. Correlational analysis will be completed in the spring semester of 2023.

Abstract Name: Competition Demands of NCAA Division III Women?s Collegiate Lacrosse

In an effort to assess the demands of NCAA DIVISION III woman's collegiate lacrosse, Global Positioning Systems (GPS) were used to quantify positional demands during the 2022 College Conference of Illinois and Wisconsin season (NCAA Division III) for the Carthage College Women's Lacrosse team. GPS data was collected from twelve female athletes using a sampling rate of 10 Hz (Titan 2, Integrated Bionics Inc. Austin, Texas). When comparing total distance by position, a statistically significant difference was found between the midfielders and attackers ($p < 0.01$; ES = 1.75, large) and between the midfielders and defenders ($p < 0.01$; ES = 1.95, large). No differences were observed between attackers and defenders ($p = 0.15$; $d = 0.34$, small). The main finding was that midfielders covered significantly more total distance than both attackers and defenders. Calder et al. (2021) observed similar distances among female defenders (7517 ± 786 m), midfielders (6972 ± 770 m), and attackers (6806 ± 586 m) at the NCAA Division I level. Calder's findings were that defenders covered the most distance during competition; conversely, the midfielders covered the most distance in this study. These differences are likely due to the teams' style of play and talent level. Furthermore, all positions experienced a decline in total distance covered as the game progressed, consistent with other studies (Calder et al., 2021; Varley et al., 2014). These effects are likely due to fatigue, and by developing positional profiles of volumes throughout match-play, coaches can ensure their athletes are prepared for competition demands. It is suggested that coaches and practitioners ensure lacrosse players can handle distances of 6130-8110 m during match play; it is best achieved if players are trained by positional needs. This specific training may help reduce the progressive loss in total distance covered with each quarter played.

Abstract Name: **Analysis of Waterfowl Browse on Wild Rice (Zizania spp.) in Northwestern Wisconsin**

In Northwestern Wisconsin, wild rice (Zizania spp.) not only serves as an important food source for people and animals, but it is also a particularly important cultural grain. Wild rice is an abundant and nutrient rich food source used by several waterfowl species including swans and geese. Although wild rice grows in a cyclic pattern, the increased presence of swans and geese on flowages in Northwestern Wisconsin may affect wild rice availability in the area. For example, waterfowl species have been observed eating wild rice stands and they appear to have been mechanically mowed in Crex Meadows State Wildlife Area. How intense use of these stands by waterfowl affects wild rice production is unknown. To measure the possible effects of these waterfowl species on wild rice, we constructed exclusionary fences on three flowages. We compared weight, height, density, and substrate samples from inside and outside the exclusions to investigate the possible overgrazing by swans and geese. We collected 10 samples from inside each fence and 10 outside (N = 60 plants) across all three flowages monitored. A sample plant was taken within each study quadrat at random, washed, dried, and weighed. Samples were processed in the herbarium at the University of Wisconsin – Stevens Point. We predict that wild rice densities and biomass will be higher within the exclusionary fencing than the wild rice outside the exclusions that is actively available to browse by resident waterfowl species. We will discuss the impacts of waterfowl overgrazing on wild rice stands in Northwestern Wisconsin.

Abstract Name: **Sexual Assault Awareness and Prevention**

This exploratory study examines the knowledge about prevention and education on sexual assault and how the topic needs to be discussed often. The research aims to inform the audience on the problem of how society discusses sexual assault, and it explores reasons for reporting.The student researcher reviewed six peer-reviewed journals about sexual assault. Trauma-Informed Perspective and Strengths-Based Perspective also informed the study. The student researcher administered 25 surveys to three different populations: college professors, advocacy directors, and college students. The researcher's hypotheses center on the perception of program effectiveness based on the type of participant. The researcher used a non-probability purposive sampling method with mixed-method survey of qualitative and quantitative questions. The student researcher collected data for 30 days. The student researcher distributed an online survey with demographic questions, questions regarding the reporting process, improvement, and needs during the duration of this process.The student researcher used quantitative analysis such as chi-square tests and correlations to determine any statistically significant findings. The qualitative data is observed from the open-ended questions to identify codes, categories, and themes.The survey contained four demographic questions regarding gender, age, race, and the participant's status. The majority of the participants were female (64%, n=16), 18 to 24 years old (80%; n=20), White American (80%, n=20), undergraduate students (72%, n=18). The student researcher ran a Bivariate Correlation to determine the relationship between age and reporting. The Pearson correlation between the two variables age and reporting revealed a moderate to a strong relationship.The student researcher examined 25 qualitative responses, of which 23 generated codes were collapsed into 4 themes.This research has implications for the micro, mezzo, and macro levels of social work practice. By exploring further information on advocacy programs, researchers will provide a better understanding of how to increase reporting on college campuses.

Abstract Name: **Neural and Behavioral Correlates of Sensation Seeking**

We sought to clarify both behavioral and neural characteristics of sensation seeking. In particular, we were interested in two components of event-related brain potentials (ERPs) elicited during a response inhibition task: the P3a, which is elicited by novel, unexpected, stimuli, and the P3b, which is elicited by targets. Participants completed self-report questionnaires to measure their sensation seeking. During the task, participants were presented with three types of visual stimuli in randomized order at a rate of approximately one every 1.25 s. The stimuli were (1) non-targets, to which they should make a response, (2) targets, to which they should withhold a response, and (3) novel stimuli, to which they should withhold a response. The targets and non-targets were relatively benign, but required sustained attention to tell them apart. The novel stimuli were photographs depicting arousing situations (e.g., skydiving). Based on previous research, we predicted that (1) the P3a would be positively correlated with sensation seeking, (2) the P3b would be negatively correlated with sensation seeking, and (3) response accuracy to novel stimuli would be inversely correlated with sensation seeking. P3a and total sensation seeking were positively correlated, but the relationship was small and not statistically significant. In contrast to our prediction, P3b was moderately positively correlated with total sensation seeking. Finally, response accuracy was not correlated with total sensation seeking. Although none of our hypotheses were supported for total sensation seeking scores, we did find relationships between the ERP components and total sensation seeking, boredom susceptibility, and disinhibition.

Abstract Name: **The Universal Mass Function and its Applicability to Organic Molecules**

The ability to predict the yield when synthesizing an organic molecule is a challenging issue in organic chemistry and a major obstacle when planning a multi-step organic synthesis.It would be beneficial to predict the yield of the product such that the most time, money, and waste efficient method can be used.The Universal Mass Function (UMF) states that cosmic objects on all scales are in direct relation to each other. It shows that massive objects are much rarer than objects with lower masses. The following research aims to examine if the UMF theory is applicable to the field of organic chemistry, specifically to theyield prediction.The primary reaction chosen for this research was the substitution reaction of alcohol to different derivatives of alkyl halides in protic environment. For that reaction, due to the widely known reactivity of the molecules in protic environment, we expect to observe results that are opposite of that which support the UMF.Due to the known reactivity of the molecules, the largest halide is expected to have the largest yield based off nucleophilic properties. However, preliminary results contradicted this and supported the UMF theory as we received higher yields from alkyl halides derivatives with lower molecularweights.Ratificationof the Universal Mass Function on small-scale molecules is significant since in addition to helping overcome a major problem in the field of organic chemistry. It would make a huge impact on the pharmaceutical industry by enabling the prediction of the most efficient drug synthesis.

Abstract Name: **Risk-sensitive behaviors vary with human activity, age, and personality in free-living California ground squirrels**

Animal personality, defined as consistent individual differences in behavioral response over time, is a well-documented phenomenon within natural populations of animals. Previous studies have examined the effects of intrinsic state and population membership on behavior; however, few have explored the effects of human presence on personality. For this study, we developed a behavioral assay to quantify individual responses of free-living California ground squirrels (Otospermophilus beecheyi) from two populations that differ in their exposure to human presence. We examined the extent to which each of the four major behavioral responses (e.g., vigilance, hiding, exploring, chewing/scratching) were repeatable for individuals over time, and the effects of age, sex, mass, and study site on these measures. We found strong evidence for repeatable personality traits for all behaviors except for vigilance. Instead, vigilance was best explained by an individual's attributes (e.g., age, sex, adjusted mass) and current environmental conditions (e.g., day of year, site of trapping). Our findings have implications for understanding the effects of ontogeny, season, and human activity on animal personalities.

Abstract Name: **Investigating Preservice Teachers' Understandings of the Causes of the Seasons**

Understanding the causes of the seasons is a major concept addressed in A Framework for K-12 Science Education and the Next Generation Science Standards (NGSS) in grades K-12, and a concept preservice K-12 teachers are expected to understand. The purpose of this explanatory mixed-methods study was to assess preservice teachers' understanding of causes of the seasons and categorize prevalent alternative conceptions they have about this domain. Seventy-two undergraduate students enrolled in education courses at a large midwestern university and a small midwestern liberal arts college participated in the study. A multiple-choice concept inventory survey including two open response tasks was developed from the research literature for the study. The survey data were then used to purposefully select a stratified sample of students to participate in a follow-up conceptual interview. Descriptive statistics were used to analyze concept inventory data, and qualitative deductive coding using a constant comparative method was used to analyze interview responses. Preliminary survey findings collected from the liberal arts college indicated an average score of 5.39 out of 15 (35.9%) with a range from 2 to 12 and a median of 5. Overall, they demonstrated greater understanding on questions answerable from an Earth-based perspective with a mean of 65% on three questions. These tasks addressed the time of year their region experiences the greatest amount of sunlight and naming the corresponding season in the southern hemisphere given the northern hemisphere season. Students scored the lowest (mean of 28% on 10 tasks) on tasks that required explanations from a space-based perspective, such as causes of the seasons and why there is more sunlight during summer in the northern hemisphere. Details from the entire data set from 72 students and concept interview also will be presented.

Abstract Name: Exploring the Contextual Interference Effect Using a Bimanual Coordination Task

Stroke, amyotrophic lateral sclerosis (ALS), and other movement disorders result in loss of upper limb function, thus impairing bimanual coordination. Motor imagery is an effective clinical intervention for accelerating recovery; however, the cognitive and neurophysiological parameters that inform effective strategies remain elusive. The study aims to explain the neural dynamics that underlie bimanual coordination during real and imagined movement. Healthy young adults (n=13) learned a visuomotor tracking task using either one or both hands in a single session. Two dials control the movement of an on-screen cursor. The left and right dials correspond to vertical and horizontal cursor movement. The participants were tasked with tracking a moving target using the left and right dials with the appropriate speed and direction. Before the session, each participant was fitted with a 40-channel EEG cap (Compumedics, Neuroscan). Two phases were tested: unimanual and bimanual control. The first phase consisted of unimanual control using the left hand to draw a vertical line and the right hand to draw a horizontal line. The second phase consisted of bimanual control in a 3:1 pattern followed by a 1:3 pattern. The pattern notation represents the ratio of left-hand turns to right-hand turns. Trials were 10 sec in duration, elapsed time from target origin to target endpoint; the intertrial interval (ITI) was 5 sec. Each trial block was followed by a mental imagery condition (MI) where participants were asked to imagine performing the task they had just completed with their eyes closed. Mental chronometric data were collected, and vividness ratings were assessed by self-report immediately after each trial block. The results indicated learning in a single secession; [F(1,10)=19.43, p<.001]. EEG analyses of active vs. rest conditions, and real vs. imagined conditions, are underway. These results may inform neurorehabilitation strategies for patients recovering from movement disorders (upper limbs).

Abstract Name: Developing A Safe-At-Home Benzoin Condensation from Imitation Almond Extract

COVID-19 remote learning forced instructors to scramble for meaningful organic laboratory experiences safe enough to perform at home. While resources are available for laboratory experiments at home, organic synthesis suffers from issues involving safety, difficulties measuring reagents, and difficulties analyzing products.Benzoin condensation reactions commonly use bases such as sodium hydroxide or triethyl amine, and organic solvents that are less safe and not widely available.We were able to use a pinch of baking soda instead of stronger and less available bases. We were able to perform the reaction with imitation almond extract with no additional solvents, eliminating the need for separate sources of benzaldehyde and organic solvent.Most laboratory reactions are measured out in grams on scales precise to the milligram unit or better.Unfortunately, most students don't have such scales available at home. For catalytic reagents, we were able to use readily available at home kitchenware such as a teaspoon or other common cooking measurements such as "a pinch". The benzoin condensation is a convenient reaction to perform at home because the benzaldehyde is self-reactive, allowing us to avoid precise stoichiometric measurements of any reagents.While many laboratory analyses will continue to remain out of reach for the home laboratory (although we have high hopes for an NMR in every kitchen), the clear development of white, needle-like crystals in this reaction offer a compelling visual confirmation of the reaction completion, while yellow tints that develop in the solution can indicate a further oxidation of benzoin to benzil, often a subsequent reaction in our in-person laboratories.

Abstract Name: **Grief Support in Nursing Homes**

A half-million older adults die in U.S. nursing homes (NHs) each year. These statistics have been compounded during the COVID-19 pandemic. As a result, growing numbers of older adults make end-of-life decisions and receive end of life services in NHs. However, only a few studies have been conducted on the experiences of the nursing home staff who provide this care. Mortality in nursing homes, staff attitudes, and environmental factors associated with mortality are important figures for health authorities and decision makers as they consider policy revisions to enhance care and outcomes. This research will provide valuable data in this area- in particular the purpose of this study is to examine the organizational practices in nursing homes specific to end of life care. Participants will be drawn from approximately 40 primarily Midwestern skilled nursing facilities utilized as administrative internship sites for students in the University of Wisconsin – Eau Claire's long-term health care administration program. Researchers will use a multi-step inductive approach to seek patterns of meaning within interview responses. The research team (four faculty members and two student researchers) will complete an initial review of the data set seeking common responses. Primary categories will be identified, and student research assistants will then code responses. After initial coding, the entire research team will meet to review and refine categories and verify coding agreement. The team will develop a master list of categories with examples of each category to reference and utilize during the coding process. The team will review the data for novel ideas that might be of interest for practitioners, providing suggestions for innovative operational improvements to end of life care. The dataset is currently being coded. A variety of both common and unique exemplars or practices that researchers believe could be considered for widespread adoption and implementation will be highlighted.

Abstract Name: **Template-Free, Scalable Manufacturing Process for Linear Periodic Microstructures with Drag Reduction Applications**

Inspired by nature, the scientific community have designed periodic micro/nano-scale surface structures for a wide variety of applications. One particular application of interest is superhydrophobic drag-reduction. By aligning these microstructures with the direction of fluid flow, prior modeling and experimentation have demonstrated up to a 75% a decrease in frictional drag. A common manufacturing process for these periodic microstructures is photolithography. This method allows for repeatable and accurate surface structures; however, it is limited by cost and scalability (typically produces one 6 in diameter surface). The limiting factors of photolithography impact the potential for practical applications, and as an alternative manufacturing approach, the scientific community have become interested in a ribbing phenomenon found in roll coating. This study controls the ribbing phenomena and demonstrates a template-free, simple, scalable manufacturing process to fabricate periodic microstructures. Carbon nanotubes (CNT) and polydimethylsiloxane (PDMS) are utilized to develop a viscoelastic composite material for roll-coating. During roll-coating, the process parameters are carefully controlled to maintain a linear structure. If the parameters are not controlled, the microstructure becomes random and emulates a surface pattern that is commonly found on lotus leaves, which is not ideal for drag reduction. The derived periodic microstructures, with a periodicity of 114-700μm, were hydrophobic with water contact angles (WCA) that ranged from 128°-158°. A model boat was then coated with a film of the fabricated microstructures and exhibited a 7-8% increase in velocity when compared to a boat coated with a flat PDMS film. Furthermore, the inclusion of CNTs improved the mechanical properties of the composite film. The cohesive failure of the CNT-PDMS composite occurred with around 90% more force than a simple PDMS film during a mechanical scratch test.

Abstract Name: Detecting a Buried Log Flume and Canals: A Geophysical Investigation of the Subsurface

In the nineteenth century, the lumber industry was the impetus for western Wisconsin's development. Lumber was transported from forests to processing facilities via rivers. Humanmade waterways, such as canals and log flumes were built to connect rivers with sawmills. One such instance is in Eau Claire, Wisconsin, where canals and a log flume were built to connect the Chippewa River to Half Moon Lake. Little evidence of the flume ditches, tunnel, and canals are present above ground as they have since been filled. Flume ditch, flume tunnel, and canal locations were identified through archival research, georectification of historical maps, and aerial photographs. Studies have shown that ground penetrating radar (GPR) is a viable method for locating tunnels and ditches. GPR is a non-invasive subsurface imaging method which utilizes electromagnetic pulses and their reflections. GPR was used to locate evidence of the flume and canals in the subsurface based on historical maps and aerial photos. Data was collected using a pulseEKKO Pro GPR system with 100MHz antennae, and a 0.25m step size along survey lines. Data was collected in reflection survey mode, with a 500ns time window. GPR transects were topographically corrected with 2m interval data collected using a Topcon RL-H4C laser level. Data was processed and visualized with EKKO_Project V5. GPR data was interpreted with considerations for land use changes over time, and with maps and aerial imagery depictions of features. Modelled results show subsurface features unique to the flume ditch, tunnel, and canal structures which have been altered by redevelopment. Unique features of these structures are size, shape, and position relative to historical maps and aerial photographs.

Abstract Name: Transgender and Gender Diverse Individuals of Various Resident Locations and Racial and Ethnic Identities Healthcare Experiences

Research has outlined barriers to quality healthcare for trans individuals. As resident location becomes more rural, healthcare access and quality decrease. Extant research has yet to determine how this impacts explicitly Black, indigenous, and people of color (BIPOC) transgender and gender diverse (TGD) patients' access to informed healthcare practitioners - an extension of historic underrepresentation in research both as researchers and participants. This exclusion, and its structural underpinnings, are illustrated in higher rates of healthcare insecurity and a medical education system that continues to teach racist and inaccurate information, lacking in the nuance of intersectional realities faced by TGD BIPOC. How does the relationship between resident location, racial and ethnic identity, and healthcare access function? This cross-sectional, mixed-methods study examines the relationships between race, location of residence (rural, urban, suburban), and healthcare access/quality for TGD healthcare patients. Our team wrote survey questions that assess various attributes of healthcare access (such as commute time to the healthcare facility, access to health insurance, emotional comfortability accessing care), healthcare experience (such as instances of discrimination in the healthcare setting), and demographic questions (such as participants location of residence (rural, urban, suburban), and racial/ethnic identity). We conducted six pilot cognitive interviews to aid in questionnaire revision. We launched our broad wave participant recruitment of a national sample, with plans to complete data collection and begin data analysis in December 2022. Anticipated outcomes include calls to action for healthcare practices and policies affecting TGD BIPOC and creating a social media page to share our findings and resources more broadly with the TGD community.

Abstract Name: Mitochondrial Transfer Between Mesenchymal Stem Cells and Cardiac H9c2 Cells

Mesenchymal stem cells (MSC) have been shown to improve heart function after myocardial infarction, but the exact mechanisms are not completely understood. Studies have shown that stem cells are able to transfer mitochondria through cytosol extensions to change the abilities and programming of surrounding cells. The purpose of this study was to determine whether mitochondrial transfer takes place between MSCs and cardiac H9c2 cells, and the effect of hypoxic conditions on this process. The mouse bone marrow MSC cells were cultured in DMEM + 10% FBS for MSC and H9c2 cells were cultured in DMEM + 10% FBS. Previous studiess stained the MSC mitochondria using MitoTracker Red CMX Ros (Invitrogen), while H9C2 cells were stained using CellTracker Green CMFDA (Invitrogen) according to the manufacturer's instructions. Following staining, the cells were co-cultured for 24 hours in Fluorobrite DMEM (Gibco) + 10% FBS in 4-well glass culture slides. After washing with PBS and mounting with ProLong Live Antifade Reagent (Invitrogen), cells were observed using an Olympus BH2 fluorescent microscope. Results showed close interactions between MSC and H9c2 cells with mitochondria in long filamentous extensions that made contact with H9c2. There was some evidence that mitochondria were transferred from MSC to H9c2 cells. We now are looking to determine whether mitochondria are able to travel in both directions. We will also study whether mitochondrial transfer is affected by hypoxic (1% O2) conditions. These results continue to suggest that mitochondrial transfer may be one mechanism used by MSC to improve heart function after myocardial infarction.

Abstract Name: Efficacy of Social and Physical Support for Cancer Patients

Cancer is the second leading cause of death in the United States. In addition, cancer treatments provoke harsh side effects that demand extra strength from the patient. Cancer causes lifestyle modifications that can be detrimental on the patients' health; however, healthy habits can potentially increase the chances of a positive prognosis. Additionally, physical, and social support has proven to help patients in their fight against cancer. Since the lack of physical and social activity in patients with cancer has been shown to correlate with mental and cognitive decline, ultimately reducing quality of life, the purpose of this study is to examine the relationship between physical activity and quality of life in patients with cancer And increase their overall quality of life.This project included eight female participants that are currently struggling with cancer, or the cancer is in remission. The program consisted of group discussions, fine motor movements, and various physical activities twice a week for three weeks. Using pre/post intervention questionnaires and a dependent t-test, the significance of social and physical activities amongst the participants were analyzed. The dependent t-test showed a significant difference (t=-3.729, p=0.007) in the overall quality of life between pre and post program. These preliminary results imply that implementing a support group such as Healthy Habits that includes the use of physical and social activity, improves the overall quality of life of patients with cancer. In conclusion, the program created an additional outlet for individuals with cancer to find a relatable support group that can aid with daily struggles. Further analyses in a larger sample and with longer duration will provide stronger evidence about the relationship between physical activity and quality of life in patients with cancer.

Abstract Name: **Artificial Intelligence-Assisted Prediction Model of Climate Change Impacted Solar Power Generation for Life-Supporting Equipment in Eastern Kentucky During Natural Disasters**

As a person who has lived in the eastern Kentucky area for most of my life, floods are something that has been a consistent problem for the people who live there. There is a great effort to help those affected by natural disasters, but there is always a greater struggle for those impacted by their diminished health during natural disasters, like the historic eastern Kentucky flooding in 2022. The frequency and intensity of heavy precipitation events will become more common, exacerbated by climate change, leading to the kinds of flooding that once skipped generations to occur every few years.To ensure the safety of the people that need on-site power generation for their life-supporting equipment during natural disasters, we have developed the prediction model of solar power generation using Artificial Intelligence (AI) techniques and programming languages such as Python and MATLAB. Models will be developed considering weather patterns and climate variability, impacted by climate change. We could analyze the correlation of historical data on the timeline of natural disasters that have happened in eastern Kentucky. Utilizing developed models, we could prepare people prior to natural disasters by predicting when the next one will occur.Solar energy is a safe, environment-friendly, and abundant energy resource available for decentralized and on-site power generation that can reduce the burden of an electric power grid. Solar panels would work well for the life-supporting equipment whenever the power goes out during natural disasters since it makes the equipment not rely as much on the house's power grid connection. To ensure the effectiveness of the solar panels, we used historic weather data to predict how many solar panels would be needed during the time of year that the floods would occur. Using batteries, we could accumulate enough energy for the life-supporting equipment to run all night.

Abstract Name: **Tactile Instructions for Wearable Physical Rehabilitation**

Patients of all ages, who have a range of medical conditions or injuries, use physical therapy to help ensure they have a full recovery. Physical therapy is useful to help manage pain, regain mobility and comfort, and return to activities. However, research has found as low as 35% of patients actively do at-home exercises for physical therapy. When patient adherence is low, recovery is less effective. This leads to further complications of the patient's condition and can hinder future recovery. Low self-efficacy is a leading reason patients say they do not do at-home exercises, as they believe they cannot effectively carry out an exercise on their own. The proposed research seeks to explore wearable computing systems to develop a device that enables patients to receive haptic feedback on their movements while at home and apply corrections as though a therapist was working hands-on with them, thereby increasing their confidence in completing the activity. To date, wearable technology most frequently uses accelerometers and inertial measurement units to track human motion and performance. Designing wearable devices that are comfortable, adjustable, and interpretable by the wearer, is challenging. Our current design uses haptic feedback to help users receive feedback on simple activities. We developed a glove with embedded motors that vibrate guiding the movement of the patient within a two-dimensional plane. Ongoing research is exploring extensions of this approach to upper-arm mobility by developing novel tactile instructions. A user study will be conducted to explore vibration patterns and examine the upper arm mobility with tactile motor instructions.

Abstract Name: Ablation of Mitochondrial RCC1-like in Dopaminergic Neurons Yields a Parkinsons Disease-like Phenotype and Abnormal Mitochondrial Morphology in Mice

Parkinson's disease (PD) is a neurodegenerative disorder that results in memory and learning deficits as well as unintentional or uncontrollable movements (i.e., resting tremors, muscle stiffness, etc.). Recently, mitochondrial dysfunction has been linked to both idiopathic and familial forms of PD. Rcc1-like (Rcc1L) protein, found in the inner mitochondrial membrane, has been identified as playing an important role in mitochondrial fusion. Our group has selectively knocked out Rcc1L in mice dopaminergic (DA) neurons within the substantia nigra pars compacta (SN), which results in PD-like phenotypes including progressive movement abnormalities and degeneration of the nigrostriatal track. In this phase of experimentation, mitochondrial morphology in the SN is being defined by imaging mitochondria shape within coronal tissue samples under a confocal fluorescent microscope. Heterozygous and wild-type models are used as comparisons to knockouts at 2 months, 3.5-4 months, and 5.5-6 months of age. Defects in mitochondrial morphology are apparent as early as 3.5-4 months, pointing to a role of Rcc1L in mitochondrial dysfunction characteristic to PD pathology.

Abstract Name: Analysis of 2 variants of CERKL, a gene associated with ocular disease

Genetic testing, including whole genome and exome sequencing, is quickly becoming a standard healthcare practice, especially for patients with rare diseases. While some changes to DNA sequences can be benign, there are several variants that have not been characterized. One large group of these variants are classified as variants of uncertain significance (VUS), as the effects have not been directly studied yet. However, effectively interpreting the relationship between identified variants and disease remains challenging. VUS can include variants that are predicted in silico analyses to affect splicing of the pre-mRNA into mature mRNA. Disruption of splicing can result in loss of a functional gene product due to exon skipping, changes in the reading frame, or introduction of a premature stop codon. In collaboration with PreventionGenetics, our lab analyzes VUS predicted to affect splicing of genes using a minigene system. Briefly, the minigene system involves cloning a single gene segment into a plasmid vector which is transfected into eukaryotic cells. Processed mRNA transcripts are then sequenced to determine the effects of the variant on splicing. We will present our analysis of 2 variants in the CERKL gene and their potential clinical relevance.

Abstract Name: **XRF Analysis of Pb Concentrations in Soils in and near Moorhead, MN**

Prior to its ban in 1996, leaded gasoline was available for use in all vehicles. We suspected there was an increased concentration of lead in the soil near Highway 10 near Moorhead Minnesota. The purpose of this experiment is to determine the impact of anthropogenic lead in soil.We collected 6 urban soil samples within Moorhead along parks, residential areas, and our college campus. We collected 18 rural soil samples east of Moorhead along highway 10 including two perpendicular transects to highway 10. A transect 1 mile, and a transect 7 miles east from Moorhead going North and South respectively. We collected both surface samples and samples approximately 6 to 12 inches in depth.We analyzed the samples by drying the samples at 100°-105°C for 18-19 hours. Using an agate mortar and pestle, we ground the samples to a powder. A Hitachi X-Met8000 Handheld-analyzer was used to analyze the elemental composition of the samples. We aimed to determine correlations in lead levels.Pb concentrations in urban areas ranged from 17 to 175 ppm. Rural variations showed a decrease in lead concentrations eastward along Highway 10 as well as a decrease away from highway 10 for the transect taken 1 mile from town. In rural and urban samples, we observed Pb statistically significantly decreased with depth.Our results show a trend in lead concentration with location and depth consistent with air-deposited lead from leaded gasoline. Although, regions with no obvious anthropogenic lead were decreasing in Pb levels relating to depth, as well. This suggests that soil genesis processes may also be a factor in the Pb concentrations, and warrants further research. Although most samples remained under the 100 ppm EPA guidelines for residential gardens, 2 urban samples taken along a major street exceeded this value.

Abstract Name: **Beyond the Injury: The Association Between Physical Characteristics and Injury in Competitive High School Dance Team Athletes?**

Our purpose is to determine the association between physical characteristics and function and injury incident and risk in competitive high school dance team athletes. Lower extremity injuries are one of the most prevalent injuries within dance, accounting for over 30% of injuries reported by dancers. Past research has investigated risk factors and patterns for injuries in pre-professional dancers. However, the association between physical attributes and lower extremity injury in high school team dancers has not been studied. Participants will be recruited through athletic directors and sport coaches at regional high schools. Prior to participation, dancers and/or guardians will provide written assent. They will be measured for various fitness and performance characteristics during the Summer of 2022, including height, weight, body composition, cardiovascular endurance, balance, flexibility, neuromuscular control, lower body relative power, and grip strength. The dancers will then be tracked through their coaches through their competitive season for lower extremity injury, and data will be collected until February of 2023. The data will then be analyzed through inferential statistics to determine differences in the measured values of those who did and did not sustain lower extremity injury. Additionally, logistic regression will be utilized to develop a predictive model for injury.

Abstract Name: A CONTINUED HIGH FIDELITY NUMERICAL ANALYSIS OF VARIABLE-SHAPE WAVE ENERGY CONVERTERS

A continued analysis of the novel Variable-Shape Buoy Wave Energy Converter (VSB WEC) to reduce reactive power requirements is presented in this paper. An original ninety degrees VSB WEC power take-off (PTO) unit connection location with a separate concrete plate was previously explored. An improved, buoy-integrated connection location of the PTO unit allows for enhanced nonlinear interactions between the VSB WEC and ocean waves, resulting in an increase in energy harvesting. The extension of the flexible buoy shell to the PTO unit connection point increases the continuous volume available for buoy deformation. A high-fidelity numerical simulation is used to contrast the energy harvesting capabilities of the improved VSB WEC with the original VSB WEC and conventional Fixed-Shape Buoy Wave Energy Converter (FSB WEC). A previously developed Computational Fluid Dynamics (CFD) Numerical Wave Tank (CNWT) using ANSYS 2-way fluid-structure interaction (FSI) is used to construct and simulate the three WEC behaviors and ocean wave conditions. Irregular ocean wave conditions in the CNWT are consistent across all three WEC simulations to accurately compare energy harvesting performance. A consistent buoy volume and mass are used to analyze the three WEC velocities, maximum displacements, PTO unit damping force behaviors, and power production. Results from the simulations indicate that the energy harvested from the improved VSB WEC shows significant increases in both transient and steady-state behavior compared to the previous VSB WEC configuration and FSB WEC energy harvesting. Future work in model development, simulation time extension, and computational cost minimization is also discussed in this paper.

Abstract Name: Shifts in Educators' Demands as a Result of a Global Pandemic

Previous researchers have found a number of demands facing K-12 educators in the height of the COVID-19 pandemic: learning loss amongst the poorest students (Moscoviz; Evans, 2022), difficulty maintaining discipline (Thakur et al., 2022), struggle to balance work with personal lives (Matthew et al., 2021), more time spent troubleshooting problems with technology (Herold; Kurtz, 2020) and barriers to e-learning (Maatuk et al., 2021). While there is some research on the needs of teachers during the peak of COVID-19 (Thakur, et al., 2022, Oramiz-Etxebarria, et al. 2021, Ansorger, 2021), there is not enough research on teachers' needs and supports in the present day as the pandemic comes to a close. Consequently, the purpose of this study was to use Maslow's Hierarchy of Needs (Maslow, 1943) to analyze the needs of teachers in a post-pandemic era. Specifically, the questions that we sought to answer were "What support mechanisms do teachers need in a post-pandemic era?" and "How do these needs differ from pre-pandemic needs?" This explanatory mixed methods study (Creswell, 2007) began with a survey that was sent out to K-12 teachers across the United States via social media to assess teachers' demands prior to the COVID-19 pandemic and present day. Following the survey, qualitative interviews were conducted with a sample of respondents to further inquire about their responses. The preliminary data suggests that present day teachers are experiencing these top three demands: student behavior, gaps in student knowledge, and respect for the teaching profession. The data also suggest that educators experienced similar demands prior to the COVID-19 pandemic, but with lesser concern. These final results will inform administrators and school districts of how to better support the present day needs of their teachers.

Abstract Name: Computer Simulation of Doped Amorphous Li3OCl Electrolyte for use in Next-Generation All-Solid-State-Batteries

As demand for renewable energy increases, the need for reliable energy storage technology becomes increasingly important. Lithium-ion batteries (LIBs) are the most widely used energy storage device in consumer electronics. However, current LIBs use flammable liquid electrolytes, which is a serious safety concern. Current Solid-state electrolytes mitigate the hazards of liquid electrolytes, but come with expensive manufacturing cost and limited ionic conductivity. Lithium-rich anti-perovskite (LiRAP) electrolyte materials have been recognized as a promising family of solid-state electrolytes for next-generation all-solid-state batteries owing to their structural stability, low fabrication cost, minimal environmental impact, and improved safety regarding chemical toxicity and flammability. Recently, doped glass electrolytes synthesized from LiRAPs have been reported to exhibit superionic conductivity with a high electrochemical window while maintaining thermal stability. However, an atomistic understanding of these electrolyte materials is lacking. Using computer simulation based on the density functional theory (DFT), the structural characteristics of doped amorphous Li3OCL (LOC) will be investigated. Ionic conductivities will be calculated using ab initio molecular dynamics (AIMD) simulations as implemented in the Vienna Ab Initio Simulation Package (VASP). Various dopants, including Barium, Magnesium, and Scandium will be studied and the effects of ionic radius, valence states, and impurity concentrations will be explored. Based on these results, strategies to further enhance the ionic conductivity of amorphous LOC will be Proposed. Our research could lead to solid-state electrolyte materials with ionic conductivities comparable to those of contemporary liquid and polymer-gel electrolytes, which will be the ideal candidates for use in the next-generation all-solid-state batteries.

Abstract Name: Mutant GBA1 Mice Show Impaired Contextual Memory and Increased Hippocampal ?-synuclein Pathology in a Parkinson's Disease Model

Parkinson's disease (PD) impacts over 2 million people in the United Statesand over 10 million people worldwide. PD is pathologically characterized by the accumulation of neuronal α-synuclein (α-syn) aggregates, termed Lewy pathology. Lewy pathology is significantly correlated with decreased cognitive function. The most common genetic risk factor for PD is mutations in the gene glucocerebrosidase-1 (GBA1), which encodes for the lysosomal enzyme Glucocerebrosidase (GCase). Approximately, 7-11% of all PD cases show a GBA1 mutation. Patients heterozygous for the GBA1 L444P (GBA1+/L444P) mutation demonstrate a 5.6-fold increased risk for developing dementia. The effects of GBA1+/L444P expression on the hippocampus, a brain region that plays an integral role in cognitive function, are not fully understood. Thus, we sought to determine the effects of the GBA1+/L444P mutation on spatial learning, memory, and hippocampal α-syn pathology. To analyze behaviors associated with hippocampal function, behavior paradigms such as fear conditioning and Barnes maze were used. Our data show that by 3-mo of age, GBA1+/L444P froze less than their wildtype (GBA1+/+) controls, suggesting impairments in contextual memory. Concurrently, data derived from immunoblot experiments suggest that GBA1+/L444P mice exhibit a lower expression of the presynaptic protein vGLUT1 in the hippocampus. We also injected mice with α-syn preformed fibrils to induce formation of α-syn inclusions. Immunofluorescence and confocal microscopy revealed that hippocampal α-syn aggregates were significantly increased in GBA1+/L444P mice compared to GBA1+/+ 9-months post-fibril injection. Overall, these data reveal that heterozygosity for GBA1 L444P contributes to impairments in behaviors associated with hippocampal function, and selectively increased α-syn pathology in the hippocampus. Recent advancements in research and healthcare have developed treatments for PD symptoms; however, studying how to prevent the formation of α-syn aggregates is crucial in developing novel treatments that will slow the progression of PD.

Abstract Name: 3D Printing to Improve Patient Outcomes for Mini-Thoracotomy Aortic Valve Replacements and Mini-Mitral Valve Repairs

Aortic valve replacement (AVR) was established in the 1960's and has become a routine therapy to treat patients with severe aortic valve dysfunction. AVR is usually performed using a full sternotomy and cardiopulmonary bypass support. Since the late 1990's, minimally invasive procedures have been developed for aortic valve surgeries, such as the mini-thoracotomy AVR. These less invasive procedures claim reduced postoperative complications, shorter lengths of stays in the hospital, and lower mortality. However, the minimally invasive nature may provide challenges in the viewing of patient anatomy during the procedure. This project will provide the 3D printing capabilities needed to investigate if using 3D printed anatomical models for pre-operative planning and/or patient education will result in better patient outcomes for mini-thoracotomy AVR surgery, particularly in those with thoracic abnormalities. For selected patient cases, the Mayo Clinic Luther Campus will provide UWEC researchers with DICOM files for segmentation and 3D printing. The UWEC research team will perform the segmentation and provide the physical 3D anatomical model with initial feedback on accuracy from Mayo physicians. Ultimately, the Mayo Clinic collaborators will evaluate the effectiveness of using the 3D models in patient outcomes as well as patient education on the procedure.

Abstract Name: Role of Motivation on Academic Success B

The collegiate world is constantly discussing how student motivation is related to studentsuccess. How true is this correlation? Does the motivation importance change with the specific course or the format the course is taught in? Can the institution or instructor impact the student motivation level by understanding intrinsic and extrinsic factors that motivate students? The aim of this study is to determine what motivation is and how it impacts the academic success of college students. Factors that will be studied are intrinsic and extrinsic motivation factors, academic performance, familial college experience (1st generation studens vs non 1st generation students), and the role of the institution and faculty. The study will be completed through a survey with a battery of questions addressing all the key areas mentioned above. Demographics will also be collected to compare possible inter-group differences. Correlational analysis will be completed through data collection in the spring semester of 2023.

Abstract Name: Studying the Electrochemical Activity of Methanol Dehydrogenase in Lanthanide-Modified Methylobacterium extorquens

Recent studies have demonstrated that some enzymes in bacteria isolated from lanthanide-rich areas use lanthanides as metal cofactors in place of more common metals like calcium and that these lanthanide-enzymes have enhanced catalytic properties. For example, Methylobacterium extorquens is a methylotroph that conducts redox chemistry using methanol dehydrogenase (MDH). MDH is a type of quinoprotein that contains a pyrroloquinone and either a lanthanum (La3+) or calcium (Ca2+) metal cofactor. Here, the bioelectrocatalytic activity of MDH from M. extorquens grown in La</sup>3+ rich media is compared to MDH from M. extorquens grown in typical Ca2+ rich media. Biochemical assays have shown that La3+-MDH has higher activity than Ca2+-MDH. However, the bioelectrochemical activities from these bacteria have not been compared. If La3+ grown M. extorquens has higher bioelectrochemical activity than Ca2+ grown M. extorquens, then improved biofuel cells and sensors can be created. M. extorquens is grown in two separate cultures, one with La3+-rich media and one with Ca2+-rich media. Methylene blue is polymerized onto the surface of a glassy carbon electrode, then harvested bacteria or isolated enzyme is immobilized on the electrode by casting a mixture of the bacteria and tetrabutylammonium bromide (TBAB)-modified Nafion® onto the electrode surface. The bioelectrochemical activity for oxidation of methanol to formaldehyde is measured by cyclic voltammetry and amperometric i-t curves for various concentrations of methanol in a tris-HCl buffer. In addition to comparing the bioelectrochemical activity of the La3+-MDH and Ca2+-MDH, the activity of the whole bacteria and isolated enzyme electrodes will be compared along with the electrode lifetimes.

Abstract Name: The Effect of Gerrymandering in the State of Wisconsin as it Pertains to Voter Turnout, the Number of Candidates Running for Office, Contested Districts, and Margin of Victory in Elections

In 2011 leaders from the Republican party in Wisconsin redrew the voting maps for the state. Their efforts resulted in a heavily gerrymandered map favoring the Republican party, which virtually assured Republican control of state level legislative politics for the foreseeable future. The issue of gerrymandered maps has been litigated at several levels including a hearing by the United States Supreme Court which issued a ruling in June 2019. The Court asserted that drawing voting maps lies within the realm of the state legislatures, and it is not the role of the federal courts to dictate rules and regulation pertaining to state voting maps. This ruling effectively quashed the most likely avenue for voters in Wisconsin to have fair voting maps.The question this correlational research seeks to answer is whether gerrymandering has had a significant cooling effect on voter turnout, the number of candidates running for state senate and assembly and the number of contested districts in the state. Additionally, researchers are interested in whether gerrymandering has resulted in a significant change in the margin of victory for either political party in gerrymandered districts. These variables will be examined by comparing pre and post gerrymandered elections in the state of Wisconsin.Researchers hypothesize gerrymandering has resulted in a significant decrease of voter turnout by district, a decrease in the number of candidates running for state legislative offices, a decrease in the number of contested districts in the state and an increase in the margin of victory in the districts that have been most heavily gerrymandered.

Abstract Name: Women's Involvement in the Economy

The research focuses on how traditional societal views of women affect their participation in the economy in rural India. The case study focuses on rural areas in India because these areas tend to have more traditional conservative gender roles (i.e., women are expected to stay at home, take care of children, cook, clean, etc.). This study suggests that one of the main reasons for low rates of women in the workforce in these regions is cultural. The objective is to propose a model to help increase women's employment. The literature review consists of previous studies that have attempted to increase female employment. In order to create the model, previous cases were analyzed. The research looks at which methods were successful and which ones needed improvement. This research found that traditional gender roles are not the only factor affecting women's employment rates. The other factors that limit women's employment include corruption, lack of education, gender-based discrimination, societal preference for boys over girls, and an overall lack of support for working women. This research's proposed model can be used in other countries where female employment, particularly in rural areas, are low.

Bol, Nazaria

Abstract Name: Factors of Education and Economical Success of Northern Indigenous Guatemalan Women

This study aims to develop a deeper understanding of the lived experiences of Indigenous women from northern Guatemala and learn about what it takes for these women to be successful in pursuing education and being financially stable. Through a snowball sampling method, the researcher will reach out to Indigenous women from northern Guatemala in order to identify six women between the ages of 20 to 35, to be interviewed for this study. Three of these women will have stopped education in Elementary school, and the other three of these women will have either begun or completed their undergraduate college education. Through this phenomenological research methodology, the researcher will identify the resources and factors needed for Indigenous women from northern Guatemala to recognize the opportunities available for them in the future. Through this study, I, the researcher, anticipate that some of these factors are necessary for women to be successful in pursuing education and being financially stable: family support, access to money, good income, mentorships opportunities, access to news sources, encouraging professors, access to transportation, personal desires to continue education, access to quality schooling, and faith.

Abstract Name: Race and Religion in Wisconsin Prohibitionist Propaganda: The Demonization of the Urban Center

Prohibition remains a widely studied period of American history at the national level, but relatively little research has been done to analyze it at the state level in Wisconsin. Specifically, using a wealth of primary sources from the National Archives at Chicago as well as the Anti-Saloon League of Wisconsin, including activist pamphlets, newspaper articles, and organization memos, I have looked into the use of race and religion in prohibitionist propaganda in the state. I have found that Wisconsin prohibitionists, like in the rest of the country, used race and religion in their propaganda as a microcosm or euphemism of their demonization of urban centers. Additionally, I have found that Wisconsin Prohibitionists uniquely catered to German-Americans in their propaganda, when Prohibitionists in other parts of the country instead targeted Germans negatively. This peculiarity of Wisconsin prohibition helps elucidate the local and regional differences present in the largely-grassroots Prohibition movement.

Abstract Name: How Did Galaxies in the Early Universe Grow?

Whereas nearby galaxies primarily grow by merging with other galaxies, cosmological simulations predict that galaxies in the distant, early universe mainly obtained fuel for new star formation by accreting gas from their environments. Galaxy growth can be observed due to star formation within a galaxy, which produces Lyman-α (Lyα) photons that illuminate extended halos of hydrogen gas, called Lyα halos, surrounding galaxies and flowing either towards or away from galaxies. Here we present observations of the Lyα halos surrounding a galaxy pair within a large-scale structure of galaxies in the early universe using the Keck Cosmic Web Imager (KCWI), an integral field spectrograph on the Keck II Telescope. The Lyα emission profiles in the spectra from these galaxies' Lyα halos exhibit indications that gas is flowing into the galaxy pair, which is rarely observed among galaxies in the early universe, rendering them excellent tools to study galaxy growth during this era. We find that the galaxies in this pair are quite close to one another, which implies that gas may be flowing into them as the result of a merger. However, these galaxies' Lyα halos are aligned with a nearby filament of galaxies, which suggests that they may be accreting gas from narrow streams of gas flowing along this filament. In order to determine the source of inflowing gas more precisely, we measured the spatially varying peak flux ratio and peak separation of the double peaked Lyα profiles throughout the galaxy pair's Lyα halos. Additionally, we fit these Lyα profiles against a Monte Carlo Radiative Transfer model which assumes that the galaxy pair's Lyα halos consist of a clumpy, multiphase gaseous medium with radially varying velocity. By investigating the source of inflowing gas in this galaxy pair, we aim to provide valuable insight into galaxy growth in the early universe.

Abstract Name: **The Impact of Oxidative Stress on Peroxisome and Mitochondrial Function in Drosophila**

Damaged mitochondria are repaired and recycled through the mechanisms of mitochondrial dynamics in response to stress; this helps in restoring cellular homeostasis. Mitochondrial dynamics have emerged as a novel regulator of aging in recent years. Researchers have performed genetic manipulations of genes involved in the fission and fusion of mitochondria, which extended the lifespan. However, the causes of the age-dependent alteration in mitochondrial dynamics remain unanswered. Our focus is to explore the involvement of the peroxisome in maintaining mitochondrial homeostasis during animal aging. In particular, we investigated the impact of oxidative stress on the transcriptional regulation of Gnpat (Glyceronephosphate O-acyltransferase), the key enzyme involved in peroxisomal plasmalogen synthesis. Plasmalogens are found in cell membranes throughout the body and help protect cells from oxidative stress. Studies have shown that plasmalogen is abundant in mitochondria and its levels decline with age. Gnpat provides instructions for making the plasmalogen enzyme and plays a role in protecting cells, particularly mitochondria, from oxidative stress. Our studies have found that oxidative stress induced Gnpat mRNA expression and this induction was specific to Gnpat rather than a widespread peroxisome gene induction. Although we understood how Gnpat was controlled at the translational level there was an unanswered question of the upstream regulators that control it. Through recent studies, we have shown that ATF4/crc transcription factor is required for the induction of Gnpat expression under oxidative stress. Thus, our future goal is to understand how peroxisomal plasmalogen synthesis pathways contribute to age-related alterations of mitochondrial functions.

Abstract Name: **Nanoporous Bi-layer Structures for the Electrochemical Conversion of Carbon Dioxide to value-added chemicals**

Prior research has shown that alloys of copper (Cu) with metals such as silver (Ag) or tin (Sn) have the ability to catalytically convert Carbon Dioxide (CO2) into economically useful products such as ethylene, methane or formate. Varying the particle size, surface morphology, texture, porosity and composition of these catalysts have been shown to dramatically change its electrocatalytic properties.However, these studies have been limited to the use of conventional liquid-phase reactors, which severely limits the rate of conversion, as determined by current densities of ~10 mA/cm2. Furthermore, translation of this catalytic performance to industrially relevant scales is not trivial, and is known to be highly sensitive to the local reaction environment, which in turn changes as a function of reaction rate.In this current work, we utilize dc/rf magnetron sputtering to deposit thin layers of copper, silver and specific combinations of the same on both stainless steel and gas-diffusion layer (GDL) substrates. Detailed characterization of these bi-layer thin films has been done through X-ray diffraction, Scanning electron Microscopy (SEM) as well as Energy-dispersive X-ray (EDX) analysis to determine relative ratios of the metals present, as well as changes in texture and porosity. Herein, we present on preliminary results showing the electrocatalytic performance of these thin films for the conversion of CO2 inside both liquid-fed conventional H-Cell reactors, as well as gas-fed flow reactors.

Abstract Name: Unmoored: Capturing Identity, Change, and Executive Dysfunction on Film

Many ofthe shifts in our identity are as surprising as they are inevitable. As with our bodies and our minds, it's easy to forget that our identities are in a constant state of change — that is, until a situation forces us to face ourselves and examine who we've become. For adolescents, college students included, reckonings with their sense of self come frequently; they feel seismic each time they occur. My undergraduate thesis incorporates a short screenplay in which the central character is recovering from severe executive dysfunction, the impairment of basic skills that include working memory, mental flexibility, and inhibitory control. She confronts the question at the heart of the Ship of Theseus: have I changed enough that I am now an entirely different person than I used to be? And if so, what now?As part of the story development process, I examined the science behind executive dysfunction and the philosophical questions surrounding identity. I also viewed films that told compelling stories about the impact physical changes can have on one's identity. My screenplay explores the ability of a change in mental health to do the same. I am currently in pre-production preparing to turn my screenplay into a short film and anticipate that I will have a finished draft of the film by the time of the conference.

Abstract Name: Examining the anxiety derived from statistics: An analysis on blended learning as an effective statistic teaching methodology

For decades sociologists have long been intrigued as to why undergraduate students hold negative perceptions and anxiety towards courses requiring a heavy quantitative curriculum. Prior research suggests blended learning may ease anxiety, promote motivation, and empower students. Existing research in this area has been limited, as it has focused primarily on predominantly white institutions (PWI). To date, we have limited understanding of whether andhow blended learning can improve student confidence and ease statistical anxiety among low-income and first-generation undergraduate communities. In this project, I focus on conducting an extensive review of new literature to identify the effectiveness of blended learning in statistical courses and the current quantitative literacy gap among first-generation and sociology undergraduate students. The review reveals students who were assigned blended learning experienced significant increases in confidence, decreased anxiety, and improved overall quantitative comprehension. These preliminary findings from the literature suggest that blended learning is not only an asset to statistics teaching but additionally a useful method for increasing students' quantitative confidence, potentially empowering students to pursue careers requiring heavier quantitative skill sets. Overall, this preliminary analysis demonstrates a vital need forfurther research on the potential benefits of embedding blended learning methodologies in courses designed to be taught at institutions with a growing number of first-generation collegestudents.

Abstract Name: **The Social Distribution of Direct and Indirect Exposure to Major Discrimination among Black Adults**

While there have been efforts to understand the relationship between health and discrimination, the ideology of this study has been limited to perceived discrimination. Additionally, studies have proven to lack information regarding the racial discrimination's significant impact on both people and their loved ones through secondhand exposure. This study conceptualizes race-related stress framework by Harrell that concluded the inclusion of vicarious experiences is critical in understanding the effect of racism. Within group differences were analyzed to improve our understanding of certain racial health inequities, such as the "race paradox". Data were taken from the Nashville Stress and Health Study which is a random sample (N=1252)consisting of 627 Black adults. Those who participated in the study resided within Davidson County, Tennessee. This area includes two large historically Black universities (Fisk and Tennessee State) along with the country's oldest historically Black medical school (Meharry Medical College). To capture the entire racial discrimination experience, personal experiences of major discrimination, and vicarious experiences of major discrimination (i.e., spousal, child, and close friend) were assessed. We found that the women had lower odds of reporting personally experienced major discrimination than the men in the sample. Additionally, respondents in the sample who had greater social support from friends had higher odds of reporting vicarious discrimination experiences, which offers partial evidence for the study's hypotheses. From the conclusions of this study, further research should examine how Black women may be disproportionately exposed to secondhand discrimination as a result of their social roles as caregivers.

Abstract Name: **Roles of Social Dominance and Empathy to Predict Theory of Mind**

Emotional intelligence is defined as the ability to identify and manage one's own emotions, as well as the emotions of others and Theory of Mind (ToM) is defined as a person's ability to reason with and predict another's emotions. Current research states that Emotional Intelligence and ToM are highly related and said to be, "conceptually-linked but distinct constructs." Empathy plays a crucial role in ToM as they both are dependent on understanding what another person is feeling. Empathy is a key part of emotional intelligence that some scholars believe is critical in an effective leader. For social dominance there is little literature on social dominance as related to theory of mind.
We hypothesize that ToM could be predicted by Social Dominance and Empathy while controlling for personality and measures of femininity/masculinity. Secondly, we hypothesize that for those low in empathy there would be a positive relationship between Social Dominance and ToM. Additionally, for those high in empathy there would be a negative correlation between social dominance and ToM.
A regression analysis was conducted to test our first hypothesis' model. Our model was not found to be significantly predictive ($p > .05$). Regarding the second hypothesis, we found partial support. We did find a significant negative correlation between social dominance and ToM for those with high empathy scores (i.e., those with scores one standard deviation above the sample mean or higher): $r = -.633$, $n = 10$, $p = .049$, two tails. However, we also found a trend towards a significant negative correlation between social dominance and ToM for those with low empathy scores: $r = -.581$, $n = 8$, $p = .131$, two tails. This research provides insight into the relationship between ToM, empathy, and social dominance which will allow us to generate further measures for people's emotional intelligence levels.

Abstract Name: Mozart Basset Horn Trio

The UWEC Clarinet Trio has prepared a performance of Divertimento No. 3, K. 229 (439b) by Wolfgang Amadeus Mozart. Although this work was originally composed for basset horns (a member of the clarinet family with a lower, rounder tone),we will beperforming this piece on the modern standard: B-flat clarinets. This five-movement work opens and closes with fast movements (the Allegro and Rondo). The middle movements are two medium-fast Menuettos, and one slower movement (Adagio). Overall, the work is light-hearted with the Adagio providing a more thoughtful character and tone. Throughout our time rehearsing as an ensemble, we have learned many things about the history of this music and the Classical style. Mozart was considered to play a big part in forming a new musical era known as the Classical Era. His groundbreaking style of composing was unique because it used a newer homophonic sound rather than polyphonic texture. Divertimen to No. 3 is homophonic, meaning it has a melody and an accompaniment. In this work, each movement illustrates a different moodvia varying harmonies that are supplemental to the melody, which is usually played by the first clarinetist. The articulations and dynamics assist in portraying the emotions of the piece. We have chosen to switch parts toallow each member of the ensemble to lead and also play the supporting parts. This is important for each member to show their take on the piece.

Abstract Name: The Self in Rugs

Textiles have always interested me. The labored, slow process of knitting and crocheting fell short of my expectations in regards to the time it takes to get a sizeable result. Several hours of work only yielded several inches of material. As I sought larger, more graphic textiles with dimensions of texture, I turned to rug making to achieve those aesthetic goals.
A rug can range in size from a handheld piece to a large wall hanging. Rather than looking at rugs as mass produced, domestic decoration, I looked to the history of textiles as an art form. The domestic decoration of rugs however, has influeneced people to easily recognize a rug. They have also become large staple items in peoples homes. This contemporary influence also interests me. In this project, I revisited an oil painting series on “The Self” and intertwined it with the medium of rug making. Battling a new medium presented many difficulties. Translating form from oil painting to rug textiles was the main struggle. I turned to artists such as Caroline Kaufman, whose works originally inspired me to make rugs, and Keith Harring for his bold, flat colors. I switched mindsets for this project and began with a master copy piece. This helped me form an eye for what translated well, visually, in rug making. As this new process began to click, skills were built up in a new textile medium. I am continuing to make pieces relating to The Self that will be presented at my Senior Thesis show in Spring 2023.

Abstract Name: **En Attendant: Digitizing Early 19th Century Advertisements of the Emerging New Orleans Theatre Scene**

After the Louisiana Purchase, New Orleans underwent rapid and complex growth from a strategic French colonial port to an early, multicultural metropolis. While there has been ample research on French theatre in France, theatre in early 19th century New Orleans has yet to be explored. As a French-established city, theatre was central to the culture of its inhabitants, guaranteeing its representation in the media of the time. Via web-based data visualization, this research exhibits the evolution of New Orleans theatre during the early Federal period through advertisements from the newspaper Le Moniteur de la Louisiane. As the advertisements reorganized and expanded over time, we altered the expression of entries in the database to better represent the information provided. For this presentation, I will address the database we created to organize the advertisements found in Le Moniteur de la Louisiane, as well as the rationale and challenges behind the decision to create a web-based calendar as the public interface for the data. This archive intends to spur further research; topics such as data analysis on trends in the expression of issued information or comparisons to the advertised theatre details of France and other French colonies will be aided by this application.

Abstract Name: **XRF Analysis of Pb Concentrations in Soils in and near Moorhead, MN**

Prior to its ban in 1996, leaded gasoline was available for use in all vehicles. We suspected there was an increased concentration of lead in the soil near Highway 10 near Moorhead Minnesota. The purpose of this experiment is to determine the impact of anthropogenic lead in soil.We collected 6 urban soil samples within Moorhead along parks, residential areas, and our college campus. We collected 18 rural soil samples east of Moorhead along highway 10 including two perpendicular transects to highway 10. A transect 1 mile, and a transect 7 miles east from Moorhead going North and South respectively. We collected both surface samples and samples approximately 6 to 12 inches in depth.We analyzed the samples by drying the samples at 100°-105°C for 18-19 hours. Using an agate mortar and pestle, we ground the samples to a powder. A Hitachi X-Met8000 Handheld-analyzer was used to analyze the elemental composition of the samples. We aimed to determine correlations in lead levels.Pb concentrations in urban areas ranged from 17 to 175 ppm. Rural variations showed a decrease in lead concentrations eastward along Highway 10 as well as a decrease away from highway 10 for the transect taken 1 mile from town. In rural and urban samples, we observed Pb statistically significantly decreased with depth.Our results show a trend in lead concentration with location and depth consistent with air-deposited lead from leaded gasoline. Although, regions with no obvious anthropogenic lead were decreasing in Pb levels relating to depth, as well. This suggests that soil genesis processes may also be a factor in the Pb concentrations, and warrants further research. Although most samples remained under the 100 ppm EPA guidelines for residential gardens, 2 urban samples taken along a major street exceeded this value.

Abstract Name: **The Development of Inhibitors used to Target Falcilysin (FLN) in the Human Parasite, Plasmodium falciparum**

There are five species of parasites that are involved in malarial infection: P.knowlesi, P.malariae, P.ovale, P.vivax, and P.falciparum. The human parasite Plasmodium falciparum causes the most severe case of malaria and is common in the Sub-saharan region of Africa and South Asia. Our study focuses on developing inhibitors against falcilysin (FLN), and metalloprotease expressed by the parasite during infection of the human host. Selective chemical inhibition is a valuable tool for understanding the biological role of falcilysin. Our group previously reported the development of potent FLN inhibitors using a piperazine-derived hydroxamic acid scaffold. This study focuses on optimizing the N1 and N4 substituents of the piperazine ring. Synthetically accessible candidate structures were DOCKed against the FLN crystal structure, and a subset of 20 promising compounds were selected for synthesis and testing against FLN and cultured P. falciparum. These studies revealed that a variety of bulky aromatic groups were tolerated at the N1 and N4 positions of the piperazine core. Introduction of naphthalene, dibenzofuran, and various substituted benzene rings resulted in improved potency relative to the previous lead compound. Notably, we also observed a correlation between the binding affinity predicted in our DOCKing studies and biochemical inhibition FLN, indicating that virtual screening is likely to be an effective tool for optimization of this scaffold against FLN.

Abstract Name: **From Massachusetts to Ravensbrück: Betty Laurie, the United States, and the Holocaust**

The United States has taken a large responsibility in regards to the remembrance of the Holocaust and World War II, yet how the country remembers the event is fairly narrow. Despite both the war and the Holocaust being a transnational event, remembrance in the U.S. is focused on American triumphs. It ignores elements that give insight into the overall understanding of the events. Why is that? The life and story of Betty Laurie provide insight into the answer. Born in 1892 in Scotland, she immigrated to the U.S. and became a citizen of Mansfield, Massachusetts, where she remained throughout childhood. In the late 1920's, she married into the French aristocracy and became the Countess Roberta de Mauduit. Years later, with the outbreak of World War II and the Nazi invasion of France, Betty was taken prisoner and sent to the Ravensbrück concentration camp. Betty is not a victim of the Holocaust, however the horrors and brutalities she experienced in captivity were similar to that of one. Which is why she is a crucial part to the overall understanding of public memory in the U.S. She transcends nationalities and borders. Betty is a key component to the overall understanding of the Holocaust and how it is remembered today. This project relies on analysis of secondary works on the subject, key institutions relating to the Holocaust in the U.S., as well as analysis of primary sources from the United States Holocaust Memorial Museum's Archives and the University of Michigan's Special Collections and Archives. The importance of this research is crucial to the understanding of the Holocaust as it is already known. The intent is to provide a deeper understanding of the Holocaust, examine the complications and limitations that leave out vital information, and expand public memory overall.

Abstract Name: Defining The Integrated Self Through Shakespearean Drama

The balance between internal and external pressures on the mind and body have been an important part of our understanding of how the mind works throughout history. The mind and body, or the “self,” can be integrated (in agreement) or disintegrated (not in agreement), causing physical and mental ills. Though they describe it differently, both early modern medical philosophy and modern psychology can be used to describe the changes made in characters’ sense of self in Shakespeare plays. The plots of several of his plays are guided by internal and external pressure on the characters’ sense of self, causing a disconnect between the mind and the body, which drives the disintegration of their self-concept. This propels the plot for Shakespeare's tragedies, but also for his comedies. In both genres, the characters sense of self is threatened by some external factor, such as other people, witches, or natural events, and they begin to struggle with their sense of self. Two characters that begin well integrated and are then disintegrated are the characters in Macbeth and Othello, who experience near total disintegration of their sense of self. Viola fromTwelfth Night is an interesting contrast because her expected full disintegration does not fully occur due to her brother’s return, which puts each character back into their proper identity. Viola’s mental strength, near disintegration of her sense of self, and comedic re-integration shows the difference in how characters are treated in different genres.Whether they are in Shakespeare’s tragedies or comedies, these characters’ integration and disintegration of their sense of self,as described by both early modern medical philosophy and modern psychology, are important aspects of their understanding of themselves and the social setting in which they live.

Abstract Name: On the Effectiveness of Augmented Data Generation of Brain Tumors Using GAN based Techniques

Deep learning models have shown promising results in the computer-assisted diagnosis of brain tumors from images. The training data should be sufficient with high quality and generalized characteristics to train the deep learning models accurately. However, in the medical domain, the training data is limited, as it is difficult to collect sufficient patient data because of the problem of patient recruitment, the burden of annotation of lesions by experts, and the invasion of patients’ privacy.Researchers have developed different automated Data Augmentation (DA) techniques, such as scaling, cropping, flipping, and Affine transformation, to overcome the problem of limited data for training. Recently, Generative Adversarial Network (GAN) based DA techniques, such as TumorGAN, PCCGANs, and CPGGANs, have shown improved results in generating augmented data. However, the evaluations of the existing GAN-based DA techniques can be questioned as the experiments were conducted either on small-sized datasets or included only some of the available datasets. In this study, we conduct a rigorous investigation to determine the effectiveness of the GAN-based DA techniques by applying those in all the available Magnetic resonance imaging (MRI) datasets.

Abstract Name: **A Comparison of Alluvial Fills in Former Glacial Meltwater Stream Valleys in West-Central Wisconsin**

The Lower Chippewa River (LCR), a tributary to the Upper Mississippi River (UMR) in west-central Wisconsin, drained meltwater from the Chippewa Lobe of the Laurentide Ice Sheet and filled its valley with glacial outwash ca. 30 to 15,000 years ago. Then, as the region deglaciated, the UMR incised abruptly, initiating a wave of incision that progressed up the LCR in a prolonged and episodic manner (Faulkner et al. 2016). For this study, we examined the LCR's two largest tributaries, the Eau Claire River (ECR) and the Red Cedar River (RCR), as part of an ongoing project to determine how incision propagated through the entire LCR fluvial system and to identify what controlled the incision process. The specific objective of our research was to ascertain the sedimentological characteristics of the alluvial fills in each river valley in order to determine if the fills are similar (as expected, given that both were meltwater streams that drained the Chippewa Lobe) or different. We accomplished this objective by kayaking each river, mapping the location of terrace cutbanks, and describing the alluvium exposed in them. Contrary to what we expected, we found the fills in the two valleys to be clearly different. While both are characterized by tabular cross beds of medium-to-coarse sand with rare gravel, along with planar interbeds of gravelly sand, gravelly sand interbeds are generally more common—and gravel-size clasts typically larger—in the RCR valley. We are uncertain why the RCR fills are coarser. One hypothesis is that the RCR was the larger meltwater river and able to transport coarser material away from the ice margin. Whatever the explanation, the differences in valley-fill sedimentology may have influenced the process of incision as it propagated up each valley. Future research should take these differences into consideration.

Abstract Name: **Minority Status and Mental Health**

Discriminatory behaviors live throughout society today and all generations of the past. How do these behaviors impact groups with minority status? The aim of this study is to research how chronic stress expereinced by people with minortity status impact mental health. There will be multiple angles applied to this study. The first area of interest is how social media either contributes to or gives a community for discriminatory behaviors or does social media allow for an outlet for those with minority status to build support and community. The second area of interest is how does stress related to choronic discrimination exposure contribute to the mental health of individuals with minority status. Previous research has shown disparities in mental health, substance use, and other factors related to mental health among groups with minority status when compared to the same age group of majority status individuals. This study will identify factors associated with positive and negative mental helath development across multiple minority status groups through a survey implemented and analyzed in the spring semester of 2023.

Abstract Name: Expressions of Cultural Identities

How might expressions of cultural identities take shape through language, stories, and other learning experiences in an elementary classroom? If preservice educators listen intentionally to the expressions of elementary students, will those studentsshare about their diverse backgrounds and cultural identities? Can these conversations support the classroom in an effort to be more culturally responsive? We will partner with a local elementary school and spendtime on site conferring withs tudents about their perceptions and contributions, connecting students' cultural knowledge to themselves and others through multimodal learning experiences, and gather data that will influencefuture teaching practices. Multimodal instruction is instruction that uses social and cultural resources such as drawings, technology resources, picture books, and storytelling. Student voice is listening attentively to students' perceptions and contributions.Cultural identity is the perception of self and others, and how children see themselves as a member of a group.

Abstract Name: Investigating the use of crayfish as environmental water quality sentinels for metal pollution in Indiana creeks

Ephemeral creeks and streams can be difficult to monitor and assess for water quality. Unfortunately, these same water systems can play a significant role in the input of metals and other pollutants into major waterways. Metals are often the result of nonpoint source or historic point source pollution that is no longer active, making assessment and exposure prevention difficult. An economical and reliable approach to determine water quality in these areas would be the use of reliable sentinel species that are endemic, easily identified, and respond in a quantifiably way to metals in the environment. Macroinvertebrate assemblages have been historically used to create comprehensive biotic indexes, but these indices can be complicated, seasonal, and difficult to assess without identification bias. For this project, crayfish samples, water samples, and sediment samples were collected in several creeks in Indiana representing a variety of environmental exposures. We hypothesized that because are omnivores and biotic engineers, their environmental interactions place them in a unique niche making them a reliable sentinel species. By testing and comparing the bioaccumulation of metals in crayfish tissue, water, and sediments to dominant species, average crayfish size, and population density, we can reliably predict creek health for metals. Our results determined thatFaxonius rusticus(rusty crayfish) were found in creeks with higher environmental metals. Also, crayfish cephalothorax measurements were smaller in higher metal environments. This data, along with metal bioaccumulation and biomagnification make crayfish an excellent sentinel for water quality in creeks.

Abstract Name: **Green Synthesis of Palladium Nanoparticles Using Upland Cress: Synthesis and Characterization**

As research for the uses and applications of metallic nanoparticles (NPs) grows, the demand for more environmentally conscious, or “green” synthesis methods also grows. Chemical synthesis for gold, silver, and other metallic nanoparticles including metallic alloys, has been successful, however the process is costly and uses compounds that are dangerous to the environment. Previously, gold and silver nanoparticles have been successfully synthesized using upland cress (Barbarea verna). This research further explores the use of upland cress in synthesizing other metallic nanoparticles. Upland cress is rich in biomolecules that act as both reducing agents that can reduce metallic ions into nonionic metallic atoms, and capping agents which stabilize the nanoparticle. Palladium nanoparticles were synthesized and characterized using Ultraviolet-Visible spectroscopy. Based on the UV-Vis graphs, the initial solution had a peak at 438 nm – characteristic of Pd2+ ions, which disappeared as the synthesis process progressed. The absorbance intensity increased from a 0.456 Abs from nanoparticles synthesized at 2 hours at 300 nm to 1.56 Abs from nanoparticles synthesized at 6 hours at 300 nm, which indicates an increase in the amount of Pd NPs present in the solution. Upland Cress has been successfully used to synthesize gold, silver, and now, palladium nanoparticles.
Keywords: Palladium nanoparticles, Green synthesis, Upland cress

Abstract Name: **Offspring Exercise Does Not Protect Against Detrimental Health Outcomes Associated with Maternal PCB126 Exposure in a Mouse Model**

Polychlorinated biphenyls (PCBs) are persistent organic pollutants that negatively affect offspring glucose homeostasis and body composition when mice are exposed in utero. This experiment aimed to test whether voluntary exercise in the offspring can be used as an intervention to protect against obesity and diabetes associated with perinatal PCB exposure in mice. Sixty female ICR mice were equally divided into two experimental groups: Vehicle Control or PCB. The female mice were exposed to vehicle or PCB once before pregnancy, once during pregnancy, and once during nursing. The offspring were weaned at three weeks. At six weeks of age, the male and female offspring were housed singly in cages that contained either no running wheel or a voluntary running wheel. The running distance was monitored daily, and body weights were collected bi-weekly. Body composition and glucose tolerance were assessed after three months of running wheel availability. We found that perinatal PCB exposure significantly reduced the body weight of both male and female adult offspring, and the reduction was caused by a significant decrease in lean mass ($p<0.01$). Exercise induced a further decrease in body weight, but this was driven by a loss of fat mass ($p<0.05$) rather than lean mass ($p>0.3$). In this experiment, PCBs did not consistently affect glucose tolerance, but exercise did improve glucose disposal two hours after the glucose challenge in both male and female offspring ($p<0.05$). While there were numerous significant main effects of PCB exposure and exercise, there were no meaningful interactions between them. Thus, exercise did not effectively ameliorate adverse outcomes associated with perinatal PCB exposure. These data suggest that exercise during adulthood is an effective way to improve health. Still, it may not specifically protect against PCB exposures that occur during fetal and early postnatal development.

Abstract Name: **Meil yra Visiems: The Evolution of Pride in Lithuania**

Baltic Pride started in 2010 with tremendous political and public opposition but is now a vibrant celebration and protest for the LGBTQ+ community in Lithuania. This project will explore the evolution of Pride, one of Lithuania's most important LGBTQ+ advocacy events, from 2010-2019. According to scholars studying Pride in Eastern Europe, a variety of political and social factors from European Union association to nationalism affect Pride's successful dissemination of rights. This project will add to this body of work by examining the growth of Pride in Lithuania despite continuing opposition in eastern Europe and around the world. Examination of the European International Lesbian, Gay, Bisexual, Trans, and Intersex Association's (ILGA) annual review, images from each year of Baltic Pride in Lithuania, and local news articles covering the event each year provide data to illustrate Pride and the social and political context of Lithuania. This project will use content analysis and thematic coding of ILGA Europe's annual review and news articles and images of each Baltic Pride to determine then compare themes in each data source from 2010 to 2019. Comparing themes over time in Baltic Pride and the political and social atmosphere in Lithuania may reveal legitimization of sexual minorities' right to assembly and growing representation of multiple gender identities. Researching change in Lithuanian Baltic Pride will initiate discovering the efficacy of this event in expanding LGBTQ+ rights and visibility.

Abstract Name: **Freshwater Mussel Surveys of Southwest Wisconsin**

Freshwater mussels are essential to our ecosystems by enriching the rivers and lakes. Their prevalence throughout Wisconsin has been a scarcely researched topic throughout the years, but the trends of their abundance have begun to emerge. This field however is experiencing renewed scientific interest due to a recent statewide survey conducted by the Wisconsin Department of Natural Resources. These studies have shown the health of northern Wisconsin mussels' communities to be thriving, particularly following rehabilitation efforts in water bodies like the Fox River. Unfortunately, studies in the southeastern part of the state show the opposite results. While there is a myriad of survey results and data from these regions, there is a lack of evidence to show the status of freshwater mussels in Southwest Wisconsin. The previously believed notion was that the populations of the southwestern regions of the state would mirror those of the southeast, particularly given the agricultural activities in the region. However, after extensive surveying of watersheds in the counties of Grant, Iowa, and Lafayette; our evidence shows their presence in select streams of the region, despite being undetected in years prior. Our team explored the factors that were contributing to this inconsistency with our counterparts in the southeast, particularly given that the distribution was patchy. The correlation of factors such as physical, biological, and chemical components was taken into consideration as possible causes of presence or absence. The findings made it apparent that the freshwater mussels were abundant in certain areas of the region but not others. The research we conducted has helped contribute to the baseline knowledgebase of freshwater mussels throughout the state and assisted in providing data for an otherwise largely unstudied region of Wisconsin.

Abstract Name: **Chlorine Dioxide Gas as an Antiviral Agent: Development, Optimization, and Application, of an Antiviral Assay based on the MS2 Bacteriophage**

Since the emergence of the SARS-CoV-2 virus, the need to identify antiviral agents for disinfection purposes has dramatically increased. Chlorine dioxide gas has previously been identified as an antibacterial agent with strong oxidizing capabilities. Additionally, the MS2 bacteriophage has been recognized as a suitable surrogate for developing and applying virucide decontamination methods. This study aimed to identify and assess the antiviral properties of chlorine dioxide gas based on the MS2 bacteriophage model system using a double-layer agar plaque assay. Results showed that the MS2 bacteriophage can be incorporated and recovered from porous (cloth coupons) and non-porous (steel coupons) surfaces and that its recovery can be diminished or eliminated based upon feasible (less than 20ppm of gas) ClO2 gas exposure parameters. These results support the potential use of ClO2 gas for both current and unforeseen future viral disinfection needs.

Abstract Name: **Development and Validation of the Pediatric Spatial Hearing Questionnaire (P-SHQ)**

Sound localization is an important auditory function that is difficult for children with hearing loss. Research indicates that children with hearing loss using hearing aids and cochlear implants have problems localizing sound compared to children with normal hearing.Spatial hearing questionnaires are reliable, valid, and sensitive to differences between adults with hearing loss and normal hearing. However, few studies concentrate on children. It is important that we focus on children, as spatial hearing is necessary for good awareness in their environment (e.g., locating a parent's voices) and for learning in a classroom setting. The purpose of this study was to develop and validate a pediatric version of the Spatial Hearing Questionnaire (P-SHQ). We developed the 24-item P-SHQ from the existing Spatial Hearing Questionnaire by modifying several items to be appropriate for children. We recruited parents and guardians of children with normal hearing and children with hearing loss from kindergarten to 8th grade to complete the questionnaire. The P-SHQ was administered as an online survey along with an 18-item demographic questionnaire. In total, 59 parents and grandparents of children with normal hearing and 9 children with hearing loss completed the questionnaire. For the children with hearing loss, 6/9 had bilateral hearing loss and 6/9 used hearing aids or a hearing aid plus a cochlear implant. The highest ratings on the P-SHQ were for items on speech perception in quiet and lowest ratings for sound localization and speech in noise. P-SHQ total scores were significantly lower for the children with hearing loss compared to the children with normal hearing. Comparing responses to adults, we found consistent responses on the SHQ for children. These results suggest that the P-SHQ is a valid and sensitive tool in determining localization and speech in noise performance for children.

Abstract Name: Entering Research for the Humanities and a Curriculum Development Institute for Program Directors

The Entering Research (ER) portfolio of resources includes nearly 100 active learning activities that have been piloted tested nationally with STEM students, and a learning assessment instrument, the Entering Research Learning Assessment (ERLA), for which evidence of validity has been published. An overview of these evidence-based resources and several new ER activities designed specifically for students doing individualistic research in the Humanities and other disciplines will be presented in this session. In addition, an overview of the ER Curriculum Development Institute, which is offered by the Center for the Improvement of Mentored Experiences in Research (CIMER), will be given. All ER resources are organized by a conceptual framework of seven areas of research trainee development: Research Comprehension & Communication Skills, Practical Research Skills, Research Ethics, Researcher Identity, Researcher Confidence & Independence, Equity & Inclusion Awareness & Skills, and Professional & Career Development Skills. Adaptation and development of new ER activities for undergraduate researchers in the Humanities is funded by a grant from the Arthur Vining Davis Foundation awarded to Northwestern University (NU). NU's Office of Undergraduate Research is collaborating with the University of Wisconsin – Madison's Wisconsin Institute for Science Education and Community Engagement (WISCIENCE) to develop and test the new activities. The activities and preliminary evidence of humanities student learning at NU will be presented, and attendees will be given information about participating in national pilot testing to gain early access to the new materials.
The ER Curriculum Development Institute guides research educators and training program directors to use a backward design process to develop research courses and training programs. In addition, participants develop learning assessment and course/program evaluation plans that align with their research trainee learning objectives and course/program goals, respectively. An overview of the institute, evaluation data supporting its effectiveness, and institute registration information will be presented.

Abstract Name: Script Focused Image Editor: Progrimage

Image editors (IE) are powerful tools but can be more difficult to work with than code for some specific tasks. IEs are great for art, but not always as good for precise image manipulation. This is where code-based editors are more effective. There are some image editors that support scripting, however, some IEs are complicated to use, with no available documentation. Others have scripting hidden within submenus making it difficult to find. Furthermore, some IE scripts have only one basic implementation where users must click a "run" button and lacks the use of tools and interactive filters. To achieve the goal of creating a scripting tool for image editing that will be user-friendly and accessible, this exploratory study examines: "How well can scripting be implemented in an image editing application when scripting is the main focus?"The objective of this study is to create an easy-to-use image editor that allows users to create scriptable tools and image filters without having to search for the ability to do so. The proposed IE application, Progrimage, uses a scripting language called Lua which was designed to be beginner-friendly. Progrimage is designed to have a dedicated button to create a tool and to create a filter that can be used for drawing and manipulating objects, processing image pixels, creating layers, and more. With this IE application, scripting has high priority.Applying a user centered design approach, Progrimage will allow users to create their own tools and filters and is intended to increase user satisfaction, and intensify learnability and user adoption.

Abstract Name: **Unexpected effects of commercial beta-glucosidase addition to mash and fermenting beers**

Enzyme additives are widely used in both brewing and winemaking to improve color, ease of handling, flavor and stability. Beta-glucosidase has been featured in several commercial preparations with the intent of liberating flavorful terpene alcohols from their glycosides. In testing this principle on a Belgian-style farmhouse test brew with a POF+ yeast strain, we added the enzyme preparation, ABV Aromazyme™, 3 days into the fermentation stage as recommended by the manufacturer. We noted few major changes in terpene alcohols by GC/MS but a large increase in 4-vinyl guaiacol (4VG), a phenolic off flavor and ferulic acid derivative. An olfactory triangle test showed statistical significance (p=0.001) in 4VG aroma vs. the otherwise identical control. We used two different substrate assays and test brews to show that ABV Aromazyme™ contains significant ferulic acid esterase activity (FAE). While ferulic acid beta glucosides exist, our data shows they are unlikely to be the source. Test brews with POF- yeast strains showed a FA increase with no change in 4VG. In test mashes, ABV Aromazyme™ can release significantly higher levels of ferulic acid than controls (200-400%). Increases occurred at both 65ºC and 45ºC. After pitching, the released ferulic acid could then be further decarboxylated by POF+ yeast or bacteria into 4VG. On the mashing side, we showed that barley malts released more FA than wheat malt and significantly more than oats. This unexpected enzyme property need not be a sensory issue if POF- yeast strains are used. In fact, due to the “nutraceutical” value and antioxidant activity of FA, increased FA could be a positive feature promoting stability and nutritional value of the product. For styles featuring the 4VG aroma, ABV Aromazyme™ could be used to enhance flavor without resorting to separate ferulic acid rest temperature stage during mashing.

Abstract Name: **Codes from Fiber Products of Curves**

When we are storing many data across multiple devices, it is possible to lose some data. We explore a way that generates and stores the data effectively and efficiently; in other words, if we lose some data, we can use our other data to recover the lost information. We are using curves with many points over finite fields by using the fiber products of curves and evaluation codes to achieve this goal. To obtain an explicit multi-dimensional recovery structure, we use fiber products of curves with many points. The data we are encoding is that of polynomials of limited degrees, which are encoded using the evaluation at the points on the curve. We compute the minimum distance, length, and dimension of these codes to get a measure on their usefulness and practicality.

Abstract Name: **Asynchronous Discussion Boards Through Text or Video: Does the Modality Affect a Student's Involvement and Interaction in a Course?**

Asynchronous discussion forums in both online and face-to-face courses provide an opportunity for interaction, collaborative problem-solving and hold potential for increased content mastery. While traditionally, these discussion forums occur via text-based postings, there has been an increase in technology and course design that allows for video-based discussions. For instance, a previousstudy concluded that students believed the asynchronous video discussion to have improved their social presence with their peers in the course. This study compares text-based vs. asynchronous video-based discussion forums within an anatomy and physiology of speech and hearing course, to better understand their respective values in supporting content understanding, connections, and relationships. Half of the class will complete discussions on each unit through text-based discussion only, while the other half will discuss through video postings. The groups will rotate the modality of discussion in every unit. In the video modality, the students will be replying to their group members' video posts with an additional video, without a limit on the number of replies. The same will apply to those assigned the text modality for that week, where the posts and replies will be in text form alone.Student submissions via each modality will be evaluated for their accuracy in addressing outcomes, their social presence and contributions in the group, and their perceptions of the design of the task. This is based on the Community of Inquiry (CoI) framework which analyzes the social, teaching, and cognitive presence involved in creating a purposeful educational experience. At the end of the experience, students will complete a survey outlined by the CoI framework to share their feedback and impressions of both modalities.

Abstract Name: **What to Watch Instead of Eating: An Exploration of Anorexia in Film and the Proana Community**

The pro-anorexia, or "proana" movement, is a phenomenon that has grown online, predominantly among adolescent girls, to share and receive advice on disordered eating habits. Proana websites contain content known as "thinspiration," or "thinspo," which often includes walls of photos, lists of advice, and films for encouraging disordered habits and avoiding recovery. This study pulls from common lists of suggested proana viewing material to provide a critical analysis of the aspects which appeal to the anorexic audience. Its aim is two-fold: first to assess onscreen images and the underlying rhetoric within the narratives that may serve as "thinspiration," and second to examine the conflict between the intended general audience of these films and the proana audience that upholds them as guides and inspiration. The analysis focuses primarily on three films that often appear in these online spaces. Thinspiration and To the Bone are two films that portray the anorexic narrative as it is commonly culturally understood, following the descent of a young female protagonist into her disorder. The girls in these films engage in disordered behaviors on screen, visibly lose weight, and conceal their anorexia from those around them. What may serve as a cautionary tale to a general audience becomes a guidebook for those with anorexia. The third, Black Swan, is a mainstream film about a ballet dancer who has an obsession with control and perfection that ultimately destroys her. In contrast to the others, it does not explicitly depict anorexia but has both visuals and themes that make it a popular choice of viewing for the anorexic audience. Analysis of the content and themes of these filmis an exploration of what makes them so appealingto the anorexic audience and raises questions of how best to depict anorexia on screen.

Abstract Name: Long-Term Efficacy and Stability of Trout Stream Habitat Restoration in the Red Cedar River Watershed

The Red Cedar River watershed in western Wisconsin is a rural and agricultural watershed that is impaired as a result of nutrient and sediment runoff from multiple sources. Poor watershed land use practices lead to the contamination of small, local streams and are detrimental to the health of macroinvertebrates and fish populations such as trout. Efforts to improve the quality of these streams and restore trout fisheries include a 15-year history of restorations focusing on improving in-stream physical characteristics including flow rates, temperature, oxygenation, and habitat. However, on-the-ground testing of water quality and the impacts of the stream restorations is currently limited due to a lack of resources and personnel, making it hard for up-to-date data to be collected and analyzed. Little follow-up beyond project completion checks and occasional fish shocking surveys have taken place to monitor the ongoing success of these restoration projects. In the summer of 2022, researchers from UW-Stout conducted watershed-scale sampling to inform stakeholders about the efficacy of ongoing conservation projects and direct future monitoring for conservation and restoration projects. Data collected at each site included biotic index, streamflow, habitat assessment, width-to-depth ratios, turbidity, conductivity, pH, dissolved oxygen, and nutrient analysis. Comparing the conditions of older streams with new restoration projects shows changes in abiotic factors including channel morphology and substrate quality, as well as differences in biotic indices and the presence of desirable macroinvertebrate species. Continuing maintenance may be necessary to maintain the biological integrity of older trout stream restorations. Ongoing research into the long-term changes in abiotic and biotic indices following restoration provides insight into the efficacy of various restoration methods and illuminates new opportunities. Data on long-term restoration will provide insights into improvingnutrient issues across the entire watershed.

Abstract Name: The Effects of Voluntary Exercise on Memory and Anxiety in Young Adult Female C57BL/6 Mice

Exercise increases spatial memory and decreases anxiety. Physiological mechanisms are unknown, but a larger hippocampus can be associated with both of these outcomes. Nonspatial memory is not necessarily associated with the hippocampus, and thus may not similarly be increased by exercise. This study investigated the effect of three weeks of exercise on nonspatial memory and anxiety levels in young adult female C57BL/6 mice using the open field test (anxiety) and object recognition test (nonspatial memory). We hypothesized that mice in the exercise group would exhibit less anxiety-like behavior and would perform better on the nonspatial memory task compared to the sedentary group. Results showed that exercise did not change nonspatial memory and may have increased anxiety, contrary to the hypothesis. These findings may have been due to the tests used, so future studies could investigate other nonspatial memory and anxiety tests.

Abstract Name: Equity and Sustainability as Community Drivers: Are We All on the Same Page?

The City of Eau Claire, a small city in Western Wisconsin, espouses the idea of becoming a “great city”; with equity and sustainability as two of the driving imperatives to move the city forward. Applying these imperatives may be challenging because the city is recovering from the effects of COVID-19, and will amass $97 million in debt by the end of 2022. In addition, community members, particularly in marginalized communities, are confronting inflation, a mounting housing crisis, and infringements upon health access and reproductive rights. If equity and sustainability are to lead the way in confronting these and future issues, do those working on the frontlines of our city share a common understanding of these imperatives? To address this question, we interviewed the leaders of over 30 Nonprofit Organizations (NPO) in Eau Claire to discuss their understanding of equity and sustainability, and the importance of these concepts within their organizations. We chose to interview leaders from NPOs because they provide services and resources that address important community needs. The NPOs in our sample represented a diversity of interests (mental health, food insecurity, racial justice, environmental, etc.), and a blend of organizational and decision-making structures; levels and types of staffing; and amounts of financial support.We utilized qualitative data analysis software (MAXQDA) to illuminate similarities and differences in conceptions of equity and sustainability. Preliminary findings from our interviews reveal that most NPOs focus on one, but rarely both of these principles. In addition, NPO leaders have differing conceptions of equity and sustainability. Findings from this study will be shared with the Eau Claire NPOcommunity and city staff. We hope to spark conversations and inform policy on how to apply the imperatives of equity and sustainability to strengthen the city of Eau Claire.

Abstract Name: Efficacy of Student Mobile Health Application: The Case of SUNY Brockport

The importance of universities to provide mobile applications for students and faculty is becoming a growing trend since business operations, as well as academic activities, are affected using technology. Research published in 2021 says that the number of health-related applications in the Apple and Google Play stores has exceeded 97,000 with approximately 100 new applications being added per month. This indicates the potential for growth in the mobile health application market. For these reasons, it is important that the SUNY Brockport Health Center investigates the importance of designing a mobile application that can benefit students and the Brockport community at large. This study aims to determine the effectiveness of a health center application that students and faculty can use. With the changes in day-to-day life since the COVID-19 era, there has been an increasing need for mobile health applications. Designing a mobile application (MyHazen App) for the Brockport community could potentially provide students easier access to the services that the online portal provides, with a more user-centered design approach and improved capabilities. This study comprises four main phases: (1) Gathering user requirements through an institutional approvement, (2) Designing a high-fidelity prototype using Figma, (3) Developing a student-based mobile health (mHealth) applicationtool using Swift and XCode, and (4) Determining if students will adopt to the MyHazen application by conducting a usability testing for student user feedback through an iterated design approach.

Abstract Name: **Integrating Dietary and Habitat-Use Biomarkers to Recreate Saltmarsh-Dependent Fish Life History**

Many fish enter estuaries during the larval stages and remain in there throughout the juvenile stage, where they feed and grow before returning to coastal areas as adults. In contrast to these transient fish, we also find permanent residents that complete their life cycle within estuaries. The first objective of this study is to understand dietary habits of two transient and one resident saltmarsh fish. To that end, fish were collected from three sites at varying distances from the coast. Muscle tissue samples from two transient species at the juvenile stage: spot [Leiostomus xanthurus] (n=14), and sand seatrout [Cynoscion arenarius] (n=7) and one permanent resident at juvenile and adult stages, Gulf killifish [Fundulus grandis] (n=17) were stable isotopes indicative of diet (13C: energy source; 15N: trophic position, and 34S: source and trophic level identification). Preliminary isotopic results suggest that sand seatrout exhibit more marine signatures and a higher trophic position than the killifish and spot. The second objective of this study is to determine otolith microchemistry differences by species and site. We anticipate fish with more marine dietary markers are more recent arrivals in the marsh, and would have signatures that differ from the marsh resident fish. To evaluate habitat use, we will examine the otolith microchemistry signatures for the same samples. Through the integration of otolith microchemistry and dietary stable isotopes, the life history of the fish will be reconstructed which provides insight into habitat use patterns across the salinity gradient.

Abstract Name: **Photorealistic Environment Generation**

There have been recent efforts to advance the overall understanding of Mars. Information remains as important as it was when the rover named Pathfinder left the Earth. As it is difficult to achieve efficient human travel to Mars, the National Aeronautics and Space Administration (NASA) has continued to send these rovers to collect information about the red planet. Bringing data and results allows NASA to test hypotheses and develop scientific theories about Mars. Our goal is to generate a reliable synthetic environment similar to the Martian surface, using the Unity engine. Robots can be simulated in this environment with the Robot Operating System (ROS) and Unity bridge to resemble the process of recording and relaying information. Simulation in robotics is an integral part of the design process, most notably in space robotics where you often only get one chance for everything to work properly. Synthesizing the environment can help provide the quantitative data used to train machine learning models. This gives artificial intelligence the ability to complete tasks like object detection and vision-based navigation. The Unity engine allows for the seamless usage of realistic 3D objects from a wide variety of libraries and resources. This simulation will be able to generate geographic features like those found on Mars; the environment includes sand-like meshes, photorealistic rock walls, and rock patches. The collaboration between our team and other teams within the research program is feeding into a larger project. We're working forward to establishing a business that finds and authenticates data using trained AI robotics.

Abstract Name: The Effect of Vitamin D on Chemotherapy Treatment of MCF7 Breast Cancer Cells

Breast cancer is one of the most diagnosed cancers in women and can also affect men. Specifically, the MCF7 strand of breast cancer cells contain estrogen, progesterone, and glucocorticoid receptors and are used for studying and researching breast cancer. Docetaxel is a chemotherapy drug that targets metastatic breast cancers, and Menadione helps to suppress the growth of tumor cells. Vitamin D (VD3) is a hormone that is made in the body in response to the sun. What is still yet to be determined is the effect of VD3 on breast cancer cells when they are treated with Docetaxel or Menadione chemotherapy. Finding the effect will be accomplished by treating the MCF7 breast cancer cells with chemotherapy in the presence and absence of VD3. Methyltransferase assays will be used in order to measure the cells that are still viable after treatment with the chemotherapy. The hope is to determine whether Vitamin D is an under appreciated therapeutic that could be used to help reduce breast cancer in the body.

Abstract Name: To Maintain Herself and Her People: Patriarchal Colonization in Early Modern Ireland and Women?s Responses

Patriarchal colonial theory provides the framework in which to understand the systems of white European colonialism as subordinating native women both as members of the colonized population and as part of the subordinated sex. In this way, Ireland is unique as both patriarchal systems featured were white European and played off of each other. In Ireland during colonization, patriarchy was heightened and violence against women was perpetuated against both the settler and native populations. This patriarchal heightening was not only perpetuated by the colonizing force, but was expressed in multiple systems, both colonized Irish and colonizer English. Violence was also expressed from multiple tensions, particularly religious tensions. Women in Ireland, in the various religious and ethnic groups, actively engaged in the religious and political conflicts of the sixteenth and seventeenth century despite the systems of colonialism and patriarchy that were imposed upon them. This can be seen especially in the reinforcement of colonial reshaping and defense of colonial holdings by New English women, as well as the participation in violent uprising, religious defiance, and political preservation of Irish language, including the actions of the Poor Clare nuns, by Irish and Old English women.

Abstract Name: **Role of CRF1 and CRF2 Receptors in Stress-induced Increase of Intestinal Permeability**

Stress has been proven to increase the permeability of the intestinal epithelial layer, contributing to the development of irritable bowel syndrome (IBS) and other intestinal diseases. Corticotropin releasing factor (CRF) has been known to mediate stress-induced increase of intestinal permeability and contribute to the etiology and symptom severity of IBS. Actions of CRF are mediated by two G-protein coupled receptors, CRF1 and CRF2, both are expressed in the intestine. However, the roles of the CRF1 and CRF2 receptors in stress-induced increase of intestinal epithelial permeability remain unknown. Since IBS is more common in females than in males, female mice were used in this study. Mice were restrained for one hour/day for five days. The selective CRF1 and CRF2 receptor antagonists were injected intraperitoneally 15 min prior to the restraint stress. Control mice were kept in their home cages without restraint. After the last restraint stress/control session, the proximal colon was removed and intestinal permeability was measured using the Ussing Chamber System. FITC-inulin (4kD) and horseradish peroxidase (HRP, 40kD) were used as tracers to measure paracellular and transcellular permeability, respectively, across the colonic epithelium. The results showed that restraint stress increased both paracellular and transcellular permeability in the proximal colon. Both the CRF1 and CRF2 receptor antagonists significantly reduced the effects of restraint stress on intestinal permeability, suggesting that both CRF receptor subtypes are involved in stress-induced increase of intestinal permeability. Targeting on both CRF1 and CRF2 receptors in the intestine may help to alleviate stress-induced increase of intestinal permeability and symptoms of IBS.

Abstract Name: **Looking Right At It: Young Adults, Social Media, and Death.**

There is a universal perception that young people think they are invincible, but are young people thinking about death more than we know? This study examines how social media affects the comfort level of young adults in talking about death, a topic that has been little researched so far. Participants ranged between the ages of 18-34 and were all students of University of Wisconsin – Superior. Through semi-structured qualitative interviews, each participant was asked about their interaction with death on social media, watched a death education video, and gave their thoughts about the video. These answers together give a glimpse into how and why young adults are thinking about death and whether they are comfortable enough to talk about it. Overall, young adults are thinking about death and have a comfort with it, but the perceived lack of comfort in others stops them from discussing freely.

Abstract Name: **Investigation of Nonlinear Polariton-Polariton Interaction and Nanobeam Cavity Coupling**

Semiconductor provides a versatile platform for light-matter coupling studies. By placing semiconductors in an optical cavity, strong coupling between light and excitation in the semiconductor, excitons, can be achieved, allowing for observation of polaritons. In an attempt to investigate nonlinear polariton-polariton interaction, we utilize photonic crystal nanobeam cavities, which induce long-surviving light confinement on the nanoscale, allowing strong polariton-polariton interaction when compared to the natural energy uncertainty of the polaritons. We will also work to optimize cavity-exciton coupling by controlling the thickness of the hBN encapsulation layers.To accomplish this, we will create heterostructures composed of combinations of MoSe2, WS2, and hBN, to integrate with nanobeam cavities, and measure excitation. These are known as Van der Waals materials, which have strong bonds in individual molecular layers, but weaker intermolecular forces. Specifically, transition metal dichalcogenides (TMD) monolayers exhibit large exciton binding energy and strong exciton-photon interaction strength- a necessity for forming polaritons. Samples of monolayers of atoms will be exfoliated from bulk materials, and then applied to substrate. These layers can then be stacked using a polymer stamp and placed into nanocavities. Then, using photoluminescence and reflectance spectroscopy, the polariton resonances can be measured and analyzed. Thus far, the results of measurements support the creation of heterobilayers and integration onto nanocavities allowing strong exciton-photon interaction with Moire excitons from the TMD heterobilayer.

Abstract Name: **Saving Golden Lion Tamarins One Nucleotide at a Time**

With only 1,400 individuals surviving in the wild, Leontopithecus rosalia is on the verge of extinction. Conservationists often use tools of modern genetics to study the genetic diversity of the population, but these tools are lacking for L. rosalia. For example, using common polymorphisms such as microsatellite markers, conservationists can identify inbreeding within a population to increase genetic diversity, but identifying polymorphic loci requires a reference genome sequence, and no such sequence exists for L. rosalia. To support conservation efforts, we are using nanopore DNA sequencing to create a draft assembly of the L. rosalia genome. Then, we will set out to find microsatellite markers to develop and validate reagents for genotyping golden-headed tamarins. These results will aid conservationists in saving L. rosalia from extinction.

Abstract Name: **Nucleosides Serve as Alternative Carbon Sources that Contribute to the Recovery of Escherichia coli from Glucose-Phosphate Stress**

To survive in their environment, organisms often rely on coordinated responses to stress. For example, enteric bacteria such as Escherichia coli have to deal with glucose-phosphate stress, a form of nutrient starvation that occurs when glycolysis is blocked, inhibiting growth. E. coli responds to this stress through the regulatory actions of the transcription factor SgrR and the small RNA SgrS, which help cells resume growth. Both are essential for the recovery from stress, as deleting sgrR or sgrS severely impairs growth during stress. While this regulatory response has been characterized, it is less clear what alternative carbon sources help cells evade the glycolytic block and resume growth. Previous research suggests that nucleosides may serve as an alternative carbon source, as cells lacking nucleoside transport (such as nupG) and metabolism (such as deoB and deoD) genes exhibit stress-specific growth defects. Here, we present further evidence that supports a role for nucleosides in the recovery from stress. Addition of the nucleoside adenosine rescues the stress-specific growth defect of an sgrS mutant, and deleting either deoB or deoD abrogates this rescue. Taken together, these results confirm the notion that nucleosides serve as a key alternative carbon source that helps cells bypass the glycolytic block and restore growth during glucose-phosphate stress. A focus of current research is analyzing the effect of deleting other nucleoside transport and metabolism genes on adenosine rescue of growth during stress.

Abstract Name: **The Effects of COVID-19 on College Students: Pre- and Post-Vaccine**

This research examined the impact of COVID-19 on college students resource loss and stress levels by offering a comparison across pre- and post-vaccine phases of the pandemic. Two research studies will be presented. In spring 2021 (n=155) and spring 2022 (n=256), business school students completed an online survey assessing their resource loss, stress, physical and psychological health, well-being, academic performance and more during the global COVID-19 pandemic. In support of COR theory, the 2021 "results demonstrated that students with lower resources (i.e., lower socioeconomic status) reported significantly more resource loss; increases in resource loss were significantly associated with increases in stress; and stress was significantly and negatively related to physical health, psychological health, and well-being. Reevaluation of resources served as a buffer in the relationship between resource loss and stress." (Murphy et al., 2022, p. 125-6). The 2022 post-vaccine results showed college students reported over five fewer resource losses, but the same levels of stress compared to the pre-vaccine sample. In support of hypotheses from Hobfoll's (1989) Conservation of Resource (COR) theory as well as Hobfoll and Lilly (1993) work on types of resources, students reported a negative impact on stress and resource loss from the COVID-19 pandemic regardless of vaccination status. Further, the effects were more negative for females than males as well as for upper-class students (juniors, seniors, super seniors) compared to lower-class students (freshmen, sophomores). This is one of the first studies to test the differential impact of resource type (personal characteristics, conditions, energies and objects) on the relationship to stress – finding that personal characteristics were the key component explaining most of the variance in stress. Overall, this is the first series of studies to explore the effects of resource loss or gains at two critical points in a global pandemic.

Abstract Name: **Trauma, Personality, and Growth: Examining the Role of Personality on Posttraumatic Growth**

The Anxiety Buffer Disruption Theory (ABDT), an extension of the Terror Management Theory (TMT), suggests that posttraumatic stress disorder (PTSD) is a result of the disruption of one's anxiety-buffering mechanisms. This disruption can lead to overwhelming emotions, hyperawareness of one's mortality, and wide-ranging reactions to traumatic events. However, the anxiety-buffer system mitigates the effects of potential terror, promotes posttraumatic growth (PTG), and is comprised of three components: cultural worldviews, self-esteem, and close personal relationships. The success of posttraumatic growth may also stem from personality traits, such as those that can be measured by the Five Factor Model, of the individual that has experienced the traumatic event, which is the focus of this current study. Past research has shown that those who score high on the scale of Neuroticism have a higher risk of developing PTSD (Cyniak-Cieciura et al.,2022), however, there has not been much research on the personality traits that would promote posttraumatic growth. To date, no research has directly assessed the relationship between personality and posttraumatic growth. Identifying these traits could direct the focus toward cultivating specific characteristics within the traumatized individual in hopes of creating a better outcome. This study aims to identify which Big Five Personality Traits are associated with posttraumatic growth. A sample of N=300 individuals with above threshold PTSD symptomology (PCL-5 scores ; 34) will be recruited via research panel to examine the relationship between personality and posttraumatic growth. All participants will complete a Qualtrics survey including demographic, PTG, and anxiety buffer questionnaires. We hypothesize that high scores in openness, extroversion, and agreeableness will be primary characteristics of those who present more posttraumatic growth.

Abstract Name: **Language Dissected: An Exploration on the Understanding of Language and its Application to Tolkien's Elvish**

Language is the primary method for communication and human connection world-wide; therefore, understanding how language works allows for more effective global communication. Language is deeply complex and comprised of many linguistic elements. Building on Noam Chomsky's work in Linguistic Theory and the work of linguistics scholars, this research seeks to better understand how language is structured through the combination of phonemes, morphemes, syntax, and sentence structure. Through the study of Biolinguistics, which holds that the principles underpinning the structure of language are biologically preset in the human mind and hence genetically inherited, and the theory of Transformational-Generative Grammar, which shows the abstract structures of specific languages and how they may relate to the structures in other languages, as well as Linguistic relativity, it is possible to understand language creation and usage. Others have attempted to understand natural language creation by creating fictional languages, such as languages which are invented to be used by characters in a book series. J.R.R. Tolkien's Elvish started as such a language, but readers have taken it a step further, studying the grammar systems, pronunciation, and dialects. Some even use Tolkien's Elvish amongst themselves as a spoken language. This then leads to questioning what part of this fictional language made it popular and how languages such as English compare to Elvish. Tolkien summarizes key aspects of invented language which can be applied to spoken language in response to this question. This current research explores Tolkein's Elvish, comparing its structure to English and German, with the eventual intention of creating a new invented language, built on the findings of these linguistic principles and synthesis of Elvish, English, and German.

Abstract Name: **Reclaiming Fairytales for Feminism: Trends in Contemporary YA Fantasy Adaptations**

The stories we are told as youth shape identities and perspectives that can take a lifetime to deconstruct. By working to program children and young adults towards a societal norm that not only includes but comprehensively necessitates toxic masculinity, misogyny,heteronormativity, and demonized sexuality, fairytales such as the Grimm's "Little Red Cap," "Briar Rose," and "Little Snow White" perpetuate sexual repression and violence, usually against the victimized woman, i.e. 'damsel', who must in some way defer to the violent, male 'hero'. Further messaging associates beauty with sexual purity and acted-on free will with responsibility for victimhood. Fairytale adaptations effectively track nuanced shifts in cultural values by acting as a vehicle for parental figures to narratively convey said values to their young, who will in turn adapt the stories to share again with the next generation. The cycle continues endlessly, transcending region, language, and time. Recently, these narratives have manifested in the popular twenty-first-century media of the Young Adult (YA) fairytale-fantasy book genre. In this project, I have created a case study of the contemporary Western tradition of Grimm-inspired fairytales. Specifically, I investigate how modern YA fairytale-fantasy texts portray feminine sexuality in relation to one another and in relation to the ancestral Grimm's tales. For example, sexual activity is initiated by female characters [Meyer's Scarlet (2013)] or queered [Wells' Briar Girls (2021)] rather than adhering to the more heteronormative, patriarchal dynamics inherent to the Grimms and reinforced by immensely popular twentieth-century Disney fairytale filmography [see unconscious kiss scenes in Snow White and The Seven Dwarfs (1937) and Sleeping Beauty (1959)]. In this study, I produce a detailed analysis of overarching trends such as these—what changes, and perhaps more importantly what does not, in the communication of women's sexuality to modern-day young adults.

Abstract Name: **Computational Investigation of Aerodynamic Drag over a Model Pickup Truck**

Vehicle aerodynamics is a key factor, which affects the fuel consumption by the vehicle and is related to the fuel economy. Therefore, a wide range of experimental and computational studies in the past have focused on the assessment of techniques that can lead to aerodynamic drag reductions. While wind-tunnel-based experimental studies can provide results much closer to a practical scenario, such studies often tend to be time-consuming and expensive. To this end, computational fluid dynamics (CFD) as a tool is a promising efficient, and affordable strategy for the design and assessment of novel techniques focused on the improvement of vehicle aerodynamics. In this study, computational investigation of aerodynamic drag over a realistic model of a pickup truck referred to as the Generic Truck Utility (GTU), is performed using the OpenFOAM software. GTU is a realistic representation of a pickup truck and an interchangeable sports utility vehicle for which reference experimental results are available. We employ unsteady Reynolds Averaged Navier Stokes (URANS) formulation to examine the flow field and obtain the resulting aerodynamic drag. The key focus of this study is to establish a computational configuration and strategy, which can be utilized further for the assessment of approaches for improved vehicle aerodynamics. In particular, we examine the role of computational domain extent, computational grid, and wind speed on the resulting drag coefficient. The analysis of the results showed some sensitivity of the drag coefficient to the employed computational domain size, whereas the effects of the grid resolution and the wind speed on the drag coefficient were found to be minimal. As expected, a separated flow region occurs at the back of the truck with a spatially evolving wake, controlling which can be helpful to reduce the aerodynamic drag.

Abstract Name: **Assessing Lupine as an Environmental Conservation Tool in Iceland**

Iceland's environment is highly prone to erosion and has conditions that make plant growth challenging. The plant lupine is a divisive solution to soil erosion and reforestation that has been found successful in some regions of Iceland but not all. We researched the issue through extensive document research, expert interviews from different perspectives, and surveys of native Icelanders, to get as complete and unbiased a picture of the issue as possible. We used this to create a decision guide that gives a comprehensive account any person in Iceland can use in order to choose what they would like to do to address soil conservation and reforestation issues on their land. Key issues the decision guide covers are soil conservation, reforestation, and removal of lupine. Along with the decision guide, we include a decisional balance sheet to show the pros and cons of lupine usage in Iceland and a plant infographic to teach about the plants in the decision guide. These tools can be used by land owners in Iceland to make decisions about restoration and reforestation on their land.

Abstract Name: **Setup and Analysis of Proposed Data Loggers Used in Telemetry for the Prime Focus Spectrograph**

The Subaru Telescope is an 8.2-meter optical-infrared telescope located on the summit of Mauna Kea in Hawai'i operated by the National Astronomical Observatory of Japan (NAOJ)/ National Institutes of Natural Sciences. The telescope contributes significant data to a wide range of astronomical research using a technology called Prime Focus Spectrograph (PFS). Within the telemetry system of the spectrograph, data loggers play an essential role such as monitor temperature, coolant flow, and pressure to control environmental conditions. Due to the demands of the telescope instrumentation, the lifecycle of the data loggers are relatively short and need to be replaced every few years. Ill-suited data loggers increase the need for telemetry system maintenance and cause research activities to halt, which also increased project costs. The objective of this project was to comprehensively review and compare available data loggers and provide documentation to minimize the time it takes for telescope technicians to install and maintain the telemetry system.The first step was to determine the telemetry system's requirement and installation parameters and systematically compare those with the features of available data loggers through a trade study. The devices were set up with preliminary IP addresses configurations and, under laboratory conditions, temperature error ranges were compared to the manufacturer's documentation to verify accuracy. Finally, a user documentation of the process and justification for component choices was created to assist with future replacements and maintenance.The DAQ970A Switch Unit and its module DAQM90 was chosen as an ideal replacement due to its improvements in memory and processing capabilities.In conclusion, the systematic component review and documentation led to an increased installation, maintenance, and operation efficiency of the Subaru telescope and its ability to conduct scientific studies. Future work includes analysis of different thermocouples and sensors within the instrumentation.

Abstract Name: **Preventing Adherence of Candida spp. with Pre-Therapeutic Drug - Filastatin**

Candida yeasts are the most common human fungal pathogens. These primarily opportunistic pathogens can infect a variety of tissues and cause a variety of infections. They are also a common cause of healthcare-associated infections (HAI) in immunocompromised individuals. Candida yeasts usually form biofilms upon adhesion, which then increases their pathogenicity due to their lack of response to conventional treatment. Candida auris is an emerging fungal pathogen with nearly a 57% mortality rate. Filastatin is a drug not yet approved for human use but has been found to uniquely inhibit adhesion of C. albicans to the surface of several biomaterials and human cells. This study will assess if Filastatin is also able to inhibit the adhesion of three other pathogenic Candida species, C. albicans, C. glabrata, and C. auris. 96 well polystyrene microtiter plates will be used to assess the inhibition of fungal adhesion using various concentrations of Filastatin. After incubation, cells grown in the wells will be stained with either crystal violet, (or alamar blue to test for viability as well). Upon washing the plate with ice water several times to clear out stained cells that didn't adhere to the surface, methanol will be added to each well and allowed to sit for 45 minutes. The solution of methanol and stained cells will then be read by a spectrophotometer at 590 nm for the varying absorbances and will be compared to our control of both saline and Candida albicans. This will be beneficial to the future of healthcare as it will allow the number of infections with Candida species to be decreased. Future medical devices coated in Filastatin would be more resistant to Candida biofilm formation and would therefore limit the number of infections and mortality.

Abstract Name: **A Qualitative Analysis of Audience Responses to StoryCorps&#65533; &#65533;One Small Step&#65533; Project: A Prejudice Reduction Program Addressing Political Polarization**

Where did the "United" part of United States of America go? How are Americans addressing political polarization in our country? Some say new media is to blame, and others simply blame the other political party. Like many other national issues, the cause of polarization is complex, intergenerational, and multi-dimensional. However, the complexity of this issue does not mean it is impossible to reconcile. The issue of polarization in the U.S. is currently being addressed by few organizations to mitigate continued division and dangerous intergroup conflict. Prejudice reduction programs and projects such as NPR's StoryCorps's "One Small Step" are addressing the hostile division in the United States and therefore serves as the case study of my research. This qualitative research observes means of American polarization reduction through the lens of communication theory as well as intergroup contact theory. Human participants of my study will view three "One Small Step" video projects on common ground via YouTube and complete corresponding pre- and post-surveys to measure change in attitudes of prejudice. Using Gordon Allport's intergroup contact theory, I hypothesize that witnesses and audience members of "One Small Step" videos can reduce their political prejudice and hostility just as direct participants in the videos can. We need more research on audience responses to prejudice reduction programs. With political polarization on the rise, it is important to understand the effectiveness of prejudice reduction programs and projects beyond simply the direct participants. This study hopes to prompt significant questions about strategies for combatting polarization and audiences' interactions with them.

Abstract Name: **Untitled (Winter)**

This creative project attempts to reconcile my few, but poignant memories of my grandfather with those of my other relatives and the pain of those who lost loved ones during the Vietnam war. This sculptural piece is a mixed-media installation, taking up a space of around 7Hx3Wx5D ft. Materials include plastic droplets, plywood, a plastic fluorescent light diffuser, a monitor, a monitor mount, monofilament, and a video player. The monitor will take up a space no larger than 28 by 32 inches and be mounted on the wall. The sculpture is made of a plywood base, where the fluorescent light diffuser will rest inside. Monofilament is used to connect the plastic droplets to the light diffuser. The sculpture hangsin front of the monitor suspending the plastic dropletsin the space between the viewer and the screen, creating distorted imagery. Droplets hanging from the ceiling symbolize the literal suspension of tears, the continuous and unresolved pain of those who lost a loved one in the war. The view through the droplets—a metaphor to pain—reveals scattered memories as a performance, I re-enact memories of personal experiences and reflections from my mother to understand her experience as the child of a Navy Sailor during the Vietnam War. The research basis for this piece is direct experience with family as well as historical record to inspire a deeper understanding of the war's emotional effect on a national and personal level. This piece draws conceptual inspiration from Lin's Vietnam Veterans Memorial,the familial-based performance art of Guillermo Gomez-Pena, and Mark Tribe's Port Huron Project. Those affected and curious about socially activist works and complex family relationships will be interested in this work. The mentor for this project works in digital media and installations and will help with the video aspect and the sculptural piece.

Abstract Name: **Preparedness and Comfort Levels in Providing Sexual Health Education on Vancouver Island**

Sex trafficking and sexualized violence are increasing in communities across British Columbia (BC). Sexual health education has been recognized as a powerful tool to prevent children and youth from experiencing these devastating forms of abuse. The question then becomes: who is providing this sexual health education to British Columbian youth, and how well is it being provided? While parents and private consultants often play a role in teaching children the basic concepts involved in sexual health education, the quality and scope of their explanations can vary widely. As such, a key source of sexual health education is teachers in primary and secondary schools. Typically, sexual health education in BC begins in kindergarten and spans through grade ten. While the topic's content is regulated through the provincial curriculum, previous research has shown that teachers are not providing consistent and thorough education. The disconnect between the curriculum and educators appears to be hinged upon two concepts: first, educators themselves do not have enough knowledge on the topics to teach them effectively, and second, educators may not feel comfortable with certain sensitive topics within the curriculum. This project sought to investigate how prepared Vancouver Island teachers-in-training are to teach sexual health education based on their knowledge and comfort levels regarding the curriculum topics. A survey was created with three sections: individual demographics, a curriculum-based knowledge test, and a subjective section focusing on comfort levels regarding various sexual health topics. The survey was open to university students enrolled in the Bachelor and Master of Education programs at Vancouver Island University and the University of Victoria. By examining these future teachers, this project aimed to illuminate how prepared the next generation of teachers are and provide insight into the future of sexual health education.

Abstract Name: The Coming-of-Age Genre: A Genre of Identity Exploration for Emerging Adults

This project aims to bring Rudine Sims Bishop's work on worldview construction alongside the cinematic theory of the female gaze to address how coming-of-age films may assist emerging adults in identity development. To do so, I will be drawing upon the work of developmental psychologist Erik Erikson, exploring what characteristics distinguish the "identity vs. role confusion" stage of psychosocial development. I will then juxtapose these characteristics to Rudine Sim Bishop's theories of representation in children's literature to argue how Bishop's ideas can be applied to cinematography. I will further support this argument by synthesizing contemporary scholarship that centers how the digital age is impacting identity development inemerging adults. After parsing through these works on child development, I will perform case studies on modern coming-of-age films from the last decade to better understand if and/or how those narratives are reinforcing intersectional representation. I will conclude this presentationby acknowledging future areas of study, as well as raising awareness of the responsibility of directors, producers, consumers, and educational figures to expose youth to diverse narratives to better assist identity development.

Abstract Name: Ties Between Social Media Use and ADHD, Depression, and Anxiety-Related Symptoms

Social media has become a staple in the life of adolescents and young adults. In a recent study, 97% of teens reported using at least one social media platform (Anderson, & Jiang, 2018). With this increased use of social media platforms, psychologists are concerned about their potential impact(s) on people's experiences in life. One avenue of interest is the relationship between social media usage and mental health conditions. Studies have reported that high social media use is positively correlated with symptoms of ADHD (Baumgartner et al., 2017), anxiety, and depression (Hussain & Griffiths, 2019). Through this study, we predict to find similar findings, hypothesizing that ADHD, depression, and anxiety-related symptoms in University of Wisconsin-Eau Claire college students will all be positively correlated with their time spent on social media. To collect this data, the research team developed a survey that asked participants to report their demographic information (age, gender identity, sexual orientation, and major), time spent using social media, and mental health-related symptoms using the PHQ-9, GAD-7, and ASRS-6 assessments. Participants will be recruited through WRIT 114-120 classes by asking the students to voluntarily participate in an online survey. To analyze the survey results, the researchers will conduct bivariate correlational analyses of the total time spent on social media in the last seven days and each set of mental health-related symptoms (ADHD, depression, anxiety). We perceive this research, and the findings, as important for furthering the understanding of the relationship between ADHD, depression, and anxiety symptoms and social media use.

Abstract Name: **Exploring the Approaches of Preventing Bias in Artificial Intelligence**

Exploring the Approaches of Preventing Bias in Artificial Intelligence
From the algorithm and input attributes chosen to the hidden correlations within training data, bias in Artificial Intelligence comes from a wide range of sources. There are three general classes used to describe bias: creeping the subject's intent into the AI implementation, skewed training dataset, and anomaly individual samples. This study aims to explore not only these classes that can cause bias but also the approaches that can help prevent bias. In the literature, a combination of quantitative assessments, business processes, monitoring, data review, evaluations, and controlled experiments can be used to help in mitigating the issues.
However, how to monitor, evaluate, and control the AI processes including algorithms and training datasets seems the key to resolving the problem. One of the potential approaches is introducing a black-box test into all the processes in the AI pipeline. Another is having the AI explainable, namely keeping the white-box model in both algorithm and the training data set. This can be an effective way to verify that the data is accurate and does not contain protected or incorrect data. However, unconscious bias within the training data set is difficult to perceive because of the nature of unconscious bias. The anti-bias approaches are also very important to evaluate the reliabilities of an AI model and validate the performance of a predictive model. While there may be no single solution to the bias in artificial intelligence, the goal of this research is to explore these biases and their best anti-bias approaches to reducing these biases in future workings.

Abstract Name: **Reimagining College Support: A Critical Exploration of the Impact of Grief and Loss on the Experiences of First-Year College Students**

Student attrition is a rising concern in higher education given the various challenges that have arisen over the past couple of years. The offset of the COVID-19 pandemic, the racial justice movements, and the current social-political climate have significantly impacted our college students like never before. Of growing concern is the rising mental health crisis that is sweeping through higher education which warrants an immediate and intentional response. Further, students are currently facing dire financial constraints, food and housing insecurities, and many other challenges that complicate their college experiences. As freshman students are now experiencing college for the first time, their experiences may vary drastically from their predecessors. Specifically, current first-year students' college transitions are muddied from their various high school experiences that may have been a remote, hybrid, or in-person with some variation of security measures. Further, the grief, loss, and trauma first-year college students have experienced during the pandemic warrant special attention as we are contending with the types of resources and support, they need to matriculate and complete their degrees. The remnants of grief and trauma from the pandemic still linger and are impacting the college experiences of first-year students and their abilities to navigate their academic and professional goals. Hence, through a qualitative research design, our research explores the lived experiences of first-year college students. Specifically, the research question explored in our study is: How or to what extent has grief and trauma from COVID impacted the educational journeys of first-year students? The aim of this research is to provide an important opportunity to investigate how to better support college students as they move through collegiate experiences.

Abstract Name: Translocation of Microplastic Fibers in Lake Trout and Their Impact on Human Health

Research on the effects of microplastic fibers have demonstrated harmful and negative impacts on wildlife and the environment. The effect studies have shown to a certain degree is that microplastic fibers can become ingested at lower trophic levels in aquatic enviornments and have led to ecosystem disturbances. An interesting observation has been proposed that microplastic fibers are able to translocate in fish from their stomachs to their liver. This has the potential for an increased concern related to human health if fish are consumed from the wild and may cause internal damage on a microscopic level. By understanding the pathology and biology of how microplastic fibers can translocate through cellular membranes will help better understand how this phenomenon is able to occur. Through performing dissections of 78 samples of Lake Trout from Lake Superior, there was no definitive evidence to support that translocation of microplastic fibers from the stomach to the liver has occurred. Throught he process of chemical digestion and the use of FTIR, this research aims to show how different controls can help assess the risk of microplastic fibers and their threat if they are able to translocate across different membranes.

Abstract Name: The Elephants of Guinea-Conakry: Nuclear and Mitochondrial Genetic Patterns

Elephant populations in Africa are threatened by poaching and habitat destruction. The disappearing elephant range has caused small elephant populations to be isolated from others which may lead to a loss in genetic diversity due to inbreeding. Non-invasively collected fecal samples were obtained from elephants in Guinea-Conakry. DNA was isolated from these samples, and a portion of the mitochondrial DNA control region and three nuclear genes (PLP1, PHKA2, and BGN) were amplified by PCR and sequenced. Sequences were analyzed to determine mitochondrial haplotype diversity and species-diagnostic single nucleotide polymorphisms (SNPs). Data from this work will aid in conservation and anti-poaching efforts by contributing to a growing genetic database of African elephants.

Abstract Name: **Quantum algorithms for the simulation of nonlinear molecular polarizabilities**

We investigate quantum algorithms to calculate nonlinear dipole responses of molecules in external fields. Computing nonlinear response on classical computers is a highly challenging task in quantum chemistry, which is crucial for computational design of organic nonlinear optical materials. We approach this problem using quantum algorithms tailored for noisy intermediate-scale quantum computers, since quantum dynamics simulations are one of the primary targets for early quantum advantage. We benchmark and compare algorithms based on Trotterized real-time evolution, against an adaptive variational approach. Taking BH as a classically tractable benchmark problem, we simulate the molecular dipolar response in a monochromatic time-dependent electric field for one period. We compute both the first order polarizability αzz(−ω; ω) and the first two nonlinear hyperpolarizabilities βzzz(−2ω; ω, ω) and βzzz(0; ω, −ω), corresponding to second-harmonic and DC dipolar response. We employ a finite difference expression that is accurate up to third order for analysis. STO-3G minimal basis is used for the calculation of hyperpolarizabilities, where βzzz(−2ω; ω, ω) and βzzz(0; ω, −ω) obtained from exact diagonalization have a relative error of 0.03% and 13% compared to the converged large basis calculations. On the contrary, we find that the αzz has a large relative error of 66% showing that the minimal basis is insufficient. Therefore, we construct a series of increasingly larger basis sets, where the obtained αzz converges gradually to exact result down to a relative error of 4%. Using these basis sets, we compare quantum resources of direct Trotter dynamics simulation with the stochastic Trotter evolution method q-drift and a variational method using adaptively constructed problem-specific ansätze. We also use the basis-set sequence for αzz to numerically demonstrate the system-size scaling of the quantum resources.

Abstract Name: **Determining the Gene Expression Pattern of Nectin Cell Adhesion Molecule 1 (Nectin1)**

Neural crest cells (NCCs) are a population of stem cells found in vertebrate embryos. These cells are induced in the neural plate border in early embryonic development. After the closure of the neural tube, neural crest cells leave through an epithelial to mesenchymal transition (EMT). This allows the cells to lose their epithelial cell characteristics, migrate throughout the embryo, and eventually differentiate skin pigment cells, craniofacial skeleton, and the peripheral nervous system. Learning more about neural crest development is vital for preventing congenital disorders. Abnormalities in the development of NCCs lead to cleft lip, cleft palate, and frontonasal dysplasia amongst many other things. Our previous work identified 674 genes that are potential novel regulators of NCC development. One of the identified genes was Nectin1. Nectin1 (Nectin cell adhesion molecule 1) is a gene that encodes adhesion proteins. Because changes in adhesion properties are central to EMT and migration, we hypothesized that Nectin1 could be essential for neural crest development, and thus would be expressed in premigratory and migratory cells. This study aimed to identify when and where Nectin1 is expressed in early NCC development. We used in situ hybridization (ISH) to determine the gene expression patterns of Nectin1 in chick embryos. Our results indicated that Nectin1 is strongly expressed in premigratory and migratory cells and because it is located at the right time and place, our future work will focus on determining if Nectin1 plays a role in NCC formation and migration.

Riley Kangas

Abstract Name: **Neurodiversity, Personality, and Mental Health Challenges**

Prominent variations of neurodiversity include autism spectrum disorder (ASD), attention deficit hyperactivity disorder (ADHD), and dyslexia. Institutions of higher education should foster an inclusive environment for these individuals, which includes understanding common behavioral attributes, limitations, predictors, prevalence, and desirable adaptations.Participants in our pilot study were 23 females and 8 males (31 total), drawn from convenience and student sources. The primary goal in this first foray into investigation of neurodiversity in higher education was to focus on personality and related associations with common attributes of these three forms of neurodiversity. Follow-up with larger samples is planned to investigate their prevalence and effects / limitations in the college environment.Results found that openness to experience correlated negatively with typical ASD symptoms such as difficulty with social norms (r = -.52, .01). Neuroticism correlated positively with ASD symptoms (r = .46, .05), and individuals higher on neuroticism were more likely to suffer burnout (r = .74, .00001). Participants endorsing ADHD symptoms also reported higher burnout (r = .50, .01), and participants not reporting ADHD symptoms reported higher levels of self-care activities (r = -.46, .01).Although this pilot study focused on associations and not causality, our results nonetheless identify several correlates of neurodiverse symptoms and provide direction for follow-up research. The potential benefits of enhanced understanding of neurodiversity in higher education include targeted resources, classroom adaptations, and counseling resources. In short, continued research offers great potential to afford neurodiverse students the same opportunity to succeed as neuro-normal students.

Abstract Name: **The Effects of Mode and Timing of the Inoculation of Azospirillum on Spring Wheat Yield and Physiology**

Azospirillum is a genus of plant growth-promoting bacteria known for its ability to fix nitrogen from the atmosphere converting it into a form that can be used by plants. There is evidence that Azospirillum benefits plants by colonizing the region around the roots and the roots themselves. Commercial products that introduce Azospirillum to crops exist but the effects of the timing and mode of their application on crop physiology and overall yield is not well known. To investigate this, hard red spring wheat plants (Triticum aestivum) are being grown at the University of Wisconsin-Eau Claire greenhouse under five treatments that vary the mode and timing of Azospirillum inoculation (none, as a seed coating, and as a soil-surface dressing at 3 stages of development; at planting, after development of the 1st true leaf, and at the tillering stage). The Feekes scale of wheat development was consulted to decern which stages plants were in at a given time. To determine the effects of timing and mode of inoculation on plant physiology and growth, plant height, leaf chlorophyll content, and developmental stage are being recorded weekly. When mature, overall biomass accumulation and grain yield will be measured. Data generated from this experiment will uncover if certain modes of Azospirillum application are more beneficial than others and inform best application practices in the field. Developing successful Azospirillum inoculation practices will also reduce the need for synthetic fertilizers and pesticides, therefore maintaining healthy soil conditions and promoting environmental sustainability.

Abstract Name: **Assessing Thiamine Deficiency in Diving and Sea Ducks in New York**

Thiamine deficiency has been linked to waterfowl decline in Europe; however, the topic remains largely unexplored in the Great Lakes region and other parts of North America. Thigh muscles and livers were collected from ten species of diving and sea ducks (greater and lesser scaup, white-winged and black scoter, long-tailed duck, bufflehead, common goldeneye, and hooded, common, and red-breasted merganser) from the Lake Ontario watershed in Fall-Winter 2021-22. Mallard x northern pintail hybrids raised in captivity on a stable diet were used as a control. Thiamine vitamers (thiamine pyrophosphate, thiamine monophosphate, and free thiamine) were extracted and quantified using high-performance liquid chromatography. Total thiamine concentrations in thigh muscles significantly differed among species (0.01), with total thiamine concentrations greater in long-tailed duck compared to all other species, except lesser scaup. Free thiamine and thiamine monophosphate concentrations significantly differed among species (0.01), whereas thiamine pyrophosphate concentrations did not (p>0.01). Based on thiamine in thigh muscles, most birds appear thiamine replete. We are currently analyzing the liver tissues and these data will provide a more holistic view of thiamine levels in diving and sea ducks from the Great Lakes region.

Abstract Name: **Designing A Metastatic Breast Cancer Support Program**

Currently,there is a significant lack of community-based support groups for individuals living with Metastatic Breast Cancer (MBC). The majority of breast cancer support groups exist for those who are breast cancer survivors, inadvertently overlooking those given a terminal diagnosis. Additionally, only about 2% to 5% of the funds raised for breast cancer research is spent towards breast cancer metastasis studies. The goal of our research is to create a patient-led, community-based support program for individuals living with MBC. This will require the collection of resources that address the specific needs of this community, which were identified through extensive literary research and comprehensive surveys. The survey we created assessed their backgrounds, capabilities, needs, and desires. Additionally, we conducted 15 one-on-one interviews with MBC individuals to gather information on their past support program experiences and program structural preferences.With this qualitative and quantitative data, we are currently developing the Charlotte MBC Program and plan on officially implementing the program in the spring of 2023. We have partnered with Carolina Breast Friends, a Charlotte-based nonprofit organization centered around providing support and resources to those who are affected by breast cancer. Carolina Breast Friends does not currently have any specialized services for those with metastatic breast cancer and partnering with this organization allows them to impact more lives within the breast cancer community. We plan on housing our program at their Pink House, a unique respite center for breast cancer survivors.

Abstract Name: **Correlations Between Breast Cancer to Health and Environmental Risk Factors**

Breast cancer occurs when cells are influenced by particular hormones and alterations to specific genes in the DNA, leading them to gradually grow out of control and becoming damaged. In the United States, breast cancer is the most common type of cancer among women. Therefore, analyzing the correlation between biological health risks and environmental risk can allow better understanding towards prevention. Viz Hub website was utilized to gather statistics on various risk factors from 10 counties across six states in the United States that showed the highest levels of breast cancer mortality; to identify possible correlations. Health is vital to maintaining homeostasis of the body and regulating hormones. The endocrine system can be disrupted by health and environmental factors.This can cause alterations inthe regulation of endocrinal glands leading to disorders and illnesses.Additionally, exceeding the body's adequate nutrients and capacity to metabolize can lead to health problems, such as, obesity, malnutrition, or anemia. Furthermore, many research studies have concluded that the use of drugs, smoking, or alcohol are risk factors.The results of this study show that diabetes has the highest correlation to breast cancer mortality rate when compared to all risk factors. Evidently, in metabolic disorders involving insulin resistance, organs with high estrogen demand like the breast and ovaries have an increased rate of cancer development. Additionally, data collected on the levels of obesity prevalence to breast cancer showed that particularly obese women have a greater risk of breast cancer compared to a healthy body composition. Anemia, smoking, and drug use also showed correlations to breast cancer mortality rate in some states. These statements are supported by data that was gathered from Viz Hub, displaying a correlation to the health and environmental risk factors and an interference within the 10 counties in United States.

Abstract Name: **Finding Fires: Drone-Based Autonomous Fire Detection**

Over the past several years, wildfires have become more extreme, destroying acres of nature and endangering lives. Recently, research in this field has turned to machine learning-based approaches to enable autonomous detection of wildfires before they cause serious damage. This proposal reviews recent scholarship applying machine learning to fire detection. While a variety of machine learning approaches have been proposed in the literature, prior work has not adequately addressed the issue of which approach is best when implemented as part of an autonomous drone platform. Recent years have seen a marked increase in drone capability coupled with decreasing cost, making them a compelling choice for implementing an autonomous flying fire detection system. This project addresses the gap by evaluating the effectiveness of two main machine learning techniques in detecting fires from the perspective of a drone camera. The two methods that will be analyzed are the Gaussian Mixture Model (GMM) and the Deep Convolutional Neural Network (CNN). Specifically, the project will compare the two approaches in terms of a variety of metrics including detection accuracy and speed to determine which is better suited for use on a drone. In addition to quantitative evaluation of performance metrics, a qualitative analysis will characterize effectiveness of the methods for a range of scenarios, such as smoke, active fires, and false alarm situations. The project outcomes will help identify where future research should focus in testing large-scale real-world scenarios on the superior system.

Abstract Name: Investigating the use of crayfish as environmental water quality sentinels for metal pollution in Indiana creeks

Ephemeral creeks and streams can be difficult to monitor and assess for water quality. Unfortunately, these same water systems can play a significant role in the input of metals and other pollutants into major waterways. Metals are often the result of nonpoint source or historic point source pollution that is no longer active, making assessment and exposure prevention difficult. An economical and reliable approach to determine water quality in these areas would be the use of reliable sentinel species that are endemic, easily identified, and respond in a quantifiably way to metals in the environment. Macroinvertebrate assemblages have been historically used to create comprehensive biotic indexes, but these indices can be complicated, seasonal, and difficult to assess without identification bias. For this project, crayfish samples, water samples, and sediment samples were collected in several creeks in Indiana representing a variety of environmental exposures. We hypothesized that because are omnivores and biotic engineers, their environmental interactions place them in a unique niche making them a reliable sentinel species. By testing and comparing the bioaccumulation of metals in crayfish tissue, water, and sediments to dominant species, average crayfish size, and population density, we can reliably predict creek health for metals. Our results determined thatFaxonius rusticus(rusty crayfish) were found in creeks with higher environmental metals. Also, crayfish cephalothorax measurements were smaller in higher metal environments. This data, along with metal bioaccumulation and biomagnification make crayfish an excellent sentinel for water quality in creeks.

Abstract Name: Targeted Messaging about Food Storage in Social Media Posts

Food waste is a major problem in the United States and around the globe. In the U.S alone, avoidable food waste exceeds 55 million metric tonnes per year, nearly 29% of annual production and it has been estimated that this waste produces life-cycle greenhouse gas emissions of at least 113 million metric tonnes of CO2 annually, equivalent to 2% of national emissions. Food waste by end consumers occurs for many reasons, including food being prepared and stored incorrectly, and misunderstandings of the “best by” date on foods. Food-related messaging is widespread on social media, with users posting comments and photographs of foods that they are preparing or enjoying. These messages are then viewed by millions of users. Targeted responses to such messages could correct some misconceptions and therefore reduce food waste. The main technical challenges for creating targeted messages are identifying food-related posts and automatically generating a relevant response. We have developed an approach that uses machine learning to identify if a social media post mentions specific foods. The approach is able to detect food entities in Twitter posts with a precision and recall of 0.8. This approach was also applied to identify foods in photographs posted on Instagram using object recognition in images algorithms. If a post is identified as likely to be about a specific food, a short message with information such as storing tips and methods to prepare that food is generated. We use the FoodKeeper dataset published by the U.S. Department of Agriculture which contains descriptions of foods and their storage methods to generate targeted responses. This approach could therefore be used as a tool for more targeted and real-time messaging of information related to food and potentially help reduce food waste by end consumers.

Abstract Name: **The implications of decriminalising domestic violence in Iran and Kazakhstan**

My research focuses on the problem of domestic violence in Iran and Kazakhstan due to growing concerns about the problem's contribution to the stagnation in the process of achieving gender equality. The chosen developing nations have similar unique characteristics such as domestic violence legality and decriminalisation, religious background and history of colonisation. The impacts on women stretch beyond physical and mental harm and cause further problems by preventing them from being active members of society in a social and economic sense. Academic literature on the topic explores the reasons behind the social acceptance of the issue while failing to estimate the economic and other implications of decriminalisation. In this study, I use official governmental statistics on crime in Kazakhstan between 2000 and 2021 to examine the consequencesof decriminalisation which went into effect in 2017. While the recent decriminalisation of domestic abuse in Kazakhstan allows me to compare direct impacts, the Iranian government has never passed a law protecting women in their homes. Due to the lack of official data on the issue, I use various scholarly articles which estimate the prevalence of domestic violence in Iran as well as qualitative studies surveying Iranians on this topic. My analysis shows a steep decrease(50.6%) in the number of reported cases of domestic abuse in Kazakhstan between 2016 and 2021 while other crimes are on the rise which signifies a growing reluctance of women to seek help. Similarly, data shows a decrease in the number of marriages which can be related to a desire not to give up legal protections upon marriage. My exploration of risk factors in Iran shows that historic highs in literacy rates and higher education obtainment have had little effect on the position of women and domestic violence rates.

Abstract Name: **?And Who Has Not Had Their Ears Tickled?? Sophia and the British Musical Miscellany**

Historian Charles Burney mentions that Plutarch and Athenaeus both wrote about a "most celebrated" Greek female flutist named Lamia. Burney's opinion is that her fame was based on her abilities as a courtesan rather than as a flutist. Greek artifacts from this time often depict female musicians erotically, though it is possible that female musicians were perceived and portrayed as sexual objects because their performances were controlled and viewed by men, and the artifacts were created by men. In the eighteenth century, similar attitudes existed about the social and moral status of public female performers. Domestic female performers, though considered socially and morally superior, treaded a fine line, and the flute was not considered a "proper" instrument. Thus, information about female flute players performing either in public or at home is difficult to find, and if it exists, is in non-traditional resources. The current research project will review non-traditional literature for clues about female domestic musicians who may have played the flute.For example, the Scottish National Library's copy of The British Musical Miscellany, Volume One bears the signature Sophia Eyre on the title page. The score includes separately notated flute arrangements of popular songs, thus opening the possibility that Sophia Eyre and other female domestic musicians could have played the flute. Results from an analysis of this score could shed light on the musical culture in which female domestic musicians lived, and add significantly to the growing body of knowledge about the musical lives of underrecognized eighteenth-century women who paved the way for female musicians of today.

Abstract Name: **(Dis)Integration and Reframing in Writing and Literary Studies**

I'm interrogating the dis-integration and integration between writing and literary studies–gaps and overlaps that have evolved out of the two fields' different histories–to ascertain how the two could be better integrated. Since the inception of literary studies, English Departments in American colleges and universities over a century ago, literature and composition have been pursued as largely separate fields of study. This study won't argue for consolidation and reintegration, but, as both a writing and literature major, I've noticed places where students could benefit from further integration.This study explores means of integration which can eventually be translated in the university setting and beyond to high schools for greater student accessibility. One way of understanding how the two fields think differently about writing (noun and verb) and reading is to look at conceptual metaphors (Lakoff and Johnson 1980) in corpora of literary and writing studies scholarship and in writing and literature classes. Conceptual metaphors allow me to directly compare these data sources for convergence and divergences in interests and values. Interviews with faculty teaching those courses provide insight into teaching philosophies, and student surveys provide feedback about effects on student learning outcomes. Furthermore, I've interviewed our English Department chair and completed discourse analyses of English Department websites to see how the departments present themselves. My poster will include a list of conceptual metaphors and a map of their influences and interactions with writing and literary studies, yielding evidence of how the two fields think differently. My hope in sharing my research is to reframe the way we think about the relationship between the two for the benefit of both fields and students.

Abstract Name: **An Elastohydrodynamic High-pressure Seal for Super Critical Carbon-Dioxide Power Plants**

Supercritical CO2 (sCO2) power cycles are superior to traditional water-based, air-breathing, direct-fired, open Brayton cycles, or indirect-fired, closed Rankine cycles in terms of efficiency and equipment footprint. They hold great potential in nuclear power production, fossil fuel power plants, concentrated solar power, geothermal power, and ship propulsion. sCO2 power cycles must be demonstrated on the scale of 10–600MWe and at the sCO2 temperatures and pressures of 350–700°C or 20–35MPa for nuclear industries. The lack of suitable shaft seals at sCO2 operating conditions is one of the main challenges at the component level. So far, conventional seals all suffer from the incapability of handling sCO2 pressure and temperature in one way or another. To this end, we propose an elastohydrodynamic (EHD) high-pressure, high-temperature, and scalable shaft seal for sCO2 cycles. The higher the pressures are, the tighter the sealing while sustaining a continuous sCO2 film. For proof-of-concept purposes, a 2" static test rig was designed at Georgia Southern University before the actual dynamic testing at the Sandia National Laboratories. For simplicity, nitrogen gas was chosen, and the tests were conducted at room temperature. The test rig consisted of a 16.5MPa N2 tank; a cylindrical housing enclosing the static shaft and the test seal; steel tubing with compression-type fittings; an OMEGA–PX5500C0-2.5KA10E pressure sensor; and an OMEGA-FMA-1623AI mass flow meter. The static shaft had a diameter of 1.9995" and was made from steel, the test seal was made from PEEK. Data was measured using LabVIEW software and a National Instruments DAQ-Module-NI-9205. The experiments were performed for 50µm initial clearance and inlet pressure increased to 600psi. Initial experiments successfully demonstrated the throttling behavior of the EHD seal. Based on these preliminary results the EHD seal design could potentially be used in sCO2 turbomachinery. US-DOE through STTR Phase I and II grants, no: DE-SC0020851

Abstract Name: **Carbon Capture by Icelandic Basalts: A Potential Way to Address Global Climate Change**

Many ecosystems can only survive in a very slim temperature range, but our increased use of greenhouse gasses, such as CO2, change global temperatures significantly. This results in those ecosystems dying off, like coral reefs for example. Iceland currently has one of the largest carbon capture plants in the world. They have implemented a way to take CO2 from the atmosphere and pump it underground.
The research question we will be answering with our project relates to carbon capture. We will be exploring how carbon can be contained within bedrock through multiple experiments and observation of basalt samples.
We collected olivine and basalt samples from the Fagradalsfjall volcano in Iceland. The collected samples were micronized and analyzed with a powder x-ray diffractometer (PXRD) before being exposed to dissolved CO2.
Preliminary results show no change in mineralization after 31 days. This is unsurprising, as a study published by researchers in Iceland showed significant mineralization after running experiments for upwards of 140 days.
Future steps include letting the two existing samples continue to react with the carbonated water, as well as running an additional experiment. This set-up is designed to continually measure pH and CO2 levels in a closed system. We will also use a scanning electron microscope (SEM) to look for any changes on the sample surfaces before and after this set-up. This experiment will attempt to minimize human error while collecting as much data as possible that would indicate mineralization.
The contributing factor of our research would be assisting in ways to lessen climate change. As we know CO2 is a greenhouse gas which largely contributes to the warming of the earth. With scientists discovering new ways to contain CO2, we have the potential to slow global warming.

Abstract Name: **Corridos and Boleros as Artistic Representations of Social Reality in Mexico**

From the themes of the songs to the instruments chosen to create a cultural product, music has a fascinating way of becoming a representation of the society that created it. In Mexico, corridos and boleros are two genres that capture the social changes that took place in Mexico in the first half of the twentieth century. War was the constant reality during the Revolution daysDuring the ten years of the revolution a normal life was the dream, and the war was the constant reality surrounding them.After the revolution life went on and changed from people in rural areas moving to the cities and having time for love and imagination. In this presentation, I will discuss how corridos and boleros captured these changes in society. I will analyze how on one hand corridos reflect the violence, death, and loss that were part of the war. Then on the other hand, once the revolution ended and society restructured, bolero depicted a different society in which a love, specifically unattainable love, became the main theme to express. I argue that while corrido focusses on tangible aspects of life, bolero created a fantasy world in which desire and love become the central themes and displays the writers abilty to imaginebeyond reality. As part of my discussion, I will also analyze “La Adelita,” which I see as a transition song in this evolution of these two genres’ production and consumption.

Abstract Name: **Investigation of Fabrication Techniques for Organic Light Emitting Diodes**

Organic electronics is an emerging field that allows for the construction of high efficiency, thin, mechanically flexible devices. They also show promise as sensors, due to their large, room-temperature magnetoresistive effects. However, the organic layers can be reactive, leading to short lifetimes and device instabilities. We investigated fabrication techniques to improve longevity and performance. Specifically, we focused on the cathode layer of organic light emitting diodes (OLED's), which is vital for the injection of charge carriers into the devicesallowing for conduction,recombination, and light emission. We used different thermal evaporation techniques, materials, heating times and pressures to study the effects on device quality. We then examined our cathode layers using a SEM, confocal microscope and profilometer. These imagining techniques allowed us to identify faults within our device construction. Device performance was measured for stability, efficiency and magnetoresistive effects. We found that tungsten baskets were the most effective way of thermally producing a cathode and that a uniform protective capping layer of aluminum on top of our cathode was essential for our OLED's performance and longevity.

Abstract Name: **The Enzymatic Activities Involved in Glypican-3 Shedding in Liver Cancer Cells.**

Liver cancer, specifically, hepatocellular carcinoma isthe third most common cancer-related cause ofdeath and is the fifth most common cancer in the world with about 728,000 cases per year. Liver cancer is very difficult to treat due to many factors that are involved in the generation and progression of the disease, which often results in 14 percent of liver cancer patients having a 5 year survival rate after diagnosis. The aggressiveness of this cancer makes it difficult to treat and diagnose in the early stage of the disease with surgery being primary treatment option. About 70% ofliver cancershave high expression of glypican-3, while normal tissues contain minimal levels. Glypican-3, a protein attached to the liver cancer cell surface, regulates pathways for the growth and migration of cells. Here we investigated enzymes involved in glypican-3 shedding (removal from the tumor cell surface) in liver cancer cells. We used an ELISA (Enzyme Linked Immunosorbent Assay) to measure the amount of glypican-3 shedding occurring in the liver cancer cells when exposed to varying concentrations of specific enzymes. Our results will help in the development of treatment options by targeting enzymes that induce glypican-3 shedding in liver cancers.

Abstract Name: **Determining the Physicochemical Changes of Hydrocarbons Triggered by Biosurfactants**

Surfactants are chemicals that can be produced synthetically or naturally and have many valuable industrial and remediation applications, like helping clean up oil spills. They are amphipathic, meaning they contain a hydrophilic (water-soluble) group, and a hydrophobic (water-insoluble) group. This allows surfactants to reduce surface tension, emulsify liquids, and break down insoluble objects. Surfactants, however, have many environmental hazards as they are toxic and cannot easily biodegrade. Biosurfactants on the other hand, are naturally produced by microorganisms, are low in toxicity, biodegradable, and are overall more eco-friendly. Over the past year, 38 microorganisms from the Foreman Research Groups isolate collection were screened for biosurfactants. Out of the 38 microorganisms, 16 have been found to be biosurfactant producers. In order to further characterize these biosurfactants, the biosurfactants were extracted, purified, and putatively identified using MALDI mass spectroscopy. These biosurfactants were found to be potential dirhamnolipids, sophorolipids, monorhamnolipids, and surfactins. I am now working on finding the exact chemical formula and surfactant types by characterizing the 16 prominent biosurfactants in much more depth, using MS/MS, as well as thin-layer chromatography.Biosurfactants have also been shown to play a role in carbon and nutrient turnover in cold temperature environments by increasing the bioavailability of complex organic hydrocarbon and aromatic compounds and improving the habitability of the environment. Biosurfactants can alter the surface charge, reduce surface tension, and emulsify hydrocarbons, which I hypothesize can counteract typical low temperature induced chemical changes and enhance the bioavailability of these complex carbon compounds. In order to see if biosurfactants can chemically modify petroleum compounds, I am working on investigating compositional changes in hydrocarbon samples using UV-Vis absorbance and fluorescence spectroscopy to determine optical properties, aromaticity and degradation status. Results from MS/MS, TLC, UV-Vis absorbance, and fluorescence spectroscopy will be presented.

Abstract Name: **Examining Racial, Ethnic, and Sex Differences as Predictors of Cannabis Use Disorder Treatment Retention**

Background: Treatment trials for cannabis use disorder (CUD) lack racial, ethnic, and sex representation. This limits the generalizability of study results and reduces access to effective therapies for underrepresented groups. While racial, ethnic, and sex differences have been explored for treatment outcomes, no literature to date has explored if underrepresented groups are being retained in research at the same rates as their non-minority counterparts. The goal of this secondary analysis is to identify racial, ethnic, and sex differences in retention in CUD treatment trials. Methods: This secondary analysis used a combined data set of seven pharmacotherapy treatment trials for CUD conducted at MUSC (five completed, two enrolling; N=948). The final dataset is 30% female; 27% African American; 11% Hispanic/Latinx. Retention was defined as completing the end of treatment visit (yes/no) and number of days engaged in the study. Mixed effects logistic regression models were utilized to assess for differences in study completion across minority groups. Results: In adjusted models, Non-Hispanic White participants were more likely to complete treatment than all others combined (66% vs. 59%; OR=1.4 (1.0, 1.9); p=0.04). This difference is primarily driven by Non-Hispanic White females (73% v. 58%; OR=2.0 (1.2, 3.4); p=0.01) as compared to all minority races. Non-Hispanic Black/African American participants had similar odds in treatment completion compared to other minority races (p=ns). Although Non-Hispanic White females had greater odds of completion than minority females, there were no overall differences between males and females (62% vs. 66%; OR=0.8 (0.6, 1.1); p=0.17). Conclusion: Results suggest that sex differences do not independently contribute to study retention, but that racial and ethnic minorities have lower retention rates- showing that one of the barriers to diversity in research is retention, not just recruitment. Future retention efforts in CUD treatment trials should ensure special attention is paid to retaining racial/ethnic minorities.

Abstract Name: **Writing to Survive: Establishing writing workshops for working class communities**

There is a widening gap between working class culture and academic culture. Elitism in the classroom has left working class students feeling unwelcome. But miscommunication between cultures inhibits attempts to bridge the gap. A collective writing voice can serve as a tool to better express the community's needs. This paper proposes specialized writing workshops for working class students to aid the development of collective creative voices. These proposed workshops will tailor itself to the student communities it serves. Working class students will be able to decide the focus of their workshops as a group. They can choose to work on creative projects, as well as resumes and grant opportunities. Further research into grants and scholarships can introduce resources into communities through writing. Student directed workshops have succeeded in the past. This paper provides a review of previous successful workshops, such as the Workshop on American Indian Affairs. And it will look at Peter Elbow's foundational workshop techniques in his book Writing without Teachers. The works of blue collar writers may give students inspiration; such as Philip Levine, Johnny Cash, Tillie Olson, and others. Working class writers should feel they have opportunities to write to survive.

Abstract Name: **Pressure Evolution of the Hubbard U in Rare-Earth Metals via the Linear Response Approach**

Calculating the properties of rare-earth metals using ab-initio methods is an important component in understanding these strongly correlated materials. Traditional density functional theory (DFT) calculations are insufficient in describing their properties and phase transitions due to electronic correlation effect. On the other hand, the DFT+U approach is a more robust method for obtaining experimentally-consistent electronic and magnetic structures. One critical question, however, is how to determine the Hubbard value from first principles. Here, we employ the linear response approach to calculate the effective U for various rare-earth metals. We study how the U value evolves as a function of unit cell size and structure type. The pressure evolution of the Hubbard U is calculated using both experimental unit cell and DFT relaxed crystal structures. The resulting U values provide important input information for DFT+U calculations to understand the behavior of rare-earth materials and their applications in extreme pressure environments.

Abstract Name: Apple iWatch Noise Meter Accuracy: Can We Make "Sound" Judgements on the Noise Alerts?

Background: Noise-induced hearing loss is a permanent type of hearing loss that is a result of loud noise exposure over time. The effects of noise-induced hearing loss often go unnoticed until irreversible damage is already done. To prevent individuals from developing noise-induced hearing loss, mobile phone companies like Apple have developed a noise monitoring application (app) for the AppleiWatch which alerts individuals when they are in the presence of dangerous noise levels. It is extremely important that this application provides accurate noise alerts to the user so that appropriate measures can be taken to limit the exposure level and/or duration. The aim of this study is to measure how accurate the noise measurements of the Apple iWatch are. Methods: Noise levels will be measured atsixteen different locationsusing various models of Apple iWatches. These measurements will then be compared to measurements obtained by the iPhone app, theNational Institute of Occupational Safety and Health (NIOSH) noise meter appwhich has been found to provide noise measurements within +/- 1 dB ofLarson Davis type 1 sound level meter (Kardous and Shaw, 2016).The noise levels in each environment will be measured by both the iWatches and the reference iPhone NIOSH noise meter app. Measurements will be compared for each environment and analyzed for significant differences in order to determine how accurate the iWatch measurements are.Data will be collected and analyzed Spring 2023 pending IRB approval.

Abstract Name: Design of a Novel Decoy FGF2 with Increased Stability and Cell Proliferation Activity

FGF2 is a multifunctional growth factor, part of the highly conserved superfamily of fibroblast growth factors. In particular, FGF2, found in embryonic and adult cell types, plays a significant role in the development and function of multiple organ systems. Furthermore, FGF2 plays roles in angiogenesis (blood vessel formation) and wound healing, which show promise in medical applications and tissue engineering. Although promising in its potential, wild-type FGF2 itself poses issues of inherent instability, which affect its overall function. By generating a recombinant protein, consensus, or "decoy" FGF2, the problem of instability in wild-type FGF2 can be solved. Consensus FGF2 can help in creating a more stable protein, thus improving function over time, as structure correlates to effectiveness in function. By eradicating this issue, a higher stability in FGF2 can be applied to biochemical and medical industries, to name a few. For example, thermal instability wouldn't be an issue with a more stable FGF2 protein when considering external factors, such as the supply chain when transporting for further biochemical research and medical applications. Thermal stability, as found in preliminary results,also indicatesa longer shelf life, if used in potential medical applications. Overall, the aim of this project is to improve the stability of wild-type FGF2, a potent but unstable fibroblast growth factor, thus improving its function via experimentative methods of small-scale and large-scale expression, purification, and characterization of structure and stability. In short, the goal of the experimental design is to compare cell proliferation activity of wild-type FGF2 and consensus FGF2 with analyses of structure and function. The ability to solve the problem of instability, which was already suggested via initial findings, in FGF2 by fabricating a more stable and functional growth factor can open new doors for further research and breakthroughs in the fields of biochemistry and medicine.

Abstract Name: **The Effect of Cultivation Season on Mechanical Properties of 3D Printed Spirulina Biomass**

Spirulina (blue-green algae) is a cyanobacteria which has been identified as a potentially valuable biomass source to replace plastics and wood in the packaging and construction industries, due to its abundance and environmental sustainability. This project uses 3D printing to produce samples of pure dehydrated spirulina biomass to understand the relationship between spirulina cultivation conditions, chemical composition, and mechanical properties of the resulting material. We compare properties of samples printed from two different crops of spirulina that were cultivated during two different seasons (spring of 2022 and summer of 2021). We found compositional variations between the different spirulina crops: the crop cultivated in the summer had a significantly higher proportion of proteins, and a slightly higher proportion of carbohydrates. These compositional differences are concluded to be the main contributor to differences in the flexural and rheological properties of 3D printed samples as a result of the higher inter- and intramolecular interactions in the proteins in the material from the summer crop. The promising flexural properties of the samples indicate that microalgae is a promising resource for potential use in biocomposites to fulfill the material demands of structural materials.

Abstract Name: **That's like the inherent sexism that we all deal with: Women's experiences running for office**

This research examines the differences women and men face when they enter the political field. Special emphasis was placed on women's experiences with sexism as they decide to run for office and throughout the election cycle. Previous studies indicate that women in politics perceive their qualifications to be less than those of their male counterparts, and men were more likely to say they were very qualified (Fox; Lawless, 2004). Previous research also showed that women were more likely to experience imposter syndrome than their male counterparts (Weir, 2013), and indicate that women feel less comfortable than men when doing political activities like door-knocking and fundraising (Fox; Lawless, 2012). This mixed-method study adds to previous research by analyzing how political communication affects cultural perceptions and how these perceptions affect the experiences of women who run for office. We collected data through surveys of both men and women who held office in Iowa, interviews with women with past or current political experience in Iowa, and conducted a content analysis of political advertisements. Our results offer updated insights that show an improvement in women's self-perception of their qualifications and give insights about how the imposter syndrome in the political pipeline shifts as women are encouraged to run by those who are already in political office. We also share new insights on how the sexism women experience regularly prepares them to overcome this barrier on the campaign trail.

Abstract Name: Utilizing Netlogo to Simulate Mobs: An Agent-based Modeling Approach

Agent-based modeling (ABM) is a powerful research tool that is used in a plethora of fields ranging from cargo routing to Artificial Intelligence. A mob is an event where a group of individuals get together online or offline (or both) to conduct an act which can range from a collective dance in a mall to collectively breaking cars' windows or hacking an electric grid. We posit that a mob can be simulated using ABM and the constructs of the collective action theory, which is defined as all activities of common or shared interest among two or more individuals. Mobbers could face various scenarios when it comes to acting in a mob or not. In this research, we build an ABM using NetLogo, that can simulate a mob. The model specification is set according to a previously published work on the logic of collective action where a mobber in the model can: act, withdraw, do power exchange (to gain utility), or act against the mob. Given the number of invited people, the number of powerful agents (e.g., organizers), and a threshold for the mob to succeed, all the mobbers in the model can decide and act accordingly. If the participation rate of the mobbers reaches a certain threshold, the mob will be marked as successful, otherwise, it will be marked as failed. Building an ABM model of the mob based on a social science theory serves as a new method to study the mob and understand the behavior of its participants. These participants form cyber-social groups on social media that act collectively online or offline. Their acts can sometimes lead to violence or societal conflicts. Understanding the mob phenomenon will lead to understanding similar collective action-based phenomena, e.g., social movements, propaganda/disinformation campaigns on social media, organized violent protests, etc.

Abstract Name: Understanding Word Finding in Older Adults; Image Naming Norms Across the Age Range

Introduction: Image naming tasks are used to better understand the linguistic processes of word finding in people without and with neurologic communication disorders such as aphasia and dementia. Neurologic communication disorders become more common with increasing age. However, word finding is affected in both, healthy aging adults and people with neurologic disorders. Therefore, norms for image naming in older adults are important for defining what constitutes normal performances and to refine markers for impaired word finding. To date, norms for image naming in older adults are lacking. The purpose of this study is to provide norms for older adults free of neurologic impairments on a large set of photographs of everyday objects, normed on younger adults, the Bank of Standardized Stimuli (BOSS).Methods: Thirty-five participants were recruited. All are native speakers of English, at least 50 years old, and free of neurologic deficits. Each participant was presented with 600 photographs derived from the BOSS on a computer screen and was asked to name each image as quickly and accurately as possible. The responses and response times (RT) were recorded. Accuracy, RT, modal name, and name agreement were analyzedResults: Preliminary results revealed a mean accuracy of 82.48% and a mean response time of 2.204 ms. Modal name agreement indicated an overall 66.34 % agreement across the 600 stimuli. The sample's demographic composition and an analysis stratified by 10-year age bands will be presented.This is one of few studies that provides norms for image naming for adults 50-80 years of age. We aim to collect data for60 older adults. Norms across the age range for image naming are a critical prerequisite for behavioral research that tackles theoretical as well as clinical questions.

Abstract Name: USE OF X-RAY FLUORESCENCE TO MAP COLORANT COMPOSITION IN CRYSTALLINE GLAZES

Crystalline glazes are ceramic glazes that are designed to trigger the growth of macroscopic crystals which can reach sizes of several centimeters in diameter. The main metallic component of the glazes is zinc, and third-row transition metals such as copper, nickel and cobalt are added at single percent-by-mass levels to generate colored macrocrystals. While the glaze application is generally homogeneous, the macrocrystal formation is not. Two-dimensional maps of the elemental composition of the glazed surfaces are created using XRF spectrophotometry. These maps detail the flow and aggregation of the colorants during the firing process, and provide some insight into optimizing the seeding process of the macrocrystals.

Abstract Name: Trauma, Personality, and Growth: Examining the Role of Personality on Posttraumatic Growth

The Anxiety Buffer Disruption Theory (ABDT), an extension of the Terror Management Theory (TMT), suggests that posttraumatic stress disorder (PTSD) is a result of the disruption of one's anxiety-buffering mechanisms. This disruption can lead to overwhelming emotions, hyperawareness of one's mortality, and wide-ranging reactions to traumatic events. However, the anxiety-buffer system mitigates the effects of potential terror, promotes posttraumatic growth (PTG), and is comprised of three components: cultural worldviews, self-esteem, and close personal relationships. The success of posttraumatic growth may also stem from personality traits, such as those that can be measured by the Five Factor Model, of the individual that has experienced the traumatic event, which is the focus of this current study. Past research has shown that those who score high on the scale of Neuroticism have a higher risk of developing PTSD (Cyniak-Cieciura et al.,2022), however, there has not been much research on the personality traits that would promote posttraumatic growth. To date, no research has directly assessed the relationship between personality and posttraumatic growth. Identifying these traits could direct the focus toward cultivating specific characteristics within the traumatized individual in hopes of creating a better outcome. This study aims to identify which Big Five Personality Traits are associated with posttraumatic growth. A sample of N=300 individuals with above threshold PTSD symptomology (PCL-5 scores > 34) will be recruited via research panel to examine the relationship between personality and posttraumatic growth. All participants will complete a Qualtrics survey including demographic, PTG, and anxiety buffer questionnaires. We hypothesize that high scores in openness, extroversion, and agreeableness will be primary characteristics of those who present more posttraumatic growth.

Abstract Name: CMinx: A CMake Documentation Generator

As software projects grow ever larger, build systems to compile such projects must grow with them. CMake is the defacto build system for C and C++ projects, but for large-scale projects, the complexity of CMake code grows to the point of incomprehensibility, as there is no built-in support for documentation. CMinx aims to rectify this by allowing inline documentation comments to be compiled into full documentation pages, much like C's Doxygen or Java's Javadoc. CMinx utilizes an Antlr grammar to parse and lex a CMake file, allowing a far greater understanding of the surrounding context than other CMake documentation generators. Thanks to this understanding, documentation authors can allow CMinx to automatically generate signatures of documented or even undocumented function or macro definitions. CMinx also includes support for documenting CTest tests. The generated documentation is output as reStructuredText using the Sphinx dialect, and can then be included in other Sphinx documentation files. CMinx is in active use in other Ames National Laboratory projects including CMakeTest and CMakePackagingProject. Its use has accelerated development, as contributors no longer need to read the CMake code directly to understand it and no longer need to spend inordinate amounts of time writing documentation manually.

Abstract Name: Expressions of Cultural Identities

How might expressions of cultural identities take shape through language, stories, and other learning experiences in an elementary classroom? If preservice educators listen intentionally to the expressions of elementary students, will those studentsshare about their diverse backgrounds and cultural identities? Can these conversations support the classroom in an effort to be more culturally responsive? We will partner with a local elementary school and spendtime on site conferring withstudents about theirperceptions and contributions, connecting students' cultural knowledge to themselves and others through multimodal learning experiences, and gatherdata that will influencefuture teaching practices. Multimodal instruction is instruction that uses social and cultural resources such as drawings, technology resources, picture books, and storytelling. Student voice is listening attentively to students' perceptions and contributions.Cultural identity is the perception of self and others, and how children see themselves as a member of a group.

Abstract Name: Why are Restaurant Firms are Going Private? Going Private Transactions and Stock Returns of Restaurant Firms

Access to capital markets is one of the key benefits of becoming a publicly traded company. However, previous research has shown that companies in more recent years have returned to the private sector rather than staying public after the initial public offering. While existing research found numerous reasons for going private, there is a limited number of studies that identify factors that influence the shareholder returns of the decision to go private. This study attempts to uncover external and internal factors that affect shareholder returns. Our study includes U.S. restaurant companies listed under Standard Industry Codes 5810 and 5812 between 1995 and 2021. Our initial sample consisted of 80 firms that had a delisting code 231. Because some of these delistings were for firms that went bankrupt, the final working sample includes 74 firms. Data on going private transactions will be obtained from media outlets and SEC annual filings (10-Ks). Data for the dependent variable (shareholder stock returns) is available in The Center for Research in Security Prices (CRSP). Potential independent variables in our study are firm size, level of undervaluation, governance issues, executive team structure, board composition, etc. Regression analysis will be used to explain the variance in shareholder returns. This study expects that board composition and the executive management structure, will emerge as important factors beyond traditional variables such as firm size as determinants of shareholder stock returns. The findings of this research study can provide important implications for firm executives who are considering going private and private equity investors who are trying to identify the best target firms that can be taken private.

Abstract Name: Diversification Factors Affecting Meal Service Recruitment

This study focuses on exploring the impact of diversity at Meals on Wheels and the factors involved in the limited number of participants of color who are part of the underserved population.There are clients that are unable to communicate with the agency because of language barriers. The type of research design is exploratory. The research explores a new topic and seeks to discover the effect that Meals on Wheels staff has on clients. Researchers created a 17-question survey that included open ended and closed ended questions to ask 100 community residents of color.

Abstract Name: Source preference for world news among college students: The role of cultural and political background

There is little research on how United States college students view world events and what news sources they tend to gravitate toward to inform themselves about events on the other side of the world.This study is guided by Confirmation Bias theory, which explains why people choose information and media that already reinforces their beliefs. This study will explore what kind of college students will use sources like Fox News and Breitbart over CNN and the New York Times, and vice versa, to consume world news.This study is interested in investigating the relationship between United States college students' cultural and political backgrounds and how they choose world news sources. The study will be conducted with students from George Mason University, which is the most diverse college in the state of Virginia.The study will be done through a 12-question questionnaire that will be distributed to college students at George Mason University through an online survey. The target sample size for the study will be at least 100 student responses. The research question of the study will be addressed by evaluating the relationships between cultural/political backgrounds of students and their selection of news sources for world news.The data for this study are anticipated to be collected and analyzed by the end of February 2023.It is important to see how the young minds of tomorrow are becoming versed in international and world events. With an ever-growing population in a diverse country like the United States, college students should get an education that makes them curious and informed about world topics while also overcoming the influence of confirmation bias. Findings of this study will be useful to such educational efforts.

Abstract Name: La Bella Vita: Rediscovering Community in a Post Pandemic World

Following the 2020 COVID-19 pandemic, many students continue to struggle with engagement outside of online activity and the classroom, returning to pandemic comfort zones. In a smaller university community, such as Jacksonville University, and across a variety of majors, students self-selected to participate in a five-week study abroad program during the summer of 2022 on location in Southern Italy. The purpose of this video project is to creatively share undergraduate student stories about how participation in the Communication, Culture, and Amalfi Coast program reignited student participation through engaged learning, while fostering a sense of community among the group. This creative work explores student understandings of the influence of social components on individual learning and the effect these social learning communities have on student health and well-being. Through qualitative video interviews with the Jacksonville University study abroad participants, students share their cultural experiences, discuss observations, and explainthe personal growth that took place because of this program. Presented over a series of videos stories, this project is a compilation of student narratives focused on growth through personal experience and global understanding. This project was produced on the campus of Jacksonville University and on location in Southern Italy. Featuring in-depth interviews, digital content creation, and personal artifacts from the study abroad program, the participants explain how the experience changed their understanding and helped them reconnect to a vibrant engaged learning community. This project includes on-camera interviews and video content produced as part of an advanced communication course.

Abstract Name: Undershot Waterwheel Energy Optimization

A waterwheel is a device that is used to take advantage of the energy produced by flowing water. In locations where the water flows horizontally, referred to as low-head conditions, an “undershot waterwheel” is employed. The head of a location is by definition the height difference between the point in which the water enters the system, and the point at which the water leaves the system. Taking into consideration the value for the head (v22G) of the location, the optimal overall diameter (3 to 6 times the head) of the wheel can be determined. We can take advantage of the low speed caused by the low- head conditions by designing a wheel with an optimal number of blades. The rationale for this lies in the fact that a higher number of blades would increase the torque, and consequently, the kinetic energy. The optimal number of blades is determined by the ratio between the working circumference and the head, where the working circumference is the difference of the overall diameter and the head multiplied by . This project aims to evaluate the effect that: 1. The number of blades, 2. The thickness and 3. The flow of water, will have on the energy production of the system. We will test each alternative design for the system individually, as well as collectively.

Abstract Name: Challenging the Tyranny of Love: Video Game Design and Critical Metaphor Studies

Language is a means of connecting and communicating effectively. Language allows us to identify with others, and make sense of the world around us. But how do we accurately describe something? Friedrich Nietzsche writes of the will to truth in language, that it is, “A movable host of metaphors, metonymies, and; anthropomorphisms: in short, a sum of human relations which have been poetically and rhetorically intensified, transferred, and embellished, and which, after long usage, seem to a people to be fixed, canonical, and binding” (4). In other words, we conceptualize much of our existence through rhetorical language, but most importantly, for the purpose of our presentation, in metaphors.Oftentimes, metaphors serve as a dominant understanding of something, especially metaphors of love. And some of these can be quite troubling, setting up love as something to be endured, tackled or overcome: Love is often metaphorized as a journey, a battlefield, a roller coaster, even a drug.As students of game design, our presentation will focus on our design of a “serious game” that both entertains an audience, and teaches them about how metaphorical language has the power to shape prevailing conceptions of love, which, as philosopher Alain de Botton suggests, have dominated Western sensibilities since the Romantic Era. In this particular game, players make choices about a metaphor of love that they associate with the most at the outset, but they might also adopt alternative metaphors of love depending on the decisions they make during the game. The game’s purpose is to entertain and educate the player on the power of language to shape meanings about a universal human phenomenon and its meaning in contexts.

Abstract Name: **Development of Photocrosslinking Click Chemistry Probes to Investigate the Function of Falcilysin, an Essential Malarial Metalloprotease**

Human malaria is a parasitic disease caused by 6 different Plasmodium species, leading to approximately 600,000 annual deaths. All clinical symptoms of the disease result from the intraerythrocytic development of the parasite. During this part of the life cycle, the parasite expresses an array of proteases to carry out many essential processes, such as host cell protein degradation, host cell invasion, and parasite protein export. Falcilysin (FLN) is an essential metalloprotease expressed by the parasite during intraerythrocytic infection, and it is known to function in host hemoglobin degradation and in processing of apicoplast-targeted parasite proteins. Recent studies have identified FLN as a target of the clinical antimalarial drug chloroquine, and it appears likely that the protease carries out additional roles in the cell.We are developing chemical tools to enable further investigation of FLN biology and its potential as a chemotherapeutic target. Here we report our work to synthesize and evaluate a series of piperazine-based hydroxamic acids as inhibitors of FLN. As well as incorporating photocrosslinking and click chemistry moieties into the scaffold. These studies will provide the rationale for the development of increasingly potent FLN inhibitors while identifying possible off-targets in the cell. This work builds upon our previous research by further optimizing the N1 position on the piperazine core. We synthesized and tested a series of 10+ compounds with diverse substituents which were installed using a range of synthetic methodologies. In a subset of compounds we incorporated diazirine and alkyne moieties to enable identification of cellular targets using a combination of photocrosslinking and click chemistry. All compounds were tested against cultured parasites and purified FLN, and we identified additional structural requirements for potent inhibition of FLN. Multiple inhibitors were discovered with similar or improved potency relative to our previous lead compounds.

Abstract Name: **The Impact of Discrimination, Community Support, and Class Modalities on Burnout in College Students**

What effects do class modality, perceived community, and perceived discrimination have on burnout scores in college students? Past research has found that students with more marginalized identities reported more instances of mistreatment and discrimination during medical school, which appeared to be associated with higher burnout (Teshome, 2022). Research has also shown that there is a positive relationship between community support and positive mental health (Hu et al., 2020). There is a gap in the literature in student burnout in association to these variables, which we plan to explore. The current study investigated the interaction of a student's class modality, perceived discrimination (from faculty and peers), as well as perceived social support, and if this influences burnout scores. Students will receive a survey asking about their class modality (online, in-person, hybrid) and will also be asked questions from the Maslach Burnout Inventory, Everyday Discrimination Scale, and SC Perceived Community Scale. The Maslach Burnout Inventory is the leading burnout indication measurement (Maslach, 1997). The Everyday Discrimination Scale (Williams, 1997), published by Harvard University, is the original and still recommended scale for daily occurrences of discrimination. These scales will deliver data that allows us to quantify burnout, perceived discrimination, and perceived social support. We will be distributing a survey through Qualtrics which we plan will receive around 120 responses from students at Kennesaw State University. We hypothesized that students who feel more perceived discrimination will have higher levels of burnout and less sense of community. We also hypothesized that students who feel a strong sense of community will have lower levels of burnout and lower levels of perceived discrimination.

Abstract Name: **Viscosity and Viscoelastic Behavior of Stimuli-responsive Copolymers for Use as Dispersants in Architectural Coatings**

Viscosity and viscoelastic properties are important for the application of stimuli-responsive polymers as dispersants in architectural coatings such as paints. Viscosity is a fluid's resistance to flow under stress, while viscoelastic materials exhibit solid-like elastic or liquid-like viscous behavior depending on experimental conditions. New stimuli-responsive polymers, which change their properties in response to changes in temperature, pH, and mechanical environments, could affect the dispersion of opacifying particles such as titanium dioxide in the coating. By adding stimuli-responsive polymers, the properties of architectural coatings can be controlled to produce a more opaque coating with controlled viscosity. This decreases costs and reduces environmental impact. A rheometer is used to test a polymer's viscoelastic properties under different pH, temperature, shear rate, and frequency conditions. Understanding how viscoelastic properties change in response to external conditions is necessary for matching these polymer properties to properties needed for architectural coatings. Viscosity testing is used to determine how well the polymer will mix with titanium dioxide particles. Ideally the coating will have the lowest polymer concentration and lowest viscosity possible to meet performance needs. Viscosity tests help determine where this minimum occurs for different copolymers. This can help determine which polymer is most suitable for dispersing titanium dioxide particles. Viscosity and viscoelastic testing can allow for determination of how changes in polymer structure result in changes in stimuli-responsive properties. The copolymer structures can be tuned, and the properties can be predicted in order to optimize properties for architectural coatings. This results in new materials to meet performance requirements to compete with traditional, commercially available dispersants.

Abstract Name: **Synthesis and Evaluation of Sel-Sepharose Resin for Redox Proteomics**

This project is focused on designing and synthesizing a unique chemical tool that will allow for the detection of persulfide modifications in proteins. These modifications are challenging to detect due to their chemical reactivity and low biological abundance. Persulfide modifications on proteins occur from exposure to hydrogen sulfide gas. Hydrogen sulfide gas is produced by human cells during normal cell function and some disease states trigger the production of this gas. Proteins can also undergo these modifications if exposed to hydrogen sulfide gas from their environment. Herein, we designed and synthesized a resin that contains a unique diselenide moiety that can bind to protein thiols and thus, the persulfide modification. Our resin is unique since the removal of bound proteins can be accomplished by addition of ascorbate (Vitamin C), which facilitates a chemoselective reduction of selenium-sulfur bonds. Use of Vitamin C as our reducing agent will allow for the retention of the persulfide modification, which can subsequently be detected by mass spectrometry. Our resin has broad applications in the field of Proteomics and in the diagnosis of diseases that are known to generate hydrogen sulfide gas.

Abstract Name: **How Radiation Pressure Affects Large Mirrors Orbiting Exoplanets of Different Mass**

Exoplanets can be found using the transit method, where light curves with regular changes indicate the presence of an exoplanet. As discussed by Korpela, Sallmen, and Green (2015), such light curves would be affected by a cloud of mirrors launched by an intelligent extraterrestrial species to redirect starlight to an exoplanet. The mirrors could be used to terraform exoplanets, including those with only one side facing the star. These tidally locked planets occur when the planet's orbit period is equal to its rotational period. When they are large and lightweight, mirrors such as this are affected by the force of photons emitted by the star, known as radiation pressure (RP). To investigate their orbit stability, we simulated a mirror orbiting an Earth sized planet at the inner edge of the habitable zone around a variety of long-lived stars, so the planet is more likely to be tidally locked and to possibly contain liquid water. RP strongly affects our simulated planar mirror of 1 km2and 1000 kg. We simulated situations when RP always affects the mirror (Always) and when RP only affects the mirror on the dark side of the planet (Night), comparing the results to the situation with no RP. We also vary mirror orbit sizes; orbit orientations. For each simulation, we determine the mirror's end state: whether the orbit ends in collision with the planet, escapes the planet's gravitational influence, or survives 1000 orbits. With only a small change in initial orbit size, a mirror's end state can change drastically due to a small difference in radiation pressure and gravitational forces. For some of these situations, we will present a comparison of our previous simulations with results for mirrors orbiting planets of different masses.

Abstract Name: **Alibi Believability and Judicial Instructions: The Role of Prosecution and Alibi Evidence**

Alibi claims can be supported by evidence that suggests the defendant did not commit the crime, known as exculpatory evidence (Olson; Wells, 2004). Alibi evidence can be countered by prosecution evidence, known as inculpatory evidence (Culhane; Hosch, 2004). Judge's instructions on the alibi defense may also affect juror views of alibis, but they have not been studied empirically. Alibi instructions inform jurors that the onus is on the prosecution to disprove the defendant's alibi (Connecticut Judicial Branch, 2019). 320 participants recruited from CloudResearch took part in this study where they read a description of an arson, police investigation, and trial. They were randomly assigned to one of eight conditions in a 2 x 2 x 2 between-subjects design. Half of the participants read that the defendant had videotaped store footage to support his alibi (alibi evidence present) and half read nothing about the footage (alibi evidence absent). Participants then read that investigators found empty gasoline containers in the defendant's car (prosecution evidence present) or read that nothing incriminating was found in the car (prosecution evidence absent). Participants either read the judge's instructions on alibi evidence (instructions present) or did not read any instructions (instructions absent). Next, participants completed a questionnaire in which they rated the alibi's believability and the defendant's character. They also individually rendered a verdict. Alibis were more believable when no prosecution evidence was found in the defendant's car versus when gas cans were found. Alibis were also more believable when the defendant had store footage to support his alibi versus no mention of footage. Having alibi evidence also led to more positive views of the defendant (more likeable, credible, etc.). The majority of participants (76%) voted not guilty and none of the independent variables affected verdict decisions. Future directions will be discussed.

Abstract Name: **Location of cartoid body oxygen sensors in the Alligator mississipiensis**

This research sought to identify the location of the carotid bodies in the Alligator mississippiensis. Biologists are interested in alligators due to their evolutionary success and distinct physiology. Their unique cardiopulmonary system has been researched, yet to date little has been published about the exact location of alligator carotid bodies. In humans, carotid bodies detect changes in blood levels of CO2, O2, and H+ and help maintain blood-gas homeostasis. Carotid body dysfunction can cause congenital central hypoventilation syndrome (or Ondine's Curse) and other forms of sleep apnea. Alligators are useful as a study model for understanding the evolution of blood-gas regulation in terrestrial vertebrates since they have changed little in the last eight million years. Further research on their vasculature and carotid bodies may help researchers understand how to treat certain human carotid body related diseases. Prior studies have determined that the carotid bodies in mammals are typically located at the bifurcation of the internal and external carotid arteries found laterally in the neck. The authors hypothesized that alligator carotid bodies would also be located at the bifurcation of the internal and external carotid arteries, although in alligators, this bifurcation is located on the posterior surface of the skull. Methods used in this study included vascular dissection of seven juvenile, female alligators, vascular casting, and Kluver-Barrera histological tissue staining for identifying myelin. The researchers' results showed that myelin was located at the bifurcations of the external and internal carotid arteries, indicating the likely presence of nerve fibers from the glossopharyngeal nerve and carotid body. Interestingly, as suggested by prior CT scans of alligator vasculature, the researchers also confirmed via direct dissection that the branching patterns of the left and the right carotid arteries were asymmetrical in the alligators studied.

Abstract Name: **Relationship Between GOES-Derived Lightning and Cloud Properties**

As satellite technology has advanced, the amount and types of information it provides has rapidly expanded as well. One of the current orbiting satellites, GOES-16, uses standard observations from the Advanced Baseline Imager (ABI) to derive cloud-related products and provide them to a diverse user community, including cloud optical and microphysical properties. Another GOES-16 instrument, the Geostationary Lightning Mapper (GLM), detects lightning flash events and creates lightning-related products, which include flash extent density.Since both GLM and ABI level 2 products are used operationally, optimizing their usage is incredibly important. This study analyzes ABI products related to daytime cloud microphysics and finds that the observed cloud microphysics and lightning properties behave in a way that is consistent with expectations. Using case study data collected during the May 12, 2022 derecho event in South Dakota and Minnesota, the connection between ice-type clouds and lightning is established to be most prevalent of all cloud types. Colder clouds generally lead to higher average flash extent density and a higher probability of lightning occurring within the cloud.

Abstract Name: **The Subcellular Activation of CREB3L2: A member of the OASIS bZIP transcription factor family in HEK-293 Cells Using Oxidative Stress**

4- hydroxynonenal (HNE) induces oxidative stress in mammalian cells by forming protein adducts due to the inability to detoxify reactive oxygen species. As a result, there is a mechanistic change in the structure and the physiological functionality of proteins. Oxidative stress has been linked to the normal aging of the brain and numerous neurodegenerative diseases, due to the degradation of neurons leading to neuronal death. Stressed cells activate the unfolded protein response (UPR), which is an evolutionary adaptation mammalian species have developed to regulate the number of proteins that exhibit an altered conformation. This study investigates the role and activation CREB3L2 (a transcription factor involved in the UPR) has on cells that exhibit HNE stress: In previous studies, this transcription factor has been linked to the activation of chondrogenesis and the protection against cells that shows endoplasmic reticulum stress. We hypothesize that cell lines that are induced with oxidative stress and protein aggregation will have increased activation of CREB3L2, while those that do not exhibit this stressor will have little to no activation of the transcription factor. HEK-293 cells were treated with HNE to induce oxidative stress and activation of a GFP-linked CREB3L2 was measured by immunofluorescent microscopy. Immunofluorescent microscopy is used to identify GFP-positive cells; cells that express stress along with the activation of CREB3L2, and its intensity. Using a combination of immunofluorescent microscopy and ImageJ; we were able to determine and quantify cells that showed relative cell death in the control and the HNE treatment as well as those that exhibits aggregation. By this analysis, we were able to detect and analyze the activation of CREB3L2 in these cells. Our results show that there is a correlation between the activation of CREB3L2 in stressed or less viable cells in comparison to those that are not.

Abstract Name: **The Effect of BMAL1 Expression on Autophagy Activity in Astrocytes**

Circadian rhythm disruption is an established symptom for neurodegenerative disease, however, there is evidence that circadian systems drive pathogenesis. The clock gene, BMAL1, regulates daily oscillations in transcriptional-translational feedback loops critical to homeostasis. In contrast, BMAL1 deletion will render tissues arrhythmic and influence non-circadian genes, thereby inducing reactive astrogliosis. There are in-vitro outcomes where BMAL1 knockout astrocytes exhibit increased lysosomal activity, which implicates circadian clocks in many cellular pathways, such as autophagy. This process maintains homeostasis through delivering misfolded proteins to the lysosome for degradation, and deficiencies in the autophagy clearance often characterize neurodegenerative diseases. Therefore, this project involves determining whether autophagy activity in astrocytes is regulated by BMAL1 expression and displays rhythmic patterns. Through employing the fluorescent (RFP)-EGFP-LC3 reporter, we can detect differential organelle pH values to reveal the autophagy dynamics. Specifically, the RFP:EGFP signal ratio represents the progression from the autophagosome to the acidic autolysosome, thereby quantitatively illustrating the protein degradation arising from autophagy machinery. When comparing astrocyte-specific BMAL1 knockout mice to the wildtype littermates, there are significant increases for EGFP and RFP channels within the white matter. Furthermore, the greater RFP:EGFP value exhibits upregulated protein degradation, which validates that BMAL1 deletion can modulate autophagy activity. Upon establishing the baseline fluorescence for wildtypes across the 24-hour cycle, the EGFP and RFP signals suggested rhythmic activity for the light-stimulated groups. Nevertheless, the insignificant sinusoidal patterns among the dark-only counterparts reduces the probability that circadian clocks regulate autophagy activity. The effect of BMAL1 deletion on autophagy within the white matter likely originates from cells that are uniquely susceptible to dysfunction in non-rhythmic pathways related to astrocytic BMAL1 expression. Ultimately, investigating how BMAL1 protects against neurodegeneration will reveal therapeutic approaches for manipulating the autophagy machinery to promote pathology clearance, along with emphasizing the importance for maintaining sleeping patterns.

Abstract Name: Drone Aided Pathfinding Car

Automation has been the cornerstone of industrialization, and in no industry has it been more important than in automobiles. Each year self-driving vehicles have the potential to save hundreds of thousands of lives and billions of man hours from accidental collisions and traffic congestion. This work takes a different approach to self-driving vehicles by using the aid of an autonomous drone. In particular it focuses on a self-driving RC car solving two dimensional mazes with the drone flying above for pathfinding imagery. Computer vision, and Convolutional Neural Networks are used to detect features and classify them for maze reconstruction in data structure. While multiple algorithms were studied, Dijkstra's shortest path algorithm is used for solving the mazes. The RC car uses an NVIDIA Jetson TX2 NX Xavier for increased parallel processing performance that is required for tracking and classifying the RC car and maze feature in real time as the maze is traversed. The RC car uses mecanum wheels to allow the car to rotate in place as well as move in any direction. Cameras and accelerometer sensors are used for positioning and control systems. This work demonstrates the feasibility of drone aided vehicles in solving mazes. First in simulation that was done in code the algorithm was able to solve mazes of various sizes and complexities. Furthermore, through the use of the current tools available and knowledge on the subject, the RC car was able to solve a physical maze autonomously with a camera positioned above. The final iteration of the solution used a drone to capture the image that was fed to the car to solve the maze. This final solution can easily be adapted to be relevant to vehicle parking and driving automation.

Abstract Name: Assessment of At-Home Genetic Testing Kit Consistency Between Identical Twins

Since their arrival on the market in the early 2000s, direct to consumer (DTC) genetic testing kits (at-home kits) have exploded in popularity. As the industry has continued to grow, questions have emerged over the accuracy and consistency of the results of these ancestry reports. Despite claims by all companies studied here of over 99% accuracy, previous research in this lab has shown significant inconsistencies between the results provided by each company. Of 42 individuals previously tested, 39 had large discrepancies in their genetic ancestry categories from company to company; results varied by up to 40% for some participants. The goal of the current study was to examine the DNA of identical twins to determine if these testing discrepancies exist within companies (since the DNA of identical twins should be the same) or only between them. The same three genetic testing companies that were previously studied were used here - Ancestry, 23&Me, and MyHeritage. To date, five sets of identical twins have received full results, and several additional sets of twins are in process. Results have remained consistent with the previous study, with discrepancies between ancestry categories reported by each company. Surprisingly, in addition to the discrepancies between companies, differences were found between twins in data reported by the same company. No set of twins had results that completely matched. In some twins, one individual was noted to have an ancestry category that the other didn't have at all. Given the claims of near-perfect accuracy reported by the companies, and the fact that some of them also market genetic health screenings for certain diseases and health conditions, these inconsistencies raise serious ethical concerns about the way on which they market and report data to under-informed consumers.

Abstract Name: **Introducing the Community of Neighboring and National Entrepreneurial Centers and Trainees (CONNECT) Network**

Entrepreneurial training is missing in current undergraduate biology education. While undergraduate biology students may be aware of entrepreneurship as a career option and may have opportunities to explore this path in graduate school, students often fail to see themselves as innovators and find the process daunting. With the National Science Foundation's (NSF) thrust into entrepreneurial spaces and the new directorate of Technology Innovation and Partnerships' focus on use-based innovation, there is an urgency to train students as both researchers and innovators to solve the nation's scientific and societal challenges. Through NSF funding, the CONNECT network will be a community of educators, students, entrepreneurs and other stakeholders, with a special emphasis on building membership from historically Black colleges and universities (HBCUs) and other Minority Serving Institutions (MSIs). There is particular urgency for more representation in STEM entrepreneurial ventures given that women make up only 28% of the STEM workforce, with women of color comprising just 5% of the total. By building this network with an emphasis on BIPOC women at the undergraduate, faculty, and entrepreneur stages, the CONNECT network is poised to transform the undergraduate biology experience for historically marginalized students across member institutions. Through this short talk session, CONNECT network directors will discuss their ongoing efforts and ways to get involved in giving voice to the faculty and student needs that underlie the current curricular gap in undergraduate biosciences entrepreneurship education. Beyond the curricular needs assessment, we will also assess the availability of undergraduate Science of Translational Science research opportunities and provide a framework for students to conduct undergraduate research that translates into future entrepreneurial ventures. The outcome of this network's work will be a data-rich snapshot of participants' needs and a directive for an inclusive entrepreneurial ecosystem that builds off of the strength of undergraduate research across the nation.

Abstract Name: **Welcoming the Dear Neighbor?**

From 2000-2018, white homeownership in Minnesota remained constant at 70%, while black homeownership saw a decline from 31% to 21% (Turtinene, 2021). Even before this decline, disparities between white and black homeownership were stark on account of discriminatory practices including racially restrictive covenants, clauses in housing deeds blocking BIPOC citizens from purchasing property. Using data from the Mapping Prejudice project that catalogs covenants in Hennepin and Ramsey county and historical data from the US census, we investigate the relationship between upward mobility and neighborhood shares of racial covenants by running regression analysis to check for correlation. Preliminary results show that neighborhoods with high concentrations of covenants have higher upward mobility for white children but not for black children. Covenants are associated with a widening opportunity gap long after they became legally unenforceable. This research informs policies that remedy longstanding disparities such as changing zoning restrictions or amending first-time homebuyer grants. Abstract Name: **Experiences of water insecurity and its relation to food insecurity, health, and well-being**

Water insecurity, characterized by uncertain access to, and availability of, clean water and poor water quality is an emerging concept in the field of nutrition. While most studies on water insecurity have been conducted in low- and middle-income country settings, water insecurity in the U.S. is documented, particularly among low-income and black, indigenous, and people of color (BIPOC) communities in both urban and rural settings. Provided the interconnections between food and water, scholars increasingly recognize the need for research strategies to better understand the role that water insecurity plays in human nutrition and well-being. Survey data were collected from residents of central Wisconsin. Chi-square tests of independence and logistic regressions were used to examine associations among key variables. Experiences of water insecurity and food insecurity were co-occurring among low-income participants but more frequently they were experienced independently. Experiences of water insecurity were associated with psychosocial stressors detrimental to mental well-being that may also impact nutrition. Most participants reported treating their water associated with a lack of trust with the quality of their drinking water. These findings have important implications for developing responsive interventions to support access to adequate food and water. Future studies to test the relationships between the characteristics of water insecurity identified in this study with food insecurity among low-income populations are warranted.

Abstract Name: **Evidential Markers in Tibetan**

This study examines the function and variation of evidential morphemes in Tibetan. The language has multiple different morphemes in order to show how the speaker knows the information they are sharing as well as how confident they are in the statement. These morphemes appear as the last in a series of suffixes on the verb. Previous descriptions categorize them into direct, indirect, ego, and neutral (Kalsang et al, 2013). After conducting elicitation sessions with Tibetan language consultants in which we asked translation questions to learn more about this feature we propose a new system to categorize these morphemes: 1) Past Direct Evidentials; 2) Present Direct Evidentials; 3) Indirect Evidentials. We found that the morphemes previously categorized under the ego label seem to work more like first-person-specific morphemes in the other categories, so our model has distributed that group. Understanding these morphemes better can provide more insight into meaning making in the language and how Tibetan speakers express themselves.

Abstract Name: **ACSS2 knockout effects on muscle phenotype, and fatty acid and glucose metabolism**

Acetyl-CoA synthetase 2 (ACSS2) is a key enzyme that converts acetate to acetyl-CoA, which is a major metabolite in carbohydrate and fat metabolism. This project focuses on the knockout effects in the muscle of mice, and measuring changes in fatty acid and glucose metabolism, as well as muscle phenotype. The phenotype of the following five muscles were dissected and snap frozen from wildtype and ACSS2-/- mice: quadricep, gastrocnemius, tibialis anterior (TA), extensor digitorum longus (EDL), and soleus using cryostat tissue sectioning and stained with H&E. The RNA was extracted and was used for qPCR to detect the gene expression of Glut4 and Fatp1 receptors. There was a significant decrease in soleus and gastrocnemius cross-sectional area (CSA), significant increase in quad CSA, and no significant change in TA and EDL. There was non-significant differential expression of Glut4 and Fatp1in quad, soleus, and TA. Since ACSS2 is a metabolic enzyme, future experiments may incorporate the effects of exercise and dietary change on muscles. The results from this study will provide more information on the effects of ACSS2 on skeletal muscle and myopathy.

Abstract Name: **Neural and Behavioral Correlates of Sensation Seeking**

We sought to clarify both behavioral and neural characteristics of sensation seeking. In particular, we were interested in two components of event-related brain potentials (ERPs) elicited during a response inhibition task: the P3a, which is elicited by novel, unexpected, stimuli, and the P3b, which is elicited by targets. Participants completed self-report questionnaires to measure their sensation seeking. During the task, participants were presented with three types of visual stimuli in randomized order at a rate of approximately one every 1.25 s. The stimuli were (1) non-targets, to which they should make a response, (2) targets, to which they should withhold a response, and (3) novel stimuli, to which they should withhold a response. The targets and non-targets were relativelybenign,but required sustained attention to tell them apart. The novel stimuli were photographs depicting arousing situations (e.g., skydiving). Based on previous research, we predicted that (1) the P3awouldbe positively correlated with sensation seeking, (2) the P3b wouldbe negatively correlated with sensation seeking, and (3) response accuracy to novel stimuli would be inversely correlated with sensation seeking. P3a and total sensation seeking were positively correlated, but the relationship was small and not statistically significant. In contrast to our prediction, P3b was moderately positively correlated with total sensation seeking. Finally, response accuracy was not correlated with total sensation seeking. Although none of our hypotheses were supported for total sensation seeking scores, we did find relationships between the ERP components and total sensation seeking, boredom susceptibility, and disinhibition.

Abstract Name: **Reimagining College Support: A Critical Exploration of the Impact of Grief and Loss on the Experiences of First-Year College Students**

Student attrition is a rising concern in higher education given the various challenges that have arisen over the past couple of years. The offset of the COVID-19 pandemic, the racial justice movements, and the current social-political climate have significantly impacted our college students like never before. Of growing concern is the rising mental health crisis that is sweeping through higher education which warrants an immediate and intentional response. Further, students are currently facing dire financial constraints, food and housing insecurities, and many other challenges that complicate their college experiences. As freshman students are now experiencing college for the first time, their experiences may vary drastically from their predecessors. Specifically, current first-year students' college transitions are muddied from their various high school experiences that may have been a remote, hybrid, or in-person with some variation of security measures. Further, the grief, loss, and trauma first-year college students have experienced during the pandemic warrant special attention as we are contending with the types of resources and support, they need to matriculate and complete their degrees. The remnants of grief and trauma from the pandemic still linger and are impacting the college experiences of first-year students and their abilities to navigate their academic and professional goals. Hence, through a qualitative research design, our research explores the lived experiences of first-year college students. Specifically, the research question explored in our study is: How or to what extent has grief and trauma from COVID impacted the educational journeys of first-year students? The aim of this research is to provide an important opportunity to investigate how to better support college students as they move through collegiate experiences.

Cano, John

Abstract Name: **Unifying Vibrations**

Rooted in tradition are these unifying Vibrations. Convention needs change in order to grow. Rooted in interest and passion are these preformal transitions. What is now is before but more; peering onward and not below. Our research was based on the diffusion of the 332 Rhythm. This is a musical rhythm of Long long short strikes. Each long is one and a half beats, or - - - . and the short is one beat - -. These are represented in half beats and look like this: - - -, - - -, - - or Long, Long, Short. We heard of this rhythm as "The World's Most Universal Rhythm." We wanted to see if there was much validity in that title but we also wanted to make something out of our research. What we made was a show; A show in which we present and perform the music we found that not only has the 332 but uses it in particular ways that we found interesting enough to share with people. We wanted to make something educational and entertaining; we wanted them to walk away feeling like they enjoyed the hour they gave us and have something new to consider in their every day. The performance expresses my relationship the music, culture, and history of each place as well as the research we did when collecting these samples of music. The music that is share: The McIntosh Shouters: Blow Gabriel; Gahu music by Africana Dance Ensemble; Taiko: Eitetsu Hayashi // Fertility of the Sea; Michalls Terlikkas: Psintri Vasilidja Mou; Płyta Tatarska: Bahczalards; Palestinian Dabkeh: Turab Beladi; Clogging: Wild Goose Chase Cloggers; RUSH: Hersey.

Abstract Name: **Evolutionary Game Theory**

While Game Theory often will reward non-cooperative and antisocial strategies, the real world exhibits the need for cooperation. In this poster, I examined ways that cooperation can be encouraged by analyzing various setups including distributions of players across a given field. Players are randomly selected to play nearby players and perform a coded version of an altered version of the Prisoner's Dilemma. Players may either form offspring or be removed from play, determined by their scores. As more rounds are played, we note the proportion of cooperative versus non-cooperative strategies and how they may change over the course of the simulation.

Abstract Name: **Education Students' Understanding of Scale and Geometric Space of the Earth, Moon, Sun System and Cause of Moon Phases**

This sequential explanatory mixed methods study examined how well pre-service teachers and education students understand the Earth/Moon/Sun scale, motion, and orbital geometry necessary to observe various lunar phases from an Earth-based perspective. Research has shown that students have great difficulty understanding the cause of lunar phases with many incorrectly explaining the phases are caused by the Earth's shadow, the Sun's shadow, or an object blocking the Sun's light (Wilhelm et al. 2018; Plummer et al. 2010). The research question investigated was: What understandings do students have about the Moon and its phases, and how do their lunar conceptions relate to their spatial ability? This question was explored with undergraduate education students from two institutions in the south-central United States. Quantitative data consisted of 72 participants completing a modified Lunar Phases Concept Inventory (LPCI; Lindel, 2002) with 25 multiple-choice questions. To better understand students' lunar-related spatial-scientific thinking, we followed the quantitative data collection with select student interviews (high, low LPCI scorers) using a semi-structured protocol concerning Earth/Moon/Sun geometry, lunar motion, and why the Moon appears different at different times. The LPCI findings showed that approximately 59.3% of students held the Earth-shadow misconception, 9.4% had an object-blocking explanation, 3.1% had the Sun-shadow explanation, while 28.2% had the scientific explanation when describing the cause of phases. We also found that 18.8% of students did not correctly understand the scale of the Earth/Moon/Sun system (e.g., distance between Earth and Moon) with many believing the Moon to be much closer to Earth than it is, which could be a possible reason students tend to hold shadow and blocking notions. Similar to the LPCI, interview results showed general misunderstandings of why lunar phases occur, with some participants not able to correctly sketch various phases, nor accurately explain the Earth/Moon/Sun geometry for particular phases.

Abstract Name: **Computational Discovery of an Inhibitor to APOBEC3B as Treatment for Cancers**

APOBEC3B is a naturally occurring protein in humans which has the purpose of fighting off certain ailments, such as HIV, by changing certain nucleic acids in our DNA. For immunity purposes, it is typically beneficial to have such a protein in our bodies. However, fitting with the textbook definition of cancer, the problem occurs when there is an overexpression of APOBEC3B in our bodies. At that point, APOBEC3B begins to convert too many nucleic acids, and this helps create more mutations in our cells which in turn creates tumorous bodies as the cells begin to replicate rapidly. The goal of this research would be to help find an inhibitor for the APOBEC3B protein from a database of unresearched ligands to keep the protein from binding to our DNA and creating hazardous cell growth. The primary source of these potential inhibitors isthe ZINC12 database from which we have already sorted through six million different candidates to find the top 200.From the six million candidates, the top 30 have been selected based on how easily they might bind to APOBEC3B. Now, similarities havebeen found between those top candidates and then improved upon using chemical intuition and drug design techniques to create the best drug possible. However, we have also used a novel technique,de novo ligand design, which uses software to assemble entirely new candidates based on those same top 30 candidates. We have now simulatedthose de novocandidates in the same manner as the previous candidates, and this analysis has produced a promising inhibitorof APOBEC3B, and keptthe drugbound to the protein in increasingly more realistic situations.

Abstract Name: **Vibrational and Coupled Frequency Response of Tensegrity Tables**

Tensegrity structures have many constructional applications to improve the stability of a design. The structure, design, and function of tensegrity systems can be better understood by researching factors that determine their stability. Stability of tensegrity structures was researched by testing vibratory resistance on a shake table and dampening factors by displacing the top of the system and calculating natural frequencies and dampening rate when exposed to various external forces. When experimenting on a shake table with a rectangular structure, it was concluded that the difference in magnitude of acceleration between the bottom and top of the structure decreased by 0.68 as the bottom was exposed to a frequency of 7.2. Compared to a difference of 4.12 at a frequency of 14.9. Showing an increasing difference in acceleration as vibration frequency increases. Tensegrity structures were also found to have multiple nonsymmetric natural frequencies. Due to the two axes of symmetry, the rectangular tensegrity structure was found to have two natural frequencies. These frequencies were found to be within 1.68 Hertz of each other and are affected by the amount of displacement. From these experiments, it can be concluded that tensegrity structures provide stability because they naturally dampen vibration between the bottom and top of the structure. By understanding the stability of tensegrity systems, their applications to architecture and construction development can be better explored and utilized.

Abstract Name: **Engineering Biodegradable Plastics Through Thermophilic Value Added Polyhydroxyalkanoates**

Thermus thermophilus strain HB8, a known PHA producer, will be tested for growth on partially oxidized plastic wastes produced through preliminary cracking and oxidation of LDPE plastic wastes. This research focuses on maximizing thermophilic microbial growth on oxidized plastic wastes and aims to explore potential thermophilic production of value-added bioplastics. The research will initially determine if Thermus thermophilus HB8 can use oxidized petroleum-based plastics as its main carbon source since it has been shown in our lab to produce PHA. It is estimated that oxidized plastics contribute up to 80% of marine debris causing serious environmental and health problems worldwide and the use of oxidized plastic wastes may offer an alternative for PHA bioproduction. The goal of this project is to identify one or more thermophiles capable of degrading oxidized plastic waste and potentially produce value-added polyhydroxyalkanoate (PHA) bioplastics. Other results showed T. thermophilus HB8 tested under nitrogen-limited conditions could produce PHAs using glucose as its sole carbon and energy source. This test was found to successfully grow and produce PHA, indicating that this thermophile could be a promising isolate for downstream testing on chemically/catalytically deconstructed plastic materials. Growth rates will be assessed using optical density measurements at 600 nm. Preliminary experiments will use sodium gluconate at 1.5% (w/v) or glucose at 2.0% (w/v) as a sole carbon and energy source for growth because they are known to enhance PHA production in T. thermophilus. Following this initial test, partially degraded plastic wastes will be incorporated as sole carbon source for growth, with downstream extraction and analysis examining PHA production levels.

Abstract Name: **Reading as a Revolutionary Act: The Resistance of and in Reading Lolita in Tehran**

What comes to mind with the phrase, ‘the right to choose?’ Given current American political rhetoric over abortion rights, a woman’s right to choose an abortion might be the conclusion one comes to in the United States. Azar Nafisi had something else in mind when she wrote ‘the right to choose’ in her book Reading Lolita in Tehran: A Memoir in Books. The complete sentence reads, “The elusive goal at the heart of democracy: the right to choose.”[1] Even this sentence does not enlighten the reader to the full context of words, that in the United States evoke the topic of abortion rights. Under the authoritarian regime of the Islamic Republic of Iran, Nafisi believed in the power of literature and the right to choose what to read. In her memoir, Nafisi constructs an analogy between reading literature that challenges the fabric of an authoritarian regime and the requirement for women to wear the veil in public. In this paper I will utilize Nafisi’s teaching of ‘immoral’ books in Iran, authors that the Islamic Republic dictates are corrupt, immoral, and materialistic. Nafisi’s actions are counter-revolutionary to the Islamic Revolution of Iran and can be used as a case study for how women every day in Iran face the choice whether to challenge the mandatory hijab laws. I will examine current protests in the country, with an emphasize on the deadly force used on women by Iran’s morality police who enforce laws that require women to wear the hijab. Through a critical analysis of Reading Lolita in Tehran, I will parallel Nafisi’s teaching of books that the Islamic Republic deemed immoral to the mandatory hijab laws.

Abstract Name: **Community College "CUREs" Engagement Deficits in Biology**

Madison Area Technical College (Madison College) is a public technical and community college serving Madison, WI, and the twelve surrounding counties. Total enrollments exceeded 24,000 students in the 2021-22 academic year, with 42.2% of entering full-time students in Fall of 2020 continuing the following Fall. The Liberal Arts transfer program offers seven tailored pre-majors designed for transfer and satisfaction of the first two years of general studies at some institutions, with the University of Wisconsin-Madison serving as our largest transfer partner. A federally funded initiative to improve transfer student success through the establishment of Course-Embedded Undergraduate Research Experiences (CUREs) was established in majors' biology courses beginning in Fall 2018. This project has resulted in over 500 students participating in skills-focused CUREs in biology courses, and is expanding beyond the target courses to include related courses and programs. Prior to our CUREs implementation, only 18% of students completed abiology majors course series within two semesters. After CUREs implementation, 32% of students complete abiology majors course series within two semesters.Our panel will discuss this, and other outcomes of implementing CUREs in our biology courses, as well as the challenges and opportunities associated with implementing CUREs at a community college. Details about two of our collaborative CUREs initiatives, including ourwork implementing Tiny Earth and Sea Phages across three different biology courses will be highlighted.

Abstract Name: **What?s all that noise about?: Alarm-calling in California ground squirrels**

Many socially-living diurnal animals have evolved vocalizations known as alarm calls as a mechanism for reducing predation. California ground squirrels are a major prey species for coyotes, rattlesnakes, and birds of prey, but must also cope with human foot traffic and anthropogenic noise. This project characterizes the acoustic structure, duration, ecological context, and timing of these calls produced by ground squirrels. Combining naturalistic and automated acoustic monitoring, we describe the extent to which humans and dogs versus natural predators trigger naturally-occuring alarm calls in California ground squirrels across the 24-hour cycle. First, from naturalistic observations as part of my Long-term Behavioral Ecology Project on California ground squirrels at Briones Regional Park, we document that calls are associated with natural predators but not humans visitors. We also describe the contexts in which squirrels produce either a short, non-repetitive vocalization or a longer repetitive bout of alarm calls. Second, we present data from acoustic monitoring devices and camera traps that confirm ground squirrels mainly call during daylight hours, a time of day before coyotes emerge at the site. Our data confirm the alarm-calling “schedule” for these animals and offer new insights into not only what triggers them to call but also the temporal patterning of fear responses over time.

Abstract Name: **Absolute Music and its Revelation of Transcendence in Eliot's Four Quartets**

T.S. Eliot scholars have long concerned themselves with the exact function of the music references in Four Quartets and the extent to which it influences Eliot's poetry. Some scholars like Helen Gardner and Aakanksha Virkar-Yates believe that music plays an integral role in the form and meaning of the poetry; in other words, the poetry is best understood when read through a musicological lens. Others, like Thomas Rees, think that the music analogy is grossly over-applied to Four Quartets and that scholars should adopt a more holistic approach to understanding Eliot's work. In this paper, I will argue that Gardner and Virkar-Yates are largely correct. I suggest that Eliot's poetic form in Four Quartets most closely resembles Wagner's idea of absolute music--a sort of all-pervading melody that transcends the bounds of human experience. Through his use of leitmotifs and musical analogies, Eliot connects music to themes of love, self-denial, and the divine in a way that enables readers to understand that only when one denies themselves and comes to understand the human purpose to love, can one understand transcendence in a way that deeply connects them to the divine realm of God.

Abstract Name: **The Prevalence of Elder Abuse Enacted by Caregivers**

Background: Elder abuse is defined as any act of abuse directed towards an elder individual by their caregiver and can include physical abuse, emotional abuse, financial abuse, social isolation, and neglect. This abuse can occur in any type of facility from any form of caregiver personnel. Most of the abuse occurs within long-term care facilities, such as nursing homes. A current review of literature shows that elder abuse has a high prevalence, yet there is a low reporting rate and low use of interventions among facilities. Of the hospitals that perform abuse screenings, studies show that many of these hospitals screen only after inpatient admission, indicating that elders seen in the emergency room or in outpatient centers are not screened. Additionally, signs and symptoms of abuse can be masked by commonly assumed signs of aging, adding to the under reporting of abuse. Purpose: This proposal will provide new information concerning the presence of elder abuse and will potentially solidify the effectiveness of education. Current practice needs to change because elder abuse is still occurring. Method: For this proposal, establishing the current knowledge of elder abuse from the caregivers will be obtained by a pre-education assessment. Caregiver education regarding risk factors, signs and symptoms, and reporting of elder abuse will be presented. This will include assessment tools to help identify abuse and interventions to decrease abusive acts. Post-education surveys will be utilized to evaluate the efficacy of the education. Conclusion: The expected results are that caregivers will have an increased understanding of elder abuse and increased awareness of recognizing and preventing it, ultimately decreasing the risk of elder abuse.Key words: Caregiver, Elder, Abuse, Education

Abstract Name: **The Impact of Sleep Duration on Anxiety Symptoms, Fear Extinction, and Brain Activation in Youth**

Background: Deficits in fear extinction learning and its later recall are linked are risk of anxiety disorders. Poor sleep and anxiety are related,and emerging studies in adults suggest that partial or total sleep deprivation is associated with poorer extinction recall and altered activation of brain regions associated with the expression and regulation of fear.However, these associations have not yet been examined duringlate childhood and adolescence, a time when sleep duration tends to decrease and risk of anxiety disorders increases. Methods: Seventy-six youth (38 female, ages 6-17) completed a two-day fear extinction and recall paradigm during functional magnetic resonance imaging scanning. Extinction recall was measured using unconditioned stimulus expectancy ratings and skin conductance responses. Youth reported on their anxiety symptoms as well as typical sleep duration on school days, free days, and between the study visits. Regressions examined associations among sleep, anxiety, extinction recall, and neural responses.Results: Average sleep duration on school days (but not free days) significantly predicted anxiety symptoms when controlling for age and sex (b=-3.837, p=.031). Sleep duration was not associated with extinction recall; however, longer sleep between the two study visits was associated with lower neural activation in the cerebellum, occipital lobe, supplemental motor area, and dorsomedial prefrontal cortex during extinction recall. Discussion: Poor sleep between study visits was associated with greater engagement of brain regions associated with the expression of fear in youth. These results have implications for future research on neural mechanisms underlying the link between poor sleep and anxiety in youth.

Abstract Name: **Designing A Metastatic Breast Cancer Support Program**

Currently, there is a significant lack of community-based support groups for individuals living with Metastatic Breast Cancer (MBC). The majority of breast cancer support groups exist for those who are breast cancer survivors, inadvertently overlooking those given a terminal diagnosis. Additionally, only about 2% to 5% of the funds raised for breast cancer research is spent towards breast cancer metastasis studies. The goal of our research is to create a patient-led, community-based support program for individuals living with MBC. This will require the collection of resources that address the specific needs of this community, which were identified through extensive literary research and comprehensive surveys. The survey we created assessed their backgrounds, capabilities, needs, and desires. Additionally, we conducted 15 one-on-one interviews with MBC individuals to gather information on their past support program experiences and program structural preferences.With this qualitative and quantitative data, we are currently developing the Charlotte MBC Program and plan on officially implementing the program in the spring of 2023. We have partnered with Carolina Breast Friends, a Charlotte-based nonprofit organization centered around providing support and resources to those who are affected by breast cancer. Carolina Breast Friends does not currently have any specialized services for those with metastatic breast cancer and partnering with this organization allows them to impact more lives within the breast cancer community. We plan on housing our program at their Pink House, a unique respite center for breast cancer survivors.

Abstract Name: **Polychromy on the Pyxis with Scenes from the Life of Christ**

This paper examines an ivory pyxis from 6th century Syria and analyzes the presence of color on its surfaces. The pyxis is in the shape of a cylindrical box and displays scenes from the life of Christ. It has a diameter of 12 centimeters and a height of 8.5 centimeters, and it is currently housed in the Cluny Museum in Paris, France. In its present condition, the color of the pyxis appears as a warm beige of the natural ivory material. However, scientific analysis has proven that this object has traces of different colors thus positing a question about how it would have originally been painted. Observations through a microscope reveal that the pyxis has traces of red, green, and brown pigments, thus suggesting that it would have been a vibrant work of art. The paper focuses on the present pigmentation of the pyxis and considers both primary, medieval written sources and contemporary scholarship to reconstruct the original appearance of the pyxis. By analyzing historical context and theological narratives, the paper compares the pyxis to similar artworks to assess the symbolism and meaning of particular colors detected on the pyxis. Moreover, the author uses 3D modeling of the pyxis to reconstruct the presence of color and the original aesthetic appeal of this object. Recreating the possible appearance of polychromatic ivories, such as this pyxis, allows us to reframe our understanding of Byzantine art, and by extension, its connection to modern society.

Abstract Name: **Stressed-Induced Grooming in Ants**

The experience of stress has been associated with psychological and physical strains in mammals and other vertebrates. Prior research conducted on vertebrates offers evidence that these animals have acquired tools to reduce stress by stress-induced grooming after exposure to a stressor. Stress-induced grooming or displacement grooming is grooming behavior unrelated to maintenance and care. There is limited research on how insects experience stress and the various responses. This study examines displacement grooming in western harvester ants (Pogonomyrmex occidentalis) following exposure to various changes in the environment to generate stress. 50 ants were randomly assigned to one of three groups; vortexed (exposed to 60 sec of vigorous shaking on vortex), sham-vortexed (exposed to 60 sec of an inactivated vortex), or undisturbed (left in containers without handling). Animal behavior was recorded, and the total time spend grooming was later measured by a researcher who was blind to the experimental condition of the animals. We hypothesized that ants that underwent 60 sec. of vigorous shaking (group vortexed) would show more displacement grooming than animals that were exposed to an inactivated cortex (group sham-vortexed) or undisturbed animals. We found that animals in the vortexed condition did groom more overall than animals in either the sham-vortexed or undisturbed groups (p's 0.02). Total grooming did not differ between the sham-vortexed and undisturbed groups (p 0.01). These findings suggest that the levels of intensity in stressors differentially affect grooming responses, with the most intense stressors eliciting more grooming and less intense stressors eliciting less grooming. This suggests a similarity in the grooming activity of invertebrates and vertebrates when exposed to environmental stressors and suggests that invertebrates can distinguish between different intensities of stress.

Abstract Name: **Investigating the Relationship between Academic Stress, Trait Self-Control, and Compulsive Behaviors in College Students**

Stress amongst college students has been at an all-time high, contributing towards issues in coping, poor academic performance, and increased dropout rates. The American Psychological Association has even identified this population as vulnerable to high levels of stress. The current study aimed to explore relationships with academic stress, trait-self control, and various compulsive behaviors including disinhibited eating, cyberloafing, and compulsive online shopping. In total, 164 college students were surveyed utilizing convenience sampling to take part in this research by volunteering their time to fill out a 71-item survey. Survey packets included the Perceptions of Academic Stress Scale (PAS), the Brief Multidimensional Self-Control Scale (BMSCS), the Dutch Eating Behavioral Questionnaire (DEBQ), the Cyberloafing in Lectures Measure (CLM), and the Modified Bergen's Shopping Addiction Scale (M-BSA). In addition, several demographic questions and daily hours spent on Social media were asked. It was hypothesized that there would be negative correlations between academic stress and trait self-control. Furthermore, it was believed that there would be negative correlations between trait self-control and the various compulsive behaviors studied. Lastly, it was hypothesized that there would be positive correlations between academic stress and the compulsive behaviors studied. Results found significant moderate positive correlations between academic stress and cyberloafing and compulsive online shopping. Furthermore, a significant moderate negative correlation was found between academic stress and trait self-control. Trait self-control and the compulsive behaviors studied were unrelated. Correlations between academic stress and disinhibited eating were also not significant. Recommendations for future research, implications, and limitations are discussed.

Abstract Name: **Borodin String Quartet No. 2**

Borodin's Second String Quartet in D Major is a piece that requires advanced ensemble techniques, fine intonation work, and balanced melodies. It is an essential quartet piece within the string repertoire, and one which our group has grown from immensely while preparing.
The passing of melodies from cello to first violin and viola to second violin requires eye contact, breathing, and togetherness as a group. Borodin includes immediate tempo changes marked at the two animatos, as well as poco a poco dim. e rit at the end of the piece.
Beginning in the deceptively easy key of D Major, intonation inaccuracies are not easily hidden in this piece. Several moments require the performers to play in unison or octaves, and every chord must be carefully tuned. Compounding this, the piece changes keys several times during its development. The F#s in these keys are naturally dissonant and difficult to tune, especially in a group setting. Our quartet has spent hours together refining our intonation.
Throughout the piece, the first violin and cello converse with each other by trading the main melody. Later in the development section, the melody is passed around to the rest of the quartet. At the recapitulation, the cello hands the melody to the viola, requiring a strong sense of balance among the group. Because of this, our quartet has been working on balancing the melody and the accompaniment. The passing melodies require each member to use the same bow techniques and distribution, keeping everything uniform and beautifully phrased.
An influential work for any group, Borodin's second string quartet blends beautiful melodies and textures with flawless technique to create a timeless masterpiece.

Abstract Name: **The Vote: The Fight For Black Women's Suffrage in the Jim Crow South**

When the Nineteenth Amendment was ratified in 1920, many women were finally able to vote alongside their family, friends, and spouses, but black women in the South faced many barriers that kept them away from the polls. Many historians have done a great amount of research regarding women's suffrage movements, but the experiences and stories about black women suffragists are predominantly excluded. This project explores several points that impacted black women in the South after the Nineteenth Amendment was passed. First, it will discuss how racism flourished within the South and how it caused millions of black women to be disenfranchised by it as well as how they responded to it. Next, my project will discuss some of the responses made by black and white female suffragists in the North and how they responded to the problems of minority women in the South. Finally, this paper will cover the attempts black women made in the South so that they could gain access to the polls. My research uncovers how some southern black women were able to register to vote after the Nineteenth Amendment was passed, specifically about a women named Mrs. Fred Wheelock who was able to vote in the South alongside three other black women. I argue in this paper that black women were very invested in gaining voting rights as well as equality for all and even though the South, for most of the twentieth century, disenfranchised many black women there were certain cases in which they were able to register to vote. For many women after 1920, the fight to obtain voting rights and equality was over, but for black women, the fight was only beginning.

Abstract Name: **Factors that Affect Perceptions of Gig-Workers**

According to Pew Research Center, 16% Americans have earned money on online gig platforms such as Uber or TaskRabbit at some point. However, research on how consumers select gig workers is still mostly underexplored. The purpose of this study is to investigate the potential impact of a gig worker's gender and self-presentation in their profile picture on consumer perceptions and choices. Specifically, we propose that smiling and quality of profile picture in terms of professionalism positively influence consumers' perceptions on the gig worker's competence, trustworthiness, and the likelihood of hiring them for a task. We also propose that these two factors will interact with gender, such that the positive effect of smiling is greater for female than for male workers, and the positive effect of professionalism is greater for male than for female workers. Lastly, we hypothesize that gender bias exists on gig platforms, such that male and female gig workers are more likely to be selected for tasks that are stereotypically aligned with their traditional gender roles. We conducted a 2 (gender: male vs. female) x 2 (smile: smiling vs. neutral) x 2 (professionalism: professional headshot vs. selfie) between-subjects experiment on Qualtrics to test our hypotheses. Eight fake worker profiles were created with different profile pictures to reflect the experimental manipulation. Undergraduate psychology students took an online survey where they were randomized to view one of the eight worker profiles. Additionally, we created one more worker profile that showed a smiling male in a professional headshot, which served as a comparison in each condition. We are currently in the process of data collection, which will be completed by December 2022. Data analyses will be completed by March 2023. Our findings will provide practical implications to gig workers regarding how to enhance their chance of being selected.

Abstract Name: **Multi-Site Electrophysiological Recordings of Neural Activity in the Infralimbic Cortex, Insular Cortex and Basolateral Amygdala Across Heroin-Seeking Behavior**

The infralimbic cortex (IL) is implicated to regulate drug seeking due to prior evidence indicating its role in promoting the extinction and inhibition of cocaine seeking. The physiological nature of the IL regarding its role in mediating the extinction of opioid seeking has yet to be determined. However, it's expected that the IL interacts with other regions known to modulate these behaviors. Previous work has demonstrated that there are extensive connections between the IL and the basolateral amygdala (BLA), and the rostral agranular cortex (RAIC). Human and rodent studies indicate the BLA and RAIC hold heavy influence in managing drug cravings and drug-seeking behavior, further reinforcing the perceived interactions between these three regions. The similarities of humans and ratsgentically, physiologically and anatomically emphsize the translation of these observations to humans.Therefore, we strove to observe the neurophysiological interactions between these regions during self-administration, extinction and reinstatement of heroin seeking through utilizing innovative electrophysiological recording techniques to simultaneously record for the regions of this network throughout this behavioral procedure. Although this work is ongoing, the appearance of a dynamic network in this IL-RAIC-BLA circuitry during heroin seeking behavior has become evident in the preliminary analyses. Specific subpopulations of units in the IL and RAIC increase in activity during goal directed behaviors, whereas local field analyses demonstrated theta and alpha oscillations varied due to altering contingencies present in self-administration, extinction, and reinstatement. Further data collection and extensive analyses may reveal how the current corticolimbic circuit forms a functional network during the extinction of heroin seeking.Upon conclusion of the current study, additional investigation of this network to determine the involvement of other regions in regulating drug seeking behavior are essential to further shape our understanding of such processes.

Abstract Name: **Investigation of Blister Formation in Post-Processing of Additively Manufactured Parts**

Support removal is a necessary post processing step in many additive manufacturing processes. Acrylonitrile-butadiene-styrene (ABS) parts printed on a Stratasys FDM (Fused Deposition Modeling) can be printed with a soluble support that may need to be dissolved in an ultrasonic tank containing sodium hydroxide. However, parts removed from the bath occasionally have voids forming within thick cross-sectioned parts, which cause blisters to be seen on the surface. This project investigates potential root causes of the void formation. Initial experiments were conducted to identify the frequency propagated in the tank and time as key factors in causing the voids. Subsequent experiments are also conducted regarding the object's position in the tank, geometry, and temperature of solution in which the results suggest that thermal acoustic energy concentrates near the center of the tank and objects closer to this area are more prone to void formation than others. Lowering the temperature and intensity of acoustic energy intensity both appear to reduce likelihood of void formation in ABS parts subjected to ultrasonic cleaning.

Abstract Name: Wearable Carbon Dioxide, Oxygen, Carbon Monoxide, and Methane Sensor within OSHA limits

According to the Center for Disease Control and Prevention, accidental gas poisoning affects approximately 50,000 people every year in North America alone across a wide variety of locations. A wearable, lightweight device that detects toxic forms of gas is ideal when prioritizing safety for individuals who need this information displayed while on the move. The purpose of this experiment is to design one device that measures exposure to common toxic compounds found in nature: Carbon Dioxide (CO2), Oxygen (O2), Carbon Monoxide (CO), and Methane (CH4). The current design uses gas sensors from Adafruit, Arduino, and Grove to detect dangerous concentration levels. The Occupational Safety and Health Administration (OSHA) defines maximum exposure in parts per million (ppm). A microcontroller and electronics have been designed to display concentrations in ppm on an LCD screen and provide a 1 second audio alert and danger signal if over OSHA standards. The system can measure CO2 within 5.7%, O2 within 4.6%, and CO within 1% of a commercial sensor. This project is 6 in x 3 in with plans to reduce to 1in x 1in.

Abstract Name: Yoga As An Approach to Mental Recovery 48 Hours After an Intense Workout

Background: Along with physiological changes, knowledge about yoga and meditation strategies for post workout mental recovery has been investigated. Results show that it improves mental clarity and reduces stress and anxiety levels. Purpose: The purpose of this study is to examine the effects of a 30 min yoga session on mental recovery 48 hours after a high intensity workout. Hypothesis: We hypothesize that if a yoga session is done immediately after an intense workout, it will produce greater mental recovery compared to those who do not participate in the yoga session. Methods: Twenty undergraduate students will complete a 30 minute intense workout. Following the workout, the intervention group will complete a thirty minute yoga/meditation session. The control group will not do anything outside of their usual routine. Conclusion: If our results align with our hypothesis, individuals can incorporate yoga into their exercise routine to benefit overall mental health and recovery.

Abstract Name: Apple iWatch Noise Meter Accuracy: Can We Make "Sound" Judgements on the Noise Alerts?

Background: Noise-induced hearing loss is a permanent type of hearing loss that is a result of loud noise exposure over time. The effects of noise-induced hearing loss often go unnoticed until irreversible damage is already done. To preventindividuals from developing noise-induced hearing loss, mobile phone companies like Apple have developed a noise monitoring application (app) for the AppleiWatch which alerts individuals when they are in the presence of dangerous noise levels. It is extremely important that this application provides accurate noise alerts to the user so that appropriate measures can be taken to limit the exposure level and/or duration. The aim of this study is to measure how accurate the noise measurements of the Apple iWatch are.Methods: Noise levels will be measured atsixteen different locationsusing various models of Apple iWatches. These measurements will then be compared to measurements obtained by the iPhone app, theNational Institute of Occupational Safety and Health (NIOSH) noise meter appwhich has been found to provide noise measurements within +/- 1 dB ofLarson Davis type 1 sound level meter (Kardous and Shaw, 2016).The noise levels in each environment will be measured by both the iWatches and the reference iPhone NIOSH noise meter app. Measurements will be compared for each environment and analyzed for significant differences in order to determine how accurate the iWatch measurements are.Data will be collected and analyzed Spring 2023 pending IRB approval.

Abstract Name: "Oohs, Ahhs, Big Applause, and a Standing Ovation": The Creation of Ambiguity-Driven In-Groups and Absurdist Humor

This research examines the relationship between three musical comedy productions, Something Rotten, Spamalot, and Spamilton, and the audience's sense of rhetorical belonging. By expanding upon Thomas Shultz's theory of incongruity-resolution based humor, the research first elucidates how ambiguity-driven humor, which has primarily been applied to linguistics, can be translated to identify musical ambiguity. Next, a comparative analysis of the three musical comedies was conducted with an emphasis on observing outrageously outlandish characters and events, levels of intertextuality, and linguistic and musical ambiguity in each. Finally, the research investigates how the humor within each production is used for promotional material with an aim of advertising the show to multiple types of audiences, including those which would not typically be associated with musical theater, to encourage the formation of new in-groups. The playwrights use meta recognition— specifically of elitism associated with history, literature and theater— to appeal to the diverse in-groups within the audience. The findings suggest the sense of belonging invites new audience members to identify with the arguably still-elitist theater community and contributes to the musical theater pop-culture movement's aim for social progressivism. Further research can include expanding the sample size of musical comedies analyzed or exploring the musicals through another theory of humor such as the superiority or violation theories.

Abstract Name: The Use of Sequential Bilingualism as Protection against the Symptoms of Alzheimer?s Disease in Older Adults

Bilingualism has been shown to promote cerebral growth, which includes increased gray matter, white matter, and cognitive reserve. These neurological benefits allow individuals to maintain cognitive function over the course of late adulthood, providing resistance against the symptoms of Alzheimer's Disease. In a comprehensive literature review, this study investigates the extent to which foreign language learning and acquisition in late-middle to late adulthood, or sequential bilingualism, contributes to cognitive reserve and gray matter volumes in the brain, with the subsequent aim of delaying the onset of Alzheimer's Disease. Experimental studies measuring cognitive ability, cerebral atrophy, and gray matter volumes were conducted among groups of bilinguals and monolinguals in various countries, including Canada, China, and the United States. Across studies, participants were designated a battery of cognitive tasks that tested selective attention, inhibitory and executive function, and language proficiency; this was followed by brain scans that measured gray matter volume and cerebral atrophy. In a majority of studies, researchers found that bilingual participants attained higher scores on cognitive tasks. For experiments in which bilinguals and monolinguals performed equally, bilinguals demonstrated less neurodegeneration and higher gray matter volume than their monolingual counterparts. Given the growing prevalence of Alzheimer's Disease among the global elderly population, novel treatment interventions that can effectively delay or mitigate symptoms of Alzheimer's are becoming increasingly important for both extending and improving quality of life. Sequential bilingualism represents a non-invasive and cost-accessible strategy in the field of neuroscience. Further research and experimental trials to validate the interventional capacities of this approach are warranted.

Abstract Name: Role of Motivation on Academic Success B

The collegiate world is constantly discussing how student motivation is related to student success. How true is this correlation? Does the motivation importance change with the specific course or the format the course is taught in? Can the institution or instructor impact the student motivation level by understanding intrinsic and extrinsic factors that motivate students? The aim of this study is to determine what motivation is and how it impacts the academic success of college students. Factors that will be studied are intrinsic and extrinsic motivation factors, academic performance, familial college experience (1st generation studens vs non 1st generation students), and the role of the institution and faculty. The study will be completed through a survey with a battery of questions addressing all the key areas mentioned above. Demographics will also be collected to compare possible inter-group differences. Correlational analysis will be completed through data collection in the spring semester of 2023.

Abstract Name: Rural Voices / Voces del Campo

In the US, Latinx; Hispanic populations have been disproportionately affected by the COVID-19 pandemic. To learn about the health concerns and life experiences of rural, migrant, and farmworking communities, in 2020, Drs. Elena N. Casey (Languages) and Cheryl Jiménez Frei (History), together with faculty and students from programs across the humanities and health sciences at UW-Eau Claire, launched Rural Voices / Voces del Campo. Rural Voices aims to create a repository of oral histories, digital exhibits, and artifacts documenting the history and lives of communities and individuals in western Wisconsin, with attention to Latinx migrant community members during and beyond COVID-19. This repository will serve as a resource to help future scholars, public health providers, policy makers, and the public understand the impact of Covid-19 and diversity of communities in the rural Midwest; a tool to enable rural and Latinx residents to express their experiences of immigration, culture, family and daily life in western Wisconsin; a teaching tool to educate students about the experiences and contributions of rural and migrant community members; and a resource with the potential to advocate for policy changes and public health services to meet the needs of rural and migrant populations. As a multidisciplinary oral history interview project, Voces trains students in a variety of research capacities: forming community partnerships, conducting, transcribing and translating interviews, creating and curating digital archives, and analyzing data for presentation and publication. The project's inclusion of Spanish-language interviews and Spanish-speaking communities expands the participation of Latinx and Hispanic students in undergraduate research. Our talk will contribute to raising the profile of undergraduate research in the arts by summarizing the structure, challenges, and progress of Voces del Campo to-date and providing ideas for embedding oral history research in courses and curricula in a variety of academic disciplines.

Abstract Name: Percussion Activities with Adaptations for DEI and Integration of National Music Standards

This presentation will showcase graphic adaptations created for the secure setting of a juvenile detention center housed inside a jail. Social-emotional learning applications and social justice standards were connected with national music standards for lesson plans integrating the adaptations. Due to interest of the students involved inside the detention center, Latin rhythms were chosen as a major focus area. Rhythmic patterns for claves and basic Latin idioms were chosen and paired with specific Latin songs. Because different students needed different types of adaptations, a composite template was developed to include cues of words, images, music notation on a staff, and adaptive notation with counting boxes integrated to depict the organizational structure of the rhythm. How to show special effects such as accents, tremolos, and brushing technique to add sound on the tabletop and on clothing will be demonstrated. Students in the juvenile detention center assisted in creating each layer of adaptations, performing them, and conducting them. Input provided from juveniles for how to best facilitate their successful responses will be shared. Latin styles reflected by properties of music included switching between major and minor chords frequently, triplet patterns in both accompaniment and melody lines, and offbeat accents were represented across different cultures. Examples will be performed while graphics are shown with audience invited to join in and participate.Rhythms included three-two Son, three-two Rhumba, Samba, Bossa Clave, Samba Clave, swing patterns, Tumba, and Merengue, with each of these rhythms being paired with one or more songs for the music lessons. Considerations for meeting the needs of everyone in the group when those needs are not the same will be explored. Hasty considerations based on jail precautions and the pandemic will be described. Charts to show connections for social justice, social-emotional learning, and national music standards will be presented.

Abstract Name: Investigating Spatial Representation of Sea Ice Concentrations at Coastal Sites in the Western Antarctic Peninsula

In 2019, the macroalgal distribution along a latitudinal gradient (64°-69° S) was sampled at fifteen coastal sites along the West Antarctic Peninsula. A strong negative correlation between total macroalgal cover and sea ice concentration was documented. However, the remote sensing-derived sea ice concentrations used in this analysis are at a larger spatial scale (25 kilometers on a side) compared to the size of the sampling sites (~100 meters across). To investigate differences in measured sea ice concentrations across these two spatial scales, moderate spatial resolution Landsat satellite imagers (30-meter pixel resolutions) were used to determine how representative the large footprint sea ice concentrations were of that occurring at the smaller sampling sites. An algorithm based on a Normalized Difference Snow Index (NDSI) approach classified the Landsat images as either sea ice, clouds, or ocean within 100, 300, and 3000 meter buffers around the site. In general, the larger footprint sensors indicated lower sea ice concentrations than the Landsat observations; the differences observed were consistent regardless of buffer size around each site. This indicates that while the sites had higher sea ice concentrations than retrieved for the larger pixels, the higher concentrations appear to be consistent at spatial scales from 100s to 1000s of meters. Wind and current exposure were ruled out as a major cause for the scatter in the observed correlation between sea ice concentrations and macroalgae coverage. Understanding the relationship of this data provides a model which can be used for global conservation of macroalgae in the future.

Abstract Name: **Mapping Walkability in Naperville, IL: A Community-Engaged Project**

Community walkability is vital for personal health, social equity, economic development, and fighting climate change. Walkability is how accessible walking is for residents in terms of leisure, exercise, access to services, or traveling to work. In order to determine the spatial variability of walkability within Naperville, IL, stakeholders including North Central College and the Naperville Environment and Sustainability Task Force (NEST) worked together to create a walkability assessment. This had never been done for Naperville; it would allow the city to see how walkable their city is in order to decrease their carbon footprint as well as to improve community sustainability. NEST identified three key characteristics for local walkability: distance to destinations, safety, and pleasantness. One of the ways this can be analyzed is through GIS, which is used to map and show spatial relationships. From each residential building in Naperville, a 15-minute walking service area was generated in ArcGIS for seven destinations: parks, grocery stores, retail centers, public transit stops, and elementary, middle, and high schools. If a house was within walking distance of one of the destinations, one point would be given to that house. A total walkability score was created and mapped in a multi-factor walkability map. The results indicated that walkability in Naperville is highly spatially variable across the city. The city can use these findings to identify and improve areas with lower walkability scores in the city, as well as to improve sustainable urban planning.

Abstract Name: **Gender Gap in Social Welfare Policy Attitudes**

Gender differences in public opinion and policy attitudes have been a hallmark of American politics for many years. Gender differences are evident in how women and men respond to contemporary issues. For example, women are more likely than men to support gun control measures, access to abortion, and increased spending on social welfare programs. Women are less likely than men to support the death penalty, the use of military force to settle international disputes, and stricter immigration policies. Furthermore, gender patterns in public opinion extend to several other public policy issues under the umbrella of social welfare. Political science studies show that women are more likely to identify as Democrats than men and are more likely to express opinions that are consistent with Democrats' policy positions. However, there are more important differences between women based on race, ethnicity, and other demographic factors. Why are there systematic gender differences in attitudes to public policy issues? What are the factors driving these differences? What role do other factors, such as partisanship and racial and ethnic identity, play? This study explores the dynamics of these gender differences and how they shape American politics. This study sheds light on what gendered patterns of public opinion look like in the United States, what the underlying factors drive these patterns, and how gender interacts with other identities to influence political attitudes. To examine how partisanship and other identities influence gender disparities in social welfare policy attitudes, this study analyzes data from the 2021 General Social Survey.

Abstract Name: Microscale Synthesis of Fusible Alloys and Low-Melting-Point Metallic Nanoparticles

Fusible alloys melt at a low temperature and typically consist of metals such as indium, gallium, bismuth tin, and zinc. These alloys can be used in applications such as electrical solder, thermal fuses, liquid metal coolants, die casting, and rapid prototyping. Additional metals such as mercury, lead, cadmium, and even thallium could also be used but are more restricted in their potential applications due to high toxicity. Some of these metals, such as indium and gallium, are relatively expensive making it advantageous to conduct microscale research of new fusible alloy compositions on a small scale. Such syntheses are challenging due to the comparatively high surface area to volume ratio of microscale samples leading to significant oxide formation when being mixed in the melt phase. A method has been developed to prepare alloy samples of various compositions at a 500 mg scale using a rosin-based flux to protect the molten surface and promote mixing without the need for a vacuum furnace or inert atmosphere. The resulting alloy samples were characterized by dynamic scanning calorimetry (DSC) and optical microscopy and were found to have the expected melting points and microstructure when compared with known phase diagrams found in the literature. Fusible alloy samples were then converted to low-melt-point metallic nanoparticles using an ultrasonic nanoemulsion method. Samples of the selected alloy were pre-heated and sonicated in mineral oil using a probe sonicator. The resulting high shear converted droplets of molten metal into particles ranging in size from tens of nanometers to a few microns depending on the intensity and duration of the applied sonication. Particle size and distribution were characterized by optical and scanning electron microscopy. The methods used to prepare and characterize fusible alloy samples and nanoparticles will be discussed.

Abstract Name: Examining the abundance, distribution, and behavior of Gray Seals (Halichoerus grypus) in the presence of white sharks (Carcharodon carcharias) off of Scatarie Island, Nova Scotia

Great white shark (Carcharodon carcharias) migratory patterns within the Atlantic Canada waters have been tracked and studied by the OCEARCH research team since 2018. As part of their migration, adult sharks typically spend most of the summer in the coastal waters of the Northern United States and Atlantic Canada. During this span, the gray seal (Halichoerus grypus) serves as an energy-rich food source for these apex predators. Gray seals form dense colonies on rocky outcrops near shore, but must travel to deeper water to forage. While traveling to deeper water, foraging, and returning to the colony, these seals are vulnerable to predation.Gray seals often congregate on “launch pads”, or shallow areas offshore of the colony, which they use as staging and return areas for their foraging expeditions. To examine the abundance of gray seals at a well-established colony in Nova Scotia, as well as the influence of nearby predators on seal behavior, small unmanned aerial vehicles (UAVs) were deployed off of Scatarie Islands. These UAVs were used to assess the abundance of seals, identify shallow water launch pads, and observe seal behavior. Data collection via drone surveillance provided high-resolution imagery of animal locations and behavior within the research area without disturbing the seal colony. The information gained through this study was then provided to OCEARCH to enhance their understanding of this popular white-shark feeding ground and assist with future fishing efforts.

Abstract Name: **Tabletop Training**

This project serves to optimize the strategies for playing two board games: Ticket to Ride and Shut the Box.The board game Ticket to Ride focuses on accumulating points by building connections between cities and completing routes specified by destination tickets. The game is designed for players to determine which routes are advantageous towards reaching the highest score, which leads to multiple avenues for mathematical and strategic analysis. This project serves to find an optimized strategy to play the game, along with marking critical routes to maximize earned points. Using R Studio and its visualization resources, the game is replicated in an online environment to be studied using different graph analysis techniques. Graph theory and optimization algorithms are then applied to study unearthed mathematics behind the game. Key objectives include a way of prioritizing destination tickets, identifying important cities, and selecting trains to collect.The board game Shut the Box focuses on shutting numbered tiles through dice rolls to minimize the sum of the remaining tiles upon completion of the match. This project serves to give players an optimized strategy which can increase their likelihood of winning based on which available tiles they shut throughout the game. Using discrete mathematics, probability without replacement, and decision tree analysis, we analyze the game from a decision-making standpoint to develop and test in-game strategies to aid in beating the game. In this project, we code a simulation of the game to gather statistics related to the performance of strategies made for the game. Following the completion of simulations, the focus is assessing decision trees that spawn from the elimination of certain tiles compared to others to find an optimized and usable strategy. A key result of this project will be a comparison of usable in-game strategies that are mathematically optimized through statistical analysis.

Abstract Name: **An Updated Examination of Climate Change Views Among Wisconsin College Students Using Surveys Conducted in 2023**

Climate change (CC) is perhaps the most important issue of our time. Citizen public opinion will likely be a significant determining factor regarding if/when CC mitigation policies will be enacted. Additionally, news media reports suggest that young people, including college students have been increasingly active in terms of calling for action to address CC. We will conduct surveys of Wisconsin (WI) college students in February 2023 with the expectation of receiving at least 600 completed surveys from at least three institutions to provide a current account of CC views among WI college students. A CC index (CCI) score will be calculated using responses to questions about if CC is happening and what are its primary causes as well as an understanding of CC science and concern about and obligation to act regarding CC. CCI scores range from -10 to 10 with higher scores indicating more alignment with the scientific realities of CC. This poster will present comparisons of CC views based on age, gender, major and political ideology as well as across the different institutions including ordinary least squares regression analysis. Because we have not collected the data yet, we cannot report any results at this time. For context, our poster will also compare the CC views from these 2023 WI college student surveys to the CC views expressed in previous surveys conducted among UW-Eau Claire (UWEC) college students in 2017, 2018, 2021 and 2022. Lastly, we will provide additional context by comparing the CC views from all of our WI college student surveys to similar work we have done comparing CC views between American and Chinese citizens from multiple survey years. This poster is connected to another submitted poster analyzing data from surveys conducted of both UWEC college students and also Chinese and American citizens in prior years.

Abstract Name: First Generation College Students and their Housing Status on College Belonging

Our population is becoming more diverse with each generation. With many financial and housing options, this has resulted in a big portion of the college student population being first-generation students yearly. This is representative in the literature, especially regarding first-generation identity and housing status. First-generation students struggle with a lack of information and unknown expectations as they face higher education with no reference point. Added to the first-year experience, it could result in a challenging and confusing year. Housing status as a topic has been explored as learning communities, residential dorms, and commuting from home. These living spaces provide different resources that could aid the college experience. Studies have investigated its impact on academic success and retention, but not college belonging. College belonging is about a sense of security, and its investigation has been seen to support academic success. Thus, focusing on this topic could bring about ways to increase the quality of the college experience. As a result of past literature, this study will explore the impact of first-generation and housing status on college belonging with first-year students. I will explore the connotations and feelings behind the statuses of "first-generation" and housing, with specifics to the terms "commuter" and "resident." I will then see if it may influence a student's sense of self and how they think others may view them, thus affecting their sense of belonging. My investigation is based on hourly in-person interviews with first-year students that fit those identities. Through this, I will explore the relationship between first-generation and housing status on college belonging. I hope to provide more support for students' overall success and well-being in college with my anticipated findings.

Abstract Name: The Promise of a Profitable Outpost: The Frontier Metaphor and Space Commodification

This study analyzes the use of the frontier metaphor in the promotion of space exploration with an aim to uncover the link between language and commercial interest in outer space. Building upon Frederick Jackson Turner's "Frontier Thesis," this investigation employs an analytical framework developed from psycholinguistic and post colonial studies to analyze John F. Kennedy's use of the frontier metaphor in his speech at the Aerospace Medical Health Center (November 1963). The framework ties American expansionism to economic profit through the work of William Appleman Williams who argues the frontier's American exceptionalism was a key factor in the growth of the American empire. Additionally, the framework establishes the influence of diction through Max Black's "interaction" and George Lakoff's "state-as-person" metaphors, which argue intrinsic connotations attached to words skew perceptions. This study highlights the practical use of this rhetoric with the inclusion of Paul Thibodeau's cognitive experiments measuring the effects of language on social policy. The analysis implies Kennedy's metaphor transforms outer space into another frontier in the American consciousness whose crossing is indelibly American and imminent. Paired with the expectation of a profitable outpost, the usage of the frontier metaphor expands American economic ambitions into outer space. This analysis serves as a point of exploration of the previous uses of the frontier metaphor to better understand their modern use.

Abstract Name: **Developing Synthetic Methodology to Optimize a Series of Novel Anti-Malarials**

The human parasite,Plasmodium falciparum, kills nearly 500,000 people a year, with the most fatalities occurring in tropical areas that disproportionately affect sub-Saharan Africa. All clinical symptoms of the disease result from the intraerythrocytic development of parasite. During this part of the life cycle, the parasite expresses an array of proteases (enzymes that degrade other proteins) to carry out many essential processes, such as host cell protein degradation, host cell invasion, and parasite protein export. Previous studies developed a piperazine-based hydroxamic acid scaffold, and we are currently testing a diverse alcohol substituent at the N4 positions. We decided to use an array of alcohols since it is inexpensive, commercially available, and structurally diverse. To achieve this goal, we developed a synthetic methodology that uses shvo's catalyst for amine and alcohol coupling. Throughout the optimization, we determined that temperature, solvent, and equivalence of the alcohol, are factors for a good starting material conversion. <p lang="EN-US">

Abstract Name: **XRF Analysis of Pb Concentrations in Soils in and near Moorhead, MN**

Prior to its ban in 1996, leaded gasoline was available for use in all vehicles. We suspected there was an increased concentration of lead in the soil near Highway 10 near Moorhead Minnesota. The purpose of this experiment is to determine the impact of anthropogenic lead in soil.We collected 6 urban soil samples within Moorhead along parks, residential areas, and our college campus. We collected 18 rural soil samples east of Moorhead along highway 10 including two perpendicular transects to highway 10. A transect 1 mile, and a transect 7 miles east from Moorhead going North and South respectively. We collected both surface samples and samples approximately 6 to 12 inches in depth. We analyzed the samples by drying the samples at 100°-105°C for 18-19 hours. Using an agate mortar and pestle, we ground the samples to a powder. A Hitachi X-Met8000 Handheld-analyzer was used to analyze the elemental composition of the samples. We aimed to determine correlations in lead levels.Pb concentrations in urban areas ranged from 17 to 175 ppm. Rural variations showed a decrease in lead concentrations eastward along Highway 10 as well as a decrease away from highway 10 for the transect taken 1 mile from town. In rural and urban samples, we observed Pb statistically significantly decreased with depth.Our results show a trend in lead concentration with location and depth consistent with air-deposited lead from leaded gasoline. Although, regions with no obvious anthropogenic lead were decreasing in Pb levels relating to depth, as well. This suggests that soil genesis processes may also be a factor in the Pb concentrations, and warrants further research. Although most samples remained under the 100 ppm EPA guidelines for residential gardens, 2 urban samples taken along a major street exceeded this value

Abstract Name: Deep Learning and Feature Selection for Classification of Kidney Tissue Microarrays

Renal function is an essential marker in the classification of renal disease and clinical symptoms of renal failure develop when there is 15% renal function. In this study, we used infrared spectroscopic (IR) imaging to investigate biomolecular markers from renal transplant biopsies. These images are used for the classification of regions of fibrosis from biopsies containing renal cell carcinoma (chromophobe and oncocytoma) and the prediction of fibrotic proliferation using biochemical signatures. IR spectroscopy is a diagnostic approach utilizing human tissue to label biochemical signatures. Images are captured in several hundred wavelengths in the infrared region of the electromagnetic giving researchers access to more information than traditional RGB images captured by a microscope. While images captured in several bands are great for disease diagnosis, it poses significant challenges for manual cell review by a pathologist. To address this issue, a fully automated pipeline for image processing is being explored. Preliminary research involves identifying feature importance using various algorithms, each of which returns the significant spectral bands necessary for detecting regions of fibrosis. The outputs are ranked and compared to find the first 150 most important features. After feature selection, a deep learning model called UNet will be applied for the classification and identification of fibrosis. Our results will then be compared to the discriminate analysis of the Bayesian classification used in clinical applications.

Abstract Name: Fourier Transform Infrared Spectroscopic Imaging for Detection of Biomarkers in Patients with Alcoholic Steatohepatitis

Infrared spectroscopic imaging has been shown to be useful as a diagnostic tool for tissue imaging. IR imaging allows for a label free approach to identifying biomarkers and molecular changes associated with disease progression. Alcoholic steatohepatitis (ASH) is a progressive liver disease caused by prolonged, excessive alcohol consumption. It often leads to liver cirrhosis. ASH is difficult to diagnose because clinically it presents similarly to other liver diseases, like non-alcoholic steatohepatitis. A liver biopsy is the current standard diagnostic method for diagnosing alcoholic steatohepatitis. The current process involves staining and diagnosis by a pathologist, which requires an extended period of time. Early diagnosis is important to prevent further liver damage. IR imaging provides a rapid imaging technique that can be used to identify biomarkers in tissue linked with ASH. In this study, we applied Fourier Transform Infrared (FT-IR) Spectroscopic Imaging to obtain detailed images of liver tissue samples from patients previously diagnosed with ASH. These images contain biochemical information that allows for the determination of biomarkers and biochemical changes associated with alcoholic steatohepatitis.

Abstract Name: **Tactile Instructions for Wearable Physical Rehabilitation**

Patients of all ages, who have a range of medical conditions or injuries, use physical therapy to help ensure they have a full recovery. Physical therapy is useful to help manage pain, regain mobility and comfort, and return to activities. However, research has found as low as 35% of patients actively do at-home exercises for physical therapy. When patient adherence is low, recovery is less effective. This leads to further complications of the patient's condition and can hinder future recovery. Low self-efficacy is a leading reason patients say they do not do at-home exercises, as they believe they cannot effectively carry out an exercise on their own. The proposed research seeks to explore wearable computing systems to develop a device that enables patients to receive haptic feedback on their movements while at home and apply corrections as though a therapist was working hands-on with them, thereby increasing their confidence in completing the activity.To date, wearable technology most frequently uses accelerometers and inertial measurement units to track human motion and performance. Designing wearable devices that are comfortable, adjustable, and interpretable by the wearer, is challenging. Our current design uses haptic feedback to help users receive feedback on simple activities. We developed a glove with embedded motors that vibrate guiding the movement of the patient within a two-dimensional plane. Ongoing research is exploring extensions of this approach to upper-arm mobility by developing novel tactile instructions. A user study will be conducted to explore vibration patterns and examine the upper arm mobility with tactile motor instructions.

Abstract Name: **Self-Esteem in Relation to Online and Offline Communities**

Peacock and Cowan (2019) found that having significant trusting relationships increases one's self-esteem. While these trusting relationships were once formed offline, they are now being developed online as well with the increase in reliance on technology. It follows that Best (2014) found some online communities may also increase one's self-esteem. This study compares the self-esteem of individuals who have a strong sense of community in an online group to those who have a strong sense of community in an offline group. We hypothesize that both groups will have similar patterns of self-esteem. We also hypothesize that those with strong connections to either community will demonstrate higher self-esteem than those with lower connections to a community. Participants were acquired through the Department of Psychology SONA system as well as recruitment in psychology courses. Participants completed the Brief Sense of Community Scale in reference to their online community and then completed it again for their offline community. Participants also completed the Rosenberg Self-Esteem Scale. Data collection is currently underway and will continue through the last week of November, with data currently obtained from 87 participants. The anticipated total number of participants is 120. Upon completion of data collection, Pearson correlations will explore a) the relationship between self-esteem and sense of community in an online group as well as b) self-esteem and sense of community in an offline group. In addition, an independent t-test will compare self-esteem between those who are most strongly connected to an online community and those most strongly connected to an offline community. With technological communication growing rapidly, our relationships with one another will change as well. With these changes, it is important to learn more about how they are affecting us and the way we relate to one another.

Abstract Name: **Music Brings a Smile to My Face: Assessing the Effects of Familiar Music on Happiness in Older Adults Living in Long Term Care**

The positive effect of music on overall health and psychological well-being has been well documented. In older adults, listening to music has been correlated to positive emotions, happiness, increased mental awareness, and decreased stress levels. Further, implementing music therapy/programs in long-term care facilities has resulted in improved depression symptoms, improved well-being, and decreased use of mood stabilizing medications.For purposes of this project, only happiness was measured, but aspredicted there wasan improvement in several other aspects of the participants' health and well-being. It is anticipated that this program will be continued beyond the designated four week mark because of interest in the service aspect of the project from current students. This programallowed students from complementary disciplines to participate in a research project that assessedthe effects of familiar music on happiness in older adults living in long term care. Two nursing students and a recent psychology graduate, who were allwell versed in Cajun and Zydeco music performed a one-hour music set once a week for four weeks for residents of a local assisted living facility. Permission was granted by the the facility and all COVID protocols were followed. Approval was also obtained from the university's IRB department prior to implementation of the program.Prior to the first music program, residents were asked to complete a reliable and validated, Subjective Happiness Scale, consisting of 4 questions with Likert scale responses via pen and paper. Students, with the assistance of their faculty advisors, enteredthis data into the Intellectus software program. At the end of the fourth/final music set, residents wereonce againasked to complete the Subjective Happiness Scale. Students are inputting post project scale data into the Intellectus software program. Data will beanalyzed using a paired t-test to evaluate effectiveness of this intervention.

Abstract Name: **Deep Learning Model for Designing High-Entropy Materials with Optimal Electronic Properties**

In recent years, high entropy alloys (HEA) and ceramics (HEC) have brought new fervor to the field of material informatics – the design and discovery of materials leveraging data-driven approaches. HEAs or HECs consist of five-or-more metals bonded together in relatively equal proportions. These materials exhibit remarkable properties, such as increased strength and wear resistance to high voltages and temperatures. Therefore, they are attractive in a broad range of applications, from power electronics and solar cells to quantum computers and optoelectronics. Despite these benefits, the largest challenge to its implementation arises due to the considerable variability of its properties. Small modifications in the crystalline lattice or composition of atomic species strongly influence the behavior and ultimate performance of HEA/HECs. It is thus essential to establish a direct structure-property relationship to leverage the full potential of these materials for various applications. We develop (1) a forward learning model to predict targeted properties of HEAs with known configurations. We use kernel ridge regression with n-gram descriptor generation for the forward learning model. This model successfully predicts the band-gap and formation energy of HEAs. A higher band-gap implies higher breakdown voltages useful for electronic devices and formation energy quantifies the stability of the material. Additionally, we develop (2) a reinforcement learning (RL) framework to discover atomic configurations that optimize those targeted properties. The RL framework will train and work within an action space, tweaking the configurations according to approved steps. A trained neural network will map how shifts in the lattice structure change the properties predicted by the forward model. Once completed, this combined model approach will guide steps to alter a given configuration to one that will exhibit desired properties for target applications. We anticipate that our approach will expedite the discovery of high-entropy materials used in a new wave of technology.

Abstract Name: **Tania Le?n's entre nos: The Art of Underlying Musical Structure**

Pulitzer Prize-winning composer Tania León (b. 1943) is a highly regarded composer, conductor, and arts advocate. León's music reflects her ethnic background and experiences, from growing up and receiving classical music training in Havana, Cuba, to moving to New York City as an adult, where she remains today. This presentation offers a close reading of León's piece entre nos, a chamber work for clarinet, bassoon, and piano. Commissioned by the ensemble Tres Neos in 1988, this work features jagged motives and lively, driving rhythms, perhaps inspired by the group's name, which translates as "young three." Upon initial listen, it might appear as if the work were loosely structured, perhaps a result of the unusual meters and indeterminate-like passages, but there is an underpinning level of organization. In this presentation, I examine León's entre nos from several angles and grapple with the following questions: How does León create formal structure? What rhythmic language does León rely on to propel the music forward with intensity? And what is the harmonic and melodic vocabulary that León uses throughout the piece? By examening the pitch, rhythmic, and timbral content in entre nos, I argue that León creates a sense of return within the work despite the lack of pitch centricity and aleatoric passages. Although the pitches and intervallic structures of the motives shift throughout the piece, León's alternation of what I call "active" and "lyrical" sections offer a coherent framework for the listener to grapple with the seemingly less comprehensible pitch content. Ultimately, this piece, which provides insight into León's compositional process and technique, invites the listener to inhabit the liminal space between what is loosely structured yet feels familiar (e.g., active/lyrical sections), and that which is rigidly notated but seems incoherent (e.g., lack of singable melody or exact motivic return).

Abstract Name: **Killer Switch: MAOA Aggression Gene Allele**

Monoamine oxidase A (MAOA), better known as the Warrior Gene, is a regulator of neurotransmitters that can be natured, nurtured, or in some cases, both. Research has found that low levels of the gene is associated with aggression. Although the gene can be present among some vile serial killers, human beings can fit the criteria for having low levels of MAOA. In order to analyze data on MAOA, peer-review articles, documentaries, and docuseries were used to characterize the gene. An aggression survey scale was used to analyze physical aggression, verbal aggression, hostility, and anger among gender and age. Analyzing MAOA will serve to determine whether serial killers are biologically influenced, environmentally influenced, or both. Based on the documentaries and docuseries, scientists assumed Ted Bundy possessed the gene since he fits the criteria of having low levels of MAOA and being raised in a "healthy" environment, so nature played a role in him being a serial killer. On the other hand, Richard Ramirez and Joseph James DeAngelo Jr. were diagnosed as "nurture" since they were both raised in poor environments that involved abuse. The ANOVA of Physical Aggression revealed to be statistically significant [F(2,155)=3.905, 0.05] indicating that there is a difference in physical aggression among the gender. Females had a tendency of being more physically aggressive compared to their male counterparts. The ANOVA for verbal aggression, hostility, and anger showed no difference among gender and age. Based on the data, the hypothesis of males ages from 18-29 being the most aggressive was proven not to be supported. Human beings may not acknowledge that their aggression levels can be high, thus this research will go more in depth on an individuals' probability to act on a dangerous scale.Keywords: MAOA, aggression, natured, nurtured, serial killers

Abstract Name: Paleontology of an Accreted Terrane, Hunsaker Creek Formation (Permian), Orgon.

Sedimentary rocks of the Permian period (~290-250 million years ago) are exposed extensively throughout the western United States, but are rare within the state of Oregon. The volcaniclastic Hunsaker Creek Formation and the Clover Creek Greenstone outcrop sporadically within Hells Canyon along the western Oregon border. As part of the Wallowa Terrane, they represent strata formed “exotic” to North America in the Permian, far outboard in Panthalassa. Collections on loan from the United States Geological Survey and the Oregon Museum of Natural and Cultural History are being processed with pneumatic air tools to liberate fossils from the hard, dense matrix. Preliminary results show the presence of the brachiopod, Megousia sp., age-diagnostic for the Middle Permian. At least three other brachiopod genera, pectenoid(?) bivalves, crinoid columnals and bryozoans are present and in the process of being identified. These data are significant for future paleobiogeographic studies in comparison with other Permian fauna to aid in determination of paleogeographic positioning of the Wallowa Terrane.

Abstract Name: Recipe for Success: Impact of Implementation of Sensory Safe Cooking Classes for Individuals with Autism

Individuals on the Autism spectrum face numerous social, motor, and sensitivity challenges that can inhibit their quality of life. The sensory issues that accompany the diagnosis of Autism Disorderestablish limitations in the amount of nutritious intake consumed; thus, leaving them in a ceaseless state of insufficient nourishment for reasons exceeding their control. The purpose of this service-learning project was to analyze the impact of the implementation of sensory safe cooking classes for individuals with Autism Spectrum Disorder. We hypothesize that the implementation of sensory-safe cooking classes will allow the expansion of their sensory development and established an openness towards experiencing abundant stimuli through tastes, smells, and textures. Eight participants attended cooking sessions catered to their age group and specific sensory needs. Prior to beginning the cooking session participants were asked to complete a pre-survey to measure their relationship with food. Recipes were designed with clear instructions on how to cook specific items such as Spider Sandwich, waffles, smoothies, and energy bites. Safe food options were provided to prevent overstimulation due to the variety of tastes, textures, and smells. Participants were encouraged to make their meals independently and to try new food items outside of their comfort zone. Participants were encouraged to use the cooking tools necessary for making these food items but were assured that if they did not feel comfortable, someone could provide help. At the end of the session, participants completed post-surveys. . T-test has shown a significant difference (t= -2.376, p= 0.049) regarding the question depicting their openness to trying new foods. This data denotes the benefits that the implementation of sensory-safe cooking classes can have on individuals with Autism Spectrum Disorder and their evolving connection to food, tastes, and textures.

Abstract Name: **Impact of ?-Synuclein Pathology on Excitatory Synapses in Parkinson's Disease**

Parkinson's Disease (PD) is the most common neurodegenerative motor disorder. It is pathologically characterized by aggregates of α-synuclein which are collectively termed Lewy pathology. α-Synuclein is normally highly expressed in excitatory neurons where it preferentially localizes to the presynaptic terminal, however little is known about how Lewy pathology affects excitatory synapses. Our research aims to understand the impact of aggregated α-synuclein on the morphology and abundance of excitatory synapses in the dorsal striatum, a PD relevant brain area.To recapitulate α-synuclein aggregation, we utilize the preformed fibril (PFF) mouse model for templated corruption of endogenously expressed α-synuclein to form insoluble inclusions. Animals received bilateral stereotaxic injections of PFFs into the striatum while monomeric α-synuclein and vehicle injections were used as controls. For synapse morphology analysis at 6- and 12-weeks post injection, we introduced the high-resolution imaging technique Expansion Microscopy (ExM). ExM overcomes the physical limitations of conventional light microscopy by physically expanding the sample in a swellable biopolymer network. Using confocal microscopy, z-stacks of synaptic markers and α-synuclein pathology were acquired in the dorsal striatum. Lastly, the z-stacks were loaded into the IMARIS software for 3D visualization and reconstruction of synapse pairs for quantification and morphology analysis.Using ExM super resolution imaging, our preliminary results show a reduction in the total number of excitatory synapses in the dorsal striatum which indicates synaptic loss 6 weeks after PFF treatment. The data also shows a significant enlargement of vGlut1 terminals containing intrasynaptic α-synuclein aggregates, pointing to a possible impact of small aggregation on synapse morphology.Our results suggest that aggregated α-synuclein causes synapse loss and also affects morphology of excitatory synapses in the dorsal striatum. Furthermore, these findings imply that the presence of Lewy pathology could disrupt excitatory synapses and potentially contributes to overall symptoms of PD.

Abstract Name: **The In-silico and In-vitro Characterization of Epigenetic Drugs (BET Protein Inhibitors and Related BET Pathway Targets) on a Colorectal Cancer Cell Line**

Bromodomain and extra-terminal domain (BET) proteins have been linked to increases in oncogene expression and tumor progression in a wide array of cancers. Previous research on BET proteins has demonstrated that BET inhibitors (BETi) and other drugs in combination can moderately reduce cancer cell proliferation in colorectal cancer. Limited treatments exist for colorectal cancer due to its malignant nature and existing treatments are often costly or ineffective. Our research centers around determining potential BETi in colorectal cancer through in-silico research and testing identified drug candidates in an in-vitro setting. While previous research has been conducted on BETi, few studies examine the effects of BETi in colorectal cancer. So far, we have created a list of one hundred possible BETi drugs. By utilizing a deep learning Cancer Drug Response (Deep CDR) prediction algorithm, we will further narrow down our list of potential drug candidates. We are also working on identifying additional targets in HCT116 cells that are related to the BET protein pathway to expand our research. In order to do this, we are analyzing gene expression datasets using R and ranking candidates related to the BET protein pathway. Once the in-silico analysis is complete, the drugs will be ordered/synthesized and tested on HCT116 colorectal cancer cells. They will be tested through MTT Assays, Western Blot and qPCR and the ones with the most BETi properties as well as the least harmful side effects will be selected. With more BETis available, we hope to increase the number of cancer treatment options for patients.

Abstract Name: **The Effects of COVID-19 on College Students: Pre- and Post-Vaccine**

This research examined the impact of COVID-19 on college students resource loss and stress levels by offering a comparison across pre- and post-vaccine phases of the pandemic. Two research studies will be presented. In spring 2021 (n=155) and spring 2022 (n=256), business school students completed an online survey assessing their resource loss, stress, physical and psychological health, well-being, academic performance and moreduring the global COVID-19 pandemic. In support of COR theory, the 2021 "results demonstrated that students with lower resources (i.e., lower socioeconomic status) reported significantly more resource loss; increases in resource loss were significantly associated with increases in stress; and stress was significantly and negatively related to physical health, psychological health, and well-being. Re-evaluation of resources served as a buffer in the relationship between resource loss and stress." (Murphy et al., 2022, p. 125-6). The 2022 post-vaccine results showed college students reported over five fewer resource losses, but the same levels of stress compared to the pre-vaccine sample. In support of hypotheses from Hobfoll's (1989) Conservation of Resource (COR) theory as well as Hobfoll and Lilly (1993) work on types of resources, students reported a negative impact on stress and resource loss from the COVID-19 pandemic regardless of vaccination status. Further, the effects were more negative for females than males as well as for upper-class students (juniors, seniors, super seniors) compared to lower-class students (freshmen, sophomores). This is one of the first studies to test the differential impact of resource type (personal characteristics,conditions,energies and objects) on the relationship to stress – finding that personal characteristics were the key component explaining most of the variance in stress. Overall, this is the first series of studies to explore the effects of resource loss or gains at two critical points in a global pandemic.

Chan, Catherine

Abstract Name: **Hidden costs of course-embedded research: Can everyone afford to do it?**

Embedding some aspect(s) of open-ended research and creative inquiry in courses can be an effective way of engaging students who have little or no prior exposure to undergraduate research, are unfamiliar with available research opportunities, or those who do not have time to engage in out-of-classroom activities due to other obligations. This can also be a way to expose students to interdisciplinary research where each student brings unique skills and disciplinary backgrounds to the table to explore a research question together. This helps students learn teamwork, problem solving, cross-disciplinary oral and written communication skills, and self-efficacy. However, despite the various benefits of research-infused courses, associated logistical and administrative challenges can sometimes be prohibitive. For example, such courses often have relatively low enrollment caps to optimize faculty-student interactions and research mentoring. The low enrollment cap can put additional pressure on departments where productivity and resource allocation are measured, at least partly, by the total number of students served. Faculty workload and time investment for teaching research-infused courses is also higher than traditionally taught courses, with little or no commensurate compensation, either financially or in consideration towards tenure/promotion evaluation. Course-embedded research may not always align with faculty's primary research agenda, potentially diminishing research productivity measured in publications. Such challenges can often dissuade instructors and departments from offering research-infused courses.In this presentation we combine the perspectives of a faculty and a campus administrator on various facets of research-infused courses. We will present an interdisciplinary team-taught travel-study course as a case study from a faculty perspective where students from different STEM and non-STEM disciplines participated in open-ended research. We will also examine such courses from the perspective of a campus administrator in terms of long-term program growth, student recruitment and retention, and faculty support.

Abstract Name: An Analysis of the Representation of Gender within Children's Books at a University CSD Clinic

Speech-language pathologists are increasingly called to provide culturally and linguistically responsive services (ASHA, n.d.). As a part of meeting this call, SLPs are tasked with using culturally responsive materials, including the use of books that are representative of a wide variety of identities across race, ethnicity, gender, religion and ability (Harris; Owen Van Horn, 2020). Research investigating gender representation within children's books has overwhelmingly found the presence of under representation of women along with pervasive gender stereotypes. The purpose of this research is to analyze the quality of gender representation within children's literature at a university clinic. The research question the study aimed to answer was, "what roles do female and male characters assume in books found within the children's literature at a Midwestern University SLP Clinic, and how do these roles relate to traditional gender stereotypes?"To complete this research project, an annotated bibliography was completed to gain adequate background knowledge. Next, a checklist for analyzing gender representation was formed to code books and pilot data was collected. A random sample of 262 books within the library have been analyzed. It was found that the presence of male main characters was higher than female main characters within narrative and expository books. Another finding was that non-human characters are more common in children's books and have male over representation at a much greater rate than books with human characters. As a next step in this study, the authors of this study will further review the 262 books that have been analyzed thus far and conduct a qualitative analysis of the stereotypes and gender roles. Findings will inform practices for evaluating clinical materials to ensure quality representation of gender within materials used for assessment and intervention services.

Abstract Name: Natural Language Processing for Understanding Persuasive Arguments

The conventional Stance Detection technique for media analysis focuses on the sentiment of the target entity, which often overlooks the source entity giving the sentiment. However, this presents limitations as media sentiments are often implicitly expressed by determining who to report and about what relationships among co-partisans to portray rather than just a face-value assessment of the target entity's sentiment. Instead, our research presents a novel model leveraging techniques from the Event Extraction area to understand media narratives better through the lens of moral events identification and moral value classification. To perform this task, we analyze a set of 10,619 events collected from news articles of various ideological leanings using a comprehensive framework. The events are scrutinized in a triplet-style annotation consisting of an agent, a patient, and a moral event classified according to Jonathan Haidt's Moral Principle Theory. Furthermore, we enhance the model with a graph encoder to summarize entity activities and external knowledge surrounding the entities. Experiments show that our Moral Event Extraction model produces a more precise analysis of moral events and embodied moral values. Our goal is to develop a more robust system that can achieve state-of-the-art performance. We have been investigating the underlying moral foundations embodied by moral events. This will help us better understand the news narratives and answer important questions about what gives rise to ideologies and stances held by media outlets. Moreover, the outcome of this project will assist social scientists to study how disparate media sway targeted audiences differently

Abstract Name: **Designing A Metastatic Breast Cancer Support Program**

Currently, there is a significant lack of community-based support groups for individuals living with Metastatic Breast Cancer (MBC). The majority of breast cancer support groups exist for those who are breast cancer survivors, inadvertently overlooking those given a terminal diagnosis. Additionally, only about 2% to 5% of the funds raised for breast cancer research is spent towards breast cancer metastasis studies. The goal of our research is to create a patient-led, community-based support program for individuals living with MBC. This will require the collection of resources that address the specific needs of this community, which were identified through extensive literary research and comprehensive surveys. The survey we created assessed their backgrounds, capabilities, needs, and desires. Additionally, we conducted 15 one-on-one interviews with MBC individuals to gather information on their past support program experiences and program structural preferences.With this qualitative and quantitative data, we are currently developing the Charlotte MBC Program and plan on officially implementing the program in the spring of 2023. We have partnered with Carolina Breast Friends, a Charlotte-based nonprofit organization centered around providing support and resources to those who are affected by breast cancer. Carolina Breast Friends does not currently have any specialized services for those with metastatic breast cancer and partnering with this organization allows them to impact more lives within the breast cancer community. We plan on housing our program at their Pink House, a unique respite center for breast cancer survivors.

Abstract Name: **Identifying most common concerns of ovarian cancer caregivers reported in online health communities (OHCs)**

Online health communities (OHCs) have been a channel for both cancer patients and caregivers to seek and share informational and emotional support. Leveraging this resource would help researchers and clinicians to identify concerns of patients and caregivers, which may guide future education materials; however, caregiver aspects have been understudied. Thus, this study aims to identify concerns among caregivers of cancer patients through analysis of OHCs. As the first step, we focused on caregivers of ovarian cancer (OvCa), the deadliest gynecologic cancer. Methods: We crawled data from the OHC managed by the National Ovarian Cancer Coalition (NOCC), and de-identified data by replacing it with random numbers . We manually classified whether a post was written by an OvCa patient or caregiver, only selected postings from caregivers. Thefirst coder (RS), a nursing undergraduate student, performed inductive content analysis by identifying keywords and phrases that had similar concepts. The second coder (CC) went through the same process and confirmed the themes. Any discrepancies between two coders were resolved through meetings with a faculty-level researcher (YL). Results: In total, 909 postings were crawled, and only 10 postings were written by caregivers. Eight postings specified their relationships to the patient (1 sister-in-law, 5 daughters, and 2 husbands). The remaining 2 postings did not specify their relationship to patients. We identified three themes: 1) emotional distress of the caregiver, 2) need of medical information for the caregiver, and 3) need of providing emotional support for patients. Discussions: We found that few caregivers used the OHCs regardless of the significance. Further studies may examine the barriers among caregivers in utilizing OHCs. Also, different types of caregivers may have different needs, thus, this relationship needs to be studied further. Our results can support healthcare providers in developing educational resources for OvCa caregivers.

Abstract Name: **Antipaluria urichi and Oecophylla smaragdina as Potential Candidates for Sericulture**

The domestic silk moth, Bombyx mori, is the most highly studied and most widely used organism in sericulture, the industry of silk production. In 2020, the Gross Production Value of silkworm cocoons suitable for reeling was 3,590,971,000 current United States Dollars. This study was conducted to determine if supplementing the silk industry with the silks of the webspinner Antipaluria urichi and the Asian weaver ant Oecophylla smaragdina would be economically viable. A literature review was conducted to consolidate information on Bombyx mori sericulture and the behavior and care of Antipaluria urichi and Oecophylla smaragdina. Antipaluria urichi of all life stages can live in the same enclosures under the same conditions, requiring fewer resources than Bombyx mori, which need different living conditions in the egg, larval, and pupal stages. As Antipaluria urichi feed off of lichens and lettuce, their food can be easily obtained year round, unlike the mulberry leaves that Bombyx mori feed on. One Antipaluria urichi specimen can produce the same order of magnitude of silk length in one day as one Bombyx mori can produce over its 6-8 week lifespan. However, the smaller diameter of Antipaluria urichi silk (100 nm versus 8200 nm) means that Antipaluria urichi produces a much lower volume of silk than a Bombyx mori silkworm. If the collection of Oecophylla smaragdina brood as a food source and the use of Oecophylla smaragdina as a natural pest control agent were combined with the harvesting Oecophylla smaragdina silk, the cost of providing habitation and sustenance for the ants would be minimal since the ants utilized in those industries live outdoors and forage for their own food. A lack of research on the amount of silk used in Oecophylla smaragdina nests prevents estimation of the potential yields of weaver ant silk farming.

Abstract Name: **Creating a Pseudoscience Scale: Identifying Gaps in Critical Thinking in Acceptance of Pseudoscience Topics**

Pseudoscience pervades discourse across the world. Acceptance and consideration of pseudoscience was especially highlighted during the COVID-19 pandemic, demonstrating the threat of pseudoscientific beliefs to public health and the prevention of disease. Teovanović et al. (2020) conducted a study that revealed those who were less likely to participate in guidelines such as hand washing or physical distancing were more likely to believe in pseudoscience practices. Additionally, a study by Desta and Mulugeta (2020) revealed that the spread of pseudoscientific beliefs related to COVID-19 had a negative effect on the containment of COVID-19. Across the world, researchers recognize the importance of understanding the origins of pseudoscientific beliefs. García-Arch et al. (2022) created a validated psychometric tool to measure a range of pseudoscientific beliefs, though this scale was developed and validated in Spain. Our goal is to create a pseudoscience scale focused on specific medical beliefs within a United States sample. This is particularly important as pseudoscience beliefs can vary significantly across cultures. We aim to investigate how pseudoscientific beliefs about health and medicine in the United States correlate with intelligence and critical thinking. We created a survey which was distributed electronically to college students, with a goal of obtaining at least 100 responses across different school levels and other demographic characteristics. We began data collection in fall 2022 and plan to continue throughout winter and spring of 2023. This study will contribute to knowledge about what gaps in logic or critical thinking contribute to acceptance and belief in pseudoscience. We hypothesize that individuals with lower levels of critical thinking and intelligence will indicate higher agreement with pseudoscientific ideas. The analysis will aid us in more effectively targeting people with pseudoscientific beliefs in an effort to reduce the acceptance of pseudoscience.

Abstract Name: **An application of a generalization of Artin's primitive root conjecture in the theory of monoid rings**

The notion of "factorization" extends far beyond the familiar realm of integers and polynomials. While efforts in Number Theory have shown that prime factorization is guaranteed in not only the domain of integers, but in lots of other structures, the computation of such factorization is highly nontrivial. This paper opens with a result from on the irreducibility of binomials over zero-characteristic polynomial rings, and will cover the consequences of allowing finite fields and restrictions to exponents. The results from such work include a classification of primes satisfying the factorization criteria, as well as a computer-assisted approach on generating such primes, and an investigation of their theoretical density under Artin's primitive root conjecture.

Abstract Name: **Virtual reconstruction of 2000-year-old Herculaneum Scrolls**

The city of Herculaneum was buried by mount Vesuvius in 79 A.D. alongside Pompeii. Because of the way the city was buried by the pyroclastic flow, organic material was better preserved than in Pompeii and notably thousands of carbonized scrolls were found inthe famous library at the Villa dei Papiri. Most of these scrolls are damaged beyond recongnition and are too fragile to be read by traditional methods. Our research aims to improve and build upon methods to digitally study these scrolls without inflictingfurther damage on the artifacts. For the scrolls that were opened in the 1800s and now find themselves mostly broken into multiple fragments called 'Pezzi', multispectral photographs were taken by our team in Naples, England, and Paris. We have improved the process of image registration and blending for these multispectral images. As for the scrolls that remain closed, the Herculaneum project aims to CT Scan them and apply our virtal unwrapping pipeline to virtually unroll these scrolls, in a process similar to the virtual unrolling of the En Gedi scroll lead by Dr. Seales in 2015. The complexity of the Herculaneum scrolls, however, requires a new approach in segmentation and ink identification. We have developed a new tool to carry out preliminary segmentations of the scrolls and tested our algorithm. The research prospectus includes the application of the machine learning algorithm for carbon ink identification developed by Parkeret al. 2019 to our newly obtained segmented fragments in order to reveal the content of the two-thousand-year-old scrolls.

Abstract Name: Men's Mental Health on College Campuses

Men's mental health is a topic that has seen an increase in attention recently, primarily due to a growing focus on societal roles and expectations surrounding gender. The subject of toxic masculinity – how it can be reinforced by society and the very men it effects, how its outcomes reinforce the behaviors it creates, and how it negatively impacts the mental health of men at every level – is an especially important topic due to how toxic masculinity affects men's relationship with their mental health. I thus explore the relationships between men and their mental health on college campuses specifically, by asking: "Are men suffering from mental health on college campuses currently undergoing a crisis?" and "Is the subject of men's mental health currently going unacknowledged?" Through mixed methods research involving a survey (N = 253) of UW-Stout students and individual interviews, trends were found regarding views on men's mental health. Participants largely agreed that the subject does not receive the attention that it needs or deserves, and that there are several issues regarding how society treats it. Students almost universally answered that they view men who suffer from mental health as stronger, but that they believe the public would do the opposite; that men are encouraged to internalize their struggles; and that progress needs to be made to combat toxic masculine gender roles. This project provides insight on societal views about toxic masculinity and men's mental health, an extremely important topic to better understand to shift and improve traditional gender roles and expectations that cause harm to men.

Abstract Name: Effects of seasonality on the infection intensity of the amphibian skin pathogen Batrachochytrium dendrobatidis on crayfish

Batrachochytriumdendrobatidis(Bd) continues to be a major contributor to global amphibian declines and lowers the quality of life of manyother creatures. Bd is a chytrid fungus that causes mortality of many amphibians and is known to damage the gills of crayfish. As potential carriers of Bd, crayfish are likely a major source of moving Bd from one aquatic habitat to another. Such aquatic environments are essential for amphibian life history patterns. One way to test the overall health ofan aquatic environmentregardingBd is to measure Bd levels in potential carriers. Since the crayfish carapace is constantly interactingwith the external environment, it is a convenient location to take these measurements. However, periodic molting can impactthese levels and skew the results. A more reliable indication of Bd prevalence and intensity in the crayfish population can befound by measuring the Bd levels in the GI tract, as it is known to embed here as well.This project investigates the seasonal Bd infection prevalence on a local crayfish populationby collecting DNA with swabs(carapace and GI tract)and by confirming infection intensity with pathogen specific real-time PCR (qPCR).

Abstract Name: **AI-mediated structure prediction reveals patterns in prion misfolding**

The precise function of soluble prion protein (PrPc) remains unknown. PrPc has been found to misfold and form a pathogenic isoform PrPSc that includes significant beta-sheet content. This same pathogenic isoform has been linked to many diseases like dementia, Familial Fatal Insomnia and Creutzfeldt-Jakob disease. To date, NMR or crystal structures have emphasized a well-structed core region spanning residues cystine 179 to cystine 214. Notably, many mutations that confer disease impact this region of the prion protein, especially the polypeptide segment containing residues 187-194, comprising the prion protein C-terminal globular region. The purpose of my research was to find patterns that influence the formation of pathogen β-sheets in prion protein. I focused on understanding how the substitution of aliphatic amino acid valine (V) at position 210 to different amino acids perturbs the folding of prion protein globular regions by examining known NMR and crystal structures of prion proteins.The predictions obtained by substituting amino acid V210 to other amino acid with different properties ended up affecting segment 187-194 that ended up forming β-sheets for certain substitutions. Those results when compared to NMR and crystal structures led us to believe theresults could potentially be classified as pathogenic prion protein structures. This will need further research to which we are working on.

Abstract Name: **Solar Cycle Variability and its effect of Geomagnetic Activity**

Variation of Sun's magnetic field and its activities are governed by an 11-year cycle, called the solar cycle. Solar cycle influences the activity on the surface of the Sun, resulting in sunspots which are caused by the Sun's magnetic fields stretching and becoming intertwined.The highly active Sun during solar maxima emits higher volume of radiation, higher energetic charge particles with magnetic flux and thus create hazardous space weather and can affect Earth’s atmosphere too. In this research, we are presenting the variability of solar activity in solar cycles 23,24 and its influence on geomagnetic activities. We have studied sunspot numbers, F10.7 flux, solar wind speed, and Coronal Mass Ejection (CME).For solar activity, we are using GOES, ACE satellite data. For geomagnetic activities we are usingKp,DsTindex data. We are categorizing the geomagnetic activity data for low latitude (0-250), mid latitude (250-500), and high latitude (>500).Understandingsolar activity and its effects onspace weather and Earth’s atmosphere is highly important.Thisworkwillbehelpfulin buildingaframework foranempiricalmodel for future solar activity prediction.

Abstract Name: Building a 1/16th scale autonomous car incorporating 3D LIDAR technology

Much research on automated vehicles has been carried out since Tesla developed the Autopilot feature on its cars. These Tesla cars use old-fashioned cameras and visualization methods, using machine learning to create the Autopilot feature. Despite the significant amount of research published on these systems, minimal research has been conducted on autonomous vehicles using the 3D Lidar SLAM (Simultaneous Localization and Mapping) technique. Hence, this study aims to investigate the accuracy and efficiency of the 3D Lidar technology on autonomous scaled cars. The study is carried out on the ROS (Robot Operating system) platform using a multi-step process. First, the vehicle is tested on the simulation environment of ROS, called the Gazebo environment, by developing a simulated map of the environment. Next, the car is tested in a natural environment by using 3D Lidar to scan the environment. This information is then used to create a map and implement SLAM by a path planning algorithm called "follow the gap" and "wall following." The benefits of building a 1/16th scaled autonomous vehicle include cost-efficient tests and the ability to be tested anywhere without harming anyone. Furthermore, these algorithms can be tested on life-sized cars to create an autonomous vehicle by considering more advanced algorithms like Traffic-Aware Cruise control, auto lane change, etc. Ultimately, this project can potentially make significant positive steps toward ensuring the safety of drivers and passengers alike.Keywords: Scaled autonomous vehicle, 3D Lidar, ROS, SLAM, Path planning algorithm, cost-efficient, safety.

Abstract Name: Camera-Based Vital Sign Detection for Telehealth

Although telehealth costs prove to be expensive, there is an alternative when it comes to measuring vitals that can help telehealth be more cost-efficient. The alternative consists of collecting photoplethysmography (PPG) signals using a method called remote photoplethysmography (rPPG). From these signals, the objective of measuring vitals using a form that does not require any costly physical devices other than a camera is possible. From these PPG signals, a heart rate is measured by taking the maximum power density in the filtered signals and is then multiplied by 60. A rPPG model programmed in Python is tested by inputting a data set of diverse human faces and retrieving the accuracy values which are measured in beats per minute. The root mean square error (RSME) is taken and compared to other models. The data is further broken down to show that the darker the skin color is, the harder it is for the program to extract accurate PPG signals.Despite having an accuracy of ~8 beats per minute (BPM), the model tested lacked robust motion tracking and region of interest (ROI) reduction. The model can be improved by adding in landmarks on the ROI to keep the skin pixels tracked and reduce false movements. ROI reduction can help in keeping the algorithm centered on the important features on the face where PPG signals can best be extracted (the forehead and the cheeks). From the PPG signals, it is also possible to get oxygenation and blood volumes. Despite telehealth's massive success in terms of approval, the addition of remote vital measurement methods can significantly improve the ability to mimic hands-on processes and can help make telehealth more accessible to people with lower incomes or no health insurance.

Abstract Name: Asynchronous Discussion Boards Through Text or Video: Does the Modality Affect a Student's Involvement and Interaction in a Course?

Asynchronous discussion forums in both online and face-to-face courses provide an opportunity for interaction, collaborative problem-solving and hold potential for increased content mastery. While traditionally, these discussion forums occur via text-based postings, there has been an increase in technology and course design that allows for video-based discussions. For instance, a previous study concluded that students believed the asynchronous video discussion to have improved their social presence with their peers in the course. This study compares text-based vs. asynchronous video-based discussion forums within an anatomy and physiology of speech and hearing course, to better understand their respective values in supporting content understanding, connections, and relationships. Half of the class will complete discussions on each unit through text-based discussion only, while the other half will discuss through video postings. The groups will rotate the modality of discussion in every unit. In the video modality, the students will be replying to their group members' video posts with an additional video, without a limit on the number of replies. The same will apply to those assigned the text modality for that week, where the posts and replies will be in text form alone.Student submissions via each modality will be evaluated for their accuracy in addressing outcomes, their social presence and contributions in the group, and their perceptions of the design of the task. This is based on the Community of Inquiry (CoI) framework which analyzes the social, teaching, and cognitive presence involved in creating a purposeful educational experience. At the end of the experience, students will complete a survey outlined by the CoI framework to share their feedback and impressions of both modalities.

Abstract Name: Examining Challenges Facing Women Pursuing Doctorate Degrees in Ghana

While women's participation in education in Ghana has improved significantly over the past years, data suggests that women are still missing at higher levels of education, especially at the doctorate level. The challenges of doctorate studies for women have been linked to societal expectations of a woman. This study examined gender-specific differences in the key identity transition to a scholarly identity for men and women pursuing PhDs in Ghana to help identify challenges specific to women. Grounded on the social identity theory and using the phenomenological hermeneutic approach to qualitative research with semi-structured interviews as a data collection tool, this study captured the experiences of 6 male and 6 female students at the University of Ghana. Data was analysed thematically. Themes were identified considering pre-existing themes in the literature and new themes that emerged. The results revealed that women in Ghana navigate greater complexity than men while on their PhD journeys and face greater challenges because of their gender identity. Men, on the other hand, do not have to navigate the same complexity and do not face as many challenges as women. Stakeholders need to pay attention to the individual contexts of PhD students, especially women to encourage more women in Ghana to enrol in and complete their doctorate studies. This study contributes to the existing literature on gender in education by uniquely explaining how a social construct like gender identity impacts women's socialization into academia differently from men, particularly at the doctoral level. It also offers a gender comparative perspective that similar studies have failed to do. This paper tackles issues related to educational inequity at the doctorate level, which has implications for policymaking in higher education and development in Ghana. It also contributes to SDG 4: Quality Education, SDG 10: Reduced Inequalities and SDG 5: Gender Equality.

Abstract Name: **Mind Library**

As part of the ICUREUS program here at Carleton , I am working with Dr Jim Davies to create software using Open AI's GPT-3 to create an interactive AI. The algorithm is the most powerful language model, creating human-like text. Our project would have users' past inputs to create useful information that could be used in the present. For example, if the user wrote a book ten years ago , the software would create insight from past input (the book) and generate information that would be useful in working on a present project. We were drawn to GPT-3 due to its use in diverse ways dealing with grief to writing articles .GPT-3 has impressive language capabilities, like its ability to create interactive human like conversation .Our software's goal is to maximize efficiency by alleviating the user from tedious amounts of cross reference on information they already know but just lost track of, like a mind library. It would be like talking to a 2015 version of yourself, how cool is that? Ideally, this project would result in an open-source piece of software that anyone would be able to apply to their own writing. Key performance indicators are ofcourse desired outputs from the model and accuracy .We expect to use huge amounts of unstructured data to test our programs . Working with AI we would need to to design and create the software and work within Google's People+Ai guidebook.To make our software user friendly.

Abstract Name: **Exploring Neuronal Structures of Male C. elegans at Elevated Temperatures**

Across many organisms, including the nematodeCaenorhabditis elegans,as temperature fertility decreases. We have found that in maleC. elegans, the main effect of increased temperature on fertility is in changes to their mating behavior. When stressed at higher temperatures, we have shown that maleC. elegans were less likely to find a mate and that they prioritize food over mating. We predict that there may be changes to their neuronal structures or signaling leading to these behavioral changes. To further understand this, I imaged CEM neurons in the male head and the RnB neurons in the male tale to determine if there were changes to neuronal number or architecture in temperature stressed males. Both neuron types are involved in male mating behaviors. Neurons were imaged in three different C. eleganswild type backgrounds: JU1171, LKC34, and N2. I predicted that when comparing temperature stressed males to unstressed males, temperature stress will cause the neurons to change shape, such as shortening or elongating. I found that there were increased defects in the RnB neurons at elevated temperatures in all three strains, but none in the CEM neurons. However,the CEM neurons in LKC34 showed an increase in length. Lastly, for the RnB neurons, in JU1171, neurons in rays 4, 5, and 7 showed an increase in length at higher temperature; whereas forLKC34,there were increases in neurons in rays 2, 3, 4, 5, and 8; and in N2, there was only a significant difference in ray 7. Therefore, we can confirm that at high temperatures, there are an increased number of defects, but that the change in behavior is not necessarily attributed to the CEM or RnB neurons.

Abstract Name: **In-Silico Study of Antisense Oligonucleotide Antibiotics: Porphyromonas gingivalis and Beyond**

Background: The rapid emergence of antibiotic-resistant bacteria directly contributes to a wave of untreatable infections. Most antibiotics today are small molecular compounds that block vital processes in bacteria, ultimately hampering growth. To achieve such effects, the 3-dimensional structure of the targeted bacterial protein must be resolved through purification, followed by X-ray crystallography or NMR. However, such a task is time-consuming and tedious. Thus, improvement in antibiotic development is imperative. Recently, a promising therapeutic technology has emerged that acts directly on mRNAs, the precursor of proteins, causing their degradation. Doing so means there is no need to determine protein structure as the sequence is readily available. This class of therapeutic technology is called antisense oligonucleotides (ASO). ASO is a short (19-20 nucleotides long) single-stranded sequence composed of modified DNAs and is a complement to the target mRNA. Upon hybridization, it will either trigger endonuclease-dependent degradation or exert steric hindrance to protein translation. This study aims to design a bioinformatic pipeline to identify unique 20-base pair (20mer) ASOs that target essential bacterial proteins. Furthermore, potential ASOs will be ranked by RNA secondary structure, RNA binding protein, phylogenetic conservation, and GC content. Results: We obtained the gene sequences of 66 bacteria from the Database of Essential Genes. The number of essential genes per bacteria ranged between 105 and 1265. Using RStudio Cloud, we developed a program to break down genes into overlapping 20mers, which were saved in a FASTA format. Discussion: To prevent off-target effects, we intend to use BLASTN to identify unique 20mers and rank them per the parameters above. By working towards a pipeline to identify unique and significant 20mers, we are one step closer to developing novel ASO antibiotics.

Abstract Name: **Loneliness and Adjustment in Young Adults: Respiratory Sinus Arrhythmia and Sleep Disturbances as Moderators**

Loneliness is a pervasive concern among young adults (Victor; Yang, 2012) that is negatively associated with mental and physical health (Peltzer; Pengpid, 2017). The present study examined the role of two bioregulatory factors, parasympathetic nervous system functioning and quality of sleep, in mitigating the detrimental impact of loneliness on young adults' mental health symptoms and well-being. Participants were 188 (71.8% women; 77.1% White) undergraduates at a liberal arts college in a rural U.S. community. Parasympathetic activity, indexed via respiratory sinus arrhythmia (RSA), was measured from electrocardiogram and thoracic impedance data collected during a 3-minute resting baseline period. Young adults self-reported loneliness, sleep disturbances, anxiety and depressive symptoms, and well-being using well-validated measures. Regression analyses revealed that higher loneliness was associated with higher anxiety and depressive symptoms and lower well-being. However, there was also a robust and consistent pattern of three-way interactions, such that the combination of high baseline RSA and low sleep disturbances protected young adults from elevated anxiety and depressive symptoms and lower well-being in the context of high levels of loneliness. These results provide the first evidence that high baseline RSA and low sleep disturbances together attenuate the association between heightened loneliness and maladjustment, which could inform strategies for coping with loneliness among young adults. Interventions that incorporate elements of both sleep education and deep breathing exercises, which may increase parasympathetic activity (e.g., Obradović et al., 2021), could be particularly valuable for protecting young adult mental health and well-being against interpersonal stressors such as loneliness.

Abstract Name: Women Composers of Modern Flute Music

Katherine Hoover, Libby Larsen, and Lisa Bost-Sandberg are three excellent examples of women composing flute music in this modern age of music. Their music outlines some of the best solo flute compositions from recent times, using extended technique and unique sounds and timbres. Three compositions stand out for their excellence in all of the above areas when it comes to these composers; these are Katherine Hoover's Kokopeli, Libby Larsen's Aubade, and Lisa Bost-Sandberg's Diandya.
Kokopeli, by Hoover, is about the Kokopeli of Hopi legend, who was a great "mahu," or hero, and also a flutist. His sounds are said to have echoed through the great canyons and cliffs of the Southwest throughout his travels. Hoover captures these ideas through echoing lines and distinct melodies. Aubade, by Larsen, captures the idea of the morning light and greeting the dawn through its free melodies and vibrant nature. The word itself means morning music, which is music played to welcome in the dawn. The piece contains extended technique through the use of wide vibrato and flutter tongue. Diandya, by Bost, is a piece that pushes the boundaries and limits of the flute. It has many extended techniques, such as pitch bends, harmonics, glissandi, improvisation, and altered pitches. Performers are challenged as they work through this gorgeous piece.
Performing pieces by women composers is really important, since works by men have dominated the field of music for a long time. It's also important to play pieces by living composers, which includes Aubade and Diandya, since many performed works are works from people who have been gone for centuries. Performing works by living composers allows us to have a direct link to the composer.
Kokopeli, as performed by Oriana Cheney on 12/13/21

Abstract Name: Data Augmentation for Improving Sentiment Analysis in Software Engineering

Natural language processing (NLP) is an essential key component in the subfield of artificial intelligence for human language analysis. It is utilized by numerous deep-learning models to perform tasks such as sentiment analysis, machine translation, and information retrieval. However, such models continually face limitations of performance accuracy when applied to a domain specific corpus, such as Software Engineering. As the amount of data accessible online is scarce, we propose a strategy to improve the accuracy and efficiency of NLP tasks by performing data augmentation in the transfer learning phase. Thus, in this study, we quantitively evaluate the performances of six versions of text-generating tools by optimizing them for sentiment analysis in Software Engineering domain. Our qualitative evaluation will advance our understanding in devising strategies to improve accuracies of domain specific NLP tasks

Abstract Name: **Parental Criticism and Willingness to Intermarry**

Willingness to marry someone of a different race is influenced by racial climate. How parents respond will impact how they present preferences for partnering to their children. Research suggests a relationship between race, gender, partner preferences, and parental criticism in partnering. This study examined the impact of race relations on marriage preferences and the role parents have in willingness to intermarry. Participants (n=207) completed a survey containing the Family Emotional Involvement and Criticism Scale I and the Personal/Global grid survey, which measures willingness to partner with someone outside of their race. First, we hypothesized that parental criticism would correlate with the likelihood that participants would partner with someone outside of their race. Data revealed no relationship between criticism and willingness to intermarry for men, but for women this relationship was significant (r=.166, p=.040). The second hypothesis was that race and gender impact partnering with someone outside their race. No differences were found. Findings can inform family therapists and educators individuals willingness to partner with people outside of their race.

Abstract Name: **Charactering Biohybrid Microswimmers as A Potential Targeted Drug Delivery System**

Guided drug delivery has evolved in recent years to allow for more effective treatment of diseases such as cancer. Cancer is often treated with intravenous chemotherapy which often involves a myriad of unwanted side-effects. In order to achieve reduced side effects and increased treatment efficacy, an innovative method would be desirable if it allows delivery of therapeutics to targeted regions instead of the body being infused with the medication. Chlamydomonas reinhardtii, biflagellate unicellular green algaes with strong positive phototaxis, may serve as a promising guided drug delivery system. The goal of this project is to utilize the phototactic properties of the algal cells that are loaded with therapeutic microspheres as cargos and direct these biohybrid microswimmers with a focused light source. We have developed effective procedures to bind microspheres to algal cell bodies. A large number of cells under various loaded or lighted conditions were recorded under a light microscopy. Their moving trajectories and velocities were tracked frame by frame using a particle image velocimetry (PIV) software. Our preliminary results showed that these algal microswimmers moved at relatively more consistent directionality towards the guided light source, compared with random moving orientation without the guided light. This study will pave the way for further characterization of the novel biohybrid microswimmers as a potential targeted drug delivery system.

Abstract Name: **Researching a Model for Community Revitalization in Urban Environments**

Over the past century, there has been an increased interest in revitalizing urban environments and communities. Revitalization is defined as the act of "giv[ing] new life or vigor to [something]" (Merriam-Webster, n.d.). Because of the lack of specificity of the above mentioned definition, individuals, groups, and organizations who have researched or undertaken a project related to revitalization have interpreted the end goal of urban revitalization differently. As a result, some initiatives have focused on the goal of stimulating the economy through tourism; others have sought to make cities more environmentally sustainable; still others have aimed to uplift communities out of poverty. For the purpose of this study, the primary emphasis of urban revitalization will be the alleviation of poverty and increasing opportunity among disadvantaged communities. The student will conduct secondary data analysis to explore the issue of urban poverty, consider the proposed Mondawmin model in Baltimore, Maryland, and examine the applicability of the model to other urban areas. Ultimately the primary objective of this research project is to investigate a collaborative, non-governmental approach to revitalizing impoverished urban communities, focusing on unifying the private sector, churches, non-profit agencies, and social workers.

Abstract Name: **Fetal hematopoietic stem cell metabolism in response to varying prenatal folate status**

Folate-mediated one carbon metabolism is essential for de novo nucleotide synthesis, cellular methylation, regulation of mitochondrial metabolism. These processes are critical to the maintenance and development of hematopoietic stem cells (HSCs). HSCs are generated during fetal development and are responsible for generation of all blood cells across the lifespan. Universal folic acid supplementation of the population is currently utilized for the prevention of common birth defects, but there are currently no known studies on the influence of prenatal folic acid supplementation on the development of HSCs. To examine the effects of prenatal folic acid supplementation on HSC function, wild type C57BL/6 female mice were weaned onto one of three diets, 0mg/kg (folate deficient, FD), 2mg/kg (folate control, FC), or 8mg/kg (folate supplemented, FS), and mice were timed mated to generate litters under each condition. Both FD and FS significantly decreased fetal weights at embryonic day (E)14.5 as compared to FC offspring. Despite growth restriction, profiling of the developing hematopoietic compartment using flow cytometry at E14.5 revealed overall expansion of all blood cells in response to FD as compared to FC offspring, whereas all blood cells were significantly reduced in FS offspring. Increased blood cells in FD offspring were driven by expansion of HSCs and all downstream progenitor and mature cells. In contrast, FS caused decreased mature myeloid and lymphoid cells at E14.5, whereas hematopoietic stem and progenitor cells (HSPCs) were unaffected. To determine the underlying mechanisms of varying prenatal folate on hematopoietic output, we metabolically profiled E14.5 HSPCs to determine OXPHOS (oxidative phosphorylation) and glycolytic activity. Preliminary results show that FS offspring exhibited higher rates of glycolytic activity as compared to FC offspring. Additionally, FS offspring had higher OXPHOS activity per cell as compared to FC offspring. These data reveal that prenatal folate alters HSPC metabolism during fetal life.

Abstract Name: **Understanding how changes in precipitation intensity will affect vegetation in the western U.S.**

Precipitation events are becoming more intense as the atmosphere warms, but it remains unclear how precipitation intensification will affect plant growth in arid and semiarid ecosystems. There is conflicting evidence suggesting that larger precipitation events may either increase or decrease plant growth. Here, we report the growth responses of herbaceous and woody plants to experimental manipulations of precipitation intensity in a cold, semi-arid ecosystem in Utah, USA. In this experiment, precipitation was collected and redeposited as fewer, larger events with total annual precipitation kept constant across treatments. Results from the first two growing seasons revealed that more intense events 'pushed' water deeper into the soil, leading to an increase in woody plant growth. To provide a longer-term and more mechanistic understanding of this response, here we will be analyzing an additional two years of shrub stem radius growth, soil water content, new root growth, root area, and herbaceous plant growth. Additionally, we performed a depth-controlled water tracer experiment to describe grass, forb, and shrub rooting distributions in different treatments. Results have implications for understanding the increase in woody plant abundance around the world in the past 50 years, a phenomenon known as shrub encroachment, and for forecasting semi-arid ecosystem responses to climate change.

Abstract Name: **Measuring the Flory-Huggins Interaction Parameter, Chi, of the PS-P4VP Supramolecular System**

The Flory-Huggins interaction parameter () is an important tool in determining the solubility of a polymer in a solvent. In most polymers, the parameter is measured by comparing it with a wide range of solvents with varying interaction parameters. Then, the interaction parameter of the polymer sample can be determined empirically from this data. Supramolecular polymer systems contain a side group that facilitates secondary bonding, to which molecules may bond. This property makes these materials highly tunable, adjusting what functional groups are introduced and their quantity. The subject of this experiment is the Polystyrene-b-Poly(4-vinylpyridine) block copolymer system. The pyridine side group of this system allows other molecules to hydrogen bond, modifying the arrangement of the chain. These systems have plenty of potential. Beyond their tunability, they also may have applications in nanolithography, the process of creating nano-scale patterns on a substrate. With the increasingly smaller electronic scales, the ability to create highly detailed and patterned nanostructures is highly desirable is generally unknown for supramolecular systems. Thus, empirically measuring for the system is valuable, as this helps with the processing and applications of the material. The goal of this study is to determine this parameter.

Abstract Name: **Universal Kryptonite: Funding Education and Monitoring in Dunn County, WI**

Lakes Menomin and Tainter are EPA-designated impaired waters in Dunn County, Wisconsin. One of the culprits for this impaired designation is nutrient runoff from agricultural land, a form of nonpoint source pollution that causes harmful algal blooms in the lakes that restrict recreation and can be toxic to humans and animals. Through a process of interviews, transcription, and thematic coding, this research explores the policy landscape governing nonpoint source pollution, alongside the education, monitoring, and funding challenges faced by local policy actors. Two main concerns were identified: educational gaps relating to nonpoint source programming, and a need for consistent sampling of water bodies and tracking of policy effectiveness. Stakeholders reported that agricultural producers are often unaware of the policy compliance expected of them, while non-farming community members are uneducated on how to keep excess nutrients out of the lake. Minimal staff capacity and funding for this outreach puts pressure on current employees to fulfill educational duties outside of their job descriptions or skillset. Stakeholders also reported a lack of consistent monitoring and sampling of water bodies. Without data showing other impaired waters in the area, the county may be less competitive for water quality grants. The county has also experienced difficulty monitoring landowner compliance with nonpoint source programming, thus impacting its ability to quantify where nutrient runoff is coming from. Ultimately, funding challenges underlie education and monitoring concerns and restrict local government's ability to perform necessary communication and sampling. This poster recommends that the local land and water conservation division hire two new positions, one dedicated to education and outreach and another focused on monitoring policy compliance and sampling of water bodies.

Abstract Name: **Spatial Footprint of Uranium Above Water Table**

In Riverton, Wyoming, traces of uranium are found in groundwater after being leached from the surface during flooding events near the Little Wind River. The objective of this experiment is to investigate and locate where most uranium resides in fourteen different locations and depths in order to understand how it mobilizes. Since uranium in water can cause long-term health issues when consumed, identifying the origin and how it mobilizes can help prevent uranium from entering our waters. In order to find how uranium mobilizes within soil, iodide with water was used to trace the movement of the infiltrated water. The method used to calculate the amount of iodide and uranium is called the standard deionized water extraction. In this method, deionized water is used to leach off any material or substance such as iodide from the soil. After adding deionized water with the soil, they are later stirred and centrifuged for hours, where certain particles are now in the water. The sample is later decanted and filtered for testing, where the data is graphed on a chart displaying where iodide and uranium are found within varying depths and locations of soil. The expected result is to find high levels of iodide in areas it originally seeped through with water while high levels of uranium would be found away from the location from where it first flowed due to the mobilization of groundwater. The findings will help understand more on how uranium mobilizes through soil and help better predict where uranium might be if ever leached from the sediments above the water table. The use of standard deionized water method can apply to other substances and can identify the quantity of the element.

Abstract Name: **Impact of Autonomous Vehicles on Roundabouts at Various Penetration Rates and Automation Levels**

Technologies have been developed in response to the various traffic demands, especially the increasing traffic volume and congestion. The modern roundabout provides enhanced efficiency and safety performance of intersections with fewer traffic enforcements to drivers. Roundabouts also decrease vehicle idling by reducing stop-and-go vehicle traffic caused by traffic signals or stop signs. Despite its geometrical and operational benefits, roundabouts are less preferred than signalized intersections due to the higher complexity and increased uncertainty associated with human engagement in multi-lane roundabout operations. Autonomous Vehicle (AV) technology has been considered a solution to minimize the uncertainty of human driving behaviors. Driving assistance of AVs minimizes the driver's contribution to vehicle operation and reduces car accidents by decreasing human errors and inconsistent driving behaviors. The purpose of the study is to investigate the impact of Autonomous Vehicles on the performance of microscopic roundabout simulation models. Single- and double-lane roundabout models were developed, and roundabout priority rules were determined using a proper calibration of microsimulation parameters to evaluate the impact of AVs under different AVs penetration levels and levels of automation. The roundabout performance was investigated in terms of the intersection level of service, the average total delay, the average stop delay, the average queue length, and the maximum queue length. The results indicate that the higher AV penetration level effectively decreases the average total delay and the average stop delay in a single-lane roundabout. It was observed that AV penetration levels contributed less to reducing delay time in a double-lane roundabout. This tendency may occur due to the complexity of yielding logic and critical gap decision in a double-lane roundabout. The higher level of automation decreased the average total delay, the average stop delay, and the queue length due to its higher sensitivity to vehicle interaction and yielding logic.

Abstract Name: **Characterizing an Exoskeleton Device for Leg Muscles Rehabilitation**

Stroke patients very often suffer from disability and are unable to walk freely. To regain their mobility, they need rehabilitation exercises. Commercial exoskeleton devices are availble but these are either very expensive or do not fulfil the patient's particular exercise requirements. An ongoing project at the San Jose State university is engaged in designing and developing an exoskeleton knee brace that will be cheap and will be user friendly [IMECE 2020, 2021, 2022, SCCUR-2022]. This knee brace relies on the fluidic muscles (Festo Corp) that use air pressure to mimic the leg muscles movement. The device consists of two parts, an upper brace for the front of the thigh holding the fluidic muscles and a lower brace behind the calf. The operating system includes a central control box that contains multiple solenoids and valves that are controlled by a central microprocessor (Arduino). The central system was activated by EEG sensors that were mounted on a human leg to activate the exoskeleton device. The EEG sensors' response was further processed for the noise reduction and was amplified by using an amplifier. Five fluidic muscles were characterized and calibrated before mounting them on a mannequin leg. Further experiments helped to optimize the knee brace design to mount it on a human leg. Experiments were performed to characterize the device operation by measuring the average leg rotation time and the maximum rotation angle as a function of applied pressure. Experiments show that the average time to reach the maximum rotation angle varied from 18 to 36 degrees where the rotation time varied from 1.58 to 1.23 seconds as the pressure increased from 30 to 60 psi. The presentation will detail the design and the operation of the exoskeleton device and will also describe the experimental results in a greater detail.

Abstract Name: Understanding the LDS Indian Student Placement Program

Operated by the Church of Jesus Christ of Latter-Day Saints from the late 1940's to 2000, the Indian Student Placement Program removed indigenous childrens from their homes on reservations to live with LDS (Mormon) families and attend school for nine months out of the year. Since its conception, the program has received a great deal of criticism, both due to its ties to colonization and its effect on indigenous families. Examining the historical context of the program is difficult, as most historical accounts and data regarding the program have been published by the Church. Through an analysis of speeches and magazine articles published by the Church during this period, it is possible to reconstruct Mormon cultural attitudes regarding Indigenous people, which can then be used to critically examine LDS accounts of the program. This project uses the speeches, talks, and articles of Mormon Prophet Spencer W. Kimball to assess the Church's messaging and attitudes during the program's peak, and then it applies this assessment to modern records and analysis of the program to demonstrate how these attitudes continueto affect scholarship about the program. Using this evidence, the project calls for more scholarship uplifting the voices of those indigenous communities that have been impacted by the Indian Student Placement Program.

Abstract Name: Transcription and Translation: Challenges, Methods, and Lessons Learned from Translating Spanish Language Oral History Interviews

Oral history interviews are a method of qualitative research that provide opportunity for stories to be heard that may otherwise be left unnoticed, in order to learn from these stories and enable change based on the perspectives that are shared. Voces del Campo/Rural Voices is a research project that aims to document and preserve the life experiences of people in Wisconsin, specifically in the Latinx community, by conducting oral history interviews. Given that Spanish is the primary language of many of the interviewees, transcription and translation of these interviews are key steps in the documenting and sharing of these experiences with a wide audience. Neither process is as straightforward as it may seem and can have crucial impacts on the integrity of the interviewee and the quality of data provided by the interview. This research first intends to explore methods of translation and transcriptions including naturalized versus denaturalized transcription and semantic versus contextual equivalence in translation. Furthermore, challenges such as accuracy, slang, word equivalency, figures of speech, and translator cultural competence and language familiarity will be examined. This will be accomplished by analyzing previous literature on these processes and offering a student perspective from the Voces del Campo project. Finally, a discussion of the lessons learned from transcribing and translating oral history interviews highlights the significance of the responsibility transcribers and translators have in accurately conveying the stories of the interviewees and the significance of the trust placed in them to do so in a respectful manner and offers practical advice for students performing interviews or oral history research in the future. The lessons additionally emphasize the importance of cultural understanding in these processes and the increased cultural understanding that comes with being a part of them.

Abstract Name: **Increased Intake of Alpha-Linolenic Acid is Associated with Higher Exam Scores**

Roughly 60% of the human brain is fat. Essential fatty acids (EFAs) Linoleic and alpha-linolenic acids are critical for building the brain's structure, synthesis of neurotransmitters, and developing the visual cortex, among other important functions.This study investigates how EFAs intake may affect brain function, and if these effects are reflected in student exam performance. We hypothesize that increased consumption EFAs will be associated with higher test scores.An analysis of cognitive function based on exam scores was conducted on 602 student participants attending Weber State University. Two-day diet records were collected. Grams as well as percentages of recommendation consumed based on required calories of linoleic and alpha-linolenic EFAs were calculated from the diet record using Diet and Wellness Plus software. The data analysis was completed using RStudio. Models were created using linear regression and variables were removed based on p-value using backward elimination. The best model created included the following variables: LinoleicCal% (the fraction of the total calories required provided by linoleic fatty acid), α-LinolenicCal% (the fraction of the total calories required provided by alpha-linolenic fatty acid), and the interaction between the previous two variables. Exam scores increased by 5.43 times, for each additional α-LinolenicCal% percentage increase ($p = 0.01$). For each percentage increase on both LinoleicCal% and α-LinolenicCal%, exam scores decreased by 0.27 times ($p = 0.02$).Our results show that it is not only the amount but also the ratio in which these two fatty acids are consumed that influences exam score performance. This is in accordance with previous studies showing that intake of omega-3 polyunsaturated fatty acids are inversely related with risk of impaired memory and flexibility in middle aged adults.

Abstract Name: **The Link Between Economic Slack and Inflation: An International Perspective**

I examine the sensitivity of the response of inflation to changes in the unemployment rate and to the output gap, or the "Phillips Curve", across a set of developed countries, using data from the International Monetary Fund's World Economic Outlook database. I then contrast the results with a subset of countries that are members of the Eurozone, using the same panel econometric methodology. Both sets of data portray a difference in the sensitivity coefficient from 1980 to 2019 compared to 1999 to 2019. In line with other research, the sensitivity coefficient is found to be of the expected sign and smaller (a statistically significant decline) in the later part of the sample when measured against the unemployment rate.The results show that the full set of countries experienced a sharp decline in the sensitivity parameter, while the Eurozone experienced a decline, but to a lesser extent. When the sensitivity parameter is measured against the output gap, this decline is no longer significant.The policy implications of these findings are that Central Banks, currently fighting inflation rates that are high by recent historical standards, may need to be more aggressive than in the past, as the smaller sensitivity parameter means that larger interest rate adjustments are required to fight inflation. However, when measured more properly (such as by looking at more homogeneous countries like those within the Eurozone), or when using a broader measure of economic activity (such as the output gap instead of the unemployment rate) the decline in the sensitivity parameter is not as large. With these new measurement standards taken into account, there is less need for a more aggressive monetary tightening by Central Banks.

Abstract Name: **Human Flourishing: A wholistic approach to healthcare**

Purpose: Human flourishing is at the heart of healthcare. Based on the work of Aristotle in Nicomachean Ethics, virtue ethics posits that an individual forms habits that promote virtuous behavior while modeling behavior after virtuous people. As an individual grows in virtue, he or she comes closer to eudaimonia, or human flourishing, an overall state of wellbeing. Virtue ethics may be a useful framework for operating as a nurse, while also benefitting patient wellness. The purpose of this project is to examine the literature on the role of virtue ethics in promoting human flourishing in the context of nursing. Methods: Keywords such as virtue ethics, flourishing, phronesis, eudaimonia, holistic, nursing, and healthcare were used to search databases searched including CINAHL, PubMed, and Ebsco Host. Thirty-six articles were evaluated for content related to virtue ethics, nursing theory, human flourishing, and nursing practice. Results: Centering care on human flourishing can promote wellbeing for patients and nurses. Implementing virtue ethics as a nursing framework may help the nurse to combat burnout, make ethical decisions, and provide holistic person-centered care through phronesis, or practical wisdom. Researchers have used different tools to measure human flourishing. Supporting a patient's ability to flourish can increase his or her quality of life and patient outcomes while decreasing cost and length of stay.ConclusionNurses have an important role in facilitating holistic care to enhance human flourishing. Understanding the individual holistically will help patients flourish and strengthen their inner capacity.Healthcare providers face challenges in implementation of human flourishing. Further research could examine measures of nurse flourishing. Nursing schools must consider this to prepare nursing students to be well-rounded, resilient nurses. Keywords: virtue ethics, flourishing, phronesis, eudaimonia, holistic, nursing, and healthcare

Abstract Name: **Growing Together: Children's Expectations and Reactions to an Urban School Garden Experience**

Children from low-income families are at high risk for food insecurity, unhealthy diets, and low intake of fruits and vegetables (Nury 2017). In general, community gardens have been suggested as a possible method to address food insecurity. Community gardens have been shown to increase intake of fresh vegetables (Algert, Diekmann, Rendellda,; Gray, 2016). These gardens can provide food insecure communities with more access to fresh vegetables and fruits that they might not have access to on a regular basis. School gardens have the potential to teach children a variety of educational concepts. Additionally, school gardens may help children increase their intake of fruits and vegetables and have been recommended as a unique way to address food insecurity by providing children with more access to more fruits and vegetables. School children play a large role in the success of school gardens. Thus, the purpose of this project is to examine children's expectations, motivations, and reactions to a school garden experience. Additionally, the project seeks to examine the impact of school gardens located within urban, food insecure communities. The project will be implemented with a partnership between Winston-Salem State University's Growing Together Program and a local Title I Elementary School in the county. Using surveys, data will be collected from elementary school children (ages 10-11) who participate in an after-school gardening club program. Data analysis will include examining children's expectations, motivations, and experiences.

Abstract Name: Family Stress and Hospitalized Children

When a child is hospitalized, the equilibrium of the family immediately becomes unbalanced. The level of stress felt by each member of the family will vary, and their resulting coping mechanisms will affect the entire family unit. Each year, more than three million children in the United States are hospitalized. The most common causes for the hospitalization of a child are premature birth, congenital abnormalities, chronic illnesses, accidents, and cancer. When a hospitalization occurs, family roles and dynamics change; older children may become care takers, or extended family members may offer aid. The leading cause of child mortality is unintentional injury, and approximately 12,000 children and young adults (aged 1-19) die every year in the United States from these injuries. Families who experience hospitalization followed by recovery often return to equilibrium, however for those families experiencing hospitalization followed by loss, the impacts limit their ability to return to equilibrium. Families who live in poverty or low-income households already experience high levels of stress due to ongoing financial difficulties. Families living in poverty face numerous health concerns related to their financial situation; children in these families face higher risks for preterm births, chronic illness, food insecurity, and stress, and they may face struggles in having adequate access to healthcare. Factors increasing resilience among children and families include a communicative and invested health care team, education about diagnoses, treatment, and recovery, adequate support systems, and counseling. Parents and siblings lend vital support to hospitalized children, and parents often find support in extended family and community support groups. Single-parents and low-income families face tend to have weaker support systems due to lack of family members able to lend time or money. Within healthcare, education and attention should be given to family stress in order to effectively care for patients and their families.

Abstract Name: Armed and Unarmed Drone Perception in Conflict Zones

This research explores the perception of armed and unarmed unmanned aerial systems (UAS) through the lens of civilians in conflict zones. The boundary of these dual-use systems is blurred and impacts drone trust between civilians and those who operate them. First, a literature review on armed and unarmed drones will be conducted to understand how much knowledge exists on the ability of a civilian to distinguish between weaponized and unweaponized drones. This will include short-term and long-term exposure to drone activity. Preliminary literature searches expose a gap in data; the response to humanitarian drones, for instance, is minimally collected. Next, language is integral to this research, and keywords will require differentiating. The terms used for these “unmanned systems” change based on the operator and mission at hand, which contributes to the perception and blurred boundaries of their utility. “Armed” means different types of weapons typically used in regions that have declared war. “Unarmed” will refer to drones used to supply aid and conduct surveillance. “Civilians” in this context will include residents in specific conflict zones around the world, along with people who travel in and out of the region for work. “Short-term” and “long-term” will describe the length of exposure to drone activity and is crucial to understanding how perception is shaped. “Conflict zone” will be defined to discern between international conflicts and domestic ones. Finally, it is important to know that the scholarly discussion around unmanned aerial systems is largely on the legal and ethical aspects of their use. There are few studies on the perception of continuous drone activity in conflict zones, where it is more likely to see armed and unarmed drones. Future research will apply this perception study to the range of psychological impacts that civilians experience.

Abstract Name: **MenomiNet: A Prototype Network for Real-Time Public Lake Data**

Currently, there is a high cost and low frequency of data collection on the Red Cedar watershed in the Midwestern United States. The existing processes involved with eutrophic lake monitoring put volunteer health at risk. Nevertheless, the regular collection of eutrophic lake data is important because it can identify which rural, suburban, and urban areas are at risk of having excess levels of nitrogen and phosphorus in their water supply. Moreover, in the Red Cedar watershed, there is a severe backlog in data collection of multiple ecological metrics. We developed the research question, what is an efficient and cost-effective way to gather lake health data in real-time? Using a submersible sensor suite, our team gathered four different kinds of lake health metrics: temperature, dissolved oxygen, turbidity, and pH. This data was broadcast through a LoRA (long-range) transmitter network at distances of approximately 500 feet between transmitter and receiver. After obtaining a running log under several physical and weather conditions, including during interactions with waterfowl, as well as under multiple time frames, ranging from multi-hour stretches in the day to overnight/multi-day readings, we stored the data into log files that capture the limnological data over time. We also began developing a web dashboard to publish this data in a readable format. Our low-cost LoRA approach uses components that cost less than $1000 per node and drastically reducethe cost of lake health monitoring relative to current state-of-the-art approaches. This may empower not only academics or students but also groups of citizens, lake associations, and lake districts throughout the Red Cedar watershed to allocate funds and resources towards local monitoring projects. This level of coordinated effort would provide continuous, distributed lake health data for the first time in the watershed's history.

Abstract Name: **Genetic Modification of Saccharomyces cerevisiae Using ADE2 Screening**

Industrial yeast strains are used in the food and beverage industry to create products we consume on a regular basis. Genetically modified yeast can be used to create new products with unique properties, but Food and Drug Administration (FDA) guidelines restrict the use of antibiotic resistance genes to construct strains that will be in products for human consumption. To solve this problem, we are developing an industrial yeast strain that uses the ADE2 gene as a marker for genetic modification. When ADE2 is knocked out, the yeast cells accumulate a metabolic intermediate and turn red. By including a functioning copy of ADE2 along with our new genetic material, we can select for successfully modified yeast by looking for colonies that are white again. This approach to genetic modification aligns with FDA guidelines for ingredients that are "generally recognized as safe" and will allow us to create genetically modified yeast strains to be used in the food and beverage industry.

Abstract Name: **The Impact of Human-Induced Climate Change on Drought and Wildfires in California**

There is a large range of impacts that human-induced climate change has on the planet, and an issue that is impacting the Western United States is droughts and wildfires. In particular, California is being impacted through changes in precipitation levels and wind patterns, which leads to changes in the intensity of droughts and wildfires. My research question is how is climate change impacting droughts in California and thus influencing the spatial occurrences and intensity of wildfires. My hypothesis is, as the effects of human-induced climate change become more extreme, there will be a decrease in precipitation causing longer and more intense droughts and this will lead to increased frequency and severity of wildfires. Global human-induced climate change can be detected by an analysis of temperature changes from year to year. In California, this global change is leading to more droughts as measured by the Palmer Drought Index which is an indicator of drought length and severity. Droughtdata are then compared to historical data on acres burned and locations where wildfires occur in California. As seen in other countries, like Russia, wildfires have gotten more frequent and severe as human-induced climate change occurs. Many researchers conclude that some of the wildfires occurring today would not take place naturally without human-induced climate change. Since this is being seen in other places of the world, it can be inferred and my expected results will be that this trend will also be seen in California. I expect to see longer drought periods, which lead to larger and more frequent wildfires in California. Human-induced climate change will continue to have a large impact on all parts of the globe, and wildfires will be a catastrophic result of climate change.

Abstract Name: **Optimal Pricing Strategy for Recycling Supply Chain**

The goal of this research is to find the optimal pricing and optimal recycling compensation. To analyze the effect of offering recycling/trade-in service on retailer's pricing decisions and profitability, we developed an analytical model to examine the optimal pricing strategy and will conduct a survey to obtain consumer's behaviors regarding second-hand transactions of vehicles. From the pricing models, we compared the retailer's profit with a recycling service vs. without. Given the cost and salvage value of cars, we determined the retailer's optimal price and recycling compensation to the consumers who are willing to trade in their used cars. Our findings indicate that when salvage value of a used car is relatively low, offering a trade-in to consumers is more beneficial by providing higher prices. We extend our basic model by focusing on the behaviors of strategic consumers. Previous studies have reviewed that ignoring consumers' strategic behaviors may lead to negative impacts on retailers' performance. However, there is little literature examining the effects of the consumers' strategic waiting on second-hand transactions. Our study bridges the gap. For strategic consumers, the existence of product depreciation causes them to have uncertainties in their purchase valuations. The consumers will estimate the product depreciation before deciding to purchase. The survey wasfirst distributed among Elon University's students, to collect their purchasing and recycling behaviors. In our preliminary findings we discovered thatpeople expect about a 55% discount on their trade-in for a new vehicle. We plan to expand our data in a second round of surveying to college students in North Carolina. The survey will identify the percentage of strategic consumers and record the responses of the student's preferences or behaviors regarding participating in second-hand transactions, the channels in which they complete their second-hand transactions, and the pricing valuation of second-hand products.

Abstract Name: Protein Structures of Prion Disease

Alzheimer's is a devastating disease that currently millions of Americans suffer from. It is a prion disease that even though is common, it is quite under-researched and there is currently no cure. Through research, scientists better understand what provokes proteins to fold into prions (disease), and work towards making better treatments. With this research, Dr. Jennifer Grant from the biology department at the University of Wisconsin-Stout and I will have a better understanding of why certain amino acid sequences misfold into prion disease. To accomplish this, AlphaFold (a software program used to predict a protein's 3-D structure from its amino acid sequence) was used on sequences from different animals with prion disease. A focus was put on the globular core of the prion protein, which has been identified as a key area that causes the proteins to fold into prions. The predicted structures we formed from sheep, cat, canine, Syrian hamster, pig, cow, rabbit, and human were evaluated for the extent of their unfolding. The directions we took with the predicted structure and susceptibility were looking at each dimer and trimer, using "Matchmaker" on AlphaFold to see how structures from different species compared to each other, and the Hydrogen bond formed from histidine and arginine. The amino acid sequences within the two cysteines and the beta sheets formed are critical points of research within Alzheimer's disease. Understanding structures and what makes proteins fold into prions is the first step to developing treatment.

Abstract Name: Historic land use/ land cover (LULC) change assessment following watershed degradation in the Whitewater River basin, southeastern Minnesota, USA

The Whitewater River basin, a tributary to the Upper Mississippi River, located in southeastern Minnesota, is the subject of a multi-institutional, interdisciplinary, NSF funded research project. Researchers are focused on modeling fluvial response to changing conditions at two time-scales. First, base level change during the terminal late-Pleistocene. Second, responses to Euro-American agricultural practices beginning in the mid-1800s, and the establishment of lock and dam structures in the early 1900s. Historical disturbances led to severe soil erosion in the upper reaches of the basin, deposition of up to meters of post-settlement alluvium in the main channel and high order tributaries (~140 homesteads and 3 small towns were buried), and inundation of the floodplain near its confluence with the Mississippi River. The purpose of this poster is to introduce one contribution, land cover change, to our efforts to reconstruct river response to historic disturbances. Historic aerial photographs are available for the basin from the 1930s to the present, in roughly decadal intervals. Photomosaics were created using ArcGIS Pro and Agisoft Metashape, allowing for seamless imagery across the study area. Agricultural fields and other areas were classified using image classification tools in ArcGIS Pro. Preliminary results show that as soil erosion in the uplands and deposition in the main channel and high order tributaries proceeded through time, agricultural fields reverted to forest starting in the late 1800s, and wetlands increased downstream around the same period of time. As soil erosion control practices were adopted, increases in non-agricultural and non-urban natural land cover signify a response to watershed management that suggests improving watershed conditions over time.

Abstract Name: **Electrochemical Characterization of Recast Nafion? Film Modified Electrodes in Nonaqueous Systems**

The behavior of recast Nafion® films on platinum working electrodes in nonaqueous solutions is characterized by cyclic voltammetry and rotating disk voltammetry. The behavior of recast Nafion® films in nonaqueous solutions has been observed to be different from the well-studied behavior in aqueous solutions. This work seeks to extensively study that behavior. The reversible redox couple tris(2,2′-bipyridine)ruthenium(II) hexafluorophosphate is studiedin nonaqueous solvent acetonitrile with different electrolytes (tetrabutylammonium tetrafluoroborate, tetrabutylammonium trifluoromethanesulfonate, tetrabutylammonium hexafluorophosphate, and ammonium trifluoromethanesulfonate). The effects of the electrolytes will be compared against each other and controls (an unmodified platinum electrode and a recast Nafion® platinum electrode equilibrated in aqueous solutions of the redox couples). Electrolytes have been chosen for a variety of ion charges and ion sizes; in aqueous solutions, Nafion® is a cation exchange polymer and will exclude neutral and anionic redox molecules, however this does not necessarily occur in nonaqueous solutions. Additionally, there is some preliminary evidence that trifluoromethanesulfonate electrolyte may interact with the Nafion® sulfonate groups, so this will also be explored. Studies of each electrolyte variation will involve both transient cyclic voltammetry and rotating disk voltammetry; the relationship between scan rate and peak current will be explored for transient cyclic voltammograms and the relationship between rotation rate and limiting current will be explored for rotating disk voltammetry. The data from both techniques will be combined to identify the thickness of the in situ film and the diffusion coefficient for each variation.

Abstract Name: **The Body is the Frame: Critiquing Traditional Masculinity through Performance and Film Form**

Through a study of Mark Ruffalo's body in I Know This Much is True (Cianfrance, 2020) and Dark Waters (Haynes, 2019), this paper discusses the ability of performance and mise-en-scène to criticize traditional masculinity and communicate non-aggressive masculinity. The texts link Ruffalo's body to either his work or his connection to family members, and as he arrives at complex solutions to societal issues through a struggle between traditional and vulnerable masculinity, Ruffalo's body is permanently changed, either by physical injury or mental strain. Through select scenes I will examine how these changes in physiology represent the uncertain solutions arrived at by Ruffalo's characters, as well as how the lack of romanticization in Ruffalo's physical changes overcomes a traditionally masculine view of power. I apply David Buchbinder's findings on the expression of power through space in the masculine body, examining how the texts reject a dominant masculinity through cinematography, sound design, and editing which amplify Ruffalo's vulnerable masculinity. An analysis of Manon Garcia's writing on Simone de Beauvoir and "Masculinity As An Impasse" will show traditional masculinity as a harmful situation for men, while suggesting that masculinity can adapt and improve as a result of lived experience, seen through Ruffalo's performances. I also discuss Béla Balázs' Theory of the Film to demonstrate the role of the close up as a method of communicating the themes of the texts through Ruffalo's face, and as an inversion of Buchbinder's findings on relation of space to power in dominant masculinity.

Abstract Name: **Enantioselective Synthesis of Metal Coordination Complexes Using ?Chiragen? Ligands**

Chiral metal complexes are commonly used for enantioselective catalysis in the synthesis of biologically active compounds and pharmaceuticals, but they generally suffer from the difficult process of obtaining one enantiomer of the complex over another. The purpose of this research is to synthesize a family of ligands that can coordinate to a metal center in an enantioselective fashion to produce chiral metal complexes that do not need to be post-synthetically separated from other enantiomers of the compound. These “Chiragen” ligands are based on two bipyridine moieties linked by a chiral backbone that can only wrap around a metal center in a certain way due to steric hindrance. The backbone of these Chiragen ligands is highly customizable, so while only the length of the backbone is being adjusted here, future works could easily test many sizes, flexibilities, and functional groups to see how different effects could improve or hinder several properties or configurations. Since bipyridines are known to complex to nearly all of the transition metals, the synthesized Chiragen ligands will be coordinated to multiple different metals to investigate the properties of the formed compounds and their potential utility in other areas. Nuclear Magnetic Resonance (NMR) and X-Ray Diffraction Crystallography (XRD) will be used to characterize the ligands and the metal complexes. Some of the complexes are also expected to exhibit interesting optical properties, which could make them useful in photo redox applications or photovoltaics. For these, UV/Vis Spectroscopy may be used to characterize the complexes even further. Currently there are few results to report on. Fortunately, once the family of ligands has been created, the formation and characterization of metal complexes will provide a lot of data and results in a relatively short timeframe. The results obtained from this should provide plenty of useful information that could guide future investigations.

Abstract Name: **Perception of Information and Source Reliability B**

The term misinformation is being used so frequently now that it has become an annoying word to represent almost nothing. The perception of whether information is valid seems to be very dependent on who is giving the information. There are many different factors that play a role in deciding whether a source is credible or not. In the US today we are seeing that individuals are siding with news sources that have a similar political ideology when deciding what is fact and what is misinformation. The purpose of this research is to determine what factors correlate with someone'ssuseptiblity to misleading information. The personal characteristincs being studied include racial/ethnic background of the messenger and receiver, political ideology of the messenger and receiver, news media sourcepreference, expertise level of the messenger and receiver, and percieved trustworthiness of the messenger. The study will use information about controversial topics given by various sources and determine the level of confidence the subjects have about the legitimacy of the information. Demographics regarding the subjects will be collected. A correlational analysis will be made between traits of the message sender and receiver and the rating of the source information. Data analysis will be completed in the spring semester of 2023.

Abstract Name: Reclaiming Stereotypes of Black Woman

My research is about racist caricatures of Black women (such as the Mammy and Jezabel figures etc) and how they have impacted Black women as well as how they navigate today's society. Most discrimination and prejudice against black women are mostly shown through microaggressions in today's society. This work could help other women of color feel seen and heard through this body of work as well as educate others about the issues of the fetishization of black women. Navigating topics of colorism, sexuality, and blackness in a society that favors heterosexual cis-white men. As an African American, I have grown up around preconceived ideas of a stereotypical Black woman. We are depicted as loud, angry, promiscuous, as well as compliant with the needs of our white counterparts in the media. I am making a body of work to reclaim these hurtful stereotypes into pieces of empowerment. The materials for this concept will range from multimedia items from antiques to copper, brass, silver, and enamel. I am dedicated to creating art that reflects my identity and allows other Black queer women to feel seen and heard through art.

Abstract Name: Shining a Light on Experimental Theatre Practices: A dissection of Neo-Futurism as it is and how it is applied in a modern performance context.

This project seeks to explore the tenets of an experimental style of theatre in a modern performance context while working with passionate students to help expand their means of artistic expression. Neo-Futurism is an active creative force and is continuing to evolve within the theatrical community. I will be basing my project on the work of The Infinite Wrench,a neo-futurist ensemble that is based in Chicago, Illinois. They are an ensemble of writers, directors, and actors that perform thirty plays in sixty minutes, all while following the four basic tenets of neo-futurism: no suspension of disbelief, speed and brevity, scripted and planned, reliance on chance. My goal is to create an ensemble of students at UWEC that mirrors this aesthetic of truthful communication between the audience and the performer. The main research questions I want to explore are 1. What exactlyisfuturism? 2. How did it evolve into neo-futurism? 3. How can we, as writers and performers, apply this specific style in a modern performance context and 4. How does a theatre practitioner develop this style of theatre? My objective for myself and the ensemble is to break out from the robotic tendencies of realism based writing and thinking and creating a new heightened theatrical sensibility. I want the audience to leave with a newfound appreciation for experimental theatre. In addition, I want our plays to evoke a particular atmosphere that challenges the audience to think for themselves. Moreover in executing this project, I want to gain dexterity in performing, writing, and directing within an experimental environment while also developing my skills as a leader amongst fellow creators. Lastly, I would like to develop this material into something suitable for a possible confrence presentation, a poster and/or a short performance at NCUR.

Abstract Name: Developing Dashboards in Python: A Case Study

This project aims to introduce the possibilities of the Python programming language in business and particularly accounting analytics. Python is a widely used language but has received very little attention from accounting professionals and academics so far. The major advantage of Python is that it is free and open-source, which makes it easily available to everyone. However, many business professionals, including accountants, auditors, etc., do not use this language. The purpose of this project is to create an application that shows how students can easily create and use analytical apps using Python. The project consists of a user-friendly stock analysis dashboard that displays information about any publicly traded company. Using Python for the coding of the analysis and public data found on Yahoo! Finance, we are able to create a free public tool. Finally, we aim to supplement the tool with proper documentation so that other faculty can teach Python by recreating this tool. This project brings awareness to open-source and what it can offer businesses of any size, as well as receiving attention in the accounting profession.

Abstract Name: Casting Heartthrob Actors as Killers: Priming Young Women to Tolerate Abusive Partners

One in three women have experienced some variation of physical intimate partner violence, and one in two women have experienced psychological intimate partner violence. Various factors increase the risk of experiencing intimate partner violence, such as previous exposure to intimate partner violence at home, but there may be predispositions from women's childhoods that cause them to tolerate partners with abusive tendencies. Young women who watched movies and shows with famous heartthrobs at the time, such as Zac Efron, Ross Lynch, and Dylan Sprouse, who portrayed good characters when they were younger may be more likely to have developed an increased liking for these actors based on effects from the mere exposure effect and media priming. The familiarity and nostalgia they may feel for these actors might increase how much they trust these actors, which may influence their view of their portrayed actions in the movies and shows they appear in. However, many of these actors are now portraying 'dark' characters, such as serial killers, with Dark Triad traits. Because these young women may have developed a preference and attraction for these actors from their childhood, they may have been primed to be attracted to the 'dark' actions and Dark Triad traits that these actors portray. Young women are more likely to be more attracted to men who exhibit Dark Triad traits, and these women tend to ignore these 'dark' behaviors. This phenomenon may cause these women to be at a higher risk to experience intimate partner violence, as men with Dark Triad traits are more likely to have abusive tendencies. The present study sought to determine if there is a possible effect on young women's intimate relationships caused by many famous actors' transition from playing 'good' characters when they were young to 'dark' characters with Dark Triad traits.

Abstract Name: **Campuswide Sustainability: Designing an Early Intervention Training Module to Cultivate a Sustainably Minded Culture**

Implementation of sustainable practices are being pursued at universities across the globe. However, getting student buy-in to adopt sustainable habits can be challenging. Over a seven-year period, the University of Wisconsin-Eau Claire has collected data on student behavior as they discard lunchtime waste and conducted audits on the waste found in the compost, recycle, and landfill bins. That data has been used in multiple intervention attempts to educate students on proper waste-sorting when having access to those bins. These interventions have had limited success in generating a statistically significant shift in student behaviors. During the 2022-2023 academic year, we are pursuing a new effort with the goal of preemptively educating students on multiple aspects of sustainability before they arrive on campus. Our university currently requires incoming students to participate in online training modules on topics such as sexual assault awareness (Title IX), equity diversity and inclusion, and information security. We have received approval to add a sustainability-focused online training module for incoming students. We are designing a module that will focus on four sustainability topics: campus-wide sustainability goals, public transportation routes, using the campus's reusable food container program, and proper waste-sorting habits. Each topic will contain microlessons consisting of readings and videos. Each microlesson has questions that must be answered before the student can progress. Our goals are to educate students on effective sustainability practices, encourage them to adopt those practices as incoming students, and for them to see our campus as a place that values sustainability. We will assess the effectiveness of this intervention through future waste audits, observational studies of student behavior and survey responses. Our training module is intended to be used by all incoming students and we expect that our audits and survey results will reflect wider adoption as more and more students complete the training.

Abstract Name: **Preventing Adherence of Candida spp. with Pre-Therapeutic Drug - Filastatin**

Candida yeasts are the most common human fungal pathogens. These primarily opportunistic pathogens can infect a variety of tissues and cause a variety of infections. They are also a common cause of healthcare-associated infections (HAI) in immunocompromised individuals. Candida yeasts usually form biofilms upon adhesion, which then increases their pathogenicity due to their lack of response to conventional treatment. Candida auris is an emerging fungal pathogen with nearly a 57% mortality rate. Filastatin is a drug not yet approved for human use but has been found to uniquely inhibit adhesion of C. albicans to the surface of several biomaterials and human cells. This study will assess if Filastatin is also able to inhibit the adhesion of three other pathogenic Candida species, C. albicans, C. glabrata, and C. auris. 96 well polystyrene microtiter plates will be used to assess the inhibition of fungal adhesion using various concentrations of Filastatin. After incubation, cells grown in the wells will be stained with either crystal violet, (or alamar blue to test for viability as well). Upon washing the plate with ice water several times to clear out stained cells that didn't adhere to the surface, methanol will be added to each well and allowed to sit for 45 minutes. The solution of methanol and stained cells will then be read by a spectrophotometer at 590 nm for the varying absorbances and will be compared to our control of both saline and Candida albicans. This will be beneficial to the future of healthcare as it will allow the number of infections with Candida species to be decreased. Future medical devices coated in Filastatin would be more resistant to Candida biofilm formation and would therefore limit the number of infections and mortality.

Abstract Name: **Human Scent Analysis in Support of Tracking Dogs**

Tracking dogs can follow the scent of a person for more than a mile after they have left the trail. The current scientific hypothesis about how this is possible involves dogs smelling the volatile organic compounds (VOCs) that emanate from dead skin cells shed as a person moves. However, data from tracking dogs is not admissible in a court case as it is not understood how this scientifically occurs. Our data involves swabs of an individual's left and right arms, using the technique of Gas Chromatography Mass Spectrometry (GCMS) to identify and analyze the amounts of compounds that make up a scent. We have found that the data of an individual's left and right arms is more correlated than two random people in the data set, suggesting that each individual has a unique scent profile. Through the comparison of left and right arms from the same individual we have noticed the same compound is not present in both due to the necessity of the GCMS reaching a threshold amount for a compound to be recognized. Using Principal Component Analysis (PCA) we found that 23.1% of the variation in individuals can be explained through the first two principal components. PCA has also determined that heptanal, acetone, and hexanal, which are commonly found in every individual, are the compounds that explain the most variation between scents. Furthermore, PCA shows that there is a difference in clustering between children (under 18 years old) and adults (18+ years old). Our investigation has shown that the age of an individual contributes to the scent profile, an individual is more correlated to oneself than another, and that there are top VOCs that contribute to the variation in individuals scent profiles.

Abstract Name: **Investigation of the Relationships Between Membrane Chemistry, Permeability, and Water Volume Fraction for Phenyl Acrylate Anion Exchange Membranes**

Commercialized polymer membranes are currently used in the energy generation industry in solar fuel devices. However, there are some issues with commercialized membranes, such as aging and cost. It is desired for a membrane to have both high selectivity and high permeability, but the commercialized membranes currently lack one or the other. There are possibilities for more efficient, lower cost membranes to be commercialized. This research focuses on testing ion exchange membranes of different compositions to determine water volume fraction and permeability to target molecules. Ion exchange membranes are used to limit the exchange of carbon dioxide reduction products in the two separate parts of the device. Here, phenyl acrylate membranes were made using two different crosslinkers, MBAA and PEGDA, with the monomer APTA. Different compositions of phenyl acrylate, PEGDA/MBAA, and APTA were made and tested in permeability experiments. Permeability is a measure of the amount of a solute that passes through a membrane. In this experiment, one side of the device starts as pure water while the other contains a target salt solution. As the experiment proceeds, the conductivity of the water side is measured over time. Conductivity is then converted to concentration of the salt based on a predetermined calibration, allowing for permeability to be calculated using Yasuda's model. Sodium acetate, potassium acetate, sodium formate, and potassium formate are the salts used in the permeability experiments; chosen to mimic the products of the CO2 reduction cells. Water uptake and membrane density are also measured to calculate water volume fraction. Water volume fraction shows how much space there is in a membrane for things to permeate through. This project investigates relationships between membrane chemistry, permeability, and water volume fraction.

Abstract Name: Modeling and Simulation of Compliant Mechanisms in MATLAB Simscape

Compliant mechanisms are the mechanisms that transfer the input force, displacement, or torque from one point to another through the deformation of its compliant members and flexible body rather than the joints such as ball bearings. They have superiorities over the traditionally designed mechanisms such that since they can be designed and manufactured as a single piece using injection molding or additive manufacturing, they are light weighted, and no need for assembly and have no friction loss. Thus, the compliant mechanisms have better performance and accuracy and find application areas in the design of locomotive robots, grippers, medical robots, and microelectromechanical (MEMs) devices. Despite all the advantages, deriving the mathematical model of compliant mechanisms is much more challenging compared to traditional rigid body mechanisms as the complexity of the design increases. Although there are several methods available to find the load-deflection curves of flexible members such as pseudo rigid body modeling (PRBM) and the first and second of the Elliptica theory, they are limited to the simple geometries including fixed-free, fixed-guided, and fixed-fixed buckling beams. In this study, we present the design, modeling, and simulation of several compliant mechanisms in MATLAB Simscape. We adopted two approaches: the model can be created using the Simulink library blocks or by importing the cad model and then introducing the flexibility using discrete beam elements. We created the models of a fully compliant five-bar mechanism including 4 rigid bars connected by large deflecting flexure hinges, a compliant dwell mechanism incorporating buckling beams, a slider, and a rail, and a compliant bistable mechanism consisting of 6 rigid bars, a slider, and fixed-free flexible beams. The Simscape models not only provide kinematic insight but also visualizes the displacement and motion of each mechanism in the mechanics explorer.

Abstract Name: Behavioral responses to water contact among different species and populations of spiders

Riparian zones are dynamic ecotones that are under constant risk of flooding. Spiders that inhabit these areas may have highly variable responses to flood events. When contacting the water surface, spiders may sink and drown, swim or walk under water, or row or skate across the surface. These response differences may be taxonomically distinct and could reflect local adaptations to riparian environments. Documenting variation in behavioral responses to flooding are critical for understanding the resilience, persistence, and/or recolonization capacity of these habitats by riparian spider communities. We measured behavioral responses of spiders to simple drop tests on the water surface. Spider survival, mean time on the surface, time spent moving, and the ability to escape via a vertical or sloped surface was measured during a ten-minute test for twelve species of spider that varied in their proximity to lotic water sources. We found significant species differences in the propensity to exit the water quickly. Ground crab spiders immediately submerged and remained on the bottom for the entire testing period. Wolf spider species associated with dry fields performed more poorly on water surfaces than riparian lycosid species. Similarly field-associated species of orb-weavers showed significantly longer time on the surface and took longer to exit than riparian orb weavers. Spiders also showed significant differences in the ability to exit water through sloped rocks or vertical surfaces. These variations in time on the surface may influence diet choice of surface-feeding aquatic predators.

Abstract Name: A Sovereign Nation: Exploring Cherokee Beloved Path and Chickamauga Consciousness' in Mary Kathryn Nagle's Sovereignty

For centuries, Cherokees have fought for self-governance not only on the battlefield and in the courts but through their literature. In Our Fire Survives the Storm: A Cherokee Literary History, Daniel Heath Justice argues that Cherokee literature should be interpreted through a Cherokee-centered lens with “intellectual sovereignty” at the center of the conversation. More specifically, when sovereignty is threatened, he identifies two culturally embedded postures as survival strategies: the “Beloved Path” when accommodation and cooperation serve as guiding principles and “Chickamauga Consciousness” when open defiance is employed.In her 2018 play Sovereignty, Mary Kathryn Nagle—attorney and descendent of the Treaty of New Echota signer John Ridge—probes the theme of Cherokee sovereignty, asking how the Nation can survive the many threats to sovereignty. The play takes the audience back and forth between the historical story of the Removal and the contemporary story of attorney Sarah Ridge Polson. She is a descendent of John Ridge working for a descendent of John Ross at the Cherokee attorney general office. Through both the historical and contemporary storylines, Nagle weaves a sense of sovereignty that extends to the 21st century Nation. Nagle’s play weighs the pluses and minuses of Justice’s two postures, representing John Ross’sdefiance of Cherokee removal while also showing “Beloved Path” themes of the Treaty Party.Ultimately, the play advocates for the “Beloved Path” posture once employed by the Treaty Party as the best way to protect Cherokee sovereignty. It’s fair to say that Nagle’s play is “intellectually sovereign,” a literary text written by a Cherokee and for Cherokees. Therefore, Nagle’sSovereigntyis Cherokee literature that is “deeply rooted in indigenousness,” as Justice says, defending sovereignty by the community-centered “Beloved Path” of nationhood and giving the best posture to the Cherokee Nation to protect against 21stCentury threats.

Abstract Name: Skunked.

Skunked is a story about darts. I started writing the script almost two years now in my script writing class. It was during both the height of the pandemic, and the middle of winter, so I was able to dedicate a lot of time to writng this story. It was designed to be the type of project I could realistically shoot once I was finished, or close to finished with college. Alot of me and my colleagues are enraptured with high concept sweeping cinema and we all really want to learn how to produce that kind of stuff. But I wanted to actively seek out a subject matter that could be realistically produced in a college town in north Wisconsin, on a college budget. And that lead me to movies like Better Luck Tomorrow, Lock, Stock and Two Smoking Barrells,and Dodgeball: A True Underdog Story. All these movies are low scale stories without much in way of grandiose spectecale. I wanted to capture the youthful complexity of Better Luck Tomorrowand the special blend of drama and comedy that movie brought. I wanted to aim for the quick wit and sharp direction of a Guy Ritchie move like Lock, Stock. Finally the absurdism of dedicating a feature length movie to a game nobody cares about came from Dodgeball.I was able to experiment with this style and tone last semester with Folded, a spiritual prequel and proof of concept for Skunked chronicalling a poker game. And now I have the oppurtunity to shoot an exert from my script this semester and hope to share it with others. Skunked started as a goofy idea but morphed into a story of freindship, finding confidence, and making your mark before its too late. Hope you all are interested in the final product.

Abstract Name: The Neoplatonic and Scholastic Influence on Leibniz

Gottfried Leibniz remains one of the most puzzling philosophers in what is considered the rationalist tradition of the 17th and early 18th century. For his metaphysics and theology, he derived many concepts from bothNeoplatonism and Scholasticism. Specifically, he developed the concept of the monad from the Neoplatonists, and, from the Scholastics, he developed a hierarchy of being to explain how the monads are organized and expressed in the world.Although scholars often seethese schools as at odds with one another, I arguethat Leibniz sought a unity of the two.

Abstract Name: Identifying the Role of MAPK15 in Triple-Negative Breast Cancer

Breast cancer is the second leading cause of cancer deaths in U.S. women, and the leading cause of cancer deaths among women worldwide. Triple-negative breast cancer (TNBC) is among the deadliest and most aggressive subtypes of breast cancer, demonstrates a high rate of metastasis, and disproportionately affects Black women and younger patients. Despite improvements in cancer treatment and increased use of mammography screenings, disparities persist within the TNBC subtype. Due to this, novel drug targets are needed. Mitogen-activated protein kinase 15 (MAPK15, also known as ERK 7/8) is a largely understudied kinase, and to date its role in breast cancer is unknown. Prior studies in other cancers demonstrated that MAPK15 is associated with increased cell invasion, metastasis, tumorigenesis, proliferation, and radioresistance. Based on this information, the aim of this study was to test the hypothesis that MAPK15 contributes to the aggressive phenotype of TNBC. This will be determined through the evaluation of cellular proliferation, drug response, cell motility and invasiveness, and epithelial-mesenchymal transition (EMT). To test this, MDA-MB-231 cells, a TNBC cell line, were transfected with a plasmid for MAPK15 overexpression. Following validation of stable transfection, survival and proliferation studies, migration assays, RNA sequencing, and qRT-PCR were conducted to assess differences in drug resistance, growth, motility, and gene expression in cells with MAPK15 overexpression. Preliminary results demonstrated that cells with MAPK15 overexpression have an increased rate of proliferation compared to control cells. Further RNA sequencing demonstrated enhanced expression of genes associated with inflammation, EMT, metastasis, and poor prognosis in breast cancer compared to the control cells. Consequently, this research has high potential to provide novel targets for individuals who have TNBC with MAPK15 overexpression through the elucidation of the function of MAPK15 in triple-negative breast cancer.

Abstract Name: Minority Status and Mental Health B

Discriminatory behaviors live througout society today and all generations of the past. How do these behaviors impact groups with minority status? The aim of this study is to research how chronic stress experienced by people with minority status impact mental health. There will be multiple angles applied to this study. The first area of interest is how social media either contributes to or gives a community for discriminatory behaviors or does social media allow for an outlet for those with minority status to build support and community. The second area of interest is how does stress related to chronic discrimination exposure contribute to the mental health of individuals with minority status. Previous research has shown disparities in mental health, substance use, and other factors related to mental health among groups with minority status when compared to the same age group of the majority stauts. This study will identify factors associated with positive and negative mental health development across multiple minority status groups through a survey implemented and analyzed in the spring semester of 2023.

Abstract Name: The Dream Machine as Confluence: Hallucination, Neuro-Diversity, and the Creative Industries.

Our research project focuses on how a social media campaign was designed and implemented to explore how people engaged with the ideas of dreams and hallucinations. Specifically, the class project involved working collectively, and in four dedicated groups, to build a dream machine* and research the idea of neuro-diversity and perception-diversity. The four groups were: designers, who constructed the dream machine; social media recorders, who developed a multi-platform media campaign for the project from inception to implementation, including documenting how the other groups worked and researched their areas; music composers who designed a soundtrack to accompany the machine; and multi-media poster designers, who researched the history and culture of the original dream machine to create a series of poster images. Each group required specific research focus as well as an interdisciplinary exchange across all the groups. In many ways we see this as 'confluence in action', breaking down disciplinary barriers to explore new ways of thinking about complex issues and ideas. Our presentation will articulate three key aspects of the project: how by working across multiple disciplines (notably, creativity studies, arts and humanities, cognitive sciences, communications) we came to understand better the confluence of ideas in practice; how various elements of social media can be utilized to explore wider philosophical and aesthetic issues; and how our University's program in Creative and Cultural Industries provided ways to connect across a wide and diverse audience to engage in the interdisciplinary nature of knowledge. In addition to the presentation, we would like to bring the dream machine to the conference so others might experience its hallucinatory effects and better appreciate the relationship between research and practice.*The dream machine was originally designed by the artist Brion Gysin and has been used in research to explore the idea of neuro-diversity and perception-diversity.

Abstract Name: **To Probe the Conformational Fluidity of the Intrinsically Disordered Protein GTPase HRas using Molecular Dynamics Simulation**

GTPase HRas is an enzyme that is linked to bladder and thyroid cancers. It belongs to the group of intrinsically disordered protein, which lacks definite protein structure. Their conformational fluidity allows them to adopt various structural forms making them efficient biomolecules. However, their three-dimensional structure is difficult to ascertain because the disorder prevents an ordered crystalline structure to form. Therefore, the role of their folding-unfolding dynamics on function, especially the effects of other biomolecules, has remained poorly understood. In the present study, the conformational changes of GTPase HRas have been investigated in the presence and absence of crowders using classical mechanics-based molecular dynamics simulations. Protein data was acquired from Alphafold - the artificial intelligence-aided protein structure database. Subsequently, the atomic coordinates of the protein were used to prepare five different simulation systems: water as a control, ethylene glycol, and three types of polyethylene glycol crowders of varying molecular weights ~ 600 Da, 8 kDa, and 20 kDa. Results will include 50 ns molecular dynamics simulation data, used for illustrating the effects of these crowders on the conformational dynamics and energetics of the GTPase HRas protein.

Abstract Name: **A survey of aquatic snails and trematodes in Eau Claire County**

Cercarial dermatitis, or swimmer's itch, is a skin infection caused by an inflammatory response to trematode cercariae, for which humans are dead-end hosts. Cercariae, the water-borne infectious stage of Trematoda (Platyhelminthes) species, escape their aquatic snail intermediate host and burrow into the skin of humans, causing a rash that lasts several days. Normal hosts for the etiological agents of cercarial dermatitis include a variety of waterfowl. Swimmer's itch is an annoyance for recreational water users and can have economic impacts on local tourism in many states of the upper Midwest, including Michigan, Minnesota, and Wisconsin. The Eau Claire City-County Health Department regularly screens seven local beaches for coliform bacteria and blue-green algal blooms, closing beaches when infectious agents are unsafe, but it does not screen for cercariae. With the goal of establishing a monitoring protocol for the causative agents of swimmer's itch, which is sporadically reported by lake goers in Eau Claire County, we surveyed four Eau Claire beaches for aquatic snails and screened them for trematode infections. Living snails were found at two locations, with most of these being the invasive Chinese mystery snail (Bellamya chinensis), as well as representatives of the families Planorbidae, Physidae, Hydrobiidae, and Valvatidae. Two snails were infected with trematodes, and DNA barcoding and life history data were used to identify these as Echinostoma trivolvis and Notocotylus urbanensis, both of which primarily infect muskrats as their definitive host. Although echinostomes and notocotylids are not known to be associated with cercarial dermatitis in human populations, our preliminary survey establishes the presence of trematode-susceptible snails and trematodes in public recreational lakes in Eau Claire. Further survey work is necessary to understand the potential effects of invasive mollusks on indigenous mollusks and their parasite populations.

Abstract Name: Should Marijuana Be Legal?

According to the National Center of Drug Abuse Statistics, 22% of men and 17% of women have used illegal drugs within the past year. Americans are using illegal drugs at a higher rate than they ever have before while simultaneously the government is legalizing marijuana. This sparked the question: what Americans really think about the legalization of marijuana? I hypothesized that party affiliation would influence people's opinions and there would be a difference in the opinions between different political parties. To test my hypothesis, I conducted a 12-question survey in Survey Monkey and collected data using Amazon M-turk. I gathered data from 186 Americans aged 18 and over with varying ages, gender, political affiliation, and education levels. The results show the vast majority ofAmericans were in opposition of the legalization of marijuana. Furthermore, I found a statistically significant differencebetween political parties and the extent of support regarding thelegalization of marijuana.Policy makers can use the results of this survey to better understand who supports drug legalization and response accordingly.

Abstract Name: A Seat at the Table? Not for Women

The number of individuals who testify before committees dealing in substantive issues before Congress each year number in the thousands, yet we know next to nothing about these participants in the policy process. This section of our study is to count the number of women who appear as congressional witnesses, analyze the gender breakdown among witnesses who testify,and explain the factors that affect those numbers. We look at the role that political party, party control, gender of chiefs of staff, of members, location of hearings, and chamber rules among others to explain women's participation as witnesses. We employ a unique regression methodology to analyze the factors driving diverse representation in our dataset.To date, we have identified the gender of more than 37,000 witnesses before over 7,500 committee hearings from the 110th through 116th Congresses, and this represents the largest published dataset on congressional witnesses that tracks witness diversity.This project also tries to determine the question, "does it matter?" by surveying current and former congressional staff members to understand if witnesses are important to the political process and through what mechanisms witnesses impact legislative outcomes. Therefore, this project not only seeks to demonstrate Congress's record in hearing from diverse witnesses, but also pioneering a new understanding of why witnesses are important to the legislative process.

Abstract Name: **Soviet Small Unit Tactics in The Battle of Kyiv**

In the Battle of Kyiv (2022), the Russian and Ukrainian fighters employed bounding overwatch, proper unit dispersion intervals, and forward security elements. Many of the tactics seen in the battle may be able to trace roots back to Soviet-era teachings. Teachings of urban combat, forged on the Volga River and during street-to-street fighting in the Battle of Stalingrad. My research explores how both the Ukrainians and Russians implemented Soviet small-unit tactics in the Battle of Kyiv. The examination of combat footage from the Battle of Kyiv and the search for the presence of Soviet small unit tactics will showcase the effectiveness and the implementation of these tactics in a modern war. I will first analyze the pre-defined Soviet Tactical Doctrine in the Red Army Archives and THE SOVIET ARMY OPERATIONS AND TACTICS (SAOT). After having examined these works detailing Soviet small unit tactics, I will then investigate online combat footage from the Battle of Kyiv and search for the presence of such tactics. The research will likely show how many combat forces fought with Soviet small-unit tactics in the Battle of Kyiv. The knowledge gained through examining archives and combat footage will help to understand how, and ifantiquated tactics hold up in a modern crucible such as Kyiv.

Abstract Name: **Quality of Care and Black American Maternal Health Outcomes Study**

Poor quality of maternity care is associated with adverse maternal health outcomes resulting in racial disparities in the United States. Historically marginalized populations disproportionately experience adverse pregnancy outcomes such as maternal mortality and morbidity. There is a need to assess the quality of maternal care for Black birthing persons who give birth in hospitals, birthing centers and at home. The purpose of this study is to investigate and explore the quality of care and treatment experiences for Black birthing persons while seeking care during pregnancy/labor/delivery, in the United States from 2018-2022. An online survey is being used to collect data on the quality of care and racism experiences of participants. The survey includes quantitative and qualitative questions, allowing participants to expand on their responses to questions beyond one-word answers. A racial equity framework was used to inform the data collection process and to take into account the historical context and multidimensional manifestations of racism. The study aims to collect positive birth experiences in particular, since positive narratives on birthing while Black in the U.S. are not well represented in the literature. Data analysis will include comparing the “positive” and “negative” experiences of those who did and did not experience maternal morbidity. Findings from this study will offer suggestions on how care providers in childbirth settings can better serve this population and make progress towards eliminating racial disparities in maternal mortality and morbidity.

Abstract Name: **Exploring Geographic Diversity of SARS-CoV-2 Genomes**

The current outbreak of coronavirus disease 2019 (COVID-19) pandemic is caused by severe acute respiratory syndrome-coronavirus 2 (SARS-CoV-2). Despite several preventive measures and initiatives from various countries, there is no improvement in the situation so far. This is presumably due to the absence of any effective treatment or therapy to date. SARS-CoV-2 is a single stranded RNA pathogen which is characterized by a high mutation rate. It is vital to explore the mutagenic capability of the viral genome that enables SARSCoV-2 to rapidly jump from one host immunity to another and adapt to the genetic pool of local populations. In this study, we analysed SARS-CoV-2 sequences collected from infected patients from various geographical regions using multiple sequence alignment and phylogenetic analysis. We found that there does not seem to be a correlation with geographic areas and mutations in the results of the trees, closely related genomes within countries such as Jamaica and Belgium or Slovakia and India show that even though the countries are not close to each other, the sequences of the SARS COV-2 genomes could be closely related. This could be due to mutations being random, it could purely be by chance.

Abstract Name: **Reality or Humanity: Using Creative Expression in the Holocaust to Rethink Jewish Historiography**

From 1939 to 1945, millions of Jewish people endured the most abhorrent and purely evil facets of humanity and human capability. However, even though the Jews in the Holocaust faced brutally oppressive and dehumanizing conditions, they chose to engage in the purest forms of human expression and creativity, in places like the Theresienstadt Ghetto. Simultaneously, however, music and art were forced upon Jews by the Nazis as a mode of torture dehumanization, and humiliation. Scholars of Jewish Historiography have typically sought to tell the story of the Jews by emphasizing themes of either persecution or empowerment. Using creative and intellectual expression in the Holocaust, this paper seeks to show that the history of the Jews is one of power and humanity without downplaying their persecution and suffering. It consults a wide array of primary sources, particularly Holocaust survivor testimonies, children's drawings, poetry, and memoirs. Finding this balance between persecution and empowerment will provide a more nuanced and human understanding of Jewish history in order to give a more accurate representation of their legacy. Stereotypes force individuals to create rigid frameworks. Scholarship must aim, therefore, to create accurate and human depictions of the histories of the Jewish people.

Abstract Name: "I Yam what I am!" the Secret to Identity and Authenticity hidden within Ralph Ellison's Invisible Man

Ralph Ellison's Invisible Man is a chaotic narrative of a black man struggling to find his identity and his way in a world where he is never certain who he is. Haunted by a deathbed comment from his grandfather, the narrator finds himself endlessly pushed from moment to moment, without space to discover his true feelings, social alignments, and personal beliefs. I argue that Ralph Ellison's Invisible Man suggests that identity is not concrete—but fluid, being highly dependent on social situations. In my essay, I trace the progression of the narrator's self-actualization. After being pushed around and abused for half of the novel, the narrator begins to embrace his likes and dislikes in a monumental scene where he accepts his past and rediscovers his love for Yams. This embracement of pleasure is key to understanding identity within the novel. I take the narrator's discoveries, and Ellison's comments on identity,and frame them in the scope of Foucault's ideas of self-hood. Through my unique reading of Invisible Man, I provide socially significant meditations upon identity, authenticity, and the self. I discover what itmeans to be invisible, and how this revelation is important for readers of all races.

Abstract Name: Parent-child weight-related conversations and body image development: Investigating the moderating effects of the parent-child relationship

The current research question explores how parent-child relationships can contribute to the effects of conversation about diet or weight on adolescent body image. Past research has shown the negative effects of mothers encouraging daughter's weight loss or dieting is buffered by mother's conversations about her own weight or diet. One possible explanation for this is that these bi-directional conversations are happening in a close, more cohesive relational context between mothers and daughters. This research uses a survey design to measure responses from participants on current relationship with parents (e.g., perceived mutuality, cohesion, parent-adolescent attachment), parent-child conversations about weight and diet, body image and disordered eating outcomes. Data in this study was collected from psychology students at the University of Wisconsin-Parkside, who responded to survey questionnaires via qualtrics. We predict that the stronger the parent-child relationship, the less negative impact conversations about body image and diet will have on adolescent body image and disordered eating. This research can help show the major effects of parent contributions to adolescent's perspective on diet and weight, in addition to highlighting key issues that could influence the impact of these types of conversation. With the growing amount of individuals experiencing low self-esteem due to poor body image and weight concerns, this research question is an important topic in today's society. Answering this research question will aid in understanding the effects of parent-child relationships on adolescent body image and disordered eating concerns.

Abstract Name: **How Gen Z Views Incentive and Productivity in the Context of Continuous Improvement (CI)**

This study examines how Generation Z views incentive and productivity in the context of continuous improvement (CI). Many industries have successfully identified CI factors that have improved overall productivity. However, applying previously found CI factors may not extend the longevity of CI. Continuous improvement is an ongoing improvement of a process, technique, or product that can be judged against its effective use of resources (productivity). As such, the question of what incentives drive a specific population of potential workforce leaders, such as Generation Z, remains. This research aims to identify the factors that impact the support for CI initiatives among college students. Specifically, the study examines how incentives encourage productivity and promote job growth and satisfaction among Generation Z students who concurrently study and work. Two hundred undergraduate junior and senior student participants will complete a survey on whether an educational process (including educational resources), an embedded incentive system, has encouraged productivity both in academics and in their current jobs. The data collected will be run through regression analysis to investigate the relationship between the current incentive system and job environment incentives toward productivity. The results of this study will add to the previous research in understanding the correlation between academic performance and what incentives motivate students to be productive in their studies and their motivation to continue working during their studies. Research on this subject is needed to build a complete understanding of the correlations between undergraduate employment in relation to academic success and workforce productivity orientation in the context of continuous improvement orientation.

Abstract Name: **Parental Criticism and Willingness to Intermarry**

Willingness to marry someone of a different race is influenced by racial climate. How parents respond will impact how they present preferences for partnering to their children. Research suggests a relationship between race, gender, partner preferences, and parental criticism in partnering. This study examined the impact of race relations on marriage preferences and the role parents have in willingness to intermarry. Participants (n=207) completed a survey containing the Family Emotional Involvement and Criticism Scale I and the Personal/Global grid survey, which measures willingness to partner with someone outside of their race. First, we hypothesized that parental criticism would correlate with the likelihood that participants would partner with someone outside of their race. Data revealed no relationship between criticism and willingness to intermarry for men, but for women this relationship was significant (r=.166, p=.040). The second hypothesis was that race and gender impact partnering with someone outside their race. No differences were found. Findings can inform family therapists and educators individuals willingness to partner with people outside of their race.

Abstract Name: **Political Divide**

The current political climate in the US is more than contentious. The current state of the us verses them attitude divided along the political lines is ever worsening. What information is fact and what is political rhetoric? How can the divide be bridged? What are the potential dangers of such a divide in a powerful country? This research is designed to study how the political attitudes across the US are shaped by unfriendly dialog and news media bias. The goal is to understand how the varying forces around the political disconnect predict the perspective of adults in the US. This research will focus on political knowledge, willingness to connect with people of differing views, commitment to current political views, and news seeking behaviors when identifying underlying reasons for the unwillingeness to accept others with different viewpoints and what can be done to mediate the negative behaviors creating an even wider divide between the groups. How does having friends with widely different political views impact inter-political discourse? What communication skill sets can be cultivated to foster necessary listening and dialogue techniques? Data analysis will be completed in the spring semester of 2023.

Abstract Name: **Monitoring Antibiotic Resistant Populations as a Correlative to Water Quality**

Agricultural land use can have adverse effects on the surrounding waterways, which may cause environmental and economical disturbances including but not limited to species assemblage disruption, loss of habitat and wildlife and human health impacts. There is a need to monitor in vivo aquatic systems, specifically those in agricultural areas, to not only provide a more holistic view into the correlation between agriculture land use and aquatic environmental disruption but also to develop more succinct and effective monitoring and management guidelines. The Blanchard River serves as an excellent model system suitable for monitoring antimicrobial resistant microbe sustainability within a highly agricultural area that serves as a contributor to the Lake Erie basin. Several indicators suggest that the Blanchard River watershed may provide a suitable habitat for the antibiotic resistant microbes including MRSA (methicillin resistant S. aureus). Outside nosocomial infections, minimal research has been completed to determine the reservoirs of MRSA and other resistant microbes. One hundred and twenty-six sites within the Blanchard River and its tributaries were monitored for antibiotic resistant microbes including MRSA. All sites had antibiotic resistant populations while twenty-six of the sites harbored MRSA. Sixteen Areas of Concern (AOCs) were chosen in conjunction with the Blanchard River Watershed Partnership to determine if traditional water quality measures of E. coli concentrations,nutrient levels and macroinvertebrate populations correlate with antibiotic concentrations and resistant populations. Additionally, microcystin concentrations were measured as they are known to enhance horizontal transfer of antibiotic resistance genes. There is no correlation between land usage or antibiotic concentrations and the presence of antibiotic resistant microbes. There were weak correlations between antibiotic concentrations and pollution resistant macroinvertebrates and a weak negative correlation between E. coli levels and pollution sensitive macroinvertebrates.

Abstract Name: **The Effect of Motivational Music on Power in an Anaerobic Sprint Test**

Background: Previous literature suggests music can enhance exercise performance. Extant work has focused on high intensity anaerobic exercise with emphasis on two conditions: 1) music preference (preferred, non-preferred, no music), and 2) music tempo (slow, middle, fast). The primary objective outcome used to define performance is peak power. To date, previous work has examined music preference and music tempo separately. More recent work has explored the influence of motivational music; posited to incorporate elements of music preference and tempo simultaneously. Purpose: The purpose was two-fold: 1) to examine the effect of music condition (motivational, non-motivational, no music) on peak power performance during the Running-Based Anaerobic Sprint Test (RAST); 2) to assess whether motivational music survey scores (assessed the degree of motivation the motivational music provided) predicts peak power. Methods: 20 college-aged participants completed a modified RAST consisting of 6 consecutive sprints over 17.5-meters. Each sprint was followed by a 10 second rest period. A total of four testing days (baseline day; three formal testing days) were completed one week apart. Participants were randomly assigned to three conditions: motivational music (Eye of the Tiger by Survivor – music selection mirrors previous literature), non-motivational music, (Window in 7's by Meredith Monk – self-selected by researchers) and a no music condition. All participants were counterbalanced to complete each music condition. Participants completed motivation music surveys each day. Results: Repeated measures ANOVA analyses showed a main effect of time (peak power increased each day). No interaction effect was found for Time X Condition. Regression analyses revealed that self-reported motivational music did not predict peak power scores. Conclusion: Findings show evidence for increased peak power over time. However, lack of differences across conditions suggests a more nuanced approach is warranted to more appropriately capture the effect of music on exercise.

Abstract Name: **A Measurement of Cocaine-Induced Locomotor Activation and Cocaine Conditioned Place Preference in Lphn3 Wildtype and Knockout Rats**

Variants in Lphn3 gene expression are associated with a pre-disposition to develop attention-deficit hyperactivity disorder (ADHD) and predict substance use disorder (SUD) in ADHD patients. To assess the impact of Lphn3 deletion on the rewarding effects of cocaine, we assessed cocaine conditioned place preference (CPP) in Lphn3-/-(i.e., knockout, KO) andLphn3+/+(i.e., wildtype, WT) rats. The CPP apparatus was equipped with photobeams to detect horizontal and vertical movement andhad2 visually distinct chambers separated by a removable door. On day 1 (habituation) and 8 (final test), each rat was placed in the apparatus with the door removed for 15 min. On days 2, 4, and 6 each rat received an intraperitoneal injection (IP) of 10 mg/kg cocaine 5 minutes before being restricted for 15 min in the chamber that was less preferred on day 1. On days 3, 5, and 7 each rat received an IP injection of saline 5 min before being confined to the other side of the chamber for 15 minutes. Horizontal beam breaks in each chamber were recorded as a measure of locomotor activity across all testing days and time spent in each chamber was recorded on days 1 and 8. Preference was determined by subtracting the amount of time spent in the drug-paired chamber on day 1 from the amount of time spent there on day 8. It was hypothesized that cocaine-induced locomotor activation would be greater in the KO rats and that they would show a greater preference for the cocaine-paired chamber. Surprisingly, the KO rats did not exhibit cocaine-induced locomotor activation. Compared to day 1, both genotypes exhibited an increase in time spent on the drug-paired side on day 8. However, there was not a difference between the genotypes in their final preference for the drug-paired side.

Abstract Name: **Living With What We Can't Remember: A Documentary on the Relationship Between Trauma and Memory Loss**

Memory tends to be thought of as something straight forward and linear, like a camcorder capturing life as it happens. But the process of how our brain goes about encoding each experience we encounter is a web still being unwound. In the case of traumatic memory, this only rings more true. Trauma, unlike non-traumatic memory, is often stored in fragments. During the event, the prefrontal cortex goes “offline”. In place of a traditional narrative consisting of a beginning, middle and end, the limbic system latches onto different sensory input (information that will often later act as triggers). It’s this fact that sits at the core of a notion growing increasingly more embraced, first by the psychology field and now by the general public: The body remembers trauma.Paper Birds is a short documentary illuminating what it’s like to live with what you can’t remember in the conventional sense, and–more importantly–demonstrates that healing is possible even in the absence of answers. Following my own story of navigating life with somatic–sometimes referred to as “body”--memories and the delayed onset of PTSD, this piece presents a complex, misunderstood facet of trauma through interviews, reenactments and symbolic b-roll in a way that can be easily digested by the general public.The long standing stigma tied to recovered memories and the complete lack of media representation regarding body memories has, for far too long, discouraged survivors from talking openly about their experiences–an act that only exacerbates feelings of guilt and loneliness. Paper Birds stands to change that.

Abstract Name: **Predator Avoidance Behavior in Grass Shrimp**

Grass shrimp (Palaemon pugio) are common and ecologically important in coastal environments along the Atlantic coast of the United States, but little is known about their behavior. Predator-prey interactions and predator avoidance behavior are particularly understudied in this species, especially because grass shrimp are a major food source for commercially and environmentally important blue crabs (Callinectes sapidus). The primary goals of this study were to categorize predator-prey interactions with blue crabs and determine if shrimp predator avoidance behavior changed in response to the ocean acidification associated with climate change. Because ocean acidification interferes with decision-making and predator response behavior in some marine animals, behavioral assays were developed in this experiment to assess shrimp predator avoidance (in a Y-maze) and escape responses under current and future ocean conditions. While shrimp made incorrect decisions slightly more often and took longer to make decisions under acidified conditions, these differences were not statistically significant, indicating the grass shrimp are likely resilient to the direct effects of ocean acidification, potentially due to large natural fluctuations in their variable coastal environments. In direct predator exposure experiments, we observed and quantified previously undescribed predator inspection behavior in P. pugio. This type of behavior is largely undocumented in invertebrates, which presented the opportunity to examine the complex and unknown predator-prey dynamics between two ecologically important species. There was a high degree of individual variation in this “bold” predator inspection behavior, suggesting a difference in behavioral traits between shrimp. Because existing research on predator inspection behavior centers almost exclusively on vertebrates, these findings have interesting implications for invertebrate behavior and the evolution of predator avoidance strategies like these. Grass shrimp appear to have complex social structures and predator avoidance strategies that are only now being documented, which is essentialfor understandingtheir ecological role.

Abstract Name: **BACK TO BENIN: AN ANALYSIS OF THREE CALLS TO REPATRIATE THE BENIN BRONZES**

The Benin Bronzes are currently globally dispersed often without acknowledging the object's origin of unethical acquisition by British troops from the Kingdom of Benin, located in present-day Nigeria. The research question attempts to investigate The Berlin Ethnographic Museum, The Smithsonian Museum, and The British Museum in their choices to create spaces for ethical repatriation for the separated collections of Benin Bronzes. Scholars examining the issue are researching how museums and educational institutions can progress in establishing systems of ethical and accountable repatriation. These newer ideas are cultivated through evaluating past repatriation cases to determine the approaches in taking accountability for previous unethical acquisitions. I will analyze data from online media publications and platforms of the three museums, historical documentation of each acquisition, and news sources engaging critically with each museum's responses to repatriating the Benin Bronzes. With the collected data, I will use descriptive and comparative analysis methods to summarize the data, providing background for each repatriation case, and then assess where the museums' public actions towards repatriating the Benin Bronzes differ. The results hope to gain a further explanation of the range in repatriation approaches allowed through the museum's first person accounts among outside criticism. Understanding each museums' stance in relation to outside criticism will display the current allowance for museums to continue hosting unethically acquired cultural objects while comparatively more progressive efforts to repatriate exist.

Abstract Name: **Plant functional community assembly along a stress gradient in Northern and Southern Wisconsin forests**

Functional community assembly seeks to understand communities in terms of mixtures of functional traits. Stabilizing ecological selection can cause communities to have lower than expected trait diversity, while disruptive ecological selection can produce greater than expected trait diversity.Similarly, directional ecological selection can alter mean trait values. Environmental stress (e.g., low soil moisture) can reduce trait diversity, but the evidence is limited. Community assembly may be influenced by the spatial extent of the species pool and the spatial grain size of the sample plot. We sampled plants in 40 locations in Northern forests (mainly evergreen conifers) and Southern forests (mainly deciduous trees) across a strong gradient in soil moisture. Each location had three sample plots with three grain sizes: (0.1m^2, 1.0m^2, 10m^2). Four functional traits (two size traits and two leaf economic traits) were collected for every plant species. We used Monte Carlo simulations to estimate the amount of functional trait diversity and mean trait values that would be found if community assembly was caused by random ecological drift. The simulations used four species pool scales: regional (all observations), within Northern or Southern Wisconsin forests, within specific forest types, and within each forest location.With a large-scale species pool perspective, communities had lower than expected trait diversity, but with small-scale perspectives the pattern switched.Leaf size diversity was greater than expected using the smallest species pool. Moisture had significant effects on both trait means and trait diversities, but the relationships strongly differed in Northern versus Southern forests. Some results supported existing theory, for example dry forests tended to have more conservative leaf traits and also lower trait diversity in some cases. Functional community assembly differed in Northern versus Southern forests, and so there are unique assembly rules for each region.

Abstract Name: **A Machine Learning Approach To Detecting Deepfakes**

The ability to manipulate videos has been around for decades but a process that once would take time, money, and professionals, can now be created by anyone due to the rapid advancement of deepfake technology. Deep fakes use deep learning artificial intelligence to make fake digital content, typically in the form of swapping a person's face in a video or image. This technology could easily threaten and manipulate individuals, corporations, and political organizations. As the technology for creating deepfakes continues to improve, these manipulated videos arebecoming increasingly undetectable. It is crucial to create methods to combat this problem. Previous research has been conducted on the various techniques to detect deepfakes, and though some models show promising results, many models struggle with reproducibility and practicality when exposed to real-world scenarios. Future work could consist of creating models without the tools used to generate deepfakes and the collected dataset in mind. Thus, we aim to create a more general model that can be repeated on a variety of real data. To achieve this, we will analyze multiple datasetsand the models that have been created from them. After comparing the strengths and limitations of the top models, we plan to achieve a new model that is more accurate at detecting real-world deepfake videos. As deepfake technology continues to accelerate, it is essential to continue building models that can detect it because if we do not, it will be impossible to discern digital truth from reality.

Abstract Name: **Cells Null For KLF4 Respond To DNA Damage Less Effectively Than Wild-Type Cells**

Aidan Conroy and Engda HagosDepartment of Biology, Colgate University, Hamilton, NY, 13346, USAKrüppel-like factor 4 (KLF4) is a highly conserved zinc-finger transcription factor involved in multiple cellular processes such as development, differentiation, and cell cycle regulation. In response to DNA damage, KLF4 expression is upregulated by the tumor suppressor p53. Furthermore, mouse embryonic fibroblasts (MEFs) null for Klf4 have been shown to exhibit increased genomic instability such as aneuploidy, centrosome amplification, and DNA double-strand breaks (DSBs). In this study, cells wild type for Klf4 (+/+) and null (-/-) Mouse Embryonic Fibroblasts (MEFs) were cultured and studied as a model for human colorectal cancer. Chemotherapeutic drug, etoposide, was utilized to induce DNA damage in Klf4 (+/+) and (-/-) MEFs with varying recovery times to investigate the role of KLF4 regulating DNA repair proteins and cell cycle regulation. Western blotting with primary antibodies for DNA repair proteins and gamma-H2AX was used as an effective biomarker to monitor DNA damage. At the basal level, immunostaining revealed that Klf4 (-/-) MEFs in comparison to Klf4 (+/+) MEFs exhibit significantly more DNA damage. Additionally, our data has shown that cells that have functional Klf4 exhibited more overall DNA damage recovery as compared with Klf4 null cells. We also found that Klf4 upregulated the DNA repair and cell cycle regulator protein, CHK1 immediately following DNA damage. Our data strongly suggest that Klf4 plays a significant role in DNA damage repair in mouse embryonic fibroblast cells. These results indicate that Klf4 plays a crucial role in maintaining genetic stability and support the previous findings that KLF4 is a tumor suppressor.

Abstract Name: **On the Kinematics of Sneezing Droplets (Computational Analysis)**

The key to the mitigation of the spread of coronavirus disease such as COVID-19 is to understand how microbial pathogens travel once they leavethe source. Tracking the trajectories of viral particles as asymptomatic carriers sneeze, cough, and even speak would provide a very good picture of what measures to take to curb disease transmission. Under this CURE project, students of Physics 251 and Physics 271 employed two-dimensional kinematic equations to investigate the trajectories of the particles leaving a simulated infected person. The novelty of this study is that we base our investigation on a single-particle approach where we follow trajectory of single particle instead of bulk movement of fluids. Using the height of the asymptomatic carriers as a controlling parameter, we assess the extent of infective range for a variety of solutions. It is worth mentioning that both groups of students, of 251 and 271, used their own recipes and method of data collection distinct from each another. As an extension of the simulation of the trajectories, 271 students used the collected data to produce computer-simulated visualizations of the individual trajectories using statistical mode approach. We focus on the computer-simulated visualization for this project.

Abstract Name: **"The Protocol of Invisibility:" Examining the Dangers of Secondary Sources of Secondary Sources**

Marilyn A. Katz's 1998 article, "Did the Women of Ancient Athens Attend Theater in the Eighteenth Century?" examines points made by Karl August Böttiger in his article from 1796 entitled "Were Women in Athens Spectators at Dramatic Performances?" She apparently aims to answer the question both Böttiger's and her own articles (at least in their titles) overtly pose: Did women actually attend ancient Greek dramatic performances? In her analysis of Böttiger's writings, Katz introduces Böttiger's assertion that ancient Athenian women were likely not present in the audience because of the theatre's status of being "a civic, political and ritual arena;" she then introduces a concept introduced by contemporary historian Simon Goldhill—"the protocol of invisibility"—which Greek women would have followed, and an idea to which she asserts Böttiger would have subscribed. But the title of Katz's article—so closely contouring Böttiger's own—implies that it is going to address this question, that is, whether Athenian women were present at ancient Greek dramatic performances; however, her text never substantively addresses the question (more than the wry paraphrase ofBöttiger in her title), instead focusing almost exclusively on the writings of Böttiger. In other words, the putative subject—women in ancient Greece—remains elusive, as if even among scholars, women as historical subjects are once again forced into a "protocol of invisibility." The following paper, in a close reading of Katz's article on Böttiger, problematizes this historiographic feint, offering up a cautionary tale regarding the dangers of secondary sources conversing with secondary sources, conversations which reveal more about the historians and their own socio-historical contexts, and which bring us no closer to the actual subject they are supposedly examining.

Abstract Name: **Exploring the Movements of Philosophy As Practice Through a Phenomenological Approach**

Historian of philosophy Pierre Hadot (1922 - 2010) revolutionized the study of ancient philosophy through his insistence that, for ancient thinkers, philosophy was more than just a framework of ideas captured in discourse; it was always and inherently grounded in a way of life and everyday practices. Theories and discourses were produced during the process of these practices, but theory was always secondary to practice in both cause and significance. In line with this, the primary concern of ancient philosophical schools was not transferring certain ideas to the minds of their students, but rather fostering a modification of the self using procedures Hadot calls “spiritual exercises.”Itrace a unifying theme throughout Hadot’s work, that of philosophy as a dynamic movement (as opposed to the static architecture of ideas it leaves in its wake). I offer two images for conceptualizing this movement: an ebb and flow (both being informed by the world and feeding into the world), and the myth of Theseus’s Ship (always being radically reborn, and yet still circling back to the same identity).While drawing out how these movements are present in Hadot’s work, it’s important to avoid reducing the discussion of philosophy as practice to merely a theoretical statement. In order to do this, I instead explore Hadot’s insights through a concrete analysis of lived life. Engaging in a phenomenological (not merely autobiographical) account of my own practices as a student of philosophy, I demonstrate how the spiritual exercises Hadot finds in ancient philosophy can illuminate and direct contemporary life.

Abstract Name: **Narrative Perception in Cy Twombly?s 50 Days at Iliam (1978)**

Cy Twombly’s series, 50 Days at Iliam (1978), asserts itself as a conflation of classical antiquity and modern art. While much of the contemporary discourse around Twombly’s work rests upon a visual and historical foundation, this paper will examine the Iliam series through interdisciplinary means, incorporating psychology and biology along with art history to interpret this group of 10 abstract paintings in a novel way. The paper begins by discussing biological structures and their connection to the brain’s processes of perception. I argue that Twombly’s Iliam paintings are decoded by what psychologists call “top-down processing”, a process by which complex narratives are understood with aid from memory. This stands in contrast to “bottom-up processing”, a process where sensual information is constructed into more detailed narratives, by which most abstract art is thought to be perceived. Biographical research into Twombly’s childhood and familial relationships provides evidence of a lifelong interest in archetypes and symbols including his work as a military cryptographer and his enduring fascination with ancient Greek mythology. Furthermore, I provide evidence of his father’s influence in his later formation of masculinity and other social relationships in the manifestation of his artistic style. Twombly’s abstract interpretation of scenes from Homer’s Iliad and the Trojan War is explored in the context of sociological themes of violence. The paper further connects concepts in Classical literature to the holistic narrative of the Iliam series, discussing themes of violence, masculinity, and identity. Finally, scientific and biological concepts of perception and preference offer a nuanced perspective into the field of art history and the analysis of Cy Twombly.

Abstract Name: **How Human Capital Flight Impacts Greece?s Economy**

This paper examines how human capital flight has impacted Greece's economy in the aftermath of the 2008 Global Financial Crisis. Human capital flight is the emigration of skilled workers from a less developed country to a more developed country. Greece has been unable to recover from the 2008 Financial Crisis which has caused the emigration of skilled workers to seek employment in other countries. Current research on Greece's human capital flight, however, does not focus on the time period of the post 2008 Global Financial Crisis. This research attempts to analyze what reasoning skilled workers have to emigrate from, such as the oppressive government, lack of opportunity, and lower wages. It investigates how the emigration of skilled workers has caused a population decline with a higher percentage of elderly citizens. This research consists of reviewing scholarly journals, books, and raw data provided by the United Nations, World Bank, etc. to decipher how emigration impacts Greece's economy. Raw data is analyzed including age, birth rate, net migration rate, GDP composition, GDP growth rate, GDP per capita, industrial production growth rate, labor force, and unemployment rate. This research will be beneficial to these countries to further understand why human capital flight occurs, and how it affects their declining population. Human capital flight's effects on the population decline of less developed countries is detrimental to their growth, and this study could help prevent this. This research will not only be applicable to these countries, but for the growing number of countries worldwide that are also experiencing human capital flight.

Abstract Name: **Investigating the Role of Acute High Levels of Vitamin D on Autism Spectrum Disorder-Associated Behaviors in Rats**

Vitamin D is essential to facilitating and maintaining healthy brain function, in part through regulating dopaminergic neuron differentiation and influencing the synthesis and metabolism of dopamine. Disrupted signaling in the dopaminergic system can lead to the presence of behaviors associated with autism spectrum disorder (ASD), a neurodevelopmental disorder characterized by deficits in social communication and the presence of restricted interests and repetitive behaviors. To further investigate the role of Vitamin D in modulating dopamine neurotransmission, our project administered acute high levels of vitamin D and evaluated the presence of ASD-associated behaviors in rats. Rats received treatment of 2 mg/kg of vitamin D or control (corn oil) by oral gavage for three days prior to behavioral testing. Thirty minutes prior to testing, half of the rats from each vitamin D treatment group were injected with 10 mg/kg of a dopamine reuptake inhibitor (GBR 12909) or saline control. Total activity was assessed, followed by a social preference task, a marble-burying task, and a nest-building task to evaluate the presence and severity of ASD- and ADHD-associated behaviors, respectively. The current study focused on ASD-associated behaviors, and we hypothesized that rats given an acute high dose of vitamin D will show differences in ASD-associated behaviors compared to rats that received vehicle when the dopaminergic system is probed by administration of a dopamine transporter (DAT) inhibitor (GBR 12909). Results showed no significant differences between the treatment groups in the social preference and marble burying tasks. However, when separated by sex, male and female rats reacted differently to vitamin D as well as GBR 12909. Future research aims to add power to this study to further investigate the relationship between vitamin D and ASD-associated behaviors.

Abstract Name: **Targeting the TRPM8 Receptor: The Gateway for Anti-Cancer Properties Associated with Carvacrol - A Plant-Derived Bioactive Molecule**

Plant-derived extracts and essential oils have been known for millennia to have therapeutic value for the treatment of various human maladies. Previously, we demonstrated the bioactive molecule in oregano known as carvacrol decreases proliferation for the TRPM8+ cancer cell line A375 (melanoma) and increases proliferation for the TRPM8+ non-cancerous epithelial cell line BEAS-2B. To further examine the role that TRPM8 has in mediating these cellular responses, exogenous small interfering RNA (siRNA) oligonucleotides were used to target and silence TRPM8 expression in both A375 and BEAS-2B. Non-targeting siRNA (scramble) was used in parallel as a negative control during the transfections. Following transfection, Western blot methods confirmed the knockdown of TRPM8 expression. Next, the transfected cells were treated with carvacrol (0 μM and 125 μM) over 72 hours. As expected, the non-targeting siRNA transfected cells showed a response to the carvacrol treatments by displaying a reduction in cellular proliferation among the A375 cells and an increase in proliferation among the BEAS-2B cells. Similar results were obtained using biochemical proliferation assays which revealed a decrease in proliferation (A375) and an increase in proliferation (BEAS-2B). More notably, these cellular proliferation responses to carvacrol were absent following the knockdown of TRPM8. Finally, programmed cell death was assessed using apoptosis activity assays. As expected, the non-targeting siRNA transfections followed by carvacrol treatments showed an increase of apoptotic activity for A375 and was absent for the non-cancerous cells, both in agreement with our proliferation data. In contrast, when TRPM8 expression was silenced the carvacrol treatments did not significantly increase the A375 apoptotic activity. Taken together, we show the TRPM8 receptor mediates the cellular responses elicited by carvacrol and serves as the gateway for this novel treatment option intended for skin cancer patients. These observations have clinical applications in the areas of diagnostics and treatments for skin cancer.

Abstract Name: **Android Malware Detection using Opcode on Machine Learning**

As the number of Android devices increases, so does the probability of downloading an application that contains malware. This is a serious issue as malware could potentially harm the device, or, even worse, harvest sensitive data from the user. To prevent this issue, a method for quickly and accurately determining if an application contains malware would be very beneficial which is what this research attempts to do. For this study, a large collection of APK files is obtained, half of which contain malware. In order to make features using opcode, each file is disassembled using a disassembler called Baksmali. The first byte of every instruction in every file is extracted and used to generate intermediate files. These intermediate files are used to create a set of 10-gram opcode to allow for the analysis of commonly occurring sequences. The desired number of files is selected, and the frequency of every line across the selected files is calculated. The top N sequences are selected and used to determine the frequency of each sequence in every file. Two CSV files, one for malware and one for benign files, are created to store the frequency of each feature within every 10-gram opcode. The files are fed into various machine learning models, such as SVM, 5-NN, CART, Random Forest, and XGboost, to find a highly accurate model. These steps are repeated with a variable number of files and selected features to determine what directly impacts the accuracy. The experimental results show that using large number files with a small number of features along with a Random Forest model generates the highest accuracy, where the highest recorded accuracy was 87.31% with 800 files and 500 features. This work demonstrates the capacity to identify malware efficiently by utilizing features developed with minimum procedures.

Abstract Name: **The Wisconsin Council on Undergraduate Research: Working Together to Promote and Support Undergraduate Research, Scholarly and Creative Activities**

Undergraduate research, scholarly, and creative activities (URSCA) have a long history in the University of Wisconsin System (UWS). Since 1999, various system campuses have hosted the UW System Symposium, an annual gathering modeled after the National Conference on Undergraduate Research. It brings together undergraduate researchers, their mentors, and program coordinators to showcase the accomplishments of and celebrate URSCA. With the support of a National Science Foundation grant awarded to the Council on Undergraduate Research to institutionalize undergraduate research at the system/consortium level, the Wisconsin Council on Undergraduate Research (WisCUR) was formally launched in 2013.The group initially consisted of URSCA program leaders and advocates from UWS institutions. Recently, its membership expanded to include private universities and technical colleges in Wisconsin. Its mission is to provide leadership to advance, enhance, and expand URSCA across the UWS and beyond in order to prepare graduates who can adapt and innovate for the challenges of the future. Since the inception of WisCUR, URSCA programs within the WisCUR network have made great strides. For example, three UWS schools (UW-Eau Claire, UW-La Crosse, and UW-Milwaukee) have won the Campus-Wide Award for Undergraduate Research Accomplishments (AURA). No other state system has received the honor of receiving multiple AURA awards. Partly due to its involvement with WisCUR, Concordia University developed an undergraduate research certificate program and Madison College created an undergraduate research program.Wisconsin higher education institutions have also faced a variety of challenges that require innovations and adaptations, and WisCUR has served as a resource and support in this area. In this presentation, we will share the organization and goals of WisCUR, typical activities (beyond UWS Symposium) we sponsor, and benefits of WisCUR to individual institutions and staff therein. We will provide suggestions on how to organize similar URSCA groups and invite attendees to share their experiences.

Abstract Name: **Isolation and identification of cyanobacterial secondary metabolites responsible for increased ubiquitin transfer**

Ubiquitination is a post-translational modification that is fundamental to most biological processes in Eukaryotes. Ubiquitin conjugation is controlled by an enzymatic cascade that comprises of the E1 (Ubiquitin-activating), E2 (Ubiquitin-conjugating), and E3 (Ubiquitin ligases) enzymes. Ubiquitination controls many cellular processes, such as DNA repair and apoptosis, but its key role is targeting proteins to the proteasome for degradation and this function is critical for normal cellular functions. Therefore, dysregulation of this process can lead to many diseases, like cancer, developmental, and neurodegenerative disease. Accordingly, discovery of small molecules that can modulate this pathway would enhance our understanding of this important pathway and could represent new therapeutic approaches for a variety of diseases.Since Prokaryotes lack ubiquitin conjugation machinery, we sought out to identify new molecules that could regulate the ubiquitin pathway. We screened crude fractionated libraries of compounds sourced from the marine cyanobacteria Rivularia spp. using in vitro ubiquitination assays. We observed that a middle range polarity fraction of the Rivularia spp. increased both substrate and auto-ubiquitination activities for several different E3s. This included UHRF1, a RING E3 ubiquitin ligase that controls DNA methylation, and IAP2, a protein that controls apoptosis. Additionally, we observed an increase in E2~Ub formed by E1 indicating that the compound was impacting steps upstream of the E3. Following our experiments, further fractionation of one of the active fractions was performed to simplify the complexity of the mixture. We are currently trying to identify the compound' structure using NMR and mass spectrometry along with determining what precise steps by which the small molecule increases ubiquitination activity.

Abstract Name: **Communication Ability Profile for Employees and Employers**

The purpose of this study is to analyze the development of the Communication Ability Profile for Employees and Employers (CAPE) as a tool that may help potential employees with a disability detail how they communicate and advocate for the ways employers and co-workers should communicate with them in the workplace. The CAPE details an overview of the employee's communication strengths, workplace qualities, communication modalities, accommodations, and beneficial ways to connect with fellow employees. According to the U.S. Bureau of Labor Statistics (2020) in 2019, 19.3% of persons with disability were employed compared to 66.3 percent of people without a disability. While the labor market has improved, the degrees of improvement are lower for people with disabilities compared to people without disabilities. Furthermore, McNaughton and Arnold (2010) completed a metanalysis and found that the keys to success in employing people with disabilities include developing employee knowledge and skills that are valued in the workplace, matching the skills and interests of the individuals who use AAC, and continue to maintain and ensure needs are met for each employee to be successful. Participants for this IRB-approved study were recruited through an emailed script, the CAPE protocol, and a Qualtrics survey link sent to 16 potential participants of which nine subjects consented and completed the survey. An analysis of the data from the study of the CAPE will inform a final version of the protocol. This data will allow us to accurately reflect on the best ways to inform the protocol to foster successful communication in the workplace for people with disabilities. Furthermore, through analyzing and shaping the CAPE we hope to answer how the CAPE identifies communication strengths and needs compared to a traditional employment application form and how participants' perspectives of benefits and recommendations vary across parent and professional disciplines.

Abstract Name: **Caught on camera: Are humans a safety cue for mammalian vertebrates?**

Anthropogenic pressures are imposing environmental modifications at unprecedented spatial and temporal scales to drive ecological change. One provocative notion is that fear of humans (so called "super-predators") in human-altered landscapes may substitute for predation pressures that were historically imposed by large mammalian carnivores. This project addresses the question of whether free-living mammals actively avoid or are attracted to human presence over space and time. We examined the impact of human activities on the assemblages of free-living mammals as part of a long-term behavioral ecology study at Briones Regional Park in California. Specifically, we characterized the presence of humans, their dogs, and native vertebrates by analyzing thousands of photos from automated-camera traps (e.g., trail cams deployed over the past several years). We tagged photos of coyotes, bobcats, deer, skunks, and ground squirrels using the image software organizer "digiKam" and analyzed the data using the R statistical package "camtrapR." We report on variation in the visitation rates by mammals across space and time to uncover the interrelationships among multiple species within the park. Our data set documents the crepuscular activities of carnivorans (e.g., bobcats, coyotes, skunks) and offers insights into the potential effects of visitation by humans (and dogs) on the lives of these elusive mammals. This information about the activity schedule of these animals offers key insights into the behavioral ecology of these animals as well as useful information for wildlife managers as burgeoning human populations visit natural areas.

Abstract Name: **Strategic Responses to Global Governance: Sustainability in the International Construction Industry**

The international construction industry has a profound impact on the lives of nearly every person around the globe. Despite this universal presence, the industry has a reputation for unsustainable practices, corruption, and negligence. In response to increasing pressure from NGOs, IGOs, and INGOs to counteract the negative dimensions of the industry, many construction firms have implemented ESG and sustainability policies. This research project quantifies the sustainability initiatives of construction firms across the globe to uncover trends in this ever-evolving industry. The database constructed to analyze this information contains 240 companies located in thirty-one countries across six continents. This study aims to determine if any country level factors are associated with firms acting as positive corporate citizens in an industry ecosystem that contains numerous actors engaged in unsustainable and unethical practices. All of the data points used to quantify these initiatives are classified into two main categories: country factors and company factors. At the country level, data points from sources like the United Nations Development Program and Transparency International are integrated to analyze the overall macro conditions in the home country of the listed firms. At the company level, firms are analyzed using numerous theoretical frameworks. One of the core frameworks within the dataset is the 4Cs of MNEs, developed by Puffer et al. which classifies firms into four archetypes based on their relationship across two dimensions (proactive vs. reactive and collaborative vs. combative) with global governance organizations. Additionally, firms are categorized in the Stages of Corporate Citizenship framework created by Mirvis and Googins. Companies are also awarded a score based on their relationship with the United Nations Sustainable Development Goals and Global Compact.

Abstract Name: **Examining the St. Olaf First Year Experience**

In the fall of the 2022-2023 school year, St. Olaf College implemented a new First Year Experience (FYE) program. This new program consists of a revamped New Student Orientation (NSO), biweekly St. Olaf Orientation to Academics and Resources (SOAR) programs, and a seminar and writing course requirement, in an attempt to improve first year student satisfaction and success. In order to measure satisfaction and success, we compared data from NSO surveys, SOAR feedback surveys, the St. Olaf Learning Goals Questionnaire (LGQ), and the National Survey of Student Engagement (NSSE), in addition to general retention and student grade information, from this academic year, to similar data collected in previous years. We conducted exploratory data analyses which indicated clear correlations between student satisfaction and the timing of various portions of the FYE program. We then compared summary statistics and ran statistical tests to quantify and validate the trends in our data. These tests and observations indicated significant improvements in satisfaction and success that may be attributed to the new FYE program, such as improved performance on the LGQ in areas corresponding to required seminar content, and increased senses of belonging and connection among students following the week of Student Orientation. However, our work also highlights some aspects of the program with little to no impact on satisfaction or success, such as a majority of required biweekly SOAR sessions. Based on our results, recommendations will be made to St. Olaf College in order to revise and alter the FYE program for future incoming students.

Abstract Name: **Characterizing the effect of nucleoside transport and metabolism on the response of Escherichia coli to glucose-phosphate stress**

All organisms need to be able to sense and respond to stress. In bacteria such as Escherichia coli, glucose-phosphate stress is caused by a block in glycolysis, resulting in growth inhibition and intracellular accumulation of sugar-phosphates. E. coli responds to this stress in part through the actions of the small RNA SgrS, which is expressed specifically during stress and blocks uptake of stressor sugar-phosphates. While this regulatory response is well understood, less is known about metabolic pathways that provide alternative carbon sources to bypass the glycolytic block. Previous research supports the notion that nucleoside transport and metabolism likely provide these carbon sources. For example, deleting nucleoside genes results in a growth defect during stress. Here, we characterize the effect of nucleoside genes on induction of the glucose-phosphate stress response, as measured by expression of a PsgrS-lacZ transcriptional fusion. Deleting deoD, which encodes a phosphorylase that cleaves the sugar from nucleosides for use as a carbon source, increases stress response induction. In contrast, deleting other nucleoside phosphorylase genes such as ppnP does not affect induction. Similarly, deleting nupG, which encodes a transporter that brings nucleosides into the cell, does not affect expression. As a whole, these results suggest that DeoD is a key player in the recovery from stress. Current research is focused on how other nucleoside transport and metabolism genes affect the response to glucose-phosphate stress.

Abstract Name: **Composer Diversity in Solo Vocal Repertoire Assignments**

Throughout history, female composers have been overlooked in favor of their male counterparts to a great degree. By ignoring female composers' contributions, the male dominance in representation in vocal literature continues without correction. Even with plentiful composed selections by females, educators remain close-minded when choosing vocal solos for their students. This paper aims to state the issue of how limited music educators are in assigning repertoire and offer suggestions that can diversify the repertoire being assigned. This paper will demonstrate the lack of female composers represented in the most commonly published vocal anthology books and vocal solo competition repertoire lists in Texas. Throughout the paper, I will be including discussions with distinguished voice teachers and significant people at the forefront of vocal diversity research. I will also be recommending art songs composed by women for high school and college singers that can function just as well as the traditional male-dominant selections. Results show that female compositions are woefully discounted in the NATS competition list, 38 published anthology books, and the list of vocal piece selections for all 3 classes on the UIL PML list.

Abstract Name: Flexible Finger Design for Robotic Gripper

In industry, the safety and productivity of collaborative robots make them a vital part of many pick and place applications in production. Collaborative robots offer many advantages including their flexibility. In keeping with the advantages of collaborative robots, this flexibility should be extended to the grippers and fingers to reflect human-like dexterity. Flexible fingers have several advantages over traditional, rigid grippers. Adaptive fingers can pick and place a much broader array of oddly shaped objects than traditional grippers. Flexible fingers are also advantageous when working with fragile objects, such as produce, as the gripping force can be distributed by the flexing of the finger.The purpose of this project was to design, optimize, build and evaluate flexible fingers which can be mounted to a Schunk gripper on the end of a Fanuc collaborative robotic arm. Flexible fingers were designed in SolidWorks to integrate with the robotic gripper assembly. By testing prototypes, aspects were identified to improve the flexibility and functionality of the gripper. Using DOE (Design of Experiment) as an optimization strategy, the effects of each variable such as material, wall thickness, infill, etc. was studied. Mechanical simulators were used to isolate and test these variables to see their effects on the system with realistic situational constraints.The manufacturing of the flexible fingers consisted of using SLA and FDM printing to test, compare, and combine the more promising features into a robust finished product, capable of gripping and lifting various objects.Using technologies such as CAD, additive manufacturing, and agile engineering methodologies; it was possible to accomplish the design process and optimize the finger design in a collaborative manner.

Abstract Name: CO2 Ventilation Testing and Air Purifier Installation to Reduce COVID Risk at NCUR

Containing and minimizing the spread of COVID-19 remains a concern for educational institutions like UW-Eau Claire, where students have returned to in-person classes and large educational conferences have resumed. The growing number of communicable disease outbreaks in recent decades have increased the need for innovative tools to predict and lessen their impact, especially in large gatherings like the 2023 National Conference of Undergraduate Research (NCUR). COVID-19 is transmitted through aerosolized respiratory particles and inadequate ventilation allows these aerosolized particles to build up in closed, indoor spaces. Filtration physically removes pathogens from a space and ventilation dilutes the concentration of infectious aerosolized particles, limiting the risk of disease transmission [1]. To maximize the safety of all NCUR participants, CO2 testing was thoroughly conducted in 64 rooms in 8 different campus buildings with a capacity of 3,024 people to evaluate ventilation and risk of COVID-19 transmission. Following CO2 measurements for a 48-hour period, air purifiers were installed in rooms exceeding a standard of 800 parts per million (ppm) of CO2 to protect NCUR participant health.

Danielle Zahn

Abstract Name: **Investigation of Ventilation and Air Quality in Classrooms**

The transmission of the coronavirus can be greatly impacted by indoor ventilation and air purifiers according to the U.S. Environmental Protection Agency and other public and private institutions and researchers. The concentration of aerosols in the air that contain the virus can be reduced by proper ventilation systems, which circulate and filter the air for increased quality. Aerosols with a diameter of 2.5µm or lessare a possible carrier of SARS-CoV-2. PM 2.5 pollution may also increase the cellular expression of ACE2, associated with greater viral susceptibility. Ventilation to reduce PM 2.5 levels addresses both risks. Tests using incense as an indicator before, during, and after burning were used to see how quickly the ventilation in the rooms was able to remove excess PM 2.5. A calibrated DustTrak II monitor was used to record particulate matter, then Honeywell HEPA air purifiers were emplaced to see if further purification would aid in ventilation compared to only an HVAC system. Room air exchange rates (ACH, hr-1) were calculated using a spreadsheet by Jimenez at UC-Boulder. ACH rates in a small (15 person) meeting room were 5.88 hr-1 with HVAC alone and 16 hr-1 with two added air purifiers. Corresponding rates in an average (35 person) classroom were 9.62 hr-1 and 12.0 hr-1 with a single purifier. In this case, HVAC and air purifier coverage was 1.25–2.72 times as efficient as just HVAC coverage. Results for local weightlifting rooms are currently being investigated and will be included. A limitation of this research was the occasional pooling of incense smoke near the opening of the air monitor leading to a temporary spike in PM 2.5 levels. Use offans can address this issue. HEPA air purifiers reduce PM 2.5 levels and in turn may help lessen transmission risk of SARS-CoV-2 aerosols and airborne viruses

Abstract Name: **Targeted Messaging about Food Storage in Social Media Posts**

Food waste is a major problem in the United States and around the globe. In the U.S alone, avoidable food waste exceeds 55 million metric tonnes per year, nearly 29% of annual production and it has been estimated that this waste produces life-cycle greenhouse gas emissions of at least 113 million metric tonnes of CO2 annually, equivalent to 2% of national emissions. Food waste by end consumers occurs for many reasons, including food being prepared and stored incorrectly, and misunderstandings of the “best by” date on foods. Food-related messaging is widespread on social media, with users posting comments and photographs of foods that they are preparing or enjoying. These messages are then viewed by millions of users. Targeted responses to such messages could correct some misconceptions and therefore reduce food waste. The main technical challenges for creating targeted messages are identifying food-related posts and automatically generating a relevant response. We have developed an approach that uses machine learning to identify if a social media post mentions specific foods. The approach is able to detect food entities in Twitter posts with a precision and recall of 0.8. This approach was also applied to identify foods in photographs posted on Instagram using object recognition in images algorithms. If a post is identified as likely to be about a specific food, a short message with information such as storing tips and methods to prepare that food is generated. We use the FoodKeeper dataset published by the U.S. Department of Agriculture which contains descriptions of foods and their storage methods to generate targeted responses. This approach could therefore be used as a tool for more targeted and real-time messaging of information related to food and potentially help reduce food waste by end consumers

Abstract Name: **From Gyil Music to Dog Meat: a Gastromusicological Autoethnography of Traditional Dagara Culture**

The Dagara people, located primarily in the Upper West region of Ghana, take pride in their careful preservation of traditional customs, amidst years of brutal colonization and ethnocide, not to mention the pervasive influence of surrounding peoples. Previous ethnomusicological research has recognized the gyil, a Ghanaian xylophone, as the focal point of Dagara society, noting how it interacts with and is inherent in all aspects of their culture. In June and July 2022, I spent approximately three weeks studying gyil repertoire at the Dagara Music Center, located in Medie, Ghana, a small town north of Accra. I participated in local Dagara traditions- attending a funeral, church celebration, and large weekend parties- all the while observing how gyil music-making is deeply connected to food and drink culture. Reflecting on these experiences through an autoethnographic discussion, I examine the gyil through the lens of gastronomy. In this study, I analyze the gyil's role in the following distinct experiences: consuming dog meat following a traditional Dagara funeral, drinking pito during weekend social gatherings, and eating some variation of saab almost every evening for dinner. My presentation will include some live demonstrations on the gyil, in order to connect the music with the anecdotes I discuss. Food and drink, paired with gyil music, is meant to be shared with company, encouraging solidarity while simultaneously resisting outside influence. Through this study, I argue that these collective activities transmit traditions across generations, thus strengthening the community. My gyil instructor Jerome Balsab told me once that "if the gyil has died, Dagara itself has died." I build on his view by showing how the acts of eating, drinking, playing, and listening sustain Dagara culture as a whole.

Abstract Name: **Pipeline to Success through Research and Community Connections for Underrepresented Women in STEM Majors**

Alverno College is the first Hispanic serving institution in Wisconsin with programs aimed to increase the population of STEM majors from underrepresented communities. In 2011, a pipeline was created with the Girls' Academy of Science and Mathematics program (GA) where high school girls work with the Natural Sciences, Mathematics, and Technology division (NSMT) faculty on Friday nights to participate in STEM activities, which encourages them to apply for undergraduate STEM programs. Since 2018, NSMT has increased its capacity to provide STEM undergraduates with on-campus summer research opportunities. Traditionally, these programs are designed for upper level students; however, Alverno's program is open to students of all grade levels. The main goal is to increase student self-efficacy in the laboratory, connect scientific research to the local community, and increase persistence in STEM majors. Alverno and the Milwaukee Riverkeeper has established a partnership in efforts to make a community-based connection and assist in water analyses researched each summer. Beginning-level students conduct water sample collection, analyses, and hypothesis building using chemistry and biology methods over a six week program. Upper-level students conduct more advanced water chemistry analyses, microbiological, and molecular biology research over eight weeks. Students attend weekly laboratory meetings and professional development sessions to learn about STEM careers, research/internship opportunities, and receive academic advising.GA has served over 730 students. The majority of participants are girls of color (96%) and those who qualify for free or reduced lunch (98%). Each year approximately 18-20 girls matriculate from GA to Alverno with about half majoring in STEM. The summer research program has supported 73 researchers (56 unique students), 65% who identify as women of color with a 95% persistence rate. A common themed found was an increase in personal identity as a scientist (self-efficacy). Furthermore, 54% of 2021 summer researchers applied for off-campus research opportunities.

Abstract Name: **Evaluation of Nematophagous Fungi Capture Efficiency and Immobilization of Parasitic Nematodes**

Nematodes are a numerous component of the world's ecosystems. Being some of the most abundant organisms on the planet, many play a parasitic role toward plants and animals. However, parasites known as Xiphinema and Pratylenchus or the dagger nematode and the lesion nematode are genuses of parasitic plant roundworm that prioritizes and negatively impact the vascular and root tissues of plant species. Our project examined the rates in which isolates of nematophagous fungi could capture and immobilize various plant-parasitic nematodes. The fungal genera used include the net-forming Arthrobotrys oligospora, and constricting hyphae loop Dactylaria. These fungi were isolated from field soils and cultivated on various agar media. Microscope slides were coated with cornmeal agar (CMA+), water agar (WA+urea), and potato dextrose agar (PDA+), to evaluate their trapping efficiency against the plant-parasitic nematodes Pratylenchus scrbneri, and Xiphinema.

Abstract Name: **Gender Conditioning and Performance**

Gender Conditioning and Performance is a theatre approach that challenges the relevance of maintaining a gender binary onstage. Actors are praised for playing villains and murderers, knowing that the actors themselves is not dangerous people. What keeps us from embracing transgender and non-binary actors in the same way we love cis-gender actors? Can we allow actors to play characters whose gender is different from actors' own gender? This is examined through the relationship between actor, character, and gender. My research deepens the understanding of gender in theatre performances through the use of somatic theatre practices. Somatic practices decrease the possibility of self assumptions and increase true, physical impulses, leading to genuine exploration of the actor and their relationship to gender. As a transgender actor, I experience the fluctating relationship with character body and personal body everyday. However, an actor does not have to be transgender to experience physical disconnect in this way. Instead of viewing this conflict as something that inhibits the actor, my work turns it into an actors power. We can encourage theatre artists to use the stage as a space to explore the gender of both performer and character. The key to this exploration is connecting to our bodies. Through engagement with the Ohad Naharin's Gaga movement, gender studies, and theatre practices, this research investigates the power of the gender binary, what holds it together, and what can break it apart.

Abstract Name: **Induced Forests and Pseudoforests in Planar Graphs**

The four color theorem is one of the most famous theorems in the field of graph theory, and is a theorem that one encounters without even realizing it when they look at a map. The theorem states that no more than four colors are needed to color the regions of a map such that no two regions that are adjacent share the same color. Despite its fame, this theorem is incredibly difficult to prove, and is the first major theorem in mathematics proven using a computer, and as such its proof is rejected by many mathematicians, although it has repeatedly been shown to hold true. We consider the following conjecture regarding induced forests in planar graphs, stating that in any planar graph G, there exists an induced forest containing at least half of the vertices of G. If this conjecture holds true, then it would in turn provide a proof of the four color theorem. This conjecture has already been shown to hold true for outerplanar graphs and triangle-free graphs. We prove that for any planar graph G with no edge adjacent triangles, such a graph may be partitioned into P1 and P2, where both are induced pseudoforests. We go on to show that for any planar graph G with triangles δ1, ..., δn, provided there exists at least one vertex in each δi with degree 2, then G may be partitioned into two induced forests. Finally, we prove that for planar graphs possessing a bounded number of triangles, there exists an induced forest on at least half of the vertices.

Abstract Name: **Studying the effect of aryl hydrocarbon receptor activation on affinity maturation**

Oral immunization with protein antigens, such as cholera toxin, will result in production of antibodies by intestinal B cells. These antibodies can neutralize the toxin's ability to cause harm. Repeated immunization will increase the average affinity of toxin-specific antibodies over time, a process called affinity maturation. The aryl hydrocarbon receptor (AhR) acts as a sensor of friendly gut microbes and, in so doing, plays a role in moderating gut inflammation. Strong activation of the AhR by drugs and other chemicals can suppress B cell function and antibody responses, but those responses recover over time with repeated immunization. It is currently unknown if affinity maturation also recovers over time after strong AhR activation. To fill this gap in knowledge, we hypothesized that average antibody affinity would decrease over time with repeated immunization, in parallel with antibody levels, after strong AhR activation in mice. Because the AhR is a target for drug therapy to treat autoimmune disease, this work is important for understanding the potential implications of drug therapy.Based on the results of preliminary experiments, we were able to determine that antibody concentration increases as number of inoculations increase, providing a baseline knowledge necessary for future AhR activation experiments.

Abstract Name: Rhetoric and the First Amendment: UWL Student Perceptions Towards their Right to Free Speech on Campus

The Supreme Court of the United States has often addressed issues pertaining to the First Amendment right to free expression using the “marketplace of ideas” metaphor. Thismetaphor has been usedto condemn the use of government censorship for types of speech that do not surpass the protections of the First Amendment, allowing underrepresented communities to voice their opinions equally. The importance of Free Speech on any college campus is abundantly clear because of these reasons, and in order to fully exercise their rights, students should be aware of what and when certain kinds of speech are protected.Recent events on the University of Wisconsin La Crosse (UWL) campusmay have altered student perceptions towards the confines of their First Amendment rights. On April 26th, 2022, UWL School of Education students protested administrative issues by chalkingmessages directed at UWL faculty. These messages, which were described in an email as "obscene, lewd, [and] profane," were subsequently removed while other unrelated messages remained untouched. Other such issues with student speech have also arisen in recent months.My research seeks to gauge UWL student knowledge,perceptions, and expectationsregarding free speech in general as comparedto free speech on a college campus. This study appliesa mixed method and multi-staged approach to textual analysis and data collection. This includes analyzing the rhetoric of certain administrative communications (e.g., emails and policies) and how they affect students. Additionally, I amconducting a series of surveys, interviews, and focus groupsto better understand multiple student perspectives. Questionspertain to students'definitions of free speech and its limitationsin different situations and settings on campus. The results of this study will provide insight intohow the First Amendment is both perceived and applied on college campuses.

Abstract Name: Optimization of Metallic Interconnectors for Clean Energy Power Systems

The need to eliminate carbon emissions coupled with intensified energy demands have led to an intensified research and development activities in clean energy technology. Taking advantage of fuels such as green hydrogen, solid oxide fuel cells (SOFC) power systems can serve as a potential energy conversion system. SOFCs combine O2 from air and H2 gas to generate electricity, consequently producing water (H2O) as the only byproduct of the electrochemical reaction. SOFCs typically have an operational temperature in the range of 500-900C and generate electricity without the requirement of recharging, so long as the fuel is supplied. A single SOFC cell contains a porous cathode electrode where oxygen reduction reaction takes place (ORR), a porous anode electrode where hydrogen oxidation reaction (HOR) occurs. A dense electrolyte separates the anode and cathode, and an interconnect (IC) is placed on both electrodes that acts like a current collector. ICs are fabricated using chromia-forming alloys due to their high electrical conductivity and robust resistance to oxidation and corrosion. Oxidation of behavior of these alloys and their influence on the electrical property of oxide scales under complex SOFC operating atmosphere largely remains unknow. This experimental research work is focused on understanding the oxidation behavior of select commercial chromia and alumina forming IC alloys and study its effect on the area-specific resistance (ASR) under SOFC operating conditions. Experimental details regarding the measurement of resistivity at elevated temperatures and the calculated time and temperature-dependent ASR will be presented. Implications of oxidation and corrosion of alloys at high temperatures under complex gas atmosphere and their effect on the electric conductive pathway will be discussed. Applications of this research pertaining to transportation, residential and commercial systems in energy storage and conversion technologies will be presented.

Abstract Name: **The effects of an ecologically relevant level of malathion on the behavior and neurodevelopment of a model organism: Northern Leopard Frog tadpoles**

Malathion is a commonly used pesticide throughout the United States, often contaminating surrounding natural habitats. Vertebrates such as amphibians are exposed to these chemicals through run-off as non-target organisms. Although these contaminants are believed to be of acceptable levels, recent literature is questioning the safety of these chemical concentrations. However, how these conditions are affecting anurans is highly understudied. Concerns have been raised that amphibian populations have been massively decreasing during the past few decades. Malathion is an organophosphate, an irreversible acetylcholinesterase (AChE) inhibitor, which has been shown to cause nausea, seizures, and death at high concentrations in previous studies. Effects have been seen in tadpoles with other AChE inhibitors even at low, ecologically appropriate concentrations, however, the impact of low, environmentally relevant concentrations of malathion on neurodevelopment and behavior have never been tested. To explore the effects of malathion on vertebrates, Northern Leopard Frog tadpoles (Lithobates [Rana] pipiens) were used as a model organism and were exposed to either a vehicle control or to 1 µg/L of malathion for three weeks in a blind-controlled laboratory study. During the exposure period, interval behavior was taken weekly. After three weeks,post-treatment behavior assays were performed. The specimens were then euthanized and weighed. Standard body and brain morphology measurements were taken and analyzed. Results revealed significant changes in brain morphology of the medulla and the optic tectum, as well as changes in the behavior of boldness, body orientation, and activity between treatments. These changes show that these putatively safe levels of malathion can affect the behavior and neurodevelopment in tadpoles.

Abstract Name: **Expression of the Apolipoprotein E (Apoe) Gene in the Murine Cingulate Cortex upon Activation of the Locus Coeruleus**

Apolipoprotein E (APOE in humans, written analogously asApoe in mice) is a gene that encodes for a protein involved in lipid transportation in the central nervous system. APOE allele variants are commonly associated with differences in Alzheimer's disease progression and severity, as well as attentional performance, in humans. Despite this knowledge, how APOE expression affects brain function during attention remains unclear. In mice, Apoe expression is increased in cortical tissue after synthetic activation of two brain regions that are associated with attention: The cingulate cortex (CC), and the locus coeruleus (LC). Deficits in attentional function associated with differences in activity in these brain regions are also implicated in neuropsychiatric disorders such as schizophrenia, attentional deficit hyperactivity disorder, and major depressive disorder. An understanding of which brain regions and cell types Apoe is expressed upon activation of the attentional circuit could inform treatment approaches for these disorders that target this molecule. Using a cohort of 24 mice (12 male and 12 female), we examined cell type-specific expression of Apoe in the CC following DREADD-mediated excitation of LC inputs. We performed viral injections, single-molecule fluorescence in situ hybridization, and subsequent analysis of gene expression to determine in which cell types (neurons vs. astrocytes, and glutamatergic neurons vs. inhibitory neurons) Apoe is expressed in the CC. The results from these experiments will yield insight into how Apoe expression affects function in cortical microcircuits that are important for attention-guided behavior.

Abstract Name: **Recall and Adherence to Safety Precautions for Prevention of Secondary Exposure to Chemotherapy at Home**

Chemotherapies are used for cancer treatment and are frequently administered intravenously at outpatient clinics. Part of the chemotherapy is excreted by the patient still in its active form, potentially contaminating the home environment and those who live in the same household. Nurses and other oncology team members instruct cancer patients and caregivers about the risks associated with exposure to chemotherapy at home. The evidence is scarce about how much patients and caregivers recall about the instructions they receive and their adherence to them.This study aimed to investigate which instructions related to preventing exposure to chemotherapy residues patients and caregivers recall and follow at home.After IRB approval, a cross-sectional study was conducted. Patients and caregivers from an outpatient cancer clinic in the Midwest answered a two-part survey regarding ten different instructions commonly provided by oncology teams: the first part asked if they received instructions, and the second asked to what degree the instructions were followed. Descriptive statistics were performed.Twenty-one patients and their primary caregivers (dyads) responded to the survey either partially or in completion. Thirteen dyads (62%) reported receiving instructions from the nurse. Twenty dyads answered the first set of questions; one dyad (5%) recalled receiving all ten instructions, and five (25%) reported receiving no instructions. Dyads recalled receiving an average of 4 (43%) instructions. Fourteen dyads responded to the second set of questions; 2 (14%) reported always following instructions, while others (n=12; 86%) reported partially following or not following instructions.Considering the increased risk of exposure each time an instruction is not followed, results indicate the need for improving delivery instruction modes and emphasizing the importance of following instructions to reduce secondary exposure to chemotherapeutic agents. Results also highlight the importance of nurses' role in educating patients and caregivers about secondary exposure.

Abstract Name: **Potential Molecular Probes from Derivatives of Diphenylpyraline for Cannabinoid Receptor**

Brain complexity regarding reward mechanisms has been studied for decades to uncover individual behavior related to motivation. Cannabinoid 1 receptors (CB1R) are located in the part of the psychoactive region of the brain and play a role in the reward system of psychostimulants. It has been shown that diphenylpyraline (DPP) and its analogs bind to CB1R. Hence, developing a CB1R selective probe could help provide more insights into brain reward mechanisms. To accomplish this, molecular modeling using Schrodinger software, synthesis, and biological testing using an iterative approach is being used to uncover the best compounds. Fortunately, the synthesis of most molecules is accomplished in under five steps depending on the method and optimization procedures are reported herein. The modeling leverages the protein data bank structure of CB1R. Molecular docking experiments performed on the CB1R structure (pdb 5TGZ) generated a five-point pharmacophore model for the binding of halogenated DPP analogs within the cannabinoid receptor. Calculated binding energies for the halogenated piperidyl analogs docked to CB1 agree with in vitro data, with fluorinated compounds having greater affinity than chlorinated compounds. This initial modeling informs a synthetic strategy where combinations of hydrophobicity and halogen additions on the phenyl rings may afford access to greater specificity and affinity for the respective protein targets. Optimization of these compounds using a pharmacophore approach could lead to greater specificity and affinity for the CB1 receptor. This rational approach to small molecule development has the potential to produce DPP analogs for use as novel molecular probes. In addition, toxicity studies conducted inform if the compound is suitable for animal models. Results from this iterative approach are reported herein.

Abstract Name: **Synthesis of Diphenylpyraline Derivatives to Study the Inhibition of Dopamine Transport (DAT)**

Dopamine (DA) a neurotransmitter closely linked with reward, causes heightened euphoria when synaptic concentrations are higher than normal. The signaling of DA is controlled by the dopamine transporter (DAT). Our group is focused on synthesizing diphenylpyralines (DPP) to bind to DAT for the purposes of uncovering the best compund that can serve as a molecular probe for DAT. This probe will allow for further examination and clarification on the complexities of the brain. The use of the Schrodinger template for molecular modeling and drug discovery works by distinguishing between structure activity relationships to improve drug developemt, based on existing models. Schrodinger will assist us in uncovering the best DPP derivative to design a molecular probe for synthesis. Because Schrodinger followsLipinski's Rule of Five, the Schrodinger platform will guide us in designing compounds that can pass the blood-brain barrier, and in turn will promote the best design for synthsizing a molecular probe. These molecular probes have also been shown to bind to cannibanoid receptors strongly. Herein are the results.

Abstract Name: **EFFECTS OF ESTROUS CYCLE ON MESOLIMBIC DOPAMINE RELEASE IN MICE**

The mesolimbic dopamine system consists of cell bodies that extend from the ventral tegmental area to several limbic structures, including the nucleus accumbens (NAc). Dopamine transmission in the NAc is known to play a central role in the regulation of reward and motivation. Abnormal mesolimbic dopamine functioning has been associated with disorders such as substance use disorder, depression, ADHD, and schizophrenia. Many studies on NAc dopamine function have relied on data from only male rodents, with the concern of hormonal fluctuations being one reason to exclude female mice. The current study aimed to determine the effects of the female estrous cycle on several aspects of phasic dopamine release in the NAc of mice. Specifically, in vivo fixed potential amperometry with carbon fiber recording electrodes in the NAc was used to measure dopamine release, the synaptic half-life of dopamine, dopamine autoreceptor sensitivity, and the dopaminergic response to cocaine in anesthetized female C57BL/6J mice. Prior to dopamine recordings, vaginal lavages were performed. These samples were stained and examined under a light microscope to determine the estrous cycle phase for each mouse. The mouse estrous cycle is 4-5 days long and progresses through 4 phases: proestrus, estrus, metestrus, and diestrus. No differences were observed between estrous cycle phases on any of the measured variables, indicating that dopamine functioning was not affected by the estrous cycle of the mice. Although more research is needed, these data suggest that variability related to estrous cycles should not be an excluding factor for the experimental design of studies related to mesolimbic dopamine release.

Abstract Name: Effect of Postural Variations on On-Task Behavior in a College Classroom Setting

Background/Study Purpose: Strategies to increase cognitive performance should be explored to increase increased attention during class in higher education. The purpose of this study was to examine the impact of sitting in a chair (traditional sitting), sitting on a physio-ball (physio-ball sitting), and standing in the classroom on on-task behavior (OTB) in undergraduate seniors. Methods: Sixteen college students, ages 20-21 years, rotated through three postures (two classes per posture) that were randomly assigned. The classes were observed for a 40-minute period, and OTB rating of 0 = “not on task” vs. 1 = “on task” was recorded 10 times (every four minutes) per class. Results: Average two-rater interrater reliability scores were 95.6% across the six data collection days. Each participant’s OTB scores were averaged between the two classes per posture. Percentages of perfect scores (scores of 10 out of 10) were calculated, and all postures had an “on-task” rate of greater than 90%. Physio-ball sitting had the lowest percentage of perfect scores. One-way repeated measures analysis of variance indicated a significant different in OTB across the three postures (.05). Post-hoc multiple comparisons using paired samples t-tests with an adjusted alpha of .0167 revealed significant difference in OTB between traditional sitting and physio-ball sitting (p = .005). There were no significant differences in OTB for traditional sitting vs. standing (p = .110) and for standing vs. physio-ball sitting (p = .351). Conclusions: Findings of the study suggest that physio-ball sitting may decrease OTB during class; however, the current sample demonstrated high overall OTB, possibly for being seniors enrolled in a course required by the major. It would be of interest to examine the impact of postural variations on OTB for a larger class size with a more diverse group of undergraduate students.

Abstract Name: Expression of CD44 and SRC through Hyaluronan and Mechanical Stimuli

Ovarian cancer is the deadliest gynecological cancer, with it being the fifth leading cause of cancer related death in women and demonstrating less than a 50% 5-year survival rate (1). Research has displayed a correlation between hyaluronan (HA) in the tumor microenvironment (TME) and metastasis through its receptor, CD44 (2). In addition, SRC, a downstream protein in the CD44 pathway, is associated with cancer proliferation (3). We hypothesize that the addition of mechanical stimulus and either soluble (SOL) or plated (PLT) HA will alter (increase/decrease) the expression of CD44 within the microenvironment. Results indicated the interaction of HA and mechanical strain differentially regulates both CD44 and Src expression in OVCAR-8 cells. The shCD44 line might have expressed higher levels of CD44 due to a splice variant not being successfully knocked down. Further work will be done to isolate a consistent knockdown line. Further investigative studies will be done to study the impact of HA presentation and mechanical stimulus on OVCAR-8 cells in a 3D environment.

Abstract Name: **Heavy Metal Accumulation onto Sediments in Northeast Iowa**

Metal supplements are commonly added to hog feed to prevent post-weaning diarrhea and promote growth in piglets. The manure that is produced by the hogs is then injected into nearby fields, where leaching or erosion could cause metal loss to the watersheds. Metal cations transported in runoff could adsorb to surfaces of sediment particles, resulting in a change to the overall sediment composition and microbial communities. To determine if metal cations are adsorbing to sediment particles due to agricultural runoff, we quantified the metal composition of sediment samples from sites downstream of fields where hog manure is injected as well as controls in northeast Iowa. Measurements of acid-digested samples were done with ICP-OES and results were used to identify differences among sampling locations. These results can be used to understand the extent to which the addition of metals to animal feed has an effect on local environments.

Abstract Name: **How Narratives Hold the Small Towns of the Midwest in Economic and Population Stagnation**

This research seeks to provide insight into rural America's economic stagnation by examining reactions in rural and hybrid towns to incoming industries through the lens of narrative. "Narrative" refers to Patterson and Monroe's definition, "the ways in which we construct disparate facts in our own worlds and weave them together cognitively in order to make sense of our reality." Narrative's influence offers an alternative explanation to anti-migrant sentiment for Midwest towns' harsh rejection of certain industries.When examining instances of political reactions resulting from new industrial plants, it is not clear that unrest is a reaction to migrant workers. Industrial plants importing similar demographics of migrant workers cause a wide variety of reactions. Additionally, rural Americans view cities as hubs for anti-rural interest groups, yet the population of the rural Midwest is steadily diversifying. Thus, an alternative diagnosis for rural protectionism than racism or nationalism seems necessary. Investigation into these instances provides a strong case for newindustries' reliance on compatibility within the rural narrative to successfully integrate intothe rural Midwest.A focus on narrative uncovers a possible cause of rural Americas' falsely primitive image formulated within narrative-forming institutions such as schools, which commonly teach subjects such as history through a clear narrative structure. Schools demonstrate that narrative can be applied to the current processes of an individual or group of individuals' self-contextualization. This research seeks to diagnose the issue of economic stagnation and outmigration that faces Midwestern states as a symptom of self-perceptions of states by their populous as consisting of homogenously rural industries and lifestyles.

Abstract Name: **New Violence for a New Fight: The Modern Far Right's Expansion Into Combat Sports Subcultures**

White supremacists across the world are turning to mixed martial arts to prepare for what they believe is an impending race war. Since the late 2000s, far-right groups emerging from the neo-Nazi hooliganism and street fighting scene have founded combat sports gyms, promotions, and fight clubs across the United States, Canada, and Europe. This paper examines how two major groups, the Russian White Rex and the American Rise Above Movement, have weaponized and modernized traditional far-right discourses on masculinity and the body in order to amplify physical violence and increase their ability to recruit from fitness and combat sports subcultures. Members of this growing movement define themselves through white supremacist ideology and narratives, positioning themselves simultaneously as in constant danger of annihilation and as righteous, formidable warriors defending Western Civilization and a white Europe. The common perceived threat in these representations comes from increased immigration from North Africa and the Middle East, something that is often a part of broader antisemitic conspiracy theoriesabout Jewish people orchestrating the domination and destruction of the white race. Many of these groups have organized acts of racially and politically motivated violence, most notably when members of the Rise Above Movement coordinated to assault numerous counter protestors at the 2017 Unite the Right Rally in Charlottesville, Virginia. Understanding how the modern far right movement expands into new subcultures and becomes more violent is urgent, especially as recent scholarship highlights the growing threat these groups pose to governmental structures and democracy.

Abstract Name: **Surveillance of local water sources for fecal contamination and prevalence of antibiotic resistant bacteria**

Authentic research is an effective tool to increase undergraduate students' interest and competency in a research career. Yet, not all undergraduate students are afforded the ability to participate in traditional research experiences. Course-based Undergraduate Research Experiences (CURE) offer students the opportunity to contribute to authentic and meaningful research endeavors while supporting course learning goals. Here, we aim to present our pedagogical approaches that support microbiological laboratory skill building while also contributing to the surveillance of our local environment. Rochester, MN has two lakes, two reservoirs, eight creeks or runs, and the Zumbro river that are used for recreational purposes. It is not unusual for the lakes to be closed temporarily due to testing positive for pathogenic microbes that exceed state guidelines. Surface water fecal pollution may introduce bacteria and bacteriophages into aquatic environments. Bacteriophages serve as indicators of fecal borne bacterial contamination. Antibiotics, antifungals, and genes that contribute to antibiotic resistance may be present in fecal waste, which may then contribute to antibiotic resistance of aquatic and soil-dwelling bacteria. Here we will present our pedagogical approaches and preliminary results of our aims which include 1) investigating local water sources for bacteriophage abundance and 2) surveillance of environmental soil samples for the prevalence of antibiotic resistant bacteria.

Abstract Name: **Young Black Mental Health In A COVID-19 Impacted South**

Young Black individuals experience stressors daily, and with the addition of COVID-19, young Blacks have been disproportionately affected. However, according to the mental health paradox even though Blacks experience the highest levels of daily stressors, the have the lowest number of mental health conditions. There is a current gap in the literature for young Black adults in the rural South, and the lack of research as to how daily stressors with the edition of pandemic stressors affected the Black population. Building on this, my research questions are as follows: 1) Among young people in the South, do those with more pandemic stressors have more mental health issues? 2) Is race a moderator in this association? To answer these research questions, the 2020 Household Pulse Survey (HPS) conducted by the U.S. Census Bureau was analyzed, specifically looking at dates April 23 through December 21, 2020. It was found that young Black adults in the South had the highest pandemic stressors in comparison to other racial groups. Among young people in the South, those with more pandemic stressors were found to experience more mental health issues. However, young Black adults were found to have the lowest anxiety and depression scores despite their high levels of stressors, supporting the mental health paradox. This study is significant because Blacks are disproportionately affected in the South. Addressing matters early on among young adults can lead to better health outcomes for Blacks in the future.

Abstract Name: **Introduction and Progression of Early Algebra in the Beast Academy Comprehensive Curriculum**

As students progress through elementary mathematics curricula, arithmetic is the main point of focus. However, a call for algebra to become a component of the elementary mathematics curriculum has gained momentum because implementing algebra in early elementary curricula increases student understanding of algebraic concepts and eases the transition to deductive algebra later in mathematics. The Beast Academy comprehensive curriculum was developed with a focus on problem solving through monster characters in a graphic novel who demonstrate different ways of mathematical thinking. Beast Academy incorporates problems where students engage with algebraic thinking earlier than suggested in the Common Core State Standards and continues to incorporate problems which emphasize algebraic thinking through practice problems in subsequent levels. This progression introduces students to algebraic language while enhancing their current learning. We are interested in the trajectory of problems which build algebraic thinking as well as problems in which students are doing algebra. We will present our findings on how this curriculum introduces algebra to students, and how current literature suggests this will impact student learning outcomes.

Abstract Name: **Evaluation of EtOH Abstinence in the Recovery of Neuropathic Evoked Behaviors in a Mouse Model of Alcohol-Induced Peripheral Neuropathy (AIPN)**

Chronic alcohol use can lead to alcohol-induced peripheral neuropathy (AIPN). The prevalence of AIPNamong patients with Alcohol Use Disorder (AUD) is 46.3%, with signs and symptoms in 44% of chronic users. Current treatments for AIPN lack clinical efficacy,therefore, physicians also encourage patients that alcohol abstinence will alleviate allodynia symptoms.Although several factors, such as duration of alcohol consumption and dose of EtOH, may contribute to the severity of AIPN, it remains unknown if abstinence will reverse neuropathic pain andcause severewithdrawal symptoms.This study tested the effects of alcohol abstinence on the recovery from neuropathic evoked behaviors in a mouse model of AIPN. Alcohol abstinence may reverse neuropathic evoked behaviors, mechanical and cold hypersensitivity, in a mouse model of AIPN. A total of 12 male C57BL/6J mice were fed Lieber-DeCarli liquid diets (0, 2.5, and 5%). Nesting, von Frey, acetone, nerve conduction, light-dark box, and somatic sign assays were conducted. Mechanical hypersensitivity developed after 7 days of chronic daily EtOH consumption in the 5% EtOH group. Chronic EtOH consumption induced multiple neuropathic behaviors, such as cold sensitivity and deficits in nesting. Increased neuropathic behaviors induced by chronic EtOH consumption and deficits in SNAP amplitude suggest the mice developed AIPN. After 5 weeks of EtOH consumption, mice underwent a two-week period of EtOH abstinence. Mice presented affective and somatic withdrawal signs, but mechanical and cold hypersensitivity were maintained. These results suggest that alcohol abstinence is not an effective therapy for reversingAIPN in mice and emphasize the need for novel pharmacological targets and treatments.

Abstract Name: **Through the Lens of Latinx/Hispanic Women: Reproductive and Maternal Experiences in the Piedmont-Triad Area.**

This study explored the decision making and experiences of Latinx/Hispanic women with regards to pregnancy, birth practices, labor and delivery, postpartum, and motherhood. Limited studies have specifically focused on the reproductive and maternal health experiences and decision-making of Latinx/Hispanic women. This qualitative, community-engaged research study provides an opportunity for young Latinx/Hispanic women to voice their reproductive and maternal experiences and the connections between their beliefs, culture, and perceptions. Participants were recruited through purposive, snowball sampling. Open-ended, semi-structured interviews were conducted with 15 Latinx/Hispanic women, aged 18-45, who gave birth between 2015-2022, and who reside in the Piedmont-Triad of North Carolina. The research team used the analytic technique, the iterative process of thematic analysis, coding and recoding, categorizing emergent patterns, and then aggregating patterns to develop thematic statements.In the sample dataset, four prominent themes, derived from the emergent categories and subcategories were found across all transcripts. All participants discussed: (1) individual, interpersonal, and structural factors that influenced their decision making; (2) the importance of support; (3) the impact of perceptions and experiences of Motherhood; and (4) their birthing experiences within the U.S. healthcare system. Ten participants stressed the importance of breastfeeding and the role this perception played in decision-making. Almost all participants described receiving either relational, financial, physical, or verbal support from a partner or family member. More than a third of participants reported engaging in cultural or traditional practices associated with birthing or motherhood. One participant stated,“during childbirth I followed the beliefs such as wearing a red ribbon with a key” while other participants described engaging in a 40-day quarantine or “cuarentena” postpartum. Additionaly, more than fiveparticipants noted fear regarding epidural use and its perceived long-term effects. These important findings contribute to the current research and to interventions that can improve maternal and reproductive care and experiences.

Abstract Name: **The road to depression: Lesion network mapping of depression over time**

Brain lesions are a type of damage within the brain typically due to disease or injury. Depression is a common concern for individuals who develop brain lesions, with prevalence for post-stroke depression being 25- 50% and prevalence for depression following a traumatic brain injury being 29-39%. Lesion-network mapping is a technique that allows you to identify neural networks likely to be functionally affected due to a lesion using normative connectivity data. While it's been shown that lesion network mapping can be a useful tool for identifying the risk of developing post-lesion depression in patients, it has not yet been established as to which assessment for depression is most accurate. Our aims were to first compare the lesion network maps of the Beck depression index (BDI) and the Geriatric depression scale (GDS), which are both assessments for depression, and second, to observe if depression and the associated neural networks change over time using the GDS.The lesion-network map using the BDI showed that the Ventral Attention Network was implicated. The maps using the GDS showed that the Frontoparietal Network was implicated at the 3 month period and the Ventrolateral Nucleus of the Thalamus was implicated at the 1 year period.Going forward, conducting a repeated measures experiment for the BDI and the GDS to observe any consistent performance as well as investigating why different networks are involved in different periods of depression recovery is needed.

Abstract Name: **Are Schools Preparing Us for Prison?**

Schools and prisons are the two primary institutions that connect with the lives of individuals'. School is the place where one receives an education not only in academia but also about the norms of society, such as following authority. Prison is the institution where one goes to be "punished" for disobeying authority and society's laws. In the state of California, there are thirty-three prisons compared to nine University of California campuses. Students of color coming from low-income communities can see the division between them and their peers. Some students are guided into the college route, while others are pushed into the incarceration system. This stems from a child's experience in primary school dealing with "good" and "bad" behavior. We believe that the school-to-prison pipeline starts with having students excessively disciplined in ways like mandatory detention or expulsion from school. Then it develops into having correctional officers on school campuses which can lead students into juvenile detention facilities. The purpose of this research is to answer "How do our schools unconsciously guide our students into prisons and not into college?". We examined who the majority of students fall victim to the school-to-prison pipeline with twelve Ted Talk videos. This method was chosen in order to understand the reasons why and how students and their communities are affected by incarceration.

Abstract Name: **Conservation Agriculture: What do farmers think?**

Surface waters in The Red Cedar Watershed contain a high concentration of nutrients that are introduced via agricultural runoff, resulting in eutrophication.The introduction of conservation in land management practices of operations across The Red Cedar Watershed provides a promising solution to the complex issue ofeutrophication. These practices include no-till/reduced-till, cover crops, rotational grazing, grassed waterways, and nutrient management plans. In this study, the factors that influence producers to adopt conservation in their operation wereexplored, along with what factors act as barriers to the adoption of conservation.Semi-structured interviews with producers were conducted along with open-ended survey questions, to determine what factorsarethe primary influencewhen implementing land management practices.A thematic analysis was applied to each interview and survey response,andcodes were formulated based on previous research, anticipated responses, and actual responses.It wasdetermined return on investment (ROI)wasone of the most important factors for producers to implement conservation practices,as ROI is increased with no-till.Otherreoccurring influences included soil health, resilience, general conservation, engagement, and financial incentives. In addition, multipleproducers began no-till to initially save time, but after seeing the benefits, they continued the practice for reasons previously mentioned.The strongest barrier in place is the uncertainty that comes with changein land management, which requires a significant amount of engagement to overcome.Therefore, increased funding to organizations that engage with producersandinvestments in assistance to producers who are in the process of adopting conservation isnecessary.

Abstract Name: **Special collaborative artistic project - NCUR Murals project**

My art journey began with cartoons. I spent hours as a kid replicating my favorite characters from the screen onto whatever I had near me. I loved escaping into the world of what I saw on TV, imagining myself there. Additionally, I have watched my dad go into surgery almost twice a year since I was born, my brother was diagnosed with Type One Diabetes and I developed a rare autoimmune condition. I saw my relationship with my health begin to impact how I create art. I started using materialthat was difficult or completely impossible to erase, teaching myself to be more comfortable with mistakes and marks that were not "intentional". My process changed from drawing what I see in front of me to drawing what I feel, mapping out my emotions on paper, and converting those feelings into artwork. I am interested in being part of a collaborative team that works on the theme of human health and well being. My health experiences have helped me to cultivate more efficient and effective team-skills. Being sick, I couldn't do everything on my own and that was a hard lesson to learn. I know how to take other people's suggestions and combine them to include my unique perspective while contributing to the process even if I am not in control. It is my belief that the only thing that separates artists from non-artists is the will to create. This passion has driven me for as long as I can remember. There is nothing more that I want to do than share what I make with the world and I'm excited by this opportunity to create a collabortive mural with unique and diverse artists.

Abstract Name: **Principle, Design, and fabrication of a next-generation superconducting quantum interference device**

Superconducting quantum interference devices (SQUIDs) are incredibly sensitive electromagnetic sensors that can detect extremely weak magnetic fields, such as those generated by the human brain and heart. Magnetocardiography (MCG) and magnetoencephalography (MEG) are examples of imaging methods that utilize SQUIDs. Specifically, a MEG can detect different neural regions of interest (ROIs) when participants are presented with various stimuli. A SQUID is fabricated by placing a pair of Josephson junction devices together, where two superconductors are spaced by an extremely thin electrical insulator. Traditionally, low-temperature superconductors are used in current SQUID systems, requiring a complex and expensive liquid helium-based cooling system. In contrast, high-temperature superconductors such as YBCO use liquid nitrogen-based cooling systems, which are significantly less costly to build and operate. Our current research involves designing and fabricating a YBCO-based SQUID, which may give a better spatial resolution and a more cost-effective solution compared tothe existing SQUID systems. Here, we discuss the ability of the SQUID-powered MEG to successfully locate brain ROIs when participants are shown various objects and highlight the shared networks for object recognition of concrete and abstract figures. We also present our experimental measurements on the superconducting and insulating materials used in fabricating a next-generation SQUID.

Cunningham, Blair

Institution: *GA - Kennesaw State University*

Discipline: **Architectural Engineering/Construction Management**

Author/Contributors:
Blair Cunningham

Abstract Name: **Reforming Concrete: Mechanical Innovation in Sustainability**

Timber frame concrete formwork can generate as much as 40% of construction waste on a given project. This study proposes a method of concrete formwork construction that aims to improve the versatility and sustainability of concrete construction processes through the application of a novel concrete reinforcement system which reduces waste generated by current concrete formwork practices. By using fabric to build formwork and provide reinforcement the possibilities of design in concrete and cementitious materials are widened. 3D printed shear dowels are placed into the formwork to transfer tension loads out of the concrete and into the fabric. The dowel is designed to have a pressure fitted locking mechanism for easy installation. The dowels are pushed through the weave of the fabric and have four points of connection to prevent a concentration of force in any one point causing the dowel to fail. There were several design iterations to ensure the dowel was able to efficiently distribute the shear forces. These parts are meant to be manufactured through 3D printing further supporting the sustainability of this process by reducing material waste and energy input for manufacturing processes. It is also cost effective; the parts can be scaled easily, and materials can be changed based on strength needs and applications. Testing is primarily focused on Selective Laser Sintering (SLA) printed resin parts because this method produces isotropic products which eliminate concerns relative to loading balance for printing and installation orientation. The material chosen for this project is a high tensile strength resin with comparable elongation at failure to steel to avoid brittle failure. This product will be analyzed by stress simulation of the design using several material parameters and compressive load testing of beams constructed with this technique.

Abstract Name: **Student Organizations as a Means to Effectively Develop Safety Culture Within Undergraduate Chemistry**

Safety education for college-level chemistry labs can be adequate for minor incidents of broken glass and small spills, but the chemical industry and graduate programs are often under the scrutiny of environmental health and safety departments that have far more stringent requirements than an average undergraduate student will encounter. Students who graduate with a bachelor's in chemistry often find themselves with a job where chemical hygiene is practiced at a level they aren't used to. Considering the professional and personal implications that poor adherence to chemical safety can have, more could be done at the undergraduate level to develop the skills and mindset associated with chemical safety. The Chemistry Student Safety Team (CSST) is a student-led, mindset-focused organization working to foster a safety culture at UWEC. The CSST is mentored by UWEC faculty and the UMN-Twin Cities Joint Safety Team (JST). The CSST uses safety demonstrations, awareness campaigns, PPE sales, and safety themed merchandise to promote safety culture. To track attitudes in the UWEC department of chemistry, the CSST uses an annual safety survey along with a system to report near miss incidents anonymously. Student safety organizations at an undergraduate level are an innovative way to promote safety-culture through peer education. With faculty support, student-led safety organizations such as the CSST can be an integral part of disseminating safety information to other students within undergraduate chemistry programs. Involving students in education and safety initiatives at an undergraduate level can lead to more effective researchers, more productive employees, lower organizational costs, and a more safe and equitable learning environment.

Abstract Name: **The struggle for restoration: how Thai villagers organize in response to environmental degradation**

This is a qualitative research study based on personal in-depth interviews (with IRB approval) of 30 residents of villages in Northern Thailand who are forced to cope with the toxic effects of contaminated groundwater from an abandoned gold mining operation. For the last 15 years, the village of Na Nong Bong and five others in the Wang Sa Phung district have been struggling to recover from the environmental impacts of a gold mining operation in their area. These communities, located in the Loei province, were excited for the opportunity to host Tungkum Limited before noise and dust pollution began, infiltrating dozens of local streams. This research project seeks to discover, through the respondents' storytelling, how they have sought, despite moments of brutality and oppression, to win government help to improve their public health and how they have altered their community strategies in seeking restoration projects. Additionally, the study relies on theories of resilience to analyze how these community members have moved toward healing after trauma. Respondents, recruited mainly through convenience sampling, represent a wide variety of ages and positions in the community. The researcher has identified themes and categories through two rounds of qualitative coding. Initial findings suggest that villagers have shifted their tactics over time and that newer generations of residents – including students who have experience with political protests in college – are inheriting roles in leading efforts to gain attention and resolutions. The author spent three weeks among the villagers during summer 2022 to conduct this research. The results of this project will provide insight into how a history of organizing in Thailand has contributed to this situation, how community organizers interact with long term restoration projects, and how communities move towards healing after traumatic experiences.

Abstract Name: **Stigma of Giving Criticism in Peer Response**

Peer response, or peer review, is a common method instructors use in classroom settings with the aim of improving students' writing. Peer response consists of students reading each other's work and making suggestions for their peers' improvement. A faculty member in the English department and an undergraduate student researcher used IRB-approved ethnographic methods to study peer response. The researchers observed peer response in the university classroom environment and interviewed students and instructors about their experiences with peer response. In this presentation, the undergraduate researcher shares a paradox she noticed that was frequently communicated to her by the approximately 20 fellow undergraduates she interviewed. The paradox is that students often expect to receive comments regarding how to improve their own papers, even as they are hesitant to give such comments to their peers.The presenter argues that peer response lacks critical feedback due to the students' fear of judgement, despite most students wanting to receive critical feedback. Students shared that they don't want to be perceived as "mean" for telling other students how to improve their papers, and students don't want to hurt their peers' feelings. However, students want to receive comments that find faults in their own paper in order to improve. Students also find that they get a better grade on their paper when their peer reviewer gives them more suggestions for improvement. The presentation will include specific examples from field notes of classroom observations and excerpts of interview transcripts to demonstrate this paradox. The presentation will close with possible changes to the peer response method to reduce this paradox, such as building relationships between students and implementing face-to-face discussions.

Abstract Name: **Arabidopsis thaliana as a Model Organism to Study Spontaneous Haploid Genome Doubling in Maize**

With the growing world population, accelerating maize breeding is essential forincreasing the earth's food, feed, and fiber supply. In maize breeding, inbred parents are needed to create hybrids, which are preferred for their vigor. Doubled haploid (DH) technology is utilized to develop homozygous inbred plants faster than traditional breeding methods. Traditionally, maize needs six to eight generations to obtain inbred parents. However, DH technology can reduce this time to as little as two generations. There are two steps involved in DH technology: a haploid induction step followed by a genome doubling step. The haploid induction step uses an inducer genotype to pollinate a donor plant. This results in haploid plants with a single copy of the chromosome. Then,the genome doubling step is used to overcome sterility in the haploid plants. Current methods for the genome doubling step are undesirable because the procedure is labor-intensive and involves toxic chemicals. Therefore, a possible solution to this problem is spontaneous haploid genome doubling (SHGD). Genotypes discovered with SHGD are haploid fertile. The goal is to discover genes involved in SHGD, as these genes are currently unknown.Arabidopsis thalianais a model organism with a shorter life cycle than maize. This research project willutilize anArabidopsis thalianascreening pipeline to identify potential candidate genes involved in maize SHGD. This presentationwill outline the various steps used to identify candidate genes, as well as the process of analyzing their involvement in haploid fertility. Ultimately, the promising candidate genes identified inArabidopsis thalianawill be eligible to repeat the pipeline to replicate results. If the results are confirmed, the candidate genes will be studied in maize.

Abstract Name: Preparedness and Comfort Levels in Providing Sexual Health Education on Vancouver Island

Sex trafficking and sexualized violence are increasing in communities across British Columbia (BC). Sexual health education has been recognized as a powerful tool to prevent children and youth from experiencing these devastating forms of abuse. The question then becomes: who is providing this sexual health education to British Columbian youth, and how well is it being provided? While parents and private consultants often play a role in teaching children the basic concepts involved in sexual health education, the quality and scope of their explanations can vary widely. As such, a key source of sexual health education is teachers in primary and secondary schools. Typically, sexual health education in BC begins in kindergarten and spans through grade ten. While the topic's content is regulated through the provincial curriculum, previous research has shown that teachers are not providing consistent and thorough education. The disconnect between the curriculum and educators appears to be hinged upon two concepts: first, educators themselves do not have enough knowledge on the topics to teach them effectively, and second, educators may not feel comfortable with certain sensitive topics within the curriculum. This project sought to investigate how prepared Vancouver Island teachers-in-training are to teach sexual health education based on their knowledge and comfort levels regarding the curriculum topics. A survey was created with three sections: individual demographics, a curriculum-based knowledge test, and a subjective section focusing on comfort levels regarding various sexual health topics. The survey was open to university students enrolled in the Bachelor and Master of Education programs at Vancouver Island University and the University of Victoria. By examining these future teachers, this project aimed to illuminate how prepared the next generation of teachers are and provide insight into the future of sexual health education.

Abstract Name: Voter Attitudes in Relation to Rural Swing State Residency

United States voter turnout related to other democratic countries is very low. Internally, the United States has several swing states that tend to swing from one party to the other during federal elections. Furthermore, Americans tend to have very strong feelings about voting, which may impact whether or not they vote at all. Voter attitudes and swing state residency have the potential for an interesting intersection of research. Understanding why people do or do not vote in swing states, especially rural areas of swing states like Dunn County, WI, can help increase voter turnout in future federal elections, thus leading to a more representative government.According to past research, during presidential elections, swing states are campaigned and paid attention to much more than other states. Additionally, research has shown that the sense of community that are commonly found in rural areas increase voter turnout. Combining these two ideas and researching how swing states are treated and ideas specific to rural areas impact voter attitudes. The goal forthis research is to see how attitudes towards voting compares when voting in a battleground state versus a non-battleground state. The present researchhopes to understand how battleground state residency can impact how individuals perceive the importance and necessity of voting. Early analysis points to factors such as feelings of closeness to one's communityand election competitiveness as being motivators to rural swing state voters.

Abstract Name: Investigating a Local Elementary School?s Implementation of the Next Generation Science Standards

Next Generation Science Standards (NGSS) are being implemented by K-12 schools throughout the United States. The Outdoor Discovery Center (ODC), a nonprofit education organization, partnered with a school in West Michigan to assist their K-5 teachers with implementation of NGSS throughout the 2021-2022 school year. The purpose of this research was to determine how effectively the elementary school teachers incorporated NGSS into their science lessons, how engaged students were during the lessons, and how comfortable the teachers were with the new standards. Researchers collected data using interviews, focus groups, and surveys from three sample groups: teachers (n=24), students (n=7), and ODC ambassadors (n=4). Qualitative data were analyzed with NVivo software using inductive methodology to determine major themes. Quantitative data were analyzed using a Wilcoxon Signed Rank Test in SPSS to determine if there were changes in teachers' attitudes over time. Qualitative results revealed that teachers often felt overwhelmed with integrating NGSS because of a lack of time, difficulties gathering appropriate learning resources, and a lack of content knowledge. However, teachers persevered and continued with implementation as they observed increased student engagement, gained experience with the new standards, and received support from the ODC. Survey data indicated most teachers felt more comfortable with this style of teaching by the end of the year, but they recognized there was room for improvement. Specifically, teachers wanted to develop more robust assessment tools, schedule more co-planning time with each other and the ODC ambassadors, and engage in more professional development to increase their content knowledge and gain experience with NGSS-based pedagogy. The research team also noted that more science and engineering practices could be incorporated into the elementary lessons. Nevertheless, the first year of implementation laid a foundation for the future of effective incorporation of NGSS in this elementary school.

Abstract Name: Finding an Identity as a First-Generation American

This article is an exploration of the struggle that first-generation Americans go through when finding their sense of identity. I analyze the issue through an autoethnography, reflecting on my own experience as a daughter of immigrant parents but born in the United States, as well as a literature review with past research on the topic. With two distinct cultures, first-generation Americans struggle to find who they are, due to living somewhat of a double life - parent's culture at home and American culture once you leave the front door. This conflict can be confusing in the development of their identity, the ability to feel accepted or fitting in completely to either culture feels quite impossible. According to my research, the ability to assimilate to American culture and feel accepted is often dependent on having "American values and traits" such as having white-passing physical features, being patriotic, and believing in democracy and freedom. But even having all these traits and beliefs, one's identity is still conflicted because their life is experienced through both cultural lenses, the fulfillment of one still leaves something to desire for the other. The journey of discovering one's identity is complex and varies depending on one's experience, it is inconsistent. The search of finding one's identity as a first-generation American cannot be encompassed and boiled down to one conclusion, and is a myriad of small details that create one's identity. The American melting pot cannot melt all things down, and this is what the beautiful experience of living two cultures is, being different. Future research or application of this research should explore more in depth the difference in western and eastern first-generation Americans.

Abstract Name: **A Natural Language Processing Pipeline for Summarizing Behavioral Health Electronic Health Records**

Doctors and nurses have limited time between patients to analyze and review a patient's documents to provide a quality assessment. This problem is supplemented by the existence of Electronic Health Records (EHR), which are essentially digital files regarding the patient. However, the length and content of each document vary greatly, reducing the system's effectiveness. Therefore, this research aims to reduce the need for medical professionals to manually search for crucial information about the patient's health history. We intend to accomplish our objective by breaking down large digital documents into small subtasks and using various natural language processing (NLP) techniques to provide a concise summary. Thus we propose a three-block pipeline to accomplish this task. The first block extracts textual information from non-textual digital documents and transfers all the content into modifiable text files. The second block is split into two parts that simultaneously extract target information regarding the patient's mental and medical history using event extraction and named entity recognition (NER). The final block uses a popular abstractive summarization model, BART, to generate summaries based on the events discovered in the previous block. To optimize the output of our pipeline, we compared the summarization and sentence transformer encoder models with other popular models in the same field to ensure optimal results. Using the ROUGE, rand index, and completeness metrics, our model can effectively extract critical patient information from long-form EHRs and generate accurate and meaningful summaries highlighting popular and recurring events from a patient's life. In future work, we intend to migrate to a closed-domain event extraction model and implement a time for easier visualization.

Abstract Name: **Political Divide**

The current political climate in teh US is more than contentious. The current state of the us verses them attitude divided along the political lines is ever worsening. What information is fact and what is political rhetoric? How can the divide be bridged? What are the potential dangers of such a divide in a powerful country? This research is designed to study how the political attitudes across the US are shaped by unfriendly dialog and news media bias. The goal is to understand how the varying forces around the political disconnect predict the perspective of adults in the US. This research will focus on political knowledge, willingness to connect with people of differing views, commitment to current political views, and news seeking behaviors when identifying underlying reasons for the unwillingeness to accept others with different viewpoints and what can be done to mediate the negative behaviors creating an even wider divide between the groups. How does having friends with widely different political views impact inter-political discourse? What communication skill sets can be cultivated to foster necessary listening and dialogue techniques? Data analysis will be completed in the spring semester of 2023.

Abstract Name: **Determination of the role of nucleoskeletal factors on mortality and seizures following traumatic brain injury (TBI)**

Traumatic brain injury (TBI) is a global public health issue affecting millions of individuals each year. One complication stemming from TBI is the occurrence of post-traumatic seizures (PTS), which affect up to 50% of individuals. Severe TBI, advanced age, and genetics are all associated with increased rates of PTS. However, these factors are poorly understood and the cellular and molecular mechanisms which initiate, drive, and maintain a PTS disease state are not known. These gaps in understanding hinder our ability to treat those suffering from PTS and prevent its development. Recurrent or lifelong PTS is associated with sustained changes in nervous system activity. Gene expression and nervous system activity are highly regulated processes. Central to gene expression are nuclear lamin proteins and associated binding partners. Interaction partners include the Linker of Nucleoskeleton and Cytoskeleton (LINC) complex which serves as a mechanical stress apparatus bridging cytoplasmic and nuclear functions. Lamins and the LINC complex are excellent candidates for factors which span contributions to aging, TBI outcomes, and PTS. We utilized the GAL4/UAS system in Drosophila melanogaster to drive RNAi-mediated knockdown of candidate genes. We specifically targeted the LINC complex factors consisting of fly Msp300, klarischt, klaroid, as well as the two fly lamins. Young flies were administered TBI via either a single, severe injury paradigm or a repetitive, moderate injury paradigm. Animals were then assessed for overall mortality, and also PTS via a simple behavioral assay. We found little evidence that genetic knockdown of candidate factors affected outcomes. Future directions include assessment of aged flies to understand if these factors are similarly negligible with advancing age.

Abstract Name: **Parental Involvement in Education B**

How relative is parental involvement in a child's education to the overall success of the child? Can parents be too involved in their child's education? In society today we are seeing an increased debate over the different types of parents and how good or bad they are to the overall growth and development of their children. Are helicopter parents harming their children's future? Are free range parents raising children with no rules or boundaries providing a need for society to deal with the evenual negative outcomes? The goal of this research is to study the different parental involvement levels in the education of their children and determine what positive and negative outcomes are present under each type of parental behavior. Some criteria that will be important in this study are the level of parental invovlement, to what age of the child does the involvement continue, academic performance and self-efficacy of the children. Other areas of interest in this study include whether gender and race/ethnicity are impacted differently under differing parenting styles. Correlational analysis will be completed through data collection in the spring semester of 2023.

Abstract Name: **Enabling a clean-energy economy from U.S. rare earth resources: characterization of low-grade allanite-based ore from Halleck Creek, Wyoming**

Rare earth elements (REEs) have significant value to technologies critical for energy infrastructure and independence, decarbonization efforts, and defense applications. REE supply is heavily constrained to deposits outside of the U.S., making economic and sustainable REE and other critical material recovery from low-grade source materialsparamount to U.S. national security.The goal of this research is tocollect, pulverize, and analytically characterize unutilized REE-containing allanite ores from primary deposits in Halleck Creek, Wyoming to define major mineralogical and elemental compositions.Halleck Creek core (130-kg) and surface (33-kg) samples were crushed to a top size of 4-mm through primary and secondary reduction processes. Mineralogical and total metal analyses were performed on screened size fractions and representative core and surface samples via X-ray diffraction spectroscopy (XRD), X-ray fluorescence spectroscopy (XRF), and inductively coupled plasma optical emission spectrometry (ICP-OES). A mineral liberation study was conducted via scanning electron microscopy with energy dispersive X-ray analysis (SEM-EDAX) to identify allanite and other REE-containing particles in the host rock. Grindability was investigated through standard rod mill laboratory tests to determine optimal conditions to generate 150- and 500-µm 80% passing size (P80) sample lots. The results of this research will identify what and where the value (i.e., REEs, critical materials) is in this uncharacterized allanite ore along with any intrinsic processing constraints.This comprehensive ore analysis will inform activities related to: REE beneficiation from the allanite-ore feedstock and outlining a REE biomining and purification workflow. Ultimately, this research will enable the development and demonstration of a modular, biobased REE biohydrometallurgy process through theDefense Advanced Research Projects Agency (DARPA) funded project titled Synthetic Biology for Biomining of Rare Earth Elements (SynBREE).

Abstract Name: **New Methods for Enhancing Detection of Microstructural Features in Cortical Bone**

Osteoporosis (“porous bone”) is a bone disease that negatively affects the structuralquality of bone tissue. Currently, it is not fully understood why some individuals develop osteoporosis and some do not, although it is known that sex, age, race, and body frame size play a role in osteoporosis development. One gap in understanding is due to an inability to properly track and analyze structurally relevant microstructural features in bone, primarily during mechanical testing of samples for basic research. There remains a need for improved study of cortical bone microstructure such as osteon alignment, positioning, and porosity. Alongside visible light microscopy, computed tomography (CT) and magnetic resonance imaging (MRI) are used currently to image bone microstructure, however, there is a constant compromise between image quality, resolution, and accuracy, along with an inability to use in-vitro with mechanical testing. By improving the ability to track the microstructure of cortical bone during mechanical testing, we may increase our understanding of how microstructure influences the likelihood of bone fracture. Thus, this project seeks to develop and apply optimized dye and stain methods to better detect microstructural features of cortical bone under visible and UV light.

Abstract Name: **Investigation Into the Creation of a Biodegradable Croc**

The popular footwear known as Crocs produces significant waste each year because they are incapable of being recycled or easily destroyed. As a result, tons of waste build up annually across the globe polluting water and land. A potential solution is for Crocs to be created from a biodegradable material, able to break down naturally. In order to test this, we used a biodegradable material called YOGA Flex and 3D printers. The research began by acquiring an STL file from Thingiverse (www.thingiverse.com) for a croc meeting the desired traits. From this, many miniature crocs were printed for later material testing, along with one adult-sized for walking tests. Aside from the crocs, small tensile testing samples were designed and printed to acquire the mechanical properties of YOGA flex. This allows for the full-size pair of crocs to be printed as strongly as possible. The miniature crocs printed as desired, with the only visible issue being their stiffness, but as observed from the large model, this is likely due to the size. The large croc was evaluated via a brief walking test, however, it quickly sustained severe cracking damages on both the interior and exterior. From the tensile testing, it was observed that YOGA Flex with vertical layering had a yield stress of 0.962 (MPA) and anultimate stress of 6.253 (MPa), while the horizontal layering was only 3.316 (MPa). The data acquired from tensile testing clearly displays greater strength when vertical layering is used, therefore being a good option for the final print. ASTM degradation standards will be investigated to determine if microbial degradation testing could yield the desired results. In order to sustain a healthy world capable of housing our civilization, it is important for society to make the necessary changes to green materials.

Abstract Name: **Effect of Nitrogen Addition in Argon DBD Plasma on Rotational and Vibrational Temperatures**

Dielectric Barrier Discharge (DBD) plasma is a non-thermal, non-equilibrium plasma that is used in the medical field for wound healing and sterilization. Reactive Oxygen/Nitrogen Species (RONS) in plasma interact with water in the blood to produce hydrogen peroxide, and thus, accelerate the wound healing and sterilization process through the production of growth factors. To optimize the concentration of RONS, this study uses small percentages of Nitrogen (up to 5%) in Argon plasma, to see the impact on radical concentrations. The Argon Plasma was generated in a multi-electrode plasma torch, with Argon flow up to 15 slpm, and an AC voltage between 5 and 10 kV (20-40 kHz). The concept of the multi-electrode plasma torch was designed at San Jose State University. This design provides us control over plasma characteristics (i.e., gas, rotational, vibrational, and excitational temperatures, and radical concentrations) without changing the operating conditions. In the current work, the impact of Nitrogen addition was investigated by conducting emission spectroscopy on the plasma. An OceanOptics UV-IR Spectrometer was used to capture the emission spectrum, and SpecAir was used to extract information on the rotational/vibrational/excitational temperatures. Experiments show that the rotational and vibrational temperatures, along with intensity the emission lines present, are impacted by Nitrogen addition. Up to 30% variation in the vibrational and rotational temperatures was observed as the Nitrogen was added into the plasma. Excitational temperatures faced minimal change, as Nitrogen was added. Addition of Nitrogen changed the relative intensities of emission lines, particularly in the NO Band (225-275 nm), Nitrogen Second Positive System (N2 SPS) (330-380 nm), and the N2 II Molecular Line (391.05 and 427.38 nm). This presentation will quantify these relative changes to plasma temperatures as a function of added Nitrogen.

Abstract Name: The effect of ethanol and adipogenic differentiation on myogenesis & insulin sensitivity in C2C12 Cells

In Type 2 diabetes skeletal muscle has a reduced sensitivity to insulin. Another characteristic of diabetic skeletal muscle is the presence of adipocytes within and between muscle fibers, which is implicated in altered insulin sensitivity. The effects of ethanol on the content of adipocytes within skeletal muscle and insulin sensitivity are not fully understood. In this study, we will investigate the effects of ethanol on adipocyte differentiation and insulin sensitivity using C2C12 cells.
C2C12 cells (20,0000 cells/mL) were cultured in tissue-cultured 24-well plates with growth media (GM) composed of DMEM, 10% fetal bovine serum, 1% Pen-Strep (P/S), and 0.2% Mycozap (M/Z) for 3 days. Upon 70% confluency, samples were then separated into different treatment groups: (1) Differentiation Media (DM) +/- Ethanol (EtOH), (2) Adipogenic Induction (AI) and Maintenance Media (AM) +/- EtOH. Samples in the DM+EtOH Group were cultured in DM (DMEM, 2% Horse serum, 1% P/S, 0.2% M/Z) along with 0%, 0.5%, 0.75%, 1%, 1.5% concentrations of 200% proof EtOH. Samples in the AI/AM+EtOH Group were cultured in AI media for 3 days (DMEM/F12, FBS, 1% P/S, 0.2% M/Z, Insulin, Forskolin, and Dexamethasone) along with the aforementioned concentrations of 200% proof EtOH prior to switching to maintenance media for the addition of adipogenic factors. Samples in the AM+EtOH Group were exposed to the established concentrations of 200% proof EtOH at the point of Induction Media and Maintenance Media (DMEM/F12, FBS, 1% P/S, 0.2% M/Z + Insulin). After performing immunofluorescence staining with myosin heavy chain (MyHC) and DAPI, confocal microscopy will be used to quantify the number of C2C12 myotubes, as well as fusion index (nuclei per myotube), average myotube length, and average myotube diameter. It is expected the Ethanol will significantly decrease fusion index, myotubes per field and total nuclei

Abstract Name: Smartphone Use and Well-being

How has Smartphone use impacted the general well-being of people today? The Smartphone usage has certainly increased over the past generation. The use is so prevalent that nearly everyone from 9-99 has one. Questions regarding how this intense Smartphonne use is impacting the overall health and well-being of society has been discussed across many different aspects of research. This research intends to study how Smartphone use impacts the physical, psychological, cognitve and social well-being of individuals across the generations. Previous research tends to focus on one aspect or another of well-being, for exmaple sleep or academic performance (cognitive functioning) or anxiety (psychological functioning). The research is lacking when looking at the global health of an individual and its association with Smartphone use. Thisstudy will also examine the specific ways individuals are using the Smartphones as well as how much of their daily life is consumed by the use. A correlational analysis will be completed in the spring semester of 2023 to determine what factors are most impacted by Smartphone use.

Abstract Name: Impact of Caffeine Combined with Resistance Training on Post-Exercise Arterial Stiffness in Habitual Caffeine Consumers

Background/Purpose: Increased arterial stiffness has been shown as a marker of cardiovascular-related events. Previous research has revealed resistance training and caffeine consumption leads to increases in arterial stiffness independently. Therefore, the purpose of this study was to determine the residual effect of combining resistance training and caffeine on arterial stiffness in resistance trained females. Methods: This experimental study was conducted on 18participants between the age of 18and 23yrs who were resistance trained in accordance to ACSM resistance training guidelines. All participants were habitual caffeine drinkers as defined by consumption of at least 200 mg/day, 5 days/wk. Pre-trial evaluation of 10-rep max was performed to determine individual training load for each exercise session. Subjects completed both caffeine and placebo conditions in a counterbalance fashion to avoid an order effect. Caffeine was administered during each trial a dose equal to 3 mg/kg body weight. Each condition was followed by an exercise intervention consisting of a full-body superset resistance training protocol. Measurements of arterial stiffness (pulse wave velocity, pulse wave analysis, and pulse pressure) were obtained using the SphygmoCor® system at 4 different time points (baseline, post-exercis, 10min post-, 20min post-, and 40min post-exercise). Results: A two-way repeated measure analysis of variance (within-subjects) did not indicate a significant difference in measurements of arterial stiffness between placebo and caffeine trials, but a time effect was revealed to be significant within both trials ($p = 0.008$). Conclusion: The results did not indicate a summative increase in measurements of arterial stiffness due to the combination of resistance training and caffeine consumption.

Abstract Name: Innate Immune Gene Expression in Bats Given Varied Diets During Influenza A Infection

Wild bats are hosts for emerging viruses that can be transmitted to humans in zoonotic spillover events when viral shedding occurs. Wild bats typically possess a high tolerance for viral infection and can suppress viral replication and shedding, but their viral suppression can be compromised when they experience stress or episodes of poor nutrition. This increases the likelihood of shedding and therefore spillover to humans. We hypothesized that inadequate nutrition alters the metabolic pathways of bats, and that these alterations fail to support the innate immune response of the bats in suppressing viral replication and shedding. To investigate the effects of diet on bat innate immune response, Jamaican fruit bats (Artibeus jamaicensis) were fed a base fruit diet or a diet consisting of fruit supplemented with either protein or fat. The bats were then infected with influenza A virus or a saline control. During infection, rectal swabs and blood samples were collected from the bats. qRT-PCR was used to examine gene expression in the immune systems of the bats. Preliminary analysis shows differences in gene expression in the innate immune systems of the bats between the different diet groups. Understanding the role bat metabolism plays in the suppression of viral shedding by the immune system could allow spillover events to be predicted by the detection of nutritional deficits in wild bat populations.

Abstract Name: Automated thought-to-text conversion through automated brainwave signal annotation

Brain-Computer Interfaces (BCIs) are a technology that directly translates the brain's electrical activity to external devices. With the advancement of BCI technology in recent decades, many developments have been made, especially in helping people who have amputated limbs, epilepsy, or are paralyzed. This research will focus on assisting paralyzed people with limited ability to communicate. This will be done through an external BCI that translates thought into text. A closely related Brain-Computer Interface is a cursor control BCI. This type of BCI has many uses, one of which is the ability to select text similar to texting on a mobile device. However, a downside to this approach is the limited rate of communication. This research will record electroencephalogram (EEG) data or brainwave signals from a subject's brain and annotate automatically using our developed annotation User Interface (AUI) while they think of writing a letter through an external headset. Finally, we envision applying a machine learning algorithm to decode human thoughts (brainwaves) to text. The algorithm will predict and output the letter the subject was thinking of and display it as text in our AUI.

Abstract Name: CBD Quantification Using 43 MHz 1H-NMR

Recently a wide variety of cannabinoid products have flooded the consumer market. The 6-billion-dollar cannabidiol (CBD) industry has been able to expand without much restraint for years due to dubious regulation and existing in a legal grey area throughout most of the United States. Claims that cannabis is a safe and effective treatment for various conditions have been made, but while manufacturers are quick to capitalize on the trend, cannabis's status as a schedule one drug has created barriers for independent research, academic studies, and clinical applications. With such dysregulation the labeling of consumables isn't held to the same accuracy as the FDA requires of traditional food and drugs. Barriers to consistent testing of these products include the cost of equipment and development of methods. This work sought to develop a procedure to measure content and concentration using benchtop NMR. Isolated cannabidiol was analyzed and used to create a calibration curve by which locally sold CBD tinctures could be tested. The method has been used successfully, producing results that agreed with the declared values on various CBD oils and it has reliably reproduced consistent results in triplicate. Rapid quantitative testing using a 43MHzbenchtop NMR could be a reasonable, affordable option for both a manufacturer's in-house product testing and for outside independent review.

Abstract Name: **GOING FOR GOLD: THE IMPACT OF SPECIAL OLYMPICS RWANDA ON SOCIAL INCLUSION FOR PERSONS WITH DISABILITIES**

This research project will examine the impact of Special Olympics (SO) participation on the social inclusion of Persons With Disabilities (PWDs) in Rwanda. Special Olympics Rwanda (SOR) strives to create an inclusive environment, encouraging the social inclusion of PWDs in Rwanda through competition and team-building activities.This research connects to previous studies by identifying effective SO organizational structures and contributions of SO participation to the social inclusion of PWDs, observable through government reports and interview data, with a narrow focus on Rwanda.The purpose of this research is to use the social model of disability to examine the social inclusion of PWDs in Rwandan community, educational, health, and employment services to identify systemic barriers inhibiting the full inclusion of PWDs in Rwandan social services. The data I will use to examine SO programs in Rwanda will be collected from interviews with Special Olympics International (SOI) and SOR personnel. Additionally, I will collect data from relevant Rwandan government reports and documents to identify possible trends towards full inclusion of PWDs in Rwandan educational and health structures. I will analyze the content using thematic coding of textual data to identify common themes in the development and evaluation of SO programs dedicated to the social inclusion of PWDs in Rwanda. The data may reveal the role of SOR in the development of inclusive spaces for PWDs in Rwanda by highlighting the organizational strategies, observable outcomes from SO participation, and positive trends in access to education and employment for PWDs. The role of SOR in developing inclusive spaces for PWDs will serve as a framework for replication in other developing nations with emerging SO programs.

Abstract Name: **Synthesis of mesalamine and curcumin capped silver nanoparticles for the treatment of Irritable Bowel Disease (IBD)**

Silver nanoparticles are innovative materials which have found uses in the field of antiseptics and drug delivery systems as of late. The term IBD (Inflammatory Bowel Disease) is used to describe the series of chronic illnesses that are characterized by inflammation of the intestinal track lining. The two main diseases are Ulcerative Colitis (UC) and Crohns' disease (CD). One (UC) affects mainly the entirety of the colon while the other (CD) affects the entirety of the digestive system (from mouth to anus). To aid in the remission of an inflamed bowel, 5-ASAs (Mesalamine, balzalaside etc.) and curcumin are beneficial, alongside corticosteroids (prednisone) and biologics (Adalimumab and Infliximab). 5-ASAs (Mesalamine) are used to halt and avert flare-ups within the digestive tract while steroids and natural supplements such as curcumin, assist in the management of inflammatory and oxidative conditions. An effective synthesis of silver nanoparticles involves the use of silver nitrate, a capping agent (such as mercaptosuccinic acid) and a strong reducer (such as sodium borohydride). The two experiments were conducted while studying pH changes at each step. Then, UV-Vis was applied to verify the appearance of the nanoparticles. Signals around the 350-400 nm area confirmed the presence of silver nanoparticles in the two experiments. This work explores conditions that are used to synthesize these nanoparticles, that could be beneficial someday, in the delivery of therapeutic agents straight to intestinal lesions in the colon or digestive track.

Abstract Name: Queer Fantasy in Printmaking

My purpose of my body of work is to create loving, comforting, and perhaps slightly risqué images of queer and trans characters. I created these artworks to exhibit and take up space in my community because they are often not visible or celebrated. My largest inspiration for this series was fantasy novels, movies, and video games. I wanted to combine queerness and these themes of fantasy because they're both aspects of who I am. I also mixed these themes because the queer and trans representation in many popular and classic fantasy genres is either absent or not very good representation. These characters in my prints are meant to represent various gender identities and sexualities; I really wanted people to feel seen through them. Queer and trans individuals deserve to have representation of themselves in ways that aren't focused on their suffering and pain. The printmaking methods I used for my finished projects are relief, woodcut, and screen-printing. Screen printing is a process where a design is applied onto a flat surface using ink, a squeegee, and a mesh screen to create the finished product. The relief print is created by carving a design into a printing block, and then pressing said block onto paper to transfer the image. The woodblock printing process is a form of relief printing, a process where a design is carved out into a piece of wood which is then pressed into paper to transfer the design. I used these various printmaking processes as a catalyst for my queer, trans, fantastical characters and imagery. I delved into the queer printmaking community and became inspired by people who were and are also creating important art that strives to make others uncomfortable in the way of learning and unlearning things about queerness, transness, and gender nonconformity in general.

Abstract Name: Self-Esteem in Relation to Online and Offline Communities

Peacock and Cowan (2019) found that having significant trusting relationships increases one's self-esteem. While these trusting relationships were once formed offline, they are now being developed online as well with the increase in reliance on technology. It follows that Best (2014) found some online communities may also increase one's self-esteem. This study compares the self-esteem of individuals who have a strong sense of community in an online group to those who have a strong sense of community in an offline group. We hypothesize that both groups will have similar patterns of self-esteem. We also hypothesize that those with strong connections to either community will demonstrate higher self-esteem than those with lower connections to a community. Participants were acquired through the Department of Psychology SONA system as well as recruitment in psychology courses. Participants completed the Brief Sense of Community Scale in reference to their online community and then completed it again for their offline community. Participants also completed the Rosenberg Self-Esteem Scale. Data collection is currently underway and will continue through the last week of November, with data currently obtained from 87 participants. The anticipated total number of participants is 120. Upon completion of data collection, Pearson correlations will explore a) the relationship between self-esteem and sense of community in an online group as well as b) self-esteem and sense of community in an offline group. In addition, an independent t-test will compare self-esteem between those who are most strongly connected to an online community and those most strongly connected to an offline community. With technological communication growing rapidly, our relationships with one another will change as well. With these changes, it is important to learn more about how they are affecting us and the way we relate to one another.

Abstract Name: Paternal Family Versus Maternal Family Involvement for Children in the Foster Care System of Chicago

Prior work on the impact of parenting on children's emotional and behavioral outcomes focused on maternal parenting and continued this path when exploring extended family involvement. When research began demonstrating the critical role fathers can play in children's mental health outcomes (Amato; Gilbreth, 1999), this work lacked the involvement of paternal extended family. Given that most children in foster care come from non-resident father homes, research regarding paternal involvement has fallen behind. Nonetheless, recent research has found that fathers of children in foster care can play an important role in supporting their children's mental health outcomes (Leon et al., 2016). Little to no research has explored paternal relatives' support of children in foster care. It seems feasible that if maternal relatives play an important role in supporting children in foster care, then paternal relatives might as well. For this study, 204 children (six to 13 years) from Chicago's foster care system were sampled and received family-finding intervention. Family finders reported on all available relatives of kin, fictive kin, and their involvement with the child. This research aimed to expand upon the Leon et al. (2016) study to compare the frequency of maternal versus paternal kinship systems involved in raising children in foster care. Through file reviews from trained family finders, it was found that maternal kin had greater involvement in childrearing; one in two reporting positive attachment figures from the maternal family. However, a significant minority of children (1 in 4) received support via a positive attachment figure from paternal kin. Though fathers and paternal family members have historically been overlooked, the current study underlines the importance of examining social support from paternal kin. Thus, the importance of the father's family in child welfare case planning should not be overlooked, and further research should be done on the subject.

Abstract Name: Beyond Translation: A Qualitative Inquiry Study for Refining a Culturally and Linguistically Adapted Health Coach Intervention for Latina Breast Cancer Survivors

Background: Latina breast cancer survivors historically lack linguistic and culturally tailored coping and management interventions. Traditional adaptation of English education materials for a Latina audience often address surface cultural features such as language, but lack nuances garnered through formative research with the target audience. This study implemented a collaborative community-academic partnership to develop a multi-module health coach intervention and coinciding workbook tailored to the needs of Latina breast cancer survivors (LBCS). All materials used in development were adapted from nationally recognized guidelines for cancer survivors. Thus, this study aimed to gather qualitative data assessing cultural relevance of the transcreated (translated + culturally adapted) health coaching intervention for LBCS. Methods: Following best practice for cultural adaptations, English materials were reviewed by cancer survivorship experts and transcreated into Spanish. Two focus groups (6-8 participants each) were held in Spanish to assess the cultural relevance of the transcreated materials to LBCS. Focus group guide questions were informed by two theories (Social Cognitive Theory, Help-Seeking Behavior Model), learner verification (a methodological approach for education message design). Guide also included questions on feasibility. Transcripts were translated into English and analyzed using thematic analysis. Community expert review confirmed findings.Results/Discussion: Emerging themes included content relevance, applicability, saliency of messages for comprehension, and areas for further refinement.Verification checks with our community partner confirmed content revision and solutions for incorporating participant feedback in future implementation. Data from focus groups allowed for further verification of acceptable content and method expansion prior to piloting with LBCS as a final refining step in the transcreation process. Conclusion: Reflection of cultural reality during program development is crucial for intervention adaptation in diverse populations while building social capital. Transcreation allowed for a collaborative process guided by the integration of cultural nuances, while participant first-hand experiences led modules toward cultural accuracy.

Abstract Name: **A platform for detecting biothreats by growing nanoporous alumina on indium tin oxide-coated glass.**

Nanoporous anodized aluminum oxide (NAAO) films are great candidates for biosensor platforms because the pore geometry can be controlled and specifically tuned to achieve pores with nanometer-sized radii and high aspect ratios. Electrochemical oxidation or anodization of aluminum in oxide-dissolving electrolytes leads to forming of an NAAO layer with nanometer-sized porous structures. Furthermore, a two-step anodization process under certain electrochemical constraints -- the type of acid, concentration, temperature, voltage, anodization time, and anodization area -- results in a self-ordered honeycomb-like arrangement of smooth-walled pores with desired diameters and interpore distances. After the first anodization, a thin NAAO layer with irregular pore walls is formed. This layer is then etched away, exposing the aluminum underneath with nanometer-sized dimples on its surface. Duringthe second anodization, the aluminum is completely converted to NAAO. To verify that the anodization process produces NAAO films with the targeted characteristics, scanning electron microscopy (SEM) is used to image the NAAO, and digital image analysis is utilized to measure the pore diameters and interpore distances. NAAO films are grown on indium tin oxide (ITO)-coated glass to be used in a biosensing platform to detect various biothreats. Since the pores are uniform and straight, the NAAO film has excellent ionic transport characteristics that can be modulated through changes in surface charge distribution. Interaction of biothreats with receptor species immobilized on the pore surface modifies the ionic transport and impedance of the NAAO layer. The electrical conductivity of the underlying ITO is needed to measure these impedance changes. Furthermore, with a high surface area-to-volume ratio in the NAAO, the biothreat/biomarker reaction signal will be amplified.

Abstract Name: **Microencapsulation of Rose Bengal for use with Sonodynamic Therapy**

Rose Bengal (RB) demonstrates toxicity to malignant cells and may induce an immune response. The purpose of this study is to attach RB to a microbubble (MB) to facilitate delivery through sonodynamic therapy (SDT) using MBs and low intensity ultrasound to release drug at a target site. A MB shell is made up of surfactants each with a hydrophilic head and hydrophobic tail. Typically, a hydrophobic drug is incorporated into the bubble shell. Since RB is water soluble, when typical encapsulation was attempted, a series of wash steps resulted in no drug loading. The later attempt focused on RBs negative charge. By adding the surfactant cetyltrimethyl ammonium bromide (CTAB) the MB becomes positively charged, and a RB wash allows the RB to be attached. Drug loading was compared between one batch loaded with CTAB and one without, the same wash steps were followed for each batch. In the CTAB batch, 2.1 mg/mL of RB were loaded compared to no evidence of loading on the batch without CTAB. These results were confirmed using both a plate reader and a fluorescent microscope. Results gave a MB diameter of 2.1 µm at a concentration of 1.35×109 MB/mL. The results demonstrate excellent potential of this method to produce RB-MB for use in SDT.

Abstract Name: **Vision Guided Drone Flight**

Drones are increasingly being used for reconnaissance, tracking, and inspection of locations that are difficult to access. Our team's research is to create increased autonomy for drone flight in physically confined environments. Our team is currently using the Tello EDU drones which can be programmed using the Python programming language. It, allows us to utilize OpenCV in conjunction with the Tello drone's built-in camera. The OpenCV software library is an Open-Source Computer Vision software. Computer Vision (CV) is the area within Artificial Intelligence (AI) that builds algorithms for computing machines to be able to make autonomous decisions based on visual data. OpenCV has built-in functions for a wide range of visual intelligence tasks including object detection. We're making use of April Tags which allows us to visually tag locations in physical space. Current work is focused on developing software for the drone which will enable it to fly through a gate to enter a confined space without collisions. In our research so far we have found that using the AprilTags to identify the border of the gate opening is an effective approach for guiding the flight path of the drone so it can enter the gate collision free. We, have also found that it is possible to incorporate YOLO, which is a CV algorithm for object detection for being able to identify objects within the field of vision of the flying drone's camera. Potential future uses for vision guided drones is the ability to navigate through environments and around obstacles to find people or objects of interest. The Tello drone's ability to fly as a swarm allows it to communicate with other drones, run tasks in parallel, to speed up task completion. Future research efforts will be directed towards swarming and task parallelization.

Abstract Name: **SUBDERMAL VERSUS EPIDURAL LONG-LATENCY AUDITORY EVOKED POTENTIALS IN RATS: A VALIDATION STUDY**

Event-related potentials (ERPs) are the summation of postsynaptic activity time locked to a stimulus which are recorded using electroencephalography (EEG). ERP's high temporal resolution reflects complex activation of neuronal networks in relation to particular events or cognitive processes. Notably, they also provide an analogous phenotypic measure between humans and animal models, and thus, are well suited for studying mental disorders and improving the validity of existing psychiatric animal models. Currently, except for auditory brainstem responses, ERP research in rodents has predominantly utilized relatively invasive EEG recording procedures like epidural electrodes. The purpose of this study is to validate the use of less invasive subdermal methods for ERP measurement. 20 adult, male Wistar rats will be implanted with subdermal needle electrodes while anesthetized with continuous isoflurane. Once fully awake, they will then be presented with a passive auditory paradigm consisting of a sequence of 5-tone trains with either 1- or 5- inter-train intervals (ITIs) presented at a frequency of either 8-kHz or 500-Hz. To assess temporal stability, subdermal needle recordings will be conducted twice for both frequencies separated by 2-3 months. Approximately 2-4 weeks following the second round of subdermal needle recordings, rats will undergo a craniotomy to implant skull screw electrodes for invasive recordings. We predict our findings will demonstrate the applicability of a semi-invasive method for recording ERPs in awake rats. Moreover, this work will allow for a better understanding of the comparability of findings between these epidural and subdermal approaches, which is vital to the replicability of findings within and across labs. Overall, this work has the potential to support the validity of an approach for measuring ERPs in awake rats that is less invasive and harmful than most conventional, invasive approaches.

Abstract Name: **The Influence of Surgical Stress and Inflammatory Biomarkers on the Occurrence of Postoperative Delirium**

Research focusing on hypothermia has established a relationship between surgical stress and inflammatory biomarkers on delirium incidents in critically ill non-cardiac surgical patients. Unfortunately, postoperative deliriumis a common complication after surgery and results in acute brain failure. Though the cause of delirium is still relatively unknown, systemic inflammation with neurological involvement is one of the leading etiologic theories. Another common complication in surgical patients, is the occurrence of unplanned hypothermia during non-cardiac surgeries. For our study, we will be looking at two inflammatory biomarkers: C-reactive protein (CRP), and Interleukin 6 (IL-6). CRP is produced in the liver and is an index of overall inflammation in the body and is found elevated in postoperative delirium. IL-6, a pro-inflammatory cytokine, promotes a variety of cell functions that stimulate end enhance inflammation and is also known as a brain-active interleukin. IL-6 is a biomarker identified as a predictor of postoperative delirium when compared to those that do not experience postoperative delirium.Delirium assessments, surgical temperatures, and blood samples will be obtained from at least 100 non-cardiac surgical intensive care patients at a local hospital for the first three postoperative days.) Our role in the project is to separate the serum from the blood and perform enzyme-linked immunosorbent assays (ELISAs) for CRP and IL-6. We will be assaying the separated serum to identify the levels of the two previously established inflammatory biomarkers. Through the comparison of inflammatory biomarker levels and surgical temperatures in non-cardiac patients with and without postoperative delirium we hope to establish the influence of inflammatory stress and unplanned hypothermia on postoperative delirium. It is hoped that the findings from this study will further the understanding of how to assess, treat, and prevent postoperative delirium. Presently, this is a work in progress and our findings will be shared at the conference.

Abstract Name: **Effect of Climate Conditions on Leaf Traits in Sunflowers**

Plants are sensitive to their environment and are phenotypically plastic, meaning that individuals are able to adjust their morphology in response to external factors. Thus, patterns of plasticity in plants are great indicators as to how our climate is changing. We are determining the effects of climate conditions, such as precipitation and temperature, on specific leaf traits in 3 species of sunflowers. These effects can help us predict and understand how sunflowers grow and acclimate in response to these climate conditions and help us understand how other plants might also change.We conducted a common garden experiment using approximately 225 plants from three species of sunflowers, Helianthus maximiliani, H. grosseserratus, and H. giganteus, planted at a site in Eau Claire, Wisconsin. We harvested leaves of each plant in July to measure a suite of traits. We focused on specific leaf area, leaf water content, and leaf thickness because these traits are often correlated and all exhibit associations with the amount of precipitation and the temperature of the environment. We are examining how these traits were affected by varying temperature and precipitation rates over the past three years and will determine if variation in trait values may be driven by environmental differences across years. These results will tell us a great deal about how sunflowers and plants in general may respond to climate change.

Abstract Name: Adolescent social isolation stress enhances nicotine conditioned place preference and disrupts stress coping behavior.

Adolescence is a sensitive period in brain development that is marked by increased susceptibility to the effects of chronic stress, which may enhance vulnerability to neuropsychiatric conditions such as depression and substance use disorders. In the present study, we used an animal model to examine the effect of adolescent social isolation stress on coping behavior and nicotine reward. During the adolescent period from postnatal day (P)35-P49, male and female C57BL/6J mice were exposed to either social isolation (SI) stress or standard rearing (SR) conditions, as well as nicotine exposure (0.35mg/kg) four times between P35-P49 during a nicotine conditioned place preference (CPP) procedure. On approximately P50, stress-coping behavior was examined following a 6-minute forced-swim test (FST). Our behavioral results show that both male and female SI mice more rapidly develop nicotine CPP compared to SR mice, that SI mice exhibit increased levels of immobility in the FST, and that prior nicotine exposure during social isolation decreases immobility in the FST. These results suggest that adolescent social isolation stress enhances the rewarding effects of nicotine and negatively impacts stress-coping behavior. To determine whether adolescence is a sensitive period for these effects, ongoing research efforts are aimed at comparing these results to adult social isolation and nicotine exposure. Furthermore, we are examining stress-induced functional (c-fos expression) differences in the brains of SI versus SR mice in response to the FST via immunohistochemistry of the dorsal raphe ascending serotonergic system. Collectively, these analyses will help determine neurological correlates of adolescent susceptibility to the negative effects of chronic social isolation stress and inform our understanding of adolescent brain development and vulnerability.

Abstract Name: Novel METH Neurotoxicity and Exercise Biomarker Discovery in Rat Striatum using RNA-Seq

Abstract: Methamphetamine (METH) is a dangerous and addictive stimulant drug that damages the central nervous system and is used by over 1.6 million people in the United States. Specifically, methamphetamine acts as an agonist to dopamine and glutamine receptors, which causes long term damage in the striatal region. Current treatments for METH neurotoxicity are ineffective and expensive, but investigation into more accessible and effective treatments is being done. Exercise has been shown to boost neuroplasticity of the brain, and also trigger the production of proteins that promote neural cell growth and survival. We previously conducted a study on a rodent model which showed that exercise after METH treatment can decrease neurotoxicity more rapidly than normal through examination of dopamine transporter protein expression. In order to further test the validity of exercise as a treatment for METH neurotoxicity, we took samples from the striatums of rodents and extracted the RNA to create cDNA libraries. These cDNA libraries were then sequenced and analyzed in order to identify biomarkers of differences between rodents treated with exercise after METH injections and those that were sedentary. The libraries were also analyzed for biomarkers of difference between rodents that were treated with METH compared to those that only received saline. A literary survey will be performed to identify the function of the genes associated with the identified biomarkers of differences between groups, with hopes of identifying novel pathways involved in recovery from neurotoxicity and addiction.

Abstract Name: **A Novel Magnetorheological Elastomer-Based Artificial Pancreas**

Automated Insulin Delivery (AID) systems are used to monitor and control blood glucose levels, which would otherwise have serious health problems for diabetic patients, including damage to the heart, kidneys, eyes, and nerves. Today there are 1.6 million Americans are living with Type 1 Diabetes (T1D), including about 200,000 youth (less than 20 years old) and 1.4 million adults (20 years old and older). Despite the demonstrated clinical benefits, T1D patients avoid taking advantage of such AP systems because of the physical and psychological burdens of wearing an on-body insulin pump. Thus, there is a pressing need for insulin delivery systems with reduced “form-factors” and other “user-centric” features to increase the greater adoption of such devices in the T1D community. To offer a potential solution, we propose a novel magnetorheological peristaltic micropump (MR-µPUMP) that has not been studied previously to offer an efficient, miniature (on the order of 1 mm), lightweight, portable, wirelessly controllable (with a fast response time of less than 100 ms), durable, low power micropump for insulin delivery. In this study, we carried out physics-based computer simulations in COMSOL Multiphysics software. The proposed micropump can transfer 1.9 µL of fluid in one pumping cycle, which is almost two times the other micropump models. Also, the proposed flap valve can reduce the backflow up to 10 times during the expansion phase in comparison with the no-valve model. The application of the proposed micropump is not limited to insulin delivery systems for T1D patients and can also potentially be used in a wide range of other applications such as artificial organs to transport blood, organ-on-chip applications, micro-cooling devices, and so on.

Abstract Name: **Creation of Anxa2 Deletion Mutants in Zebrafish Using CRISPR/Cas9 Gene Editing**

Annexin A2 is a calcium-dependent phospholipid-binding protein that facilitates angiogenesis via endothelial barrier maintenance and sprout formation. However, the functions of Annexin A2 are not well established in endothelial cells in vivo. The Annexin A2 gene in humans corresponds to a duplicated locus in zebrafish, called anxa2a and anxa2b. We are using CRISPR-Cas9 to make mutations of the Annexin A2 homologs in zebrafish to take advantage of the optical clarity of the early embryo to follow endothelial morphogenesis. Due to the possible overlapping functions of these homologs, we designed gRNAs that, when complexed with Cas9, targeted the 5’ and 3’ UTRs of both anxa2a and anxa2b. This was done to induce whole gene deletions instead of creating loss-of-function mutants through indel formation. These whole gene deletions would allow us to avoid genetic compensation induced by mutant transcripts. We also designed a tag-RFP construct flanked by short homology arms for integration into the deleted locus to visually track anxa2a and anxa2b expression during development. Here, we describe a whole gene deletion of anxa2a (14,172 base pairs) via CRISPR-Cas9 injection in fli1-egfp embryos. We have recovered a stable germline deletion in anxa2a. Our next steps are to induce a whole gene deletion in anxa2b for further functional analysis and create mutants homozygous for both deletions. This will allow for loss-of-function analysis of the Annexin A2 duplicated locus in zebrafish for a more complete phenotypic analysis and characterization of the genetic requirements of anxa2a and b during endothelial morphogenesis.

Abstract Name: **The Defictionalization of Pre-21st Century Pandemic Narratives in Social Media Responses to COVID-19**

Society is no stranger to pandemic narratives, which have found a renewed public interest throughout the COVID-19 pandemic. This surge in popularity has resulted in the use of these texts as medical and moral authority by people communicating about them online. In this paper, I analyze rhetoric in Twitter posts (“tweets”), independent website articles, and the limited scholarly research that has been published about COVID-19 in relation to three classic pandemic narratives (The Last Man, The Plague, Journal of the Plague Year). When looking at the language used in these modes of digital communication, I found a clear trend of defictionalization through both the medical and moral authority given to the texts, with posts in both categories making allusions to their supposed prophetic nature. This indicates a tendency to reduce the ability of the past to produce fictional work, emboldening greater leeway with narrative interpretations and the potential for equating them to reality.Subsequently,the observed rhetoric suggests that people are escaping perceived responsibility for the events of the pandemic by seeing the texts as both factual and prophetic. These findings provide context through which we gain a new understanding of the social construction of illness and the impact of how it positions these narratives as being capable of providing beneficial, actionable advice.Additionally, knowing the implications of our interpretations of literature and how it is applied to real-world events offers insight on the spread of misinformation. The ability—or inability—to differentiate between truth and fiction online isand will continue tobecrucial to the stability of our collective systems of knowledge, particularly when they concern matters of public health and safety.

Abstract Name: **Anti-Microbial Properties of Cobalt Complexes**

Disease can be transmitted in a variety of pathways, including bacteria. The study and eradication of disease is important to help increase the general health of the population. Cobalt is an element known to contain anti-microbial properties that inhibit the growth of bacteria. To test the inhibition of bacteria, tris ethylenediamine cobalt iodide was synthesized in two enantiotopic, Dextrorotary and Levorotary, forms. Three other cobalt complexes were also synthesized for use. The chemical formula for these complexes are [Co(NH3)4CO3]SO4, [Co(NH3)4CO3]NO3, and Co(NH3)5Cl3. The next step is examining the anti-microbial properties cobalt complexes contain by using a Minimum Inhibitory Concentration (MIC) plating technique. Four types of bacteria will be tested in combination with each cobalt complex, in triplicate, using a 96 well plate. The four types of bacteria being tested are E. Coli, Klebsiella Pneumoniae, MRSA, and Streptococcus A. The five different concentration levels that will be used are 0.1M, 0.01M, 0.001M, 0.0001M, and 0.00001M. Triplicate data for each compound at each concentration will be recorded for the results. The purpose of the project is to discover the most effective technique and determine which cobalt complex is the best inhibitor. Using that information, we could propose a drug treatment that can be used to prevent diseases and conditions caused by the bacteria. With future projects, we hope the medicinal applications and toxicity levels of the cobalt complexes from this research project are explored. This would help increase the chance of finding a cure for the diseases and conditions these bacteria cause.

Abstract Name: The Dream Machine as Confluence: Hallucination, Neuro-Diversity, and the Creative Industries.

Our research project focusses on how a social media campaign was designed and implemented to explore how people engaged with the ideas of dreams and hallucinations. Specifically, the class project involved working collectively, and in four dedicated groups, to build a dream machine* andresearch the idea of neuro-diversity and perception-diversity.The four groups were: designers, who constructed the dream machine; social media recorders, who developed a multi-platform media campaign for the project from inception to implementation, including documenting how the other groups worked and researched their areas; music composers who designed a soundtrack to accompany the machine; and multi-media poster designers, who researched the history and culture of the original dream machine to create a series of poster images. Each group required specific research focus as well as an interdisciplinary exchange across all the groups. In many ways we see this as 'confluence in action', breaking down disciplinary barriers to explore new ways of thinking about complex issues and ideas. Our presentationwill articulate three key aspects of the project: how by working across multiple disciplines (notably, creativity studies, arts and humanities, cognitive sciences, communications) we came to understand better the confluence of ideas in practice; how various elements of social media can be utilized to explore wider philosophical and aesthetic issues; and how our University's program in Creative and Cultural Industries provided ways to connect across a wide and diverse audience to engage in the interdisciplinary nature of knowledge. In addition to the presentation, we would like to bring the dream machine to the conference so others might experience its hallucinatory effects and better appreciate the relationship between research and practice.*The dream machine was originally designed by the artist Brion Gysin and has been used in research to explore the idea of neuro-diversity and perception-diversity.

Abstract Name: **Analyzing Interdisciplinary Teaching on Utilization of Math and Health Children's Books to Support Diverse K-8 Children?s Math Learning in Urban Classrooms**

This project aimed at 1) analyzing pre-service teachers' interdisciplinary teaching using math and health children's books and 2) identifying difficulties and challenges in a diverse learning environment with this interdisciplinary approach in urban K-8 classrooms in Southern California. About 78 pre-service participants from three math method classes participated in this study. Data collection includes pre- and post-questionnaires that assess their disposition and knowledge of interdisciplinary teaching, their creation of math and health children's books, and their reports of fieldwork teaching from the children's books. Data analysis includes both quantitative and qualitative methods. Quantitative methods were used to analyze the differences in pre-service teachers' disposition, knowledge of interdisciplinary teaching, children's math skills, health awareness and their disposition toward STEAM learning. Qualitative methods were used to analyze the approaches of interdisciplinary teaching used by the pre-service teachers, and to analyze the difficulties and challenges in a diverse learning environment. The preliminary analysis shows that the pre-service teachers were able to use a variety of ways in teaching math and health children's books in their fieldwork, and, as a result, their knowledge of interdisciplinary teaching and disposition were improved. There are some difficulties and challenges in children's learning: suggestions were identified for more effective interdisciplinary teaching, such as using manipulatives and teaching vocabularies before reading.

Abstract Name: **DO NATURAL HABITATS SUPPORT BETTER BIVALVE HEALTH RELATIVE TO HUMAN-INTRODUCED HABITATS?**

Estuarine habitats worldwide have been extensively modified by human-introduced structures such as seawalls. Human-introduced structures may favor non-indigenous species (NIS), but few studies have directly compared species' health (i.e. condition index) on various habitat types. NIS Mytilus galloprovincialisis a dominant space occupier on seawalls throughout Southern CA estuaries including Newport Bay. In a preliminary study, ithad better conditions on natural cobble vs. human-introduced seawall (2-way ANOVA, site*habitat, p=0.0001)but tidal elevation was not controlled, confounding our ability to discern a habitat effect. Lower tidal elevation should improve species condition due to longer immersion time, so for this follow-up study, we hypothesized that condition index (CI) would vary both across habitats and among tidal elevations. M. galloprovincialis were collected from a seawall and from cobbles at a site in upper Newport Bay, CA while recording tidal elevation for each individual. M. galloprovincialis experienced a nominally significant habitat*elevation interaction (2-way ANOVA, elevation*substrate, p=0.0595) with higher CI at lower elevations on seawalls only, and higher CI on cobble versus seawall but only at higher tidal elevations. Understanding habitat and tidal elevation effects on the health of a broader selection of both native and non-native bivalves will inform future management decisions about the use of natural and anthropogenic habitats.

Abstract Name: **Bovine Serum Albumin Encapsulated Poly-L-Lysine-Graft-Poly(ethylene) Glycol (PLL-g-PEG) Nanoparticles: Synthesis, Characterization, and Evaluation of Stability in Serum**

Nanotechnology and the use of nanomaterials has caused rapid development in the process of diagnosis and treatment of diseases.Therapeutic proteins have been shown to be an effective treatment against a variety of diseases.Protein therapeutics can be actively targeted towards malignant cells using cell surface receptors and/or other markers specifically associated with or overexpressed on tumors versus healthy tissue. However, protein therapeutics have intrinsic drawbacks such as low stability, short circulating lifetime in the blood stream, and low catalytic activity under physiological conditions. To address these drawbacks our primary goal of this project is to synthesize and characterize a model protein, bovine serum albumin (BSA), encapsulated PLL-g-PEG polymer nanoparticles. Additionally, this project will provide useful insight into using albumin-based nanoparticles as carriers in nanomedicine. The successful encapsulation of catalytically active BSA in nanoparticles and assessing their stability in serum at physiological conditions are important for the therapeutic efficacy of these particles. PLL-g-PEG co-polymer was successfully synthesized and characterized using1H NMR spectroscopy. Nanoparticles were formed through electrostatic attraction of the cationic backbone of the PLL-g-PEG copolymer and negatively charged BSA. The average hydrodynamic diameter of these nanoparticles was 104 nm. Polyacrylamide gel electrophoresis (PAGE) was used to analyze the extent of BSA encapsulation. According to PAGE data, there were no free proteins present in our nanoparticle formulations confirming that all the BSA has been encapsulated. These nanoparticles are stable in serum at physiological conditions for up to 5 days. Long term stability studies in serum, catalytic activity studies of encapsulated BSA, and compatibility assays of these nanoparticles with red blood cells are currently in progress and will also be presented.

Abstract Name: **Migration Act (Who are Migrant Workers?)**

Migrant Workers make upa large part of the Agricultural Industryof the United States.Manyof them happen to beundocumentedworkers who, while working hard to supply needed labor for a variety of regional agricultural and manufacturing employers, live and work in constant fear of repercussions and possible deportation. Many others are here legally, but still face difficulties inspired by information spread in news andother sources of the media that often tell only fragments of the layered and complex story of the migrants and their communities, and what they bring to the communities that they are now a part of. My focus is to,hopefully,bring an added awareness and an overall element of understanding to the South Dakota Community, by photographing them in the context of their communities and in the places where they work, and the environments where they play. I believe that Migrant Workers are under appreciated and deserve a place and a voice in this regional agricultural community for which they hope to be a positive addition, as well as a valued source of added cultural diversity. Migrant people undertake many risks and emotional strain to provide for their families and their communities. They are a community of people who make a great positive impact on the places where they settle, bringing needed labor, cultural richness,economic growth and development, and the expanse of colors that make up a diverse population.

Abstract Name: Low Cost Filter Media for the Removal of Phosphorus in Agricultural Runoff Treatment Systems (ARTS)

Seasonal hypoxia of lakes in the Midwest, Gulf of Mexico, and surface waters around the world as a result of excessive algal production, has a detrimental effect on the local aquatic species, environment, and recreation. Despite investments in point source reductions, seasonal hypoxia is persistent, in part due to non-point agricultural sources of phosphorus (P) (35% of total P load to Lake Michigan). Agricultural runoff treatment systems (ARTS), consisting of sedimentation basins and phosphorus removal structures, are an effective field treatment to reduce nutrient pollution .pollution. Numerous media (>80) for phosphorus removal structures have been investigated for their P removal potential and the hydraulic conductivity; Ca, Fe, Mg and Al content of media are important factors. Reactive media derived from waste products would create a product from waste, extending time prior to disposal, supporting a circular economy. Waste residuals (e.g. drinking water treatment residuals, wood waste, vegetative waste) will be modified (through metal additions, heat treatment, pelletizing, and binder addition) for and evaluated for dissolved P removal from agricultural runoff.. Treatment potential of modified waste media will be measured using flow through lab scale reactors constructed out of 0.75-inch diameter PVC pipe. Columns will be completed in triplicate for each media. Influent and effluent samples will be collected every 5 to 10 hours until effluent P is >50% of influent P. Ortho-phosphorus will be measured in collected samples using a discrete analyzer (Seal AQ300) at UWGB. Media will be designed to maximize P sorption capacity, hydraulic conductivity, mechanical strength, efficacy in high flow systems (< 10 min retention times), and reuse potential; minimize toxic side effects, energy consumption, and cost, critical to adoption. Results from flow through analysis will guide selection of reactive media deployed for field evaluation.

Abstract Name: Comic Book of the Complexities of a Young Man's Mental Health

Remembrance is a comic book illustrating the complexities of mental health. Through fantastical imagery embedded into everyday situations, the book provides a glimpse into a young man's mundane life. Pulling from personal journal entries, I created these comic strips through traditional and digital illustrations.The project began with selecting entries from personal journals around common themes or imagery. These entries reflect on my life as a first-gen college student and an only child with two families, while also helping to find peace with my experiences. After selecting the entries, I referenced well-known mythological stories to visualize the emotions. For example, the book starts with a drawing of me in my graduation gown falling through a black hole and rolling a rock up a hill like Sisyphus, referring to the time when I graduated with my associates and was feeling lost about what's next. Through metaphors like this, I conceptualized the entries into stories and brainstormed distinct compositions with pencil drawings and other traditional mediums. Using Procreate, I finalized the illustrations as colored, digital drawings.The book is connected through the central theme of mental health and the main character's environment. Each page is a stand alone story and does not need the context of another page to be complete. However, all the pages that jump through time using different colors produce an abstracted autobiography when read together. There is no text to encourage deeper and more universal interpretation through visual language. Instead of words, metaphors such as black holes and quicksand are used to communicate the character's psyche.Remembrance was a cathartic project that helped me process my life as a first-gen student, an aspiring teacher, and a practicing artist. By sharing it with a wider audience, I hope that others with similar experiences feel heard, understood, and could relate.

Abstract Name: **Implementing a Biocompatible Foam to Improve Tumor Ablation**

Biocompatible materials can be utilized to improve current medical techniques, leading to improved patient recovery. Tumor ablation is a current cancer removal procedure that will benefit from the application of a biocompatible foam. The procedure involves a needle-like probe which can burn or freeze the cancerous area of interest. In an attempt to protect the surrounding areas from extreme temperatures, current methods use saline or carbon dioxide to separate the healthy tissue from the cancerous site. However, the effects of gravity cause a loss of separation between the targeted area and healthy tissue. As a result, the patient may suffer from postoperative pain due to the lack of contact with the separation medium. The purpose of this project is to develop a biocompatible foam composed of FDA approved materials that will maintain contact with target tissue and withstand extreme temperatures of the ablation probe. Foam has mechanical properties of stability and stiffness, as well as insulative properties. Characterization of stability and stiffness includes tracking the rate of foam collapse through time-lapse photography. Both foam preparation variables and external variables have been tested to ensure foam stability for the ablation procedure, and for biocompatibility. Through these experiments, an optimal method was generated to provide a foam that will last the duration of the ablation procedure and eventually dissipate in the body cavity. In addition to foam stability and stiffness, the insulative properties of the foam were quantified using thermochromic tissue mimics. Further experimentation involved additional characterization methods including rheology and pendant drop tensiometry. Significant progress in lab experiments has allowed for further investigation through in vivo studies, as well as preparation for clinical trials. Evaluation of the foam via lab experimentation allows for clinical application of the material, with the ultimate goal of improving cancer treatment and minimizing patient risk.

Abstract Name: **The In-silico and In-vitro Characterization of Epigenetic Drugs (BET Protein Inhibitors and Related BET Pathway Targets) on a Colorectal Cancer Cell Line**

Bromodomain and extra-terminal domain (BET) proteins have been linked to increases in oncogene expression and tumor progression in a wide array of cancers. Previous research on BET proteins has demonstrated that BET inhibitors (BETi) and other drugs in combination can moderately reduce cancer cell proliferation in colorectal cancer. Limited treatments exist for colorectal cancer due to its malignant nature and existing treatments are often costly or ineffective. Our research centers around determining potential BETi in colorectal cancer through in-silico research and testing identified drug candidates in an in-vitro setting. While previous research has been conducted on BETi, few studies examine the effects of BETi in colorectal cancer. So far, we have created a list of one hundred possible BETi drugs. By utilizing a deep learning Cancer Drug Response (Deep CDR) prediction algorithm, we will further narrow down our list of potential drug candidates. We are also working on identifying additional targets in HCT116 cells that are related to the BET protein pathway to expand our research. In order to do this, we are analyzing gene expression datasets using R and ranking candidates related to the BET protein pathway. Once the in-silico analysis is complete, the drugs will be ordered/synthesized and tested on HCT116 colorectal cancer cells. They will be tested through MTT Assays, Western Blot and qPCR and the ones with the most BETi properties as well as the least harmful side effects will be selected. With more BETis available, we hope to increase the number of cancer treatment options for patients.

Abstract Name: **Phylogenetic Diversification of Monkeypox and Related Poxviridae**

Monkey pox (hereinafter MPXV) is a zoonotic virus that is localized in Western and Central Africa but has recently spread to 82 non-endemic countries with roughly 66,000 cases worldwide, as of September, 2022 (CDC.org). MPXV can enter the body via the oral or skin routes. MPXV mainly targets theairway epithelium leading to infection of nearby immune cells. For the skin route, the virus first infects keratinocytes and fibroblasts. Similarly, to the oral route, MPXV thereafter infects nearby immune cells, such as dendritic cells, and macrophages. In both cases, the infected immune cells allow MPXV to gain access to a draining lymph node. It is hypothesized that an infected draining lymph node subsequently becomes a site of MPXV virion dissemination. The WHO declared MPXV an international health emergency in July of this year (aha.org) and advised caution regarding travel to countries with rising caseloads. As a virus of the Orthopoxvirus genus, which contains the Vaccinia virus that causes smallpox disease, MPXV has a similar double-stranded DNA genome, life cycle, and mode of transmission. Double-stranded DNA (ds DNA) genomes are generally associated with lower mutation rates. In contrast, the current outbreak exhibits an unexpectedly high level of mutations,roughly 6 times the typical rate for ds viral DNA. To pinpoint the evolutionary origins of this elevated mutation rate, we will: (1) reconstruct phylogenetic relationships among MPXV and its relatives in the Poxviridae, using MrBayes; (2) calibrate a penalized-likelihood molecular clock, using BEAST, to estimate divergence times within the clade; (3) compare rates of molecular evolution for selected proteins among Poxviridae sub-lineages, using Mesquite; and (4) model patterns of structural evolution in viral proteins using PyMol. These results have the potential to shed light on the underlying causes of shifts inprotein evolution rates and the shifting dynamics interactions with host immune systems.

Abstract Name: **Skill Assessment of Caregivers who Serve People with Intellectual and Developmental Disabilities**

This quantitative study assesses the knowledge and skill of caregivers who serve people with Intellectual and Developmental Disabilities (IDD) and explores the aspects of training they received prior and during their time serving the population. In order to test the skill of caregivers, studentresearchers created a survey with 15 qualitative and quantitative questions. There are 4 demographic questions that ask about age, gender, and ethnicity; and there are 11 questions that ask about prior experience, personal opinions of their training, and certifications. The collected data was received by sending out an electronic version of the survey to caregivers for people with IDD. Using 75 participants, this research aims to see how effective training is when used in practice. The research allows student researchers to explore solutions to maximize effectiveness. Once the data was received, it was entered into an excel codingsheet and copied into SPSS. This software provided student researchers with insight about their data based on correlations between prior training, certification and years of experience compared to their comfort level as caregivers. Student researchers used quantitative analysis such as Measures of Central Tendency, Chi-Square tests, and Correlations to find any statistical significance. The nonparametric testing that wasconducted for the research is the goodness of fit method. Student researchers thenran correlations between the variables of caregivers' age, gender, and education level.Overall, results indicate that participants felt the training they receive was beneficial, positive, and thorough (40%, n=30). The results also indicated that most of the participants had a high comfort level when it comes to caring for individuals with IDD (84%, n=63). The qualitative data is observed from open-ended questions. Student researchers intend to use these results to change training to maximize skillset and improve living conditions for people living with Intellectual and Developmental Disabilities.

Abstract Name: Examining Low-Income Household Shopping with Supplemental Nutrition Assistance Program Benefits at the Eau Claire Downtown Farmers? Market Using the Market Match Incentive Program From 2018-2022

Food insecurity is a significant issue facing many American households. The Supplemental Nutrition Assistance Program (SNAP) provides increased access to food for families in need. Additionally, fruit and vegetable (FV) consumption has been shown to improve health and reduce the risk of a variety of chronic diseases. However, poor nutrition among children and adults, including low FV intake have contributed to rising rates of obesity among US children which have been shown to persist into adulthood. It is particularly challenging for low-income households to purchase/eat the recommended amount of FV. Farmers' markets offer a wide variety of fresh, local and healthy foods, especially FV, but data show that low-income households are much less likely to shop at farmers' markets. The Eau Claire Downtown Farmers' Market (ECDFM) sponsors a Market Match Program (MMP) incentivizing SNAP households to shop at the market. In 2020, COVID-19 increased the number of families facing food insecurity while the ECFM also faced challenges regarding how to operate safely. This poster uses administrative data to analyze shopping by SNAP households at the ECDFM using the MMP between 2018-2022. The number of SNAP households shopping at the ECDFM increased in 2020 and 2021 while the associated spending also increased in both years as the SNAP caseload was rising due to the pandemic. As the SNAP caseload declined to about the same level as in 2020, the number of SNAP households shopping at the ECDFM using the MMP and the corresponding spending declined in 2022. The remainder of this study provides more detailed results regarding the patterns in SNAP household shopping at the ECDFM using the MMP over this period. This poster is connected to a another submitted poster analyzing a variety of data from surveys of SNAP households shopping at the ECDFM using the MMP during these years.

Abstract Name: Mother of India: Queen Victoria & Duleep Singh

Duleep Singh, the last maharajah of the Punjab, was deposed in 1849 by the British East India Company. At eleven years old, his kingdom, sovereignty, and rightful possessions were taken from him, and he was put under the care of a Scottish doctor. In 1854, he traveled to England and met Queen Victoria. She "adopted" him as her godson, bringing him into the life of the court. My research analyzes the relationship between Duleep Singh and Victoria. This presentation will begin with an introduction to the circumstances of Duleep Singh being deposed by the British. Then, I will go over my analysis of the interactions, events, and correspondence that surrounded Victoria and Duleep Singh's relationship from 1854 to 1857. I claim that Victoria maintained the belief that Duleep Singh could assimilate into English society and expectations while also reveling in his "exoticness." I also claim that she showed sympathetic support in the face of his loss of power and title, but failed to understand the gravity of his reality and upheld limits to her support that kept British interests at the forefront. First, I analyze the portrait that Victoria commissioned of Duleep Singh to argue that to Victoria he was both exotic and English. Then, I conduct a detailed examination of the correspondence Victoria wrote that addressed Duleep Singh to reveal that she engaged in baseline sympathies on his behalf but failed to understand the reality of his situation as a conquered subject. Next, I analyze Lady Login's account of Victoria presenting the Koh-i-Noor diamond to Duleep Singh to illustrate the unbalanced power dynamic that defined their relationship. Lastly, I analyze more letters from Victoria that show clear support for Duleep Singh while also revealing the limits of her support that stemmed from keeping British interests at the forefront.

Abstract Name: The Aztec?s Powerful and Influential Design

This paper will discuss just how influential and meticulous ancient Aztec culture and rituals have been on art and design today. The Aztec empire lived as one of the many early civilizations with a thriving community and like many other early Mesoamerican cultures, a strong affiliation with religious beliefs and practices. They frequently and primarily utilized this religious motive to express significant iconography and experiences in their architecture, stonework, jewelry, and ceremonial garments. This iconography often depicted Gods, warriors, and virtues that communicate religion, creation, and prosperity, and these elaborate pieces were created solely for religious and sacrificial purposes. These geometric and detail-oriented pieces were extremely intricate and created only by exceptionally skilled craftsmen. Although it is difficult to fully understand the entirety of their principles of design it is apparent this influenced much of Mexican and Central-American design functions throughout history.

Abstract Name: Invisibly Here: The Future of Life Writing in Writing Centers

In writing studies, Jonathan Alexander has employed the term “life writing” to describe the work of encapsulating the complexities of one’s lived experiences through writing (“Writing a Queer Life” 1). For us, such a theory extends the work of writing center scholars considering ways in which private and public struggles take shape through writing centers (Denny, Mundy, Naydan, Sévère, Sicari). These struggles remain increasingly tied to questions around agency and expression in the context of larger unstable social and cultural contexts. And so, we define “life writing” more broadly to encapsulate the work of helping students find meaning, voice, and agency within larger systems of inequity. Indeed, this roundtable starts by positioning life writing as a bridge between personal and academic. Yet, it builds toward offering life writing as praxis—as a writing center method for connecting with writers in a world torn apart, so often, these days.Questions around how students engage, and grow, are always tied to embodied struggles and histories they share with us, through conversation. These struggles manifest through traditional academic prose. At the same time, life writing recognizes writing centers as spaces that welcome creative fiction and nonfiction writing to process mental health and pain—that take seriously students navigating invisible struggles, including histories of shame and repression. We consider, too, how it enables us to better understand advocating for students navigating social anxieties.Presenters will begin by reviewing life writing as an emerging genre and lens we see taking shape in our writing center. Next, before opening for discussion, presenters offer what it might take—including community partnerships-- to develop life writing a genre, as a critical modality, and as a writing center method. We look forward to hearing ideas from other writing centers practitioners.

Abstract Name: Where Have All the Office Hours Gone?: A Qualitative Study of University Instructor/Student Immediacy During and After the Covd-19 Pandemic

This study seeks to understand the effects of Covid-19 pandemic on teacher-student immediacy, and how classroom habits may have changed in a post pandemic world. This study's research questions are two-fold, first, how do students perceive changes to student-teacher immediacy during and post-pandemic? Second, how do professors/teachers perceive changes to teach-student immediacy during and post-pandemic? For this study, students and professors will participate in in-depth interviews to understand their experiences and perspectives on how student-teacher immediacy has been affected during and after the pandemic. Student participants include those who tookcourses prior to, during, and post pandemic, as the primary audience and subjects affected by the potential changes they saw in immediacy, as well as their own classroom engagement habits.Professor/instructor participants will be those who taught prior to, during, and post pandemic to understand how the pandemic affected their ability to maintain immediacy in the classroom, as well as changed how it affected their ability to deliver class material effectively. The researchers will conduct a thematic analysis and use a theory-guided approach when examining the interview transcripts. These themes will hopefully reveal specific experiences students and professors had during the pandemic and give insight as to how both professors and students can help create more immediacy in unique or challenging circumstances.The goal of this research is to identify changes made by professors during the pandemic that either had positive or negative effects on students in their ability to gain valuable relationships with their professors as well as educate on the importance of quality teacher-student immediacy even in difficult circumstances.

Abstract Name: Determining Hydroxyl Radical Production and Metal Contaminants in Marinas near Downtown Pensacola

Environmental contamination from petroleum products present hazards to marine life and humans. Implications of petroleum contamination include negative impact on the biosphere and potential reduction in tourism in impacted areas, leading to economic decline. Sources of oil contamination include industrial collection points, recreational and commercial motor vehicles. Analysis of local water bodies in the Pensacola, FL area help uncover potential sources of contamination from recreational boating. Consequences of petroleum contamination on wildlife include damage to DNA, reproductive impairments, and organ mutations. Damage to aquatic life has long lasting effects on businesses who operate under the assurance they can produce services backed by marine life.Effects on the health of the marine ecosystem are demonstrated in studies of adult fish showcasing reproductive impairments, reduced growth, and organ and fin damage. This can cause havoc on the life cycle of any marine life exposed to the petroleum introduced into their ecosystem. Economic repercussions for the fishermen, restaurants, and businesses that survive off of tourism will occur if not resolved.This project will examine photochemical production of hydroxyl radical (·OH) various samples including accommodated fractions (WAFs) created from crude oil (Jay, FL) and water sampled from local marinas. WAFs incubated with Jay, FL crude oil will be collected after 7 days and tested for ·OH formation using the method of Zhou and Mopper via high-performance liquid chromatography with UV/VIS detection (1). WAFs and water samples from local marinas will be tested for ·OH formation (using the HPLC method mentioned previously) as well as trace metals by ICP-OES. Trace metals such as iron are known to produce ·OH photochemically through the photo-Fenton reaction (2, 3). This will help determine the source of ·OH formation in locally obtained waters.

Abstract Name: **Long-COVID Trends and Risk Factors**

My project aims to explore the neurological changes underlying post-COVID neurological symptoms as well as to identify trends and possible risk factors in surveys of COVID survivors for developing these symptoms.SARS-CoV-2 is a highly transmissible and pathogenic coronavirus that emerged in late 2019 and is responsible for the COVID-19 pandemic. It has since infected more than 625 million people and caused more than 6 million deaths globally. Studies have shown that the effects of COVID-19 linger even after the infection has been resolved. There is strong evidence of neurological abnormalities post-COVID infection such as loss of taste and smell and difficulty thinking or concentrating, commonly known as “brain fog.”Studies have shown that individuals who develop more severe cases of SARS-CoV-2 infections experienced higher levels and more severe degrees of cognitive impairment. However, even those with mild or asymptomatic SARS-CoV-2 infections experienced some degree of cognitive impairment. The neurological mechanisms underlying these impairments are currently unknown, but researchers have found changes in the brain regions associated with memory and sensation post-COVID infection. Considering the number of COVID-19 cases in the USA is almost 100 million, most individuals experiencing these symptoms may be going undiagnosed. Unfortunately, there is a lack of screening protocols for detecting cognitive impairments in survivors of COVID-19. Therefore, it is unknown how many people experience post-COVID neurological symptoms.My research aims to analyze surveys of COVID-19 survivors and people with long-COVID. I plan to use various statistical methods to determine if long-COVID is more prevalent in some populations than others. Some of the variables I plan to examine are differences between age groups, gender, race/ethnicity, education level, disability status, and state/location. This research will help identify trends that would aid in identifying at-risk populations and developing screening and therapeutic options for these individuals.

Abstract Name: **Development of Whey Protein-Lignin Based Film Materials for Food Packaging Applications**

Whey protein (WP) and lignin are by-products of cheese industry and the pulp and paper industry, respectively. This project aims to combine WP, glycerol, and lignin to develop biodegradable films with improved water barrier and mechanical strengths for food packaging applications. Reconstituted WP solutions (6% w/v) were held in a water bath with glycerol and lignin (if applicable) at different temperatures (60-95°C) for 30 mins to induce different levels of WP denaturation.SDS-PAGE showed that the film-forming solution prepared at 90°C for 30 min resulted in 88.7% WP denaturation, while it was only 12.3% for WP prepared at 60C for 30 min. Further results revealed that WP denaturation increased available thiol groups, which were likely responsible for forming the polymeric structure of WP films. With altered polymeric structures, different levels of WP denaturation altered film properties such as film thickness, water vapor permeability (WVP), and water solubility. Both WVP and water solubility were inversely correlated with the percent denaturation of WP.WVP of 60°C and 90°C WP films was 2.20 ± 0.34 mg·m-1·hr-1·kPa-1 and 1.83 ± 0.41 mg·m-1·hr-1·kPa-1, respectively. WVP of 20°C film could not be measured as the film started to rupture within 3-4 hrs of the WVP measurement, indicating its inability to block moisture due to its extremely hygroscopic nature. As for water solubility, 20°C and 60 °C WP films were completely dissolved within 24 h, whereas the water solubility of 90°C WP films was 58.36%±1.8% after 24 h. The results indicate that WP denaturation is critical to the properties of the resultant WP films. Lignin-incorporated WP films are prepared and currently being tested to study the effects of different types and concentrations of lignin on improving film properties, especially mechanical strength, light barrier and antioxidative properties.

Abstract Name: Analysis of PHYB Mutations Identified in a Genetic Enhancer Screen in Arabidopsis thaliana

The plant Arabidopsis thaliana contains the genes LRB1 and LRB2 (Light-Response BTB 1 and 2) that encode proteins functioning as target adaptors in complexes that initiate degradation of the phytochrome red/far-red-light receptors. Plants containing mutations of both the LRB1 and 2 genes are hypersensitive to red-light, because there are increased levels of the phytochromes in these lines. Genetic screens were conducted in the Gingerich lab to identify mutations that increased the red-light hypersensitivity of LRB1 and LRB2 double mutant plants. Such mutations might occur in additional genes involved in red light responses. In several of the lines the putative “enhancer” mutations were found to be within the PHYB gene, which encodes the phytochrome acting as the major red-light receptor in Arabidopsis. Recent work has focused specifically on two of the enhancer mutant lines, each of which has a point mutation in the PHYB coding region which is predicted to change a single amino acid in the encoded phytochrome B protein. We believe these forms of phytochrome with the single amino acid change may have increased activity and we have been characterizing the effects of these mutations on light responses and phytochrome action. One of enhancer mutant lines also has a blue-light hypersensitive phenotype, and we have conducted genotype/phenotype co-segregation experiments to determine if the PHYB mutation in that line may also be responsible for that phenotype. Progress on these projects will be presented.

Abstract Name: Intraspecific variation in the Galapagos mistletoe, a potential endemic species

The Galapagos Islands are renowned as an ecological hotspot for their distinct environment and number of endemic species; new species are still being described with relative regularity to this day in the archipelago. The Charles Darwin Research Station is the primary institution categorizing and investigating the biodiversity of the Galapagos and contains the most complete record of the islands' plant and fungi species in its herbarium as an invaluable resource for research. Mistletoe grow on every continent except Antarctica, with over a thousand species worldwide—however, only one is found on the Galapagos islands as their only parasitic plant.The aim of this investigation was to determine if there is regional distinction within Galapagos mistletoe associated with elevation, island, host, or locality, and furthermore, if the Galapagos mistletoe is a distinct, smaller endemic species from the mainland mistletoe species found in Ecuador.In this observational study, I measured 68 mounted herbarium specimens of Phoradendron berteroanum from the CDRS Herbarium, collected from 1963 to 2022, recording the leaf length/width, internode length, floral spike length and number of floral segments for each specimen. Measurements were taken by hand with the aid of a mounted magnifying lens. In preliminary analyses, elevation was found to be a significant stratifier for mistletoe samples. Determining if this is a physiologically distinct endemic species will provide acurrent description of the islands’ flora and will provide accurate information for a conservation status ranking. Endemic species are subject to higher protections than non-endemic species, and as the islands’ only parasitic plant, found in the vulnerable highlands, Galapagos mistletoe should be protected and further investigated if found to be endemic in order to preserve the biodiversity of this fragile and unique ecosystem.

Abstract Name: **Analysis of 2 variants of CERKL, a gene associated with ocular disease**

Genetic testing, including whole genome and exome sequencing, is quickly becoming a standard healthcare practice, especially for patients with rare diseases. While some changes to DNA sequences can be benign, there are several variants that have not been characterized. One large group of these variants are classified as variants of uncertain significance (VUS), as the effects have not been directly studied yet. However, effectively interpreting the relationship between identified variants and disease remains challenging. VUS can include variants that are predicted in silico analyses to affect splicing of the pre-mRNA into mature mRNA. Disruption of splicing can result in loss of a functional gene product due to exon skipping, changes in the reading frame, or introduction of a premature stop codon. In collaboration with PreventionGenetics, our lab analyzes VUS predicted to affect splicing of genes using a minigene system. Briefly, the minigene system involves cloning a single gene segment into a plasmid vector which is transfected into eukaryotic cells. Processed mRNA transcripts are then sequenced to determine the effects of the variant on splicing. We will present our analysis of 2 variants in the CERKL gene and their potential clinical relevance.

Abstract Name: **Mitochondrial Dysfunction in Striated Muscle Is Related to Muscular Dystrophy.**

Background:Duchenne muscular dystrophy (DMD) is a genetic disorder caused by a lack of the dystrophin protein, leading to muscle deterioration and weakness. The current standard of care is glucocorticoid therapy, which focuses on delaying complete loss of muscle function. Although the cause of the disease is genetic, recent studies using a novel and more relevant mouse model of DMD, the D2-mdx mouse, suggest mitochondrial dysfunction is an early event in the disease process. However, the mechanism through which loss of a cytoplasmic structural protein disrupts the electron transport chain is poorly understood. The aim of this study was to investigate how mitochondrial dysfunction is related to weakness in the D2-mdx mouse model of DMD.Methods:Muscle function was assessed by measuring plantarflexion in vivo. Mitochondrial function was assessed using high resolution respirometry, and reactive oxygen species production was measured using AmplexRed fluorescence.Results:Consistent with the literature, we found that D2-mdx mice were significantly weaker, and muscle mitochondrial function was decreased, compared to the control, DBA/2 mice. Further, we found that peak torque was significantly reduced by 44%, which was associated with lower Complex I and II activity in the D2-mdx mice, compared to the control. Additionally, we found that reactive oxygen species production was elevated in D2-mdx mice, compared to the control.Conclusions:Cardiac and skeletal muscle in the D2-mdx murine model of Duchenne muscular dystrophy exhibit lower mitochondrial oxygen consumption capacity and higher reactive oxygen species production. These changes may worsen the muscle weakness that is already present due to loss of the dystrophin gene in Duchenne muscular dystrophy.

Abstract Name: **Panel discussion: Creating a developmental curriculum to build research skills**

In this panel discussion, moderated by Abby Hemmerich, four panel members will share examples of undergraduate research embedded across the curriculum and within individual courses. These examples will highlight principles of research woven through progressive courses in chemistry, psychology, kinesiology, and natural sciences, helping students build skills developmentally from their first year to graduation.David Durkin (co-author, Darion Isom) will discuss a series of integrated labs to grow research skills throughout the middle years of the chemistry major, culminating in an independent, problem-based learning project. Details about the final “Special Project” will be presented; this project requires students to utilize all of their skills to independently design the experiment, request materials, perform of the experiment, and write the research report.Nicole Depowski will present a case study of a psychology program with research introduced at the introductory level, integrated practice across the curriculum, and a capstone senior thesis project. Early exposure to scholarship focuses on locating and reading research, while students gain skills in research ethics and design at the next level. The third year requires use of primary sources, with synthesis and analysis, culminating in a senior thesis project in which students produce their own research.Brian Wallace will discuss the process for building evidence-based practice and research principles into the kinesiology curriculum to prepare students for graduate school or health and fitness professions. Changes to student engagement in research and outcomes related to faculty-mentored research will be discussed.Chimdimnma Esimai (co-author,George Ude) will present a series of course-based research experiences that engage a whole class of students in a research question or problem. Although individual projects are restricted to a single course, students experience multiple opportunities for these projects across the curriculum, providing complementary content and developmental progression in skills.

Abstract Name: **Radiation dose studies in fruit flies with 350keV electrons**

The effects of beta radiation on fruit flies (Drosophila Melanogaster) were studied using the Applied Nuclear Science lab AN400 accelerator modified for electron acceleration and extraction. Dose-dependent effects up to 800 Gy have been observed, with significant effects well below the LD-50 dose for 2-day old larvae. These effects include reduced larvae and aborted development to adulthood. The goal of establishing a population of viable adults in samples showing clear radiation dose effects to study inherent radiation resistance has now been met. The data gathered in the process of this experiment will be used to further calibrate the accelerator for future research.

Abstract Name: **Cocoa Oil Extraction and Energy Content Measurements**

The goal of this research was to find a sustainable alternative to palm oil, which is unethically produced and environmentally destructive. Therefore, thisresearch examinesthree oil extraction methods from Columbiancocoa beans. Bomb calorimetry is also used to measure the energy content of the extracted oil. The three methods include hot oil press extraction, Broma extraction method, and Soxhlet extraction. Methods were compared to measurethe most oil removed from the cocoa beans. The most convenient extraction method is the hot oil press method. The Soxhlet extraction method is the best method for receiving pure cocoa oil without any solid contamination due to the process. Due to the conditions of the lab and the fermented cocoa beans provided, the Broma extraction method was not successful in this research. The 2-hour Soxhlet extraction produced a 0.4% oil recovery yield;and a 0.6% oil recovery yield for the 4-hour extraction. The average energy found in the cocoa solid residue was determined to be 4475.28 cal/g with an oil percent of 33.25 %. The average energy found in cocoa oil was found to be 7695.62 cal/g, with an oil percent of 81.96%. This study aimed to compare different methods of extracting cocoa oil and investigate the energy produced from the cocoa solids to numerically investigate the effect each method has in extracting cocoa.

Abstract Name: **Comparison of Asthma Patient Visits By Demographics for Coach McLungs Implementation**

This state-wide study aims to summarize the demographic characteristics of asthma-related patient visits over the past 5 years and to serve as a pre-analysis of the demographic statistics before the implementation of Coach McLungs. Coach McLungs is a virtual program that generates a treatment plan for the patient and provider with both their inputs. A final sample of 21 family medicine and pediatric clinics based in Charlotte and its surrounding areas were recruited in 2022 to provide demographic input of their patients aged 5 to 17. This sample in turn allows for an exceptional analysis of the patient's race, sex, ethnicity, and gender in relation to asthma treatment and documentation. The analysis showed that over the past 5 years, 60.9% of the visits were made by male patients, while the other 39.1% were female patients. The analysis of race showed that White/Caucasian patients had a slightly higher number of visits than Black/African American patients at 44.3% vs. 44.5%. However, White/Caucasian patients had on average 5.0 outpatient visits, while Black/African American patients had on average 5.7 visits. These results suggest that Black/African American patients have more outpatient utilization than White/Caucasian patients. A further analysis of this observation shows that there is no significant difference between the average number of outpatient visits by race, as a two-sample t-test resulted in a p-value of 0.1004. In conclusion, race disparities do present themselves with outpatient utilization, but not at a significant level. Further research is being conducted on the significance of sex disparities; therefore, no correlation can be determined on these factors right now.

Abstract Name: Increasing Participation in Mindfulness-Based Art Therapy in Teenage Oncology Patients

The incidence of cancer in adolescents has risen dramatically in the last 30 years, with cancer as the fourth leading cause of death in the teenage age group. Adolescent patients typically present with a higher symptom burden and rates of depression and other psychological disorders. The inclusion of mindfulness-based art therapy (MBAT) programs in patient treatment has been shown to decrease the prevalence of mental and physical trauma endured by cancer patients. While adolescent patients benefit greatly from these programs, the lack of tailored activities creates lower engagement amongst the teenage cancer population. This review aims to explore how increasing adolescent cancer patients' participation in mindfulness-based art therapy programs may address their higher physical and mental health issues.Adolescent cancer patients face disruptions in their developmental trajectory and thus experience unique problems such as a loss of independence and abnormal relationship with peers compared to other age groups of patients that can trigger higher levels of stress, anxiety, and depression. MBAT programs have been proven to reduce stress and mental and physical trauma, and teenage oncology patients stand to benefit the most from MBAT activities despite participating the least in them. A review of the literature on MBAT programs and cancer patients found a link between increased participation and engagement in MBAT and decreased levels of mental and physical health trauma. For example, studies on the biological pathway behind pain in cancer patients found that increased levels of stress and anxiety that cancer patients experience open a neuronal gating mechanism that results in a higher perception of pain. This research proposes that increased engagement in MBAT activities may benefit adolescent cancer patients in terms of their physical and mental health. Due to these findings, a tailored program including MBAT activities made for teenagers should be developed by clinicians and nurses.

Abstract Name: Energy Balance Influences on Avoidance Behavior in Wistar-Kyoto and Sprague-Dawley Rats

Previous research has shown physiological state changes caused by caloric deficits can attenuate behavioral responses to stress. While these behavioral and endocrine stress responses during negative energy balance seem adaptive, as they may promote food seeking behaviors, the underlying mechanisms remain poorly understood. Our study seeks to probe specific neuropeptide effects on the role of physiological state in guiding avoidance behavior in Wistar-Kyoto (WKY) rats. WKY rats show consistent behavioral inhibition (BI), as demonstrated by performance in open field testing and enhanced acquisition in signaled lever press avoidance relative to Sprague-Dawley (SD) rats, which serve as non-behaviorally inhibited (NBI) controls. Here female WKY (n = 8) and SD (n = 8) rats were trained on a partial predictability signaled lever press avoidance task in which a tone conditioned stimulus (CS) signaled a foot shock unconditioned stimulus (US) only 50% of the time. We sought to determine how overnight fasting may contribute to guiding avoidance behaviors. Our data demonstrate that following overnight fast, non-behaviorally inhibited SD rats significantly increased avoidance responses to the level of avoidance demonstrated by behaviorally inhibited WKY rats. Overnight fasting elicits a variety of physiological changes that could contribute to avoidance behavior. It is well established that fasting increases circulating levels of the hunger hormone ghrelin, thus we hypothesized that central ghrelin signaling may contribute to the observed behavioral effect of the overnight fast. The same cohort of rats were implanted with cannulas targeting the lateral ventricle. Rats received intra-LV injections of ghrelin or saline 45 minutes prior to the signaled lever press avoidance session. Surprisingly, central injection of ghrelin significantly reduced avoidance performance in WKY rats and did not affect avoidance in SD rats. Ongoing analyses will assess neuronal activation in the hindbrain following avoidance in fed and fasted WKY and SD rats.

Abstract Name: **Supporting Student Success in a Classroom Setting via Course Undergraduate Research Experiences**

Course-based undergraduate research experiences (CUREs) provide valuable research knowledge and skills to students. Supporting faculty as they develop and implement CUREs ensures sustainability and the quality of student learning experiences. There are few qualitative studies of faculty perspectives on the faculty experiences implementing CURES. This research provides insights into what is working well and what needs to change when facilitating professional learning associated with CUREs. Faculty and Students completed interviews via a protocol approved by the CSUMB IRB. When interviewed, faculty and students responded to a series of questions about their CUREs and their experiences. Researchers identified themes associated with faculty participation in the CURE Faculty Fellows program, as well as themes about student learning. Faculty affirmed the value of the CURE Faculty Fellows program, and students believed research in a classroom setting to be beneficial. Several themes have emerged from the analysis including: the structure of CUREs, common activities, as well as strategies for belonging, persistence, and developing identity as a scholar. Analysis of the themes led to the conclusion that faculty viewed students as having mixed responses when engaging in research, while students felt that conducting research was both challenging and exciting.

Abstract Name: **Relationship Between Inclusion in Schools and College Student's Subsequent Comfort with Disabled Peoples**

I sought to determine whether past inclusion in schools correlated with current comfort levels in interacting with people with disabilities in undergraduate students at John Brown University. Little previous research has been done regarding the efficacy of inclusion on the future attitudes of nondisabled peers, but what has been done indicates the importance of inclusion and its educational benefit for all involved. My hypothesis was that students with a background in inclusive elementary or high schools will have higher comfort levels and more involvement with people with disabilities post-high school than those in largely separate elementary and high schools. In order to test this, an online survey was conducted among college-aged students. Participants in this survey were chosen randomly from a list of all undergraduate students at John Brown University. Analysis revealed a significant correlation between elementary school inclusion levels and later comfort with people with disabilities with an effect size of R=0.38 and a 95% confidence interval of [0.02, 0.65]. There was also a positive correlation between inclusion in elementary and high schools combined and later comfort. These results provide evidence for the connection between inclusion and improved disabled/non-disabled interactions. Future research should be focused on inclusion's effects in high school and studies of a wider population. Keywords: disability, inclusion, mainstreaming, efficacy

Abstract Name: Development of a Shape-Memory-Alloy-Based Remote Actuator for Precision Optical Measurement Systems

In the Laser Interferometer Gravitational-Wave Observatory (LIGO), there is limited capacity to adjust the positioning of small optics. This results in system-wide optical losses between 40-50%. Currently employed methods of actuation for these optics obstruct the backside of the optic. This makes them incompatible for use with lenses and limiting potential avenues for system control. This project's goal is to develop a mechanism using Shape Memory Alloys (SMAs) forremote actuation in precision optical systems. SMAs are alloys that change their shape to a "remembered" state when the temperature of the SMA increases. For our purposes we are using a simple circuit that induces Joule heating to actuate the SMAs. To test the efficacy of SMA-based actuation, a tabletop prototype has been developed to show how precise of a control we can have while using SMAs. We present progress on this prototype and preliminary performance measurements, with an emphasis on suitability for future use in precision optical control. This prototype can lead to a larger application of SMAs used to adjust equipmentin LIGO which will help to reduce optical loss and improve observation quality.

Abstract Name: Developing a Machine Learning Algorithm using Pattern Recognition to Analyze Experimental Data from Photoelectrochemical Systems

The purpose of this research is to develop a machine learning algorithm that will use pattern recognition to match experimental voltammograms with model responses to understand the physical parameters of an artificial photosynthetic system. Photosynthesis, the process in which plants convert light energy from the sun into chemical energy, can be replicated artificially in a photoelectrochemical reaction powered by natural light that generates hydrogen fuel at a semiconductor electrode. Semiconductors, such as silicon, are an essential part of converting light into usable energy. The potential and current recorded with semiconductor electrodes as working electrodes and separate reference; counter electrodes contain useful information about the reactions if proper analysis can be performed. Performing data analysis on the data collected from cyclic voltammetry allows the photoelectrochemical reactions to be examined in a systematic manner to determine the best conditions for conducting the reactions. Experimental variables include the type of semiconductor used to construct the electrode, the surface area of the semiconductor, and the dopant density of the semiconductor. The developed algorithm allows for more precise measurement of the system parameters that control the reaction properties. The present data were recorded in the absence of light to control the variability of the experiment. Future experiments will utilize visible light to drive the current that powers the reactions. This algorithm will aid in the understanding of the reactions taking place to move forward towards the end goal of creating hydrogen fuel solely through the use of natural light.

Abstract Name: **Using Audio Manipulation to Interact with Hearing Loss**

Since the advent of technology, methods used for assistance and education surrounding the hard of hearing community have been focused on increasing the hearing capability of those with hearing loss, or supplementing auditory senses with the use of visual aids. This current strategy of hearing assistance focuses on changing how those who are hard of hearing experience sounds, rather than changing the sounds that are experienced. Using modern programming languages we are able to host software in a web application that takes an input audio file and passes it through a Fast Fourier Transform algorithm, so that the audio can be modified and visualized as a sum of frequencies rather than amplitude. In transforming the audio this way, we can apply volume filters for specified frequency ranges within the web application interface. The resulting audio output then mimics how someones specific sense of hearing loss would sound, and the web application visualizations would replicate an audio feed in the format of an audiogram. The development of this audio manipulation software allows someone with a full range of hearing to hear the input sounds as heard by someone with a more limited range of hearing, as well as see how the audio is manipulated. In developing these tools; audiologists, education faculty, family and friends of individuals with hearing loss, sound designers and more, can create auditory experiences that are more accessible for a larger population of hearing levels.

Abstract Name: **Biofilm Formation Contributes to Antibiotic Resistance in the Sheep Respiratory Pathogen Mycoplasma ovipneumoniae**

Mycoplasma ovipneumoniae (M. ovi) is a respiratory pathogen associated with polymicrobial pneumonia in domestic and bighorn sheep. Increased antibiotic resistance has been reported in sheep infected with M. ovi, but the mechanism of this resistance is not well characterized. One possible mechanism of interest is the formation of biofilms. In our research, we show that M. ovi can form biofilms and investigated whether these biofilms lead to increased antibiotic resistance.To grow M. ovi biofilms, we incubated M. ovi in wells with glass coverslips placed at the bottom. Biofilms attached to the glass coverslip, allowing for staining and imaging via brightfield and confocal microscopy. Antibiotic susceptibility was investigated using a serial dilution of gentamicin ranging from 128 µg/mL to 1 µg/mL. The minimal inhibitory concentration (MIC) was defined as the lowest concentration of gentamicin where M. ovi failed to grow.Two strains of M. ovi, a reference strain (Y98) and field isolate (MSU-NW4), showed robust biofilmformation when cultured for 8 days in an aerobic environment. Biofilm formation was visualized using crystal violet staining, and formation of a characteristic 3-D structure was demonstrated using confocal imaging and a SYTO9/PI stain. M. ovi biofilms exhibited increased antibiotic resistance, with a reduction in biomass for concentrations at or above 32 µg/mL for gentamicin compared to a 4 µg/mL MIC for planktonic populations.We are the first to demonstrate robust formation of biofilms by multiple M. ovi strains and to show that M. ovi biofilms have increased resistance to antibiotic treatment.

Abstract Name: **A Computer-Based Model to Capture Gastric Electrophysiology Through Bio-Impedance Analysis**

The ability to monitor the bioelectrical activity of the gastrointestinal tract, in a non-invasive manner is essential for the diagnosis and management of functional gastrointestinal disorders. Electrical bio-impedance (Bio-Z) analysis is a promising method to acquire a wide range of human electrophysiological activities, through wearable electrodes. The Bio-Z sensing system consists of a four-electrode configuration on the body surface in which the two outer electrodes deliver a sinusoidal excitation signal transcutaneously, and the two inner electrodes acquire a differential potential which will be conditioned, processed, and mapped to the electrophysiology of interest.To this end, we developed a computer-based model of the human gastric system in COMSOL Multiphysics, a simulation platform based on the finite element method. Through the model, we simulated the Bio-Z analysis to capture the gastric electrophysiology, through the body surface. The objective of the project is to simulate the penetration depth of the Bio-Z analysis as a function of frequency and find the optimum frequency for the clinical data collection on human subjects. We developed the model of the abdomen through four layers of skin, fat, muscle, and peritoneum. Besides, we developed the model of the gastrointestinal tract through four layers of serosa, muscularis, submucosa, and mucosa. The model of four AgCl electrodes was added to the model of biological layers, too. The frequency-dependent permittivity and conductivity parameters were assigned to each biological layer for the simulation at each Bio-Z frequency. In COMSOL, we generated the electric fields resulting from the applied sinusoidal excitation signals at various frequencies in the range of 10 kHz to 250 kHz to the stomach, transcutaneously. Then, we plotted the power spectrums of the electric fields and compared them at the penetration level of the gastric tract.

Abstract Name: **Perceptions of Veterans from Hollywood Movies**

Portrayal of veterans in Hollywood movies may create polarized perceptions on military service members. Most existing research on media coverage of veterans and its impact on individual perceptions focus on news media and social platforms. However, there's a lack of research on how Hollywood movies could shift an individual's view on veterans. In this study, Cultivation Theory will be used to analyze how watching Hollywood movies could influence an individual's viewpoint. This study will help provide evidence in this area. In this study, individuals will be randomly placed in two different groups and they will view different movie scenes where veterans are portrayed in a positive vs. negative light. Participants will be students from George Mason University recruited through a variety of different ways, such as flyers, kiosk events, and a University platform called Mason 360. In the experiment, participants will answer baseline questions about their initial opinion of veterans and then complete another questionnaire after viewing the assigned videos. Data collection will be done by mid-March 2023 and analysis will be concluded by the end of March 2023. Findings of this experiment will help us understand movie portrayals as a source of influence on public perceptions of veterans.

Abstract Name: **The role of Cry1 in Glucagon-receptor (GCGR) signaling and GCGR-mediated hepatic glucose metabolism.**

Glucagon (GCG) is a 29-amino acid peptide released from alpha cells of the pancreatic islets. Glucagon is best known for its counterregulatory actions against insulin-stimulated hypoglycemia via hepatic glycogenolysis and gluconeogenesis. However, glucagon also regulates a range of actions such as amino acid catabolism, lipolysis, ketogenesis, fatty acid oxidation, satiety, thermogenesis, energy expenditure, and bile acid metabolism. These GCG-mediated improvements in lipid and energy metabolism may be desirable in patients with the metabolic syndrome. Consequently, glucagon-receptor (GCGR) agonism has been added to classic incretin hormones in single-molecule, multi-receptor co-agonists that elicit superior therapeutic efficacy in metabolically compromised rodent models and emerging clinical trials. Importantly, the addition of GCGR activity to these molecules did not impair glucose metabolism. Therefore, understanding the mechanisms by which GCGR regulates glucose homeostasis is of great value.Previous studies suggest Cry1 regulates GCGR-signaling via inhibition of cAMP in the liver. Intriguingly, our data supports that GCGR stimulates hepatic Cry1 expression, suggesting a feedback loop between these pathways. However, temporal regulation of this feedback as well as its overall effect on hepatic glucose output and whole-body glucose homeostasis is incompletely understood. Our studies utilize GCGR pharmacology and shRNA knockdown of Cry1 to interrogate this signaling axis in primary hepatocytes and cultured cell lines. Further investigation in this area will improve our understanding of GCGR signaling and its regulation of glucose homeostasis.

Abstract Name: **Hollywood and Marxism**

Must a production be independent of Hollywood in order to truly convey a Marxist ideology? May, for example, a television show such as Succession (2018-22) or film such as The Menu (2022) truly criticize corporate America and the one percent when coming from corporations and studios such as Warner Brothers, and Walt Disney? While theorists such as Theodore Adorno and Max Horkheimer would argue that such productions are regardless, oppressive, it is important to explore in what production contexts can media successfully criticize the system it is produced in. Further, how do these productions compare to an independently produced film such as Pier Paolo Pasolini's 1975 Salò or 120 Days of Sodomy. This, considering the nature of its production and distribution, is able to criticize the nation of Italy, fascism, capitalism, materialism, and those who benefit from such structures. Through the lens of Jean-Louis Baudry's 1970 paper, 'Ideological Effects of the Basic Cinematographic Apparatus' I am able to analyze these three pieces in the entirety of their social field. It is that media such as Succession and The Menu are not able to criticize the system they are developed in because those who provide the funds along with the final approval are the same people these pieces are trying to condemn. Meanwhile, Pasolini is able to stay true to his ideology with Salò as there is no 'man' for the production to answer to. At the final light of the candle, it is not possible for a product of a capitalist system to in whole truly criticize that structure.

Abstract Name: Variations in System Parameters at Low Energy Input on Thermosiphon Collector Efficiency

A thermosiphon is a system of components that passively generates a closed cycle of flowing water wherein solar energy is stored as useful thermal energy. Systems used in real-world applications contain no mechanical or electrical components, making it useful in areas lacking capable infrastructure. Flow starts in the collector by heating the water, decreasing its density, and creating a buoyant force, which drives the fluid through a hot leg pipe into a raised tank. This heat contained in the tank could be extracted for domestic hot water heating or building supplemental heating applications. The water cools, increasing its density, and sinks down the cold leg pipe and re-enters the collector where the process continues cyclically. Thermistors, located at the collector inlet and outlet pipes, measure system temperatures and an open-bore flowmeter measures flow through the system. During steady-state, a period where flowrate, inlet and outlet temperatures remain relatively constant, collected data is used to calculate the instantaneous efficiency of the system. The discreet efficiency values are then used to calculate overall efficiency. Components of the system allow the ambient temperature around the device to be controlled, a parameter overlooked by most thermosiphon research projects. These components include insulated, removable walls enclosing the device, a fan to circulate the air inside the enclosure, and a space heater and AC unit to control the temperature. Previous research has used high-power input to the collector simulating sunny-days, but current research conducted low-power tests simulating cloudy-days to compare trends across both conditions. The base parameters that are varied and researched are collector angle, hot leg height, cold leg height, hydraulic resistance, and input power. By conducting a range of diverse test series, each investigating the effect of altering a single parameter, the team explored the effects of each system parameter on overall efficiency trends.

Abstract Name: HVAC Design of a Performing Arts Center to be Located in Sidney, Australia

This work was done as an entry tothe 2022 HVAC Design Calculation Competition being held by the American Society of Heating, Refrigerating and Air-Conditioning Engineers (ASHRAE). The complete HVAC design calculations were performed for a large (over 200,000 ft2, over 500 spaces) higher education performing arts building placed in Sydney, Australia.The calculations required the analysis of heating and cooling loads, and determination of the necessary airflow to each space based on usage and size. The HVAC system was then designed and optimized to maximize the building energy efficiency. The project demonstrated compliance with four standards from ASHRAE: 55, 62.1, 90.1, and 189.1, which are thermal comfort, ventilation for indoor air quality, energy standards, and high efficiency, respectively. As first steps, load calculations were performed by hand to find peak amounts of cooling required, and the necessary airflows were determined to meet the required ventilation levels. Next, the use of Carrier's Hourly Analysis Program (HAP) allowed for a more robust look at each of the five hundred and forty-four rooms. This allowed for structural coordination of placing a roof top unit to serve half of the top floor of the building. Special consideration was given to energy efficiency and sustainability. The energy intensity usage was found to be 27.8 kBtu/ft2 which is compliant with expectations from the New Buildings Institute to be within 30 kBtu/ft2. Overall, the project came together to generate detailed floor plans of the entire building and a detailed model to represent the finalized building layout.

Abstract Name: **Text Summarization For E-Commerce Reviews Using NLP Techniques**

Consumers always want the best experience possible. In e-commerce especially, potential customers value finding the best viable product in the least amount of time. User reviews are usually the method by which users make informed decisions on what they want to purchase. Reading user reviews is time-consuming and includes having to search for comments about specific aspects of a product. Thus, in this research, we build a framework that summarizes the lengthy reviews into concise star ratings based on features of the product using Sentiment Analysis and Topic Modeling. The framework uses the Gensim Word2Vec machine learning Python model to pull topics from reviews, giving a sentiment rating to each topic and a concise summary. For example, the user can choose to shop at a pizzeria and start by searching for the word “pizza.” The program will then search through a csv file containing publicly accessible reviews (in this case, Yelp review data) at that specific business. From this, the user will be shown similar topics like “pepperoni,” “cheese,” and “anchovies” via Gensim Word2Vec. The user is then presented with these subtopics and gets a star rating using NRC Emotion Lexicon, as well as a summary of the subtopic using Pipeline Summarizer. The hypothesis is that using this proposed framework will make it easier and quicker for customers to understand the sentiment around the products they are interested in purchasing. The results show that using the framework allows a user to understand the sentiment around certain aspects of a product quicker than just manually reading through reviews. The user also gets a summary of each topic, further increasing their understanding of the sentiment of the product.

Abstract Name: **Design upgrade for a Petawatt class laser**

The objective of this project was to design target chambers and target laser beam transport for laser-created plasma experiments utilizing a Petawatt (PW) class laser. The laser to be used will be an upgrade to the current laser facility at Colorado State University which is known as Advanced Laser for Extreme Photonics (ALEPH). The purpose of the upgrade is to significantly increase the energy of the laser to increase the overall output power from 0.85 PW to 4 PW. This design allows for multiple options in experiments which consist of both short focal length and long focal length focusing optic configurations. Importantly, this system will have two independent beamlines that will allow multibeam experiments to be conducted which include advanced laser wakefield acceleration, inverse Compton scattering, probing the proton stopping power of warm dense matter, and the study ofatomic physics at and above solid density., With short focal length optics,we can expect intense x-ray and gamma-ray flashes for the tomography of dense objects, neutron generation, micro-scale fusion, and ultra- high energy density plasma generation. With long focal length optics, we could expect the acceleration of electrons to GeV energy levels and the generation of coherent x-ray radiation. The work involved extensive use of 3D CAD using Solidworks to design the vacuum chambers and the hardware for the Petawatt class laser pulse compressor. Additionally, the design model underwent rigorous simulations using finite element analysis. This was an important tool to help determine structural integrity as the chambers had both gravitational forces and internal vacuum pressures applied to them. Vibrational analysis was also key in mitigating sources of low vibrations in order to improve laser focusing. This upgrade will be essential as it would provide years of new advancements in the field of plasma physics and extreme photonics.

Abstract Name: **The Sickness**

"The Sickness", a typographic poster design, focuses on raising the public's attention to the problems and negative effects of the American healthcare system. The research that I conducted was concentrated on real-life experiences of those who suffered from the negative effects of the American healthcare system. Through research, I collected countless recollections, including the disheartening case of Susan Finley who lost her job at a company for taking too many sick days. She also lost her health insurance while struggling to recover from pneumonia. Finley passed away from flu-like symptoms after avoiding a doctor's visit she simply could not afford. Stories like these were incorporated into my design, along with dark tones and torn newspaper effects to express the impact they hold. It is critical to recognize how an unprecedented ailment can put a family into incredible disparity. Without universal health care, the US health system forces Americans to feel strongly apprehensive of even calling for an ambulance. The American healthcare system takes advantage of how helpless one can feel when they are denied help in times of need, merely because they cannot meet the price tag. The typography in the design was shaped into a medical syringe, with all the words included correlating to the theme of both America and general health topics. The colors chosen for the type are red, white, and blue, to symbolize the overarching subject of the United States. There is a large dollar sign in the negative space of the syringe overshadowing the other words, to conceptually represent a debate over who the system benefits and helps. I hope that my design can raise the public's attention. We need to break the silent taboo shrouding this problem and push for the system to work for the people, not big pharma or private insurance companies.

Abstract Name: **Evaluating a revised protocol for the chamber-specific differentiation of iPSC-derived cardiomyocytes**

The prospective utility of cardiomyocytes (CMs) derived from human induced pluripotent stem cells (iPSCs) is largely dependent on their ability to be efficiently and precisely produced as subtype-differentiated (chamber-specific) tissues. Chamber-specific monolayer and three-dimensional tissues have the potential to revolutionize the study of cardiac disease and drug development as in vitro models of disease and accurate, ethical models for testing the chamber-specific cardiotoxicity of clinical drugs. However, the majority of differentiation approaches to date produce a mixture of atrial and ventricular CMs which, without further treatment, progress to predominantly (but not exclusively) ventricular cardiomyocytes (VCMs) over 15-30 days. Treating cardiac progenitors with retinoic acid (RA) produces sub-specified atrial cardiomyocytes (ACMs) showing strong atrial protein markers when these cells are further treated on RPMI 1640 media with no glucose and high levels of lactate to select for exclusively metabolic CMs. The goal of this study was to determine whether healthy atrial cardiomyocytes could be produced with high specificity through treatment with RA but without the use of metabolic CM selection media. Four batches of ACMs and two of VCMs, all derived from iPSC line 19-9-11, and one human VCM sample were evaluated. Successful ACM differentiation was determined based on functional response (quantified through calcium flux imaging) to cardiac drugs with known effect and Western Blotting analysis of β-myosin heavy chain protein abundance. It was found that while this protocol effectively produces cells in high number with low functional variation and which respond as expected to drug treatment, most ACM/VCM samples tested continue to demonstrate a degree of mixed ACM/VCM protein characteristics. More research is needed to determine and reduce the subtype variability between and within cell lines and determine the timeline of progression of ACMs differentiated by RA addition towards exhibiting VCM characteristics.

Abstract Name: **Affect of the Mystic in Film: Whereof One Cannot Speak, Thereof One Must Make a Movie**

In spite of his broad reaching influence over the field of philosophy, Ludwig Wittgenstein has been curiously neglected in the developing field of media studies, which historically favors continental and post-structuralist approaches to media affect and ideology. With attention to Wittgenstein's discussion of the function of language, picture theory, and the limits of what language can access (the mystic), this paper seeks to recontextualize Wittgenstein's philosophical project – specifically, his singular treatise Tractatus Logico-Philosophicus – within the realm of filmmaking and viewership. The paper proposes a Wittgensteinian photo-ontology utilizing his picture theory, constitutively suggesting cinema, as a medium which stimulates sight and sound to often profound somatic effect/affect in the viewer, can capture the limits of language and being: the "mystic" in the same way our own sensory data in life can experience but fail to translate, or signify directly. Cinema is therefore framed as a form of "silence," playing with Wittgenstein's famous quote – we cannot speak directly of the limits of experience, but we can show it through images in the same way we experience it in life. Cinema is the language of the mystic, and through cinema the mystic can be explored and felt as an end in itself – the paper explores the short works of filmmakers such as Apichatpong Weerasethakul and Stan Brakhage in this capacity, and further the possibility of "mystic" style in popular filmmaking. Wittgenstein can be used as an extension or alternate approach to a cinematic theory of affect, as a fundamental experience which denies language in its ontological primacy.

Abstract Name: **Presumptive Diagnosis of Alcohol as the Etiology of Altered Mental Status in Collegiate EMS**

Altered mental status (AMS) is a common emergency call on college campuses, and for Collegiate-Based Emergency Medical Service (CBEMS) providers this chief complaint is frequently found secondary to alcohol intoxication. Although it is important to consider alcohol when determining the etiology of AMS patients, a presumptive diagnosis of intoxication without a thorough differential diagnosis can delay or prevent vital treatments of life threats. The purpose of this study is to determine if CBEMS providers make premature diagnoses of alcohol intoxication as the etiology of AMS due to underutilization of key AMS assessments. This study was conducted as a retrospective analysis of de-identified Patient Care Reports (PCRs) submitted between 2015-2022 from one service. Each PCR was compared to predetermined criteria for AMS and examined for evidence of alcohol consumption and key assessments for AMS differential diagnosis (blood glucose, pupils, SpO2, head trauma assessment, temperature, stroke assessment). Differential diagnoses were underutilized on all AMS calls with respect to key assessments; furthermore, there was a 15% decrease in assessments completed when alcohol consumption was reported compared to when it was not (0.05). These results may suggest an underestimation by CBEMS providers of the seriousness of AMS and intoxication as medical emergencies.

Abstract Name: Efficacy of Cryotherapy Modalities

Cryotherapy and compression are frequently used treatments for acute injury and post-operative healing, but the pricing of these treatments isa major concern in today's healthcare world. A common cryotherapy modality used following orthopedic surgeries or injuries is the GameReady which circulates ice water through a sleeve while compressing the area, however, it is quite expensive (~$4000). A relatively new option for cooling and compression is a device called Hyperice, a sleeve with fans attached to blow cold air, and is less expensive (~$400). In this study, we compared the two modalities for effectiveness in reducing intramuscular temperature. We inserted a thermocouple into the largest girth of the subject's lower leg (1 cm deep to the layer of subcutaneous fat) and measured the decrease in temperature due during a 30-minute treatment and during 25 minutes of rewarming after the treatment was removed. 20 subjects volunteered to participate in this randomized, cross-over trial (10 males, 10 females, age=24.65 ± 2.7 years, height= 173.86 ± 9.83 cm, weight= 78.22 ±16.17 kg). There was a statistically significant difference between the two treatments over time, F(11,209)=9.08, p=0.001, observed power= 0.947. By 5 minutes into the treatment, there were statistically significant differences between the devices, which continued throughout the entire treatment and rewarming phase, with the GameReady causing larger decreases in intramuscular temperatures. We also saw a clinically significant difference (2.1℃) between the two treatments at most of the time points. The GameReady lowered the intramuscular temperature more than the hyperice did, indicating that it is more effective, but it is also more expensive. Future research should evaluate the cost-effectiveness of other cryotherapy/compression modalities

Abstract Name: Exploring Family Dynamics, Mental Health and Well-Being Among Former Foster College Youth

The impact of foster family environment on mental health and well-being has been studied; however less is known regarding the experiences of foster youth who have transitioned out of foster care and are now pursuing post-high school education. This study aimed to explore foster college-aged students' experiences of their foster family environment and their mental health and well-being. Using a Qualtrics survey of closed- and open- ended survey questions, we gathered data from 56 former foster youth from around the United States. Results demonstrated an array of experiences from positive to negative regarding former foster youths' perceptions toward their foster family support, dynamics, and their own mental health. Overall, we found that our sample reported more mild symptoms of anxiety compared to more severe levels which are often found in other research working with this population. Suggestions for future research are discussed.Keywords: foster college aged youth, family dynamics, mental health, well-being

Abstract Name: **Rhizosphere Microbiome Structure Under Drought Stress**

Shifting precipitation regimes caused by climate change necessitate extensive research of plant responses to drought. Under stressful conditions such as drought, diverse rhizosphere microbiomes can improve plant fitness by increasing plant growth and supporting nutrient uptake. These interactions occur through the release of carbon-rich photosynthates from plant roots to the rhizosphere. In return for the readily-available carbon, microbial mutualists are able to increase nutrient turnover and water availability for the plant. However, it is unknown how historical climate regimes influence plant-microbial interactions. Here we show that the rhizosphere microbiome assemblies of the montana-native blue grama (Bouteloua gracilis) prairie grass under drought conditions are distinctly different from when grown under ambient conditions regardless of historical climate regime. Blue grama grown in drought-adapted rhizosphere inoculum showed less indication of physiological stress and recovered from drought more quickly than blue grama grown with non-drought-adapted inoculum. The results indicate that under drought conditions blue grama may select for a unique root microbiome structure that enhances survival. Variation in root microbiome assemblages due to climatic conditions could be applied to agricultural crops to maintain crop yield despite changing climatic conditions. More research regarding specific microbial species that increase plant survival under drought stress could assist in developing agricultural practices that can adapt to meet the needs of climate change.

Abstract Name: **Selective Anti-Cancer Effects of Piper methysticum (Kava) on Human Cancer Cell Lines**

Kava is a common beverage in the South Pacific derived from the roots of the plant Piper methysticum. It is known to act as a sedative that acts as an anxiolytic, aiding in the reduction of stress and anxiety. This product is not isolated only to the South Pacific but is available for purchase in many countries including the United States. Interestingly, the instances of lung cancer rates in the South Pacific are below average despite high tobacco use, and previous research suggests that the consumption of kava in these populations may play a role in this phenomenon. Previous studies have identified specific constituents of kava (e.g. flavokawains) that display antiproliferative effects against cancer cell lines. However, novel components of kava and the synergistic interactions of both known and unknown compounds in preventing cancer cell growth are poorly understood. To isolate compounds found within cude kava root powder, a hot and cold hexane and methanol extraction was followed by flash chromatography. These fractions were used in various concentrations to determine antiproliferative effects on human cancer cell lines compared to non-cancer cells. Cytotoxicity, and proliferation of cultured cell lines including lung cancer cells (H232A), cervical cancer cells (HeLa), and human primary non-cancer fibroblast cells (NHDF) were determined using an MTT colorimetric assay. Treatment with specific Kava isolates exhibited a significant reduction in cell proliferation on various cell lines, while also having limited anti-proliferative effects on NHDF cells. This study suggests that kava may have novel compounds that function to prevent cancer progression leading to further cancer therapeutic approaches.

Abstract Name: **Investigating the Intersection of COVID and Mental Health: A Text Mining Approach**

This research explores how topic modeling can be used to describe the intersection of the conversations about Covid-19 and mental health using Twitter data. To identify themes around the conversations people are currently having about these Covid-19 and mental health, this project analyzed approximately 2,000 Tweets that mentioned both mental health and COVID-19. Using traditional qualitative methods of identifying themes of textual data by reading and re-reading all the Tweets is a daunting task. For this project, we compared how a semi-supervised and unsupervised topic modeling method performed in analyzing the Twitter data. Seeded topic modeling, a form of text mining using semi-supervised learning methods, was used to identify common themes among the Tweets. Seeded topic modeling is a semi-supervised learning method that identifies topics among large textual datasets, using a predetermined seeded dictionary of terms. The seeded dictionary was created using traditional qualitative methods to analyze 30 college students' free response essays on their experiences with mental health and COVID-19. The essays were analyzed using the Systems Theory Framework, using five levels of interaction: individual, microsystem, mesosystem, macrosystem, and exosystem. The unsupervised topic modeling method creates topics, or themes, using a latent dirichlet allocation model. These themes consist of a collection of words associated with each topic that then must be interpreted by the researcher. The topic modeling approaches were validated and compared to determine which participants were assigned themes that aligned to their Tweet. Findings show that the unsupervised topic model assigned themes more appropriately than the supervised topic model. The findings of this research will help those in psychology to understand better what concerns people are still facing between the intersection of COVID-19 and mental health. The methodology will also prove useful for those interested in analyzing large amounts of textual data using topic modeling.

Abstract Name: **The Confluence of Dance, Photography, and Lighting**

Compelling images require a confluence of ideas to thoughtfully provoke emotions in the viewer. In my dance photography practice, I find the intersection of movement, lighting, and location most helpful in my pursuit of a storytelling image. To construct an image, I incorporate unique individuals who contribute dialogue to the creative process. These participants are artistically driven people with interests in many different mediums including dance and theatre. My gallery of photos tentatively titled "Midday Dreaming" were inspired by the work of Shana Simmons in shooting her upcoming film Living Landscapes. To explore the ideas presented in her film, I took dancers to McConnell's Mill to experiment with structured improvisations with nature; I gave them prompts as well as creative liberties to create still photographs of movement. Prompts guided dancers in the exploration of the landscape's texture, construction, and principles of lighting. As a choreographer, lighting designer, and photographer, this project helped me consider the impact of nature on dancers and the potential for this to influence my choreographic and lighting design choices. This endeavor also cultivated a collaborative environment of dancers and artists who contributed dialogue and perspective to the project. This oral presentation featuring images and reflections will offer inspiration and insight into collaborative practices among dancers, photographers, and lighting designers.

Abstract Name: **Linguistic Relativity in Bilingual Speakers**

The Sapir-Whorf Hypothesis has shown that the language we speak alters how we perceive the world around us. For example, a group of German and Spanish participants might be asked to describe pictures (e.g., a bridge), which is a feminine gendered word in German and a masculine gendered word in Spanish. Native German speakers would use more adjectives associated with feminine attributes (e.g., elegant and beautiful), while Spanish speakers used words with more masculine attributes, such as “sturdy” and “strong”. This study sought to extend the Sapir-Whorf Hypothesis by investigating whether Linguistic Relativity would generalize to non-gendered languages among bilingual speakers. That is, would bilingual speakers exhibit linguistic relativity when describing objects in English.We hypothesized that participants would demonstrate no linguistic relativity when explaining words in English. We further hypothesized that fluency in the target language (e.g., Spanish) would correlate withlinguistic relativity.Overall, there was no evidence of linguistic relativity in English among bilingual speakers. However, when we analyzed the results separately by sex, we found that while males did not exhibit any linguistic relativity in English, females did trend towards significance. Among females, there appeared to be a stronger correlation for the feminine themed objects (r = .33, N = 33, p = .058, r2 = .11) as compared to the masculine themed objects(r = .29, N = 33, p = .099, r2 = .08). Therefore, among females, feminine objects were more likely to be correctly explained with adjectives that were stereotyped to be feminine. While masculine objects were less likely to be correctly explained with adjectives that were stereotyped to be masculine. This research provides additional data for a greater understanding of how bilingual individuals perceive the world around them, elucidating the link between language and culture, while also clarifying the extent/limitsof the Sapir-Whorf Hypothesis.

Abstract Name: **Burnout, Compassion Fatigue, and Compassion Satisfaction in the Social Work Field Practicum**

Field social work students are often in contact with traumatized clients who go through a variety of negative life experiences such as abuse, disaster, drug dependency, crime, and illness. These students are experiencing vicarious exposure to such negative life events, and therefore, may develop compassion fatigue and burnout. Whereas both compassion fatigue and burnout report negative consequences of working with traumatized clients, compassion satisfaction adversely contributes to the positive well-being of the workers themselves. Compassion satisfaction stems from the satisfaction that is gained from helping others, and this feeling may serve to limit the effects of both burnout and compassion fatigue.This research serves the following purposes: addressing the existence and implications of burnout and compassion fatigue among social work students in field practicum; assisting in determining the need for additional attention in burnout- and compassion-fatigue-prevention for future field practicum students; determining the prevalence of compassion satisfaction among students; and drawing on the benefits of compassion satisfaction to provide strategies to better social work education.The research uses a classic experimental design: pretest/posttest, control/experimental group design. Social Work students who are in field practicum of the Spring 2023 semester are the experimental group, while students who are in Preparation for Practicum class, will be the control group. Both groups took a 30 item self-report questionnaire called the Professional Quality of Life Scale (ProQOL). This scale is equipped with subscales for burnout, compassion fatigue, and compassion satisfaction, thus measuring both the positive and negative effects in working with vulnerable and traumatized clients. As this is an experimental design, both groups took the questionnaire twice – once in the Fall and once in the Spring. This questionnaire assesses the three variables to see if they have fluctuated with more prolonged experience to working with clients, in terms of the experimental group.

Abstract Name: **Waste-Deep in Covid: The effects of COVID-19 on waste accumulation and sustainability programming on college campuses**

The demand for disposable products like hand sanitizers, wipes, cleaning supplies, and plastic bags has increased dramatically since the spring of 2020. Quantifying the environmental impacts of this increased consumption, however, has proven difficult and the environmental effects of COVID-19 on college campuses has yet to be addressed. This is a critical gap, for while universities serve as think tanks for solutions to real-world problems, they also produce heavy waste streams and have their own unique waste generation as a result of the communal living of young adults. This dynamic echoed thousands of times across the United States alone must be studied within the context of COVID-19 regulations in order to understand the true implications of the pandemic on society and sustainability initiatives in the United States. This research captures the observations and suggestions of Sustainability Coordinators, Environmental Services Directors, and others with similar positions within university environments regarding changes to their sustainability programs and waste accumulation since the establishment of pandemic regulations on campuses. Additionally, the research highlights Elon University as a case study for an in-depth look at waste accumulation and diversion during and after the height of the pandemic. Survey responses of these sustainability leaders are the bulk of the data analyzed for this study, while interviews with a subset of this population augment these results. These data were open coded to unearth common themes related to waste accumulation during the pandemic. Preliminary findings show themes of labor shortages, shifting administrative priorities, and diminishing student involvement to be symptoms of the pandemic within collegiate sustainability programs. Results and conclusions from this study will be used to create pragmatic policy suggestions specific to Elon University sustainability efforts in the future, serving as a resource for other collegiate institutions as well.

Abstract Name: **Abdication, Elite Structure and State-building: The Acquiescence of the Daimyo and its Role in the Creation of the Japanese State**

Traditional theories of elite behavior predict the privileged to resist and suppress any challenges to the status quo that preserves their position (Lachmann 2000). While this prediction is borne out in studies of European revolutions, these models cannot explain cases whereelites relinquish power and submit. Such is the case of the Japanese feudal lords (daimyo), whose collective abdication in 1869enabled the rise of the modern Japanese state. While some explanation of collective abdication has been elucidated in the parliamentarian context (Ermakoff 2008), it has yet to address the process of state formation and its relationship to elite relational structures and their transformations (Wang 2022). This study proposes to analyze the acquiescence of the daimyo to centralization and its role in determining the path of Japanese state development. I argue that the (relatively) non-violent regime transition achieved by the collective abdication of the daimyo enabled the Japanese state's growth in capacity. This growth was possible because the previous weak ties between national and local elites (daimyo) were replaced by the strong ties of samurai, whose independent political action cut across the boundaries of feudal domains and presented a new elite relational structure onto which the Japanese state was built. Focusing on the timeline of feudal abolition, I use social network analysis of samurai ties to demonstrate how elite relational structures shifted from a vertical to a horizontal network as the samurai built relationships across domain boundaries. This network then became the basis for state growth, as it connected actors with a vested interest in centralization to the budding imperial government. This study contributes to the fields of contentious politics and state formation by examining a contradictory case of elite behavior and through its analysis of a non-violent regime transition's effects on state development.

Abstract Name: **An Exploratory Study of the Effect of Varying Musical Genres on Cardioelectricity**

Music is a universal language that tends to have both a positive and negative emotional impact on individuals and affects the body's energy. Based on one's mood and settings, the quality and interpretation of music can be affected in numerous ways. The beats and tempo of a song have an emotional effect,andcanpotentially influence the body's electrical activity such as heart rate, blood pressure or skin conductivity. In this study, we address the impact of a select set of musical genres on skin conductivity of participants by measuring their galvanic skin response (GSR). To correlate, the cell viability of Human Aortic Endothelial Cells (HAoECs) in response to musical genres was also obtained. We hypothesize that both skin conductivity and HAoECs viability will be affected based on genre and tempo. A musical playlist was curated consisting of three musical genres: R&B, Country, and Rap. Each genre had three songs which were played for 120 seconds, followed by a period of silence for 120 seconds. TheHAoECswere exposed to music daily for30min and cell viability was determined after 5 days of exposure. Each participant's electrical response was measured through skin conductivity using a Q-S222 GSR sensor. Our results indicate thatRap had a GSR of1.12±0.05μS, R&B had a GSR of1.19±0.06μS, and country had a GSR of1.28±0.08μS. When consideringcell viability, the cell exposed to music exhibited a greater viability than cells that were not treated with music. The combined results provide insight into the body's electrical response to music as it relates tothe specified genres. We can conclude that variations in musical genres and tempo can moderately influence the cardiovascular properties within the body.

Abstract Name: **Cultural Capital: How High School Experiences Influence Chinese International Students' Interactions with Peers, Faculty, and Staff**

Although the number of East Asian international college students has increased in recent years, studies show that these students often form few connections with students and faculty on campuses, suggesting that they may not reap the same rewards from their college education as U.S students. Scholars argue that this lack of connection stems from cultural differences and language barriers which hinder their integration into college. Most research, however, focuses on East Asian international students as a whole, with little attention to variation among this population. In this study, I address this issue by examining whether and how high school contexts--U.S. or Abroad--influence their engagement with faculty members in elite U.S. colleges. I recruited 60 interviewees to conduct semi-structured interviews, and half of the participants attended high schools in the United States while the other half attended Chinese high schools. To further address the diversity within the Chinese international student community, I recruited participants from two liberal arts colleges, two public research universities, and two private research universities.I discovered that Chinese international students who attended U.S. high schools are more willing to interact with professors and feel more comfortable during the process since high school dorm or homestay experience provides more exposure to local residents and teachers. Moreover, students who attended Chinese high schools face different challenges in different types of U.S. colleges. Participants studying in liberal arts colleges often found it more challenging to engage in casual talks and develop personal relationships with professors while those in big research universities struggled to reach out to professors effectively. This research shows how colleges should target students' needs when providing student support and how the high school experience can serve as guidance to improve student services, facilitating minority students' contribution to campus diversity.

Abstract Name: The Power of Feminist Philosophy for Women at Work

In this paper, I demonstrate the ways in which feminist insights on reasoning can be applied to the workforce and offer possible means to mitigate sexual violence in corporations. I begin with a brief history of past connections between feminist philosophy and the business world. I utilize a case study, Victoria's Secret, a corporation riddled with sexual violence since its conception. I detail the development, business practices, and recruitment strategies employed by Victoria's Secret. Further, I describe the corporation's downfall, which occurred by and through women coming together, both within the company as employees and models, as well as externally via social media. I assess that these groups of women practiced collective group reasoning, which ultimately led to exposing years of sexual violence. In an effort to support women in other corporations, I propose new modes of work that promote collective consciousness-raising that can be embedded in the culture of a corporation, with the aim that these connections might mitigate sexual violence. Finally, I demonstrate why corporations should look inward to prevent sexual violence, as opposed to looking to societal or legislative changes.

Abstract Name: Identifying Amyloidogenic Proteins within the Acrosome of Bull and Rhesus Macaque Spermatozoa by Mass Spectrometry

Under certain conditions, proteins aggregate into highly orderedcross-beta-sheet structuresknown as amyloids. While amyloids are linked to several human diseases such as Alzheimer's and systemic amyloidosis, they have also been found in conditions that do not cause disease. Currently, they are thought to contribute to the normal functioning of some neuroendocrine cells and reproductive tissues. The findings in mice that amyloid structures are present in epididymal fluid and spermatozoa initially suggested that amyloids might be connected to successful sperm maturation and fertilization.However, most of these studies utilized epididymal and not ejaculated spermatozoa, the latter representing sperm cells that are competent to fertilizein vivo. Previous experiments in our lab with fresh ejaculates of bull and Rhesus macaque revealed that amyloids are present in the acrosomal matrix (AM) isolated from sperm acrosomes and in the detergent-resistant pellet (AM core), as it was previously described in mice. To test the hypothesis that amyloid protein structures are conserved among mammalian species, we isolated the AM and AM core fractions from bovine and macaque ejaculated spermatozoa and identified their protein content by mass spectrophotometry. Our study led to the identificationof more than 600 AM proteins of which~100 were specific to the AM core,including new and previously identifiedmurine proteins. Preliminary results with the protein sequence predictor Waltz determined that the AM proteins Cystatin E/M and lysozyme like-1 and 6 possess motifs associated with amyloidogenic proteins, which make them good candidates for forming amyloid structuresin vivo. A similar proteomic study with human spermatozoa is currently underway in our lab.Demonstrating that amyloid protein structures are evolutionary conserved will strongly suggest they serve an important function in reproduction and help decipher between the mechanisms involved in mammalian fertilization. Ultimately, this might provide insight into amyloid-associated pathologies and treatments.

Abstract Name: **Utilizing Machine Learning algorithms trained on Recent Music-Listening Activity in Predicting Big Five Personality Traits: A Novel Ongoing Investigation**

Music has been important to everyday life since long before modern civilization and has been a subject of study for many years. It has been known to be a positive predictor of personality traits due to the individuality of personal preference. These personality metrics are typically evaluated using a Big 5 trait inventory that measures personality into 5 categories: Openness, Conscientiousness, Extraversion, Agreeableness, and Neuroticism. The study will attempt to assess the prediction quality of an individual's Big Five personality traits from a week worth of recent participant music listening activity from the Spotify Application Programming Interface using machine learning (ML). The created dataset will allow for correlating each of the 5 Ten Item Personality Inventory dimensions with music genres, artists, year, beats per minute, energy, danceability, loudness, length, acoustic, popularity, and other features in a vector. The dataset will be standardized and used to train on ML models such as Random Forest, Decision Tree, K-Nearest Neighbors, Logistic Regression, Support Vector Machine, etc. Prediction accuracy will be compared to previous works. Metrics include accuracy, FPR, TPR, and ROC/AUC scores. Both regression (continuous numeric value) and classification (Likert scale) will be used. A full literature review showed this is the first study to use both Spotify API data, rather than self-reported music preference, and ML classification, rather than traditional statistical tests and regression models, to predict the personality of a college student demographic. Applications of this study include custom advertisement recommendations and music therapy. Approval has been granted to administer the survey by Irvine Valley College's Institutional Review Board.

Abstract Name: **Identifying Cognate RNA Sequences of Non-Structural Protein 9 in SARS-CoV-2**

As an RNA+ virus, SARS-CoV-2 infection (COVID 19) leads to direct translation of viral RNA to produce non-structural proteins (Nsp) responsible for viral replication. For example, Nsp 7 and 8 are thought to act as a helicase, Nsp 9 as a single stranded RNA binding protein and Nsp 12 as the replicase essential to the proliferation of the virus. Studies of homologous, Nsp 9 proteins in HSV, MERS, and SARS-CoV-1 indicate this protein binds both DNA and RNA sequences. In SARS-CoV-2, Nsp 9 contains an unusual OB, greek key motif thought to keep RNA single stranded for efficient replication in other viruses. Together these results suggest, Nsp 9 may function in SARS-CoV-2 to keep the viral RNA linear for replication by Nsp 12; however, little is known about the RNA binding requirements or structural contacts and interactions in this protein-RNA complex. Tryptophan fluorescent studies of Nsp 9 have been developed to identify cognate RNA binding sequences and structures. Initial studies indicate binding of an RNA pseudoknot structure in the 3'-untranslated region of the viral RNA. Further analysis of RNA structural requirements for stable Nsp 9 binding will be important in further deciphering the role of Nsp 9 in SARS-CoV-2 as pseudoknot structures in the 5' and 3'-UTR have served as a switch from viral RNA translation to replication and may serve as a handle for control of this ever infecting and mutating virus.

Abstract Name: **How did the Cold War Affected Asian American Stories?**

My research project's purpose is to highlight the impact of Western influences, especially post-Cold War influences, in Asian countries and how they affected the output of literature from those countries. I believe the Cold War had a far-reaching, systemic impact through its political conflict between the United States and the Soviet Union in how the politics of the countries they assisted or opposed changed.My methods for doing research will include gathering historical knowledge to develop a deeper understanding of the Asian regions I plan on examining, along with how they shifted in response to Cold War pressures. I am also researching, although to a lesser extent, some of the psychological effects of trauma caused by the Cold War's presence and how that uniquely impacts Asian American literature.I am also reviewing literature that either includes Cold War narratives or themes that are shared with stories transformed by the Cold War's influence.Some of my key results at the moment are the identification of key themes in Asian American literature; these themes are generational difference, generational trauma, and family. I acknowledge thatthese themes are hardly unique to countries destabilized by the presence and military or covert operationsof the United States. However,Asian families especially must contend with the difficulty of foreign interference and how it constrains Confucian values. As a result of foreign interference, there are powerful feelings of insecurity and fear throughout many Asian American stories; Asian parents who struggled immensely due to the Cold War raging throughout their country taught their children to survive, rather than thrive.

Abstract Name: **Inversion of In-Group Favoritism in Adversarial Conditions**

Introduction: In-group favoritism (Sumner, 1906; Taijfel & Turner, 1986) is the phenomenon of giving preferential treatment towards individuals within the same perceived social group (e.g., age, race, gender).
Purpose: To experimentally assess whether in-group effects will negate and even invert when one party exhibits actions / demands that exceed the boundaries of a normal in-group association.
Procedure: See Appendix. We created a workplace scenario where the participant assumes the role of a co-worker. In the first segment, the participant is assigned to work with Mary, who requests some minor favors (baseline condition), and responds to the five assessment items shown in the Appendix. In the second segment, Brittany joins the workgroup, and does things that should go beyond in-group boundaries (inversion condition), and then the participant responds to the same five items.
Hypotheses: (1) sum of the five ratings will be significantly lower in the inversion (I) condition relative to the baseline (B); (2) participants who are around the same age as the scenario models will show a stronger inversion difference relative to those who are not; (3) because of its nurturing facets, the Big Five trait agreeableness will moderate the effect such that more agreeable participants will be less affected by the inversion effect.
Participants: 63 total from convenience and classroom samples, age ranging from 16 to 62.Results:Hypothesis 1: Baseline (mean=17.4, sd=3.0), Inversion (mean=10.8, sd=3.3), t=14.82 (p<.00001)Hypothesis 2: Same age (B-I mean=3.94, sd=3.6), different age (5.1 / 2.9), t=2.09Hypothesis 3: Correlation Agreeableness vs B-I difference r = -.24 (p<.05)Discussion: H1 was supported, H2 was significant but in the wrong direction (non-matching aged participants showed a larger inversion effect), H3 was supported (more agreeable, smaller B-I difference). Follow-up research suggested for H2.

Abstract Name: Balance and Postural Control of Hearing Impaired vs Non-Hearing Impaired Pre-Pubescent Children

This study will investigate balance and postural control in children with sensorineural hearing loss versus non-hearing impaired children. Sensorineural hearing loss occurs when the inner ear becomes damaged, resulting in vestibular dysfunction in up to 70% of hearing loss cases. Vestibular dysfunction has been associated with reduced balance and postural control performance. No prior studies have investigated balance and postural control performance in elementary school aged pre-pubescent children without hearing loss versus those with vestibular dysfunction associated sensorineural hearing loss. We will recruit approximately 40 prepubescent children, divided evenly into non-hearing impaired and those that have vestibular dysfunction associated sensorineural hearing loss. Each will be assessed for dynamic balance with the Y-balance test. Static balance performance will be assessed with the Modified Clinical Test of Sensory Interaction in Balance (MCTSIB), which consists of four tests with eyes open and closed on firm and unstable surfaces. A portable force plate recording vertical ground reaction force variability while standing on one foot on a firm and unstable surface will be used to assess postural control. The standard deviation of these forces will be normalized to body mass for analysis. A multivariate analysis of variance will be utilized to determine differences between groups for the dependent variables. The level of significance will be set at 0.05. The planning of this study is already underway, with data collection to occur in January 2023, and data and statistical analysis in February 2023. We hypothesize that pre-pubescent children with vestibular associated sensorineural hearing loss will have reduced balance and postural control than non-hearing-impaired children.

Abstract Name: A Case Study: Exploring the Impacts of Social Enterprise on Trauma-Impacted Women

Adverse Childhood Experiences (ACEs) identify how exposure to negative events in childhood may affect a person's development and can indicate how high-risk a person is for different health issues (Felitti et al., 1998). To mitigate these outcomes, studies have been conducted examining how community engagement can affect ACEs and have shown that social enterprises can lead to stronger and safer communities. Providing social supports in marginalized communities benefits trauma-impacted people living in those areas (Ebrahim, 2019; Macaulay et al., 2018). Various interventions have been noted to reduce and mitigate negative outcomes from ACEs and other traumatic experiences.Mothers in marginalized communities may experience a harder time buffering their children from these adverse experiences and would benefit from interventions such as social enterprise, community services, and therapy aimed at addressing impacts from their childhood ACEs and mitigating ACEs for their children. This project examined the impact that a local social enterprise, the First Ladies of the Hillside, provides to women who have experienced trauma. Participants were recruited from supportive housing units and had previously experienced homelessness.Participants completed a demographic/ACEs survey and interacted in a focus group surrounding their beliefs on how partaking in a social enterprise has impacted them. The women expressed feelings of support, empowerment, personal growth, and community. They also discussed the benefits their children were able to experience due to social enterprise, such as opportunities to interact with university students, explore new activities, and expand their world view.Results are displayed in a graphic recording, a real-time translation of conversations into text and pictures and indicate that the First Ladies of the Hillside offer support, community, and empowerment for those who partake. Their social enterprise and community engagement positively affect trauma-impacted and marginalized women living in their community.

Abstract Name: Perceptions of supporting and cultivating partnerships with families of children with differing abilities.

The purpose of this research is to examine strategies and supports used tocultivate partnerships with families who have children with differing abilities. We know that thereare many benefits to partnering and working collaboratively with families, but how do early childhood educators support and share resources? Along with a review of literature, surveys will be used to seek early childhood educator perspecives regarding supports and resources for children with differing abilities. Participants will bre provided a survey with questions pertaining to their experiences with children with differing abilities and their families. They will also be asked about their ability to find, access and share community resources.

Abstract Name: Electrode Sharpness, Spark Gap, and Spark Prevention

Ben Franklin's experiments with lightning in the 1700's showed that sharp-tipped metal rods reduce the chances of a strike near the rod itself. This has been confirmed as recently as the early 2000's e.g. by C.B. Moore et al, 2000, 2002, in research with actual thunderclouds. Similarly, sharp-tipped "needle" electrodes are commonly observed to prevent fully-developed sparks from laboratory electrostatic charge generators. In this case, (1) just how sharp must the electrodes be for spark prevention? And (2) by what process does a sharp electrode prevent emphatic sparks? We seek to answer these questions experimentally, by (1) using a Van de Graaf charge generator with spherical-tipped "receiving" electrodes of varying sizes, and (2) by investigating the phenomenon of "corona" as the discharging mechanism: What is corona? How does it differ from an emphatic spark? We compare our small-scale findings to the present view of how lightning rods reduce the chances of nearby strikes.

Abstract Name: **Challenging the Tyranny of Love: Video Game Design and Critical Metaphor Studies**

Language is a means of connecting and communicating effectively. Language allows us to identify with others, and make sense of the world around us. But how do we accurately describe something? Friedrich Nietzsche writes of the will to truth in language, that it is, “A movable host of metaphors, metonymies, and; anthropomorphisms: in short, a sum of human relations which have been poetically and rhetorically intensified, transferred, and embellished, and which, after long usage, seem to a people to be fixed, canonical, and binding” (4). In other words, we conceptualize much of our existence through rhetorical language, but most importantly, for the purpose of our presentation, in metaphors.Oftentimes, metaphors serve as a dominant understanding of something, especially metaphors of love. And some of these can be quite troubling, setting up love as something to be endured, tackled or overcome: Love is often metaphorized as a journey, a battlefield, a roller coaster, even a drug. As students of game design, our presentation will focus on our design of a “serious game” that both entertains an audience, and teaches them about how metaphorical language has the power to shape prevailing conceptions of love, which, as philosopher Alain de Botton suggests, have dominated Western sensibilities since the Romantic Era. In this particular game, players make choices about a metaphor of love that they associate with the most at the outset, but they might also adopt alternative metaphors of love depending on the decisions they make during the game. The game’s purpose is to entertain and educate the player on the power of language to shape meanings about a universal human phenomenon and its meaning in contexts.

Abstract Name: **Artifact Test of a Nitinol Breast Biopsy Clip in an Ultra-High Resolution Magnetic Resonance Imaging (MRI) Environment**

Introduction: Most breast biopsy clips have not been artifact tested in 7T MRI environments. Artifacts, such as image distortion or signal loss, are caused by the metallic properties of these objects, which negatively affects the resulting image quality. This project evaluates the extent of the artifact in 7T MRI for Ultracor Twirl, an untested nitinol clip.Methods:Image acquisition: Implant images were taken with combinations of imaging settings, including orientations relative to the magnetic field, spin or gradient echo, and readout or phase encode directions. A reference (without object) image was acquired for each image setting to compare the voxel (3D pixel) intensity difference between the metallic object present and absent. The artifact test measures the size of significant intensity differences.Image processing: Deformable and rigid image registration via Advanced Normalization Tools Software (ANTs) corrected motion errors by aligning the artifact and reference image. The background image intensities were matched via histogram matching.Results:All implant images taken contain an artifact. The largest artifact volume of the nitinol biopsy clip is 4049.25mm^3 when applying deformable registration without histogram matching. The imaging settings to obtain the volume were axial view, gradient echo sequence, frequency encoding in the A-P direction, and perpendicular orientation. The reference image imaging settings were axial view, gradient echo sequence, frequency encoding in the A-P direction, and perpendicular orientation.Discussion/Conclusion:The current results indicate that the nitinol biopsy causes a noticeable artifact in a 7T MRI environment. The use of this clip in the region being scanned is likely to negatively affect the imaging quality in terms of signal loss and distortion. The limitation of the current result is that using deformable registration setting slightly misrepresented the artifact by deformation. Better methods of representing the artifact are currently being explored.

Abstract Name: **The Hedging Prescription: FX risk in Ghana?s Pharma**

This paper aims to diagnose and address the specific currency exposure risk facing Ghana's pharmaceutical industry in the wake of Ghana's depreciating currency and this industry's high import dependency. Going further, this research seeks to explore the role hedging and other currency risk management strategies can play in addressing the identified problem and informing the decisions of pharma firm managers and policymakers. A mixed-methodology model would be used by extracting information from both semi-structured interviews and survey data collected from a sample of twenty-nine non-listed importing firms. Subsequently, the currency exposure measure propounded by Bodnar et al, and a hedging decision analysis would be used for data analysis; and the relationships between variables of interest would be statistically tested and established. The study's findings have the potential to provide policy and financial managers a realistic framework for managing currency exposure which would drastically cut losses faced in Ghana's pharma industry and allow for re-investment towards increasing the affordability and accessibility of medicines in Ghana.

Abstract Name: **Coping with a Partner's Death due to COVID-19: The Impact of Coping Styles on Posttraumatic Growth and Complicated Grief**

A loved one's unexpected death from COVID-19 relates to higher levels of prolonged grief (Eisma et al., 2021). Prior to COVID-19, unexpected loss research suggests that avoidant coping (e.g., denial) significantly predicts complicated grief (Schnider et al., 2007), while problem-focused (e.g., positive reframing) and emotion-focused (e.g., support) coping predict posttraumatic growth (Fisher et al., 2020). Our study examined what coping styles predict complicated grief and posttraumatic growth for individuals whose partner unexpectedly died from COVID-19. Participants (N=37; 36 females; Mage=52.57 years) completed an online survey (MTimeSincePartnerDeath=9.74 months). Measures included Inventory of Complicated Grief (Prigerson et al.,1995; α=0.89), Post-Traumatic Growth Inventory (Tedeschi & Calhoun, 1996; α=0.95), and Brief-COPE (Carver, 1997; α=0.74), comprised of problem-focused, emotion-focused, and avoidant coping facets. Table 2 presents target variable correlations.
Analyses included simple and multiple linear regressions controlling for age, education level, and time since death. Specific to avoidant coping, denial (β=7.71, p=.001) significantly predicted complicated grief (R2=0.40, F(1,31)=24.29, p=.001). Specific to emotion-focused coping, acceptance (β=-5.24, p=.008) and self-blame (β=5.23, p=.009) significantly predicted complicated grief (R2=0.39, F(2,30)=12.01, p=.001). Specific to problem-focused coping, active coping (β=12.41, p=.001) and positive reframing (β=10.29, p=0.006) significantly predicted posttraumatic growth (R2=0.58, F(2,30)=20.72, p=.001). Specific to emotion-focused coping, acceptance (β=13.02, p=.001) and religion (β=8.60, p=.005) significantly predicted posttraumatic growth (R2=0.60, F(2,30)=21.89, p=.001). Findings support previous research suggesting problem-focused coping and religion lead to grief management and posttraumatic growth (Fisher et al., 2020; Zara, 2020) and avoidant coping predicts complicated grief (Schnider et al., 2007). Future research should further examine emotion-focused coping facets, as they predicted both outcome variables in this sample.

Abstract Name: **Business Model for a Food and Beverage Truck on Campus**

This presentation articulates about the different aspects of designing and launching a business model for a beverage and food truck at a college campus. It covers the specifics of the bureaucracy, regulations, and legal implications; the cost and benefit analysis, including start-up and operating costs; and the marketing study, considering students' interests and habits, and cafeteria operation hours. The business model provides an extended menu along with additional hours of operation past what the cafeteria offers. The business works alongside the campus cafeteria, not competing with it though. The business model also provides experience and skills for the members of our community. It plans on partnering with local non-profit organizations to get the labor needed to operate the food and beverage cart on the day-to-day basis, creating in this way job or internship opportunities for students and people who otherwise would have a harder time obtaining a first managerial, cooking, marketing, or in general, professional experience.In addition to describing how to operate a food and beverage truck, the presentation will also show how beneficial it will be in the long run for the students at a community college and the local community at large. We have funds to actually launch the project and we expect our presentation to be detailed enough as to help other campuses actually launch their own beverage and food truck staying within an initial budget of $20,000. The operational costs and the numbers needed to make it sustainable and profitable in the long run are also included.

Abstract Name: **Insights Learned by Solving Mathematical Questions**

I have solved two open problems in mathematics. One was published inthe College Mathematics Journal bythe Mathematical Association of America;the other in the New York State Mathematics Teachers'Journal bythe Association of Mathematics Teachers of New York State. In my presentation, I will talk about the specifics of each problem, methods I found to be successful, and methods I found whichdid not lead to a solution. These lessons I learned are useful to anyone who is interested in problem solving and mathematical puzzles.The problem by the MAAstates: "Let a,b, and c be positive real numbers. Prove that the natural log of(27abc/(a+b+c)^3 is less thanor equal to ((a-b)^2+(b-c)^2+(c-a)^2)/3".While this question initially seems algebraic, it can very easily be modeled with geometry and mathematical analysisto produce an elegant solution. This shows the value of using creative interdisciplinary thinking. The problem by the AMTNYS was very geometric in itself. It gave an arbitrary circumference and point within a certain distance from each other, and required to obtain, using compass and edge,two points in the circumference meeting certain conditions.Certain techniques such as algebra and trigonometry doprovide solutions, but the most elegant was, indeed, with compass and edge, reasoning bysymmetry and similarity between triangles. This shows the value of having an in-depth understanding of a question, and understanding whatyou can draw from the axioms of a question in order to find a very simple and robust solution.By presenting the insights I learned while attempting these questions, I hope to teachmy peers the same methodsso that they may be more capable of finding elegant solutions to puzzling questions.

Abstract Name: Etching and Characterization of REBCO Tape to Assess Damage from Tape Synthesis and Mechanical Slitting

Rare-earth doped barium copper oxide (REBCO) superconductors are promising materials for high-field magnet applications due to their extremely high upper critical field values. The REBCO tape is comprised of several different layers to create epitaxy for the superconductor itself, but defects in the tape are possible due to mechanical slitting of the tape. In this study, we sought to understand where these defects are located within the tape and correlate them with underlying structures. Chemical etchants were developed to remove the exterior stabilization copper and the silver capping layer, and varying concentrations of nitric acid ranging from 0.5%-2% were used to enhance the cracks in the REBCO layer and subsequently etch the REBCO and LaMnO3(LMO) layers of the composite tape, allowing direct imaging of key layers of the tape. Through imaging and analysis of the cracks in each layer, we have determined that the REBCO layer has the most cracks followed by LMO and then Al2O3. We found that the number of cracks in each layer was 78, 58, and 20 respectively for a 0.2 mm section of tape. The left edge of the tape typically has longer crack lengths in all layers and the edge cracks are longer than the vertical cracks. On average, the alumina layer has the longest cracks at 54.1 um followed by LMO at 46.3 um and REBCO at 12.8 um. These results demonstrate that the REBCO layer is the most susceptible to crack initiation (with the highest number of cracks), but that the underlying LMO and alumnia layers are more susceptible to crack propagation (with longer cracks). Our work will lead to a better understanding of defect formation in this important tape superconductor and improve the reliability of the fabrication of REBCO tapes.

Abstract Name: Genetic Contributions of APOE & TOMM40 to Mitochondrial Morphology & Alzheimer's Disease

The strongest genetic risk factor of late on-set Alzheimer's disease, LOAD, is the apolipoprotein allele APOE ε4. APOE is an apolipoprotein that transports cholesterol and amyloid-beta proteins between cells and across the blood-brain barrier. Previous research suggested APOE ε4's relation to LOAD is tied to inefficient cholesterol; lipid transportation. Thus causing amyloid-beta protein accumulation and plaque formation in the brain. New research suggests that APOE ε4 affects other cellular functions, such as cellular glucose metabolism. TOMM40 rs2075650, a translocase of the outer mitochondrial membrane, is another single nucleotide polymorphism tied to Alzheimer's disease. Interestingly, genes APOE and TOMM40 are in proximity on chromosome 19 and share linkage disequilibrium. In order to study their effects on cellular level, HEK293 cell lines carrying combinations of these alleles will be created using Piggy-bac homology-directed repair method facilitated by CRISPR Cas9 technique. The Piggy-bac plasmid vector contains GFP, Puromycin resistance and hsvTK genes for cell selection. Once the cells are verified through sequencing, we will evaluate the effect of APOE ε4 on the distribution and transportation of cholesterol inside and outside HEK293 cells, glucose metabolism through mitochondria, and also to study its interaction with TOMM40 rs2075650.

Abstract Name: **Understanding an Engineer's Brain: Developing Problem Solving and Intuition**

Ever wonder how intuition affects individual problem-solving skills? Does getting an A in a class correlate to an increase in intuition in that subject? As technology-aided problem-solving increases, it is critical for engineering students to develop the necessary skills to predict and analyze solution outcomes, which we call engineering intuition. Intuition has been previously studied in nursing, business management, and law, and is a key component in the development of expertise. To increase how intuition is taught in classrooms, we need to first understand how intuition is used in problem-solving and then develop a method to measure it. With the goal of measuring intuition, we analyzed results from a survey with two statics inventory concept questions based on the Concept Assessment Tool for Statics (CATS) (Steif; Dantzler, 2005). The first question focused on assessing a problem outcome as a sensibility check and the second question focused on predicting the outcome. In addition to solving the concept questions, participants were asked questions based on their confidence in the answer, how they answered the question, the likelihood of taking additional steps to justify their answer, and the likelihood of going to a manager with just the answer. We analyzed open-ended responses from 271 participants and identified emergent themes across the responses. We used these themes to create a codebook that was applied to all open-ended responses. The resultant coding showed the correlation between the open-ended questions and qualitative analysis of the multiple-choice questions, confirming that the questions were answered in similar ways. Efforts are ongoing to determine how well the survey measured intuition, but we believe this survey is the first step to encourage intuition use in the classroom.

Abstract Name: **Synthesis of flexible tridentate pincer ligands featuring a rigid backbone and pendant carbene**

Catalysts are involved in the production of fuels and feedstock chemicals and are even found in living organisms as enzymes. An important classification of catalysts are organometallic complexes whose identity and reactivity are correlated to the coordination sphere defined by its ligand(s). Tridentate pincer ligands, which coordinate to a metal center via three different atoms within a plane, have been of interest for redox active and polymerization catalysis among other catalyzed reactions. Our interest is to explore the incorporation of flexibility to an asymmetric pincer ligand to identify which geometric or electronic properties influence catalytic behavior. Variation in ligand flexibility may afford unique properties that tune the action of the metal center. We are developing a ligand to feature two unique imine-N and pendant N-heterocyclic carbene-C to complex with a metal. The ligand is labeled as an NNC-type ligand by the three elements that coordinate to the metal; nitrogen, nitrogen, and carbon. Our NNC ligand features a bisimine rigid backbone and a pendant N-heterocyclic carbene which can flex to accommodate a range of coordination motifs of pentacoordinate complexes. Presented is the multi-step synthesis using air-sensitive techniques and the precursor structures that have been identified. Molecules obtained throughout the process are analyzed using 1H-NMR, FT-IR, single crystal XRD and computational analysis for prediction of optimal geometry of the target organometallic complexes. Future work will detail the properties of precursors and the synthetic approaches to metallate the NNC tridentate pincer ligand with first-row transition metals.

Abstract Name: **The Woman's Building at the 1893 Chicago World's Columbian Exposition**

The Woman's building and its contribution to art, literature, and architecture were pivotal not only for women but each category respectively. In its curation, the Woman's Building spearheaded the concept of the female gaze, in resisting and reforming the male gaze. The space reflected the ways that artists constructed femininity, reflecting the volatility of gender relations in Gilded-era Chicago. In feminizing the mainly male-determined narratives and iconography within the Fairgrounds, the building placed women at the center of a singularly determined space. The building also offers an understanding of how visual images and rhetoric contributed to the women's emancipation movement towards the end of the 19th century.The building acted as a space designed by women, for women, an oddity in cultural terms.In this Essay, I will be discussing how the Exposition ultimately reflected three interrelated narratives: evolutionary progression, the emancipatory freedoms of modern democracies, and the triumph of modernity. I will be relating how these themes that were exhibited throughout the fair were taken feminized by the women in charge of the Woman's Building. This narrative expands to a more intersectional narrative of race, culture, and gender.In general, this narrative also reflects a theme of historical progressionthat was threaded throughout the Fairground. The triumph of modernity places American innovation at the forefront, as the exposition used concepts and iconography of colonial America to place emphasis on the triumph of the modern era. Overall, it was a look into how far America had come as a society, and a celebration of modernity equally. The Exposition offered a forum for collective discussion on the political and social climate of the nation, and of Chicago. It allowed for global art, ideas, thoughts, iconography, and literature to be shared in one particular forum.

Abstract Name: **Environmental Equity and Social Justice: The Interdependence of Redlining and Present-Day Water Quality in Atlanta, GA**

Redlining is a term that was created in the 1930's for security maps that were created by the Home Owners Loan Corporation (HOLC). The HOLC would rate neighborhoods by environmental and racial criteria with the use of colors to rank neighborhoods. The green neighborhoods were ranked as the "best" neighborhoods, blue neighborhoods would be ranked below this and as "still desirable", followed by yellow neighborhoods ranked as "declining", and red neighborhoods ranked the lowest as "hazardous". People that predominantly lived in green neighborhoods were White, whereas people in the red neighborhoods were predominantly Black. Due to these neighborhoods being labeled as hazardous, people in these communities would not be offered loans and the neighborhoods would not receive improvements to their infrastructure. I wanted to find out whether this redlining and lack of improvement would affect present day water quality? Due to infrastructure influencing water quality, I hypothesized that historically redlined communities would be disproportionately affected by poor water quality. The objective of this project was to integrate information about watersheds and water quality with human demographics to apply an environmental justice lens. All detected concentrations of E. coli and enterococci were below the EPA recommended threshold for fresh recreational waters (a GM of 33 enterococci cfu per 100 ml and a GM of 126 E. coli cfu per 100 ml). Ongoing efforts seek to better understand and explore the environmental gentrification hypothesis that predicts that environmental quality improvements in poor communities may spur gentrification and the displacement of residents.

Abstract Name: **The Wisconsin Council on Undergraduate Research: Working Together to Promote and Support Undergraduate Research, Scholarly and Creative Activities**

Undergraduate research, scholarly, and creative activities (URSCA) have a long history in the University of Wisconsin System (UWS). Since 1999, various system campuses have hosted the UW System Symposium, an annual gathering modeled after the National Conference on Undergraduate Research. It brings together undergraduate researchers, their mentors, and program coordinators to showcase the accomplishments of and celebrate URSCA. With the support of a National Science Foundation grant awarded to the Council on Undergraduate Research to institutionalize undergraduate research at the system/consortium level, the Wisconsin Council on Undergraduate Research (WisCUR) was formally launched in 2013.The group initially consisted of URSCA program leaders and advocates from UWS institutions. Recently, its membership expanded to include private universities and technical colleges in Wisconsin. Its mission is to provide leadership to advance, enhance, and expand URSCA across the UWS and beyond in order to prepare graduates who can adapt and innovate for the challenges of the future. Since the inception of WisCUR, URSCA programs within the WisCUR network have made great strides. For example, three UWS schools (UW-Eau Claire, UW-La Crosse, and UW-Milwaukee) have won the Campus-Wide Award for Undergraduate Research Accomplishments (AURA). No other state system has received the honor of receiving multiple AURA awards. Partly due to its involvement with WisCUR, Concordia University developed an undergraduate research certificate program and Madison College created an undergraduate research program.Wisconsin higher education institutions have also faced a variety of challenges that require innovations and adaptations, and WisCUR has served as a resource and support in this area. In this presentation, we will share the organization and goals of WisCUR, typical activities (beyond UWS Symposium) we sponsor, and benefits of WisCUR to individual institutions and staff therein. We will provide suggestions on how to organize similar URSCA groups and invite attendees to share their experiences.

Abstract Name: **In Silico studies and Synthesis of Modified Nucleoside Analogues for Pancreatic Cancer Therapeutics.**

Pancreatic ductal adenocarcinoma (PDAC), the most prevalent type of pancreatic cancer with a high mortality rate due to a lack of early detection techniques, leading to diagnosis at a terminal stage and limiting treatment options. The nucleoside analogue Gemcitabine, while the most effective chemotherapeutic, faces drug resistance that hinders its therapeutic potential. We propose nucleoside analogues that feature a polyethylene glycol amino (PEGA) modification. This modification reduces the hydrophilic nature of the drug. The PEGA group is also hypothesized to serve as a chelating agent for both zinc and iron ions required for RNR activity. We have done computational studies including molecular docking using the internal coordinate mechanics algorithm (ICM), SWISS Absorption, Distribution, Metabolism and Excretion (SWISSADME), and prediction of activity spectra for substance (PASS), utilizing way2drug online application. We have also begun synthesizing the intended compound and plan on performing biological and enzymatic assays afterward.The edock scores, the root mean square deviation (RMSD), and the H-bonding formation were analyzed on ICM. Edock scores showed a higher binding affinity than gemcitabine, with an average value of -48.52 KJ/mol and an average RMSD value of 2.69. The PEGA moiety indicated a strong binding affinity to a known substrate binding residues in the catalytic sites such as amino acid Asn211, a vital component to the catalytic processes. The pharmacokinetics and toxicity were assessed through SWISSADME which demonstrated excellent solubility scores of logS -0.37 and showed non-toxic interactions to CYP isoenzymes. Through PASS prediction, the biological activity of the compound showed high potential as an RNR inhibitor with a probability of activity (Pa) to probability of inactivity (Pi) of 0.174 to 0.011. In conclusion, the proposed analogues demonstrated improved target inhibitions making them strong candidates for further investigation via in vivo and in vitro studies.

Abstract Name: **Vibrational and Coupled Frequency Response of Tensegrity Tables**

Tensegrity structures have many constructional applications to improve the stability of a design. The structure, design, and function of tensegrity systems can be better understood by researching factors that determine their stability. Stability of tensegrity structures was researched by testing vibratory resistance on a shake table and dampening factors by displacing the top of the system and calculating natural frequencies and dampening rate when exposed to various external forces. When experimenting on a shake table with a rectangular structure, it was concluded that the difference in magnitude of acceleration between the bottom and top of the structure decreased by 0.68 as the bottom was exposed to a frequency of 7.2. Compared to a difference of 4.12 at a frequency of 14.9. Showing an increasing difference in acceleration as vibration frequency increases. Tensegrity structures were also found to have multiple nonsymmetric natural frequencies. Due to the two axes of symmetry, the rectangular tensegrity structure was found to have two natural frequencies. These frequencies were found to be within 1.68 Hertz of each other and are affected by the amount of displacement. From these experiments, it can be concluded that tensegrity structures provide stability because they naturally dampen vibration between the bottom and top of the structure. By understanding the stability of tensegrity systems, their applications to architecture and construction development can be better explored and utilized.

Abstract Name: **Promoting Adult Literacy Programs in Southwest Missouri**

Literacy has become recognized as an important skill in the last century; however, programs targeting adult literacy have fallen behind in favor of programs targeting childhood literacy. Using data provided by the National Center of Education Statistics and the United States Census, this paper looks to pinpoint the communities most at risk of low level literacy in the United States along with the root issues that create disparity in literacy rates between different socioeconomic and ethnic groups. Further works in the field by Murnane et al. and Philliber et al. are used to discuss the benefits of literacy programs for the adult population, including increased economic outcomes and quality of life, in addition to arguing for the need for said programs. This paper focuses on the region of Southwest Missouri and makes comparisons between Greene county and other counties in the state. This paper gives a background on the literacy programs available in Southwest Missouri, as well as the areas where programs are lacking. This paper recommends strategies to improve access to literacy programs in the Greene county area while also calling for more research to be done on the specific demographics present in the area to help further develop more impactful programs for thecommunity.

Abstract Name: **Quantifying Transcription-Translation Coupling Escherichia coli**

Transcription-translation coupling is a phenomenon in bacteria in which an mRNA strand is translated as it is being transcribed. It is still largely unknown how the ribosome and RNA polymerase interact in this process. This work was done to develop a construct to insert two cassettes into the LacZ gene in the E.coli genome in order to better understand transcription-translation coupling. Each cassette contains ends homologous to the LacZ insertion site, either a hairpin or no hairpin sequence, nLuc, and thyA. Because one of the types of transcription termination is hairpin formation, this was used to infer how closely coupled the ribosome can be to the RNA polymerase. PCR was used to generate DNA fragments containing the cassette, which were transformed into E.Coli cells with a thyA deletion. Luciferase production was measured, which indicated how closely the ribosome and RNA polymerase were coupled. It was found that the hairpin had less of an effect in the open reading frame of LacZ, while at the end the hairpin had a greater effect. The ribosome was closest to the RNA polymerase at an insertion site closest to the end of LacZ and farthest away at the beginning. This suggests that at certain points in a gene, the ribosome and RNA polymerase could be at a certain distance apart. This can be further investigated by inserting into more sites within LacZ.To continue this work, efp genes were deleted on either side of proline codons to test the reliability of the assay. This portion of the research is still ongoing.

Abstract Name: **Exploring Underrepresented Aviation Students' Mental Health and Success in Higher Education: A Phenomenological Study**

In recent years, college students' mental health has significantly declined, especially within minority student populations. Within the aviation industry, unattended mental health concerns in pilots have led to various fatal accidents. With devastating mental health-related incidents in the aviation industry, educational institutions must take the necessary steps to set their students up for long-term success in every aspect of life. Furthermore, due to the ongoing pilot shortage crisis across the United States, the aviation and aerospace industry has launched diversity, equity, and inclusion (DEI) campaigns designed to attract future employees from underrepresented groups. This project aimed to study the student experience regarding mental health in underrepresented minorities in aviation and aerospace degree programs. To do so, the researchers deemed it crucial to understand the aviation and aerospace students' psychological symptoms through the use of a feasible and reliable instrument such as the Counseling Center Assessment of Psychological Symptoms (CCAPS-34). The resulting data was used to provide the initial step in determining the acceptability, feasibility, and potential of the CCAPS-34 as a measure of distress in help-seeking aviation and aerospace students. Additionally, qualitative focus groups were conducted across two aviation-focused higher education campuses to understand the needs and wants for mental health. Our results showed an ongoing need for widespread, comprehensive reform through social support, promotion of psychological well-being, and activities with minimal psychological distress.

Abstract Name: **Investigation of Facet Orientation of Al-Cu-Fe Alloy with Scanning Electron Microscopy**

Crystalline facets are surfaces on single crystals that are smooth down to the atomic level, and they provide information on the internal crystalline structure of a material. While methods for quantitative facet analysis exist, these typically necessitate the use of specialized or expensive equipment. To make this type of research more accessible, a procedure to determine the orientation of crystalline facets using Scanning Electron Microscopy (SEM) and Electron Backscatter Diffraction (EBSD) is proposed and tested. In contrast to the equipment used in other methods, this procedure makes use of relatively common, versatile, and inexpensive equipment. The present research focuses on the use of SEM in this method.The material used for this analysis is an alloy of composition Al60Cu25Fe15 prepared by arc melting. It exhibits various interesting structures that can be observed with SEM, among which are spherical particles approximately ten micrometers in diameter. Distinct concentric rings, which are believed to be facets, can be observed on their surfaces. Three unique types of these facets have been observed. Each type corresponds to a unique crystalline direction of a cubic cell, which can be predicted by observing its rotational symmetry. The orientation of these facets is determined through visual examination using SEM and the built-in stage transformation operations which allow for quantitative analysis of the angles between them.To verify the accuracy of this procedure, the measured angle is compared to the theoretical angle between the crystalline directions that correlate to each facet. The angle measured using this approach is in agreement with the theoretical prediction, and it is supported by the crystalline structure determined by EBSD analysis. The results suggest that the use of SEM visual examination for determining the orientation of facets is a viable method, but the procedure must be further refined to yield more accurate data.

Abstract Name: **Deconvoluting the sesquiterpenoid biochemical pathway of Artemisia annua**

Malaria is a mosquito-borne disease that affected 229 million people worldwide in 2019, resulting in more than 400,000 deaths. The most effective antimalarial medicine is the natural product from the herb, Artemisia annua called artemisinin. Artemisinin is a sesquiterpene lactone compound, which structure is too complex to synthesize in vitro. Although bioreactor production of feasible with microorganisms, the product become too expensive for governments in many poor countries to purchase. Therefore, in planta production remains the most economically viable way to produce artemisinin. The overall goal of this research is to enhance terpenoid biosynthesis in A. annua and boost artemisinin accumulation in glandular trichomes of artemisia. We used Gas Chromatography – mass Spectrometry (GC-MS) to quantify and compare the abundance of mono- and sesquiterpenoids of 13 accessions of the A. annua germplasm collection at WVU. We have also started assessing volatile organic compound (VOC) headspace losses during artemisia cultivation in greenhouse conditions.

Abstract Name: **The Unbelievable Survivor Impact of Victim-Blaming**

Abstract: This project was designed to explore how victim-blaming and support are portrayed in television representations of sexual assault experiences. Sexual assault is one of the most underreported violent crimes nationwide. This underreporting has historically been attributed to a multitude of factors, including fear of experiencing revictimization during disclosure experiences to law enforcement, as well as loved ones. Secondary victimization generally refers to the trauma experienced by survivors based on the reactions of others following disclosure of their victimization. Evidence of victim-blaming (i.e., the belief that survivors are at least somewhat to blame for their victimization) has continued to be a reoccurring feature in media portrayals of sexual assault survivors. On September 13, 2019, Unbelievable, the onscreen adaptation of T. Christian Miller and Ken Armstrong's (2015) Pulitzer Prize winning article, A False Report: A True Story of Rape in America, premiered as a new eight-episode mini-series on Netflix. The purpose of this project was to explore how the nature and source of the victim-blaming impacts the survivor in this television adaptation. Using a content analysis of all episodes of Unbelievable, the following areas were considered: (a) the nature of victim-blaming, (b) the sources of victim-blaming, (c) the sources of support, and (d) type and level of impact of victim-blaming or support on survivor.

Abstract Name: **Why do You Sit There? A Study on Factors Influencing Seating Preferences in the Classroom**

In college, it is rare that professors assign seats, but students still have their spots. But why do students choose to sit where they do? Where a student sits when they walk into a class for the first time is based on several factors, though research exploring the factors behind seat choice is scant. Current exploration of seating preferences focus on factors including territoriality, perceptions of work ethic, and interpersonal relationships with the professor. As technology becomes more prominent in the classroom, students may prefer seats near outlets, suggesting that non-social/psychological factors may be involved in selecting seating. Various pedagogical approaches including, lectures, discussions, labs, and online classes suggest a situational reading of the social environment by the student. Employing an online survey containing both open and closed-ended questions this research looks at what factors affect seating choice and seating preferences in a mid-sized east coast college setting.A subset focus of this research is on students with accommodations and their seating preferences. As disability needs are being addressed through the American Disabilities Act of 1990, more disabled students are getting mainstreamed in higher education and accommodations are becoming standardized practices. An accommodation seen across a variety of disabilities is "preferential seating." By allowing students to position themselves in the classroom, they are being taught to adapt their environment to best support their learning. This exploratory study offers data containing a preliminary list of factors affecting where students sit in a classroom and avenues for further research.

Abstract Name: **Low-Carbon Footprint Concrete for 3D Printed Buildings**

3D printing concrete has recently emerged as a revolutionary technology. Over the past two decades, developments in the technology have allowed a wide variety of applications, e.g., the fabrication of buildings. Cement manufacturing accounts for approximately 5% of anthropogenic CO2 emissions worldwide. The carbon footprint created from concrete is unsustainable for the environment. New forms of concrete containing alternative materials such as waste products and bio-aggregates are being implemented to reduce the overall carbon footprint. In our research, we are testing various mixes of concrete containing shredded wind turbine fibers, recycled glass powder, corn stover, and biochar. These materials were chosen as they provided a balance of strength, workability with the 3D concrete printer, and lower carbon emissions. To test our mixtures, we developed the following workflow: mix, cure, test, and evaluate. Each concrete mixture contained varying mix ratios of cement, sand, water, and one of the alternative materials. To ensure proper test results, we made 4 test mixtures containing 3 specimens for each material. This resulted in a total of 12 specimens for each material. Each specimen was cured for 28 days under water. After curing, we tested the compressive strength of each specimen on a hydraulic press machine and analyzed measurements of the load and stress. We then calculated the carbon footprint of the concrete mix with each alternative material. This data allowed us to analyze the mixtures and determine the most suitable candidate for 3D concrete printing. The new concrete mixes showed a varying level of compressive strength and showed a noticeable reduction in carbon footprint compared to the standard concrete mix. The technology of 3D concrete printing in combination with eco-friendly concrete will lay the foundation for a more sustainable future for housing.

Abstract Name: **Utilizing Obstetric Nursing Simulations to Strengthen Clinical Judgement in Undergraduate Nursing Students**

Background: Clinical Judgement is an integral part of nursing practice, guiding the assessments and decisions of nurses every day. Yet, research revealed that 77% of new nurses lack sufficient clinical judgement skills to translate this principle into practice after graduation. This cognitive dimension has historically lacked a concrete definition, but it can be conceptually viewed as the culmination of critical thinking, decision making, and knowledge application utilized by a nurse. From this definition, a tool used to evaluate Clinical Judgement through faculty observation, the Lasater's Clinical Judgment Rubric (LCJR), was developed to measure the level of judgement nurses and especially new graduate nurses possess. Following the American Association of Critical-Care Nurses (AACN) Essentials (2021) and The National Council of State Board of Nursing (NCSBN) Clinical Judgement model (2019), this study aims to create an obstetric simulation to enhance the level of Clinical Judgement in undergraduate nursing students in accordance with LCJR.Methods: An obstetric nursing simulation is being formulated to enhance clinical judgement in undergraduate nursing students. The simulation will be piloted in junior undergraduate nursing students currently taking the obstetric nursing course in their curriculum. Throughout the simulation, Clinical Judgement is planned to be measured utilizing a student self-assessment tool created through this study based on outlines set from the LCJR.Results: Following the simulation, a t-test will be completed utilizing the participants' completed self-assessments to analyze change in Clinical Judgement levels. Non-biased faculty surveys will be used to validate anticipated outcomes.Conclusion: Obstetric Nursing Simulations will be found to be an effective teaching method to increase Clinical Judgement levels in undergraduate nursing students, increasing the confidence and ability of new graduate nurses entering into the work force.

Abstract Name: **Investigation of Glacial Relictual Populations in the Piedmont of North Carolina**

During the Pleistocene Epoch, glaciers covered about 5,000,000 square miles of North America and spread as far South as the latitude 37 degrees North. These glaciers allowed cold adapted flora—otherwise referred to as relictual populations—to flourish. Yet, as the glaciers retreated, these relictual populations did as well. However, small populations continue to persist in higher elevations within southeastern and western North America; this is because higher elevations provide for a colder atmosphere due to the adiabatic lapse rate concept. This study investigates the relictual population Quercus montana—commonly referred to as Chestnut Oak—to characterize the populations of Chestnut Oak, to determine which environments relictual populations grow best in, and to discover whether the relictual populations will continue to persist within a warming climate. This past year, data was collected and analyzed over 50 plots on the two mountains in the North Carolina Piedmont, Occoneechee and Cane Creek. While analyses on the older tree populations has been conducted—including the Shannon index, basal area, importance value, and aspect transformation—it was revealed that the tree populations are healthy going into a changing climate and that the warming climate has not significantly impacted the older populations yet. However, further community analyses are to be conducted on the seedlings and saplings data to determine if the newer generations are being impacted by the warming climate. Additionally, soil analysis is to be conducted on all plots to investigate what environments and with what nutrients relictual populations, particularly Chestnut Oak, grow best with.

Abstract Name: **SEX EFFECTS ON MESOLIMBIC DOPAMINE RELEASE IN MICE**

The mesolimbic dopamine system is known for regulating reward, motivation, and attention. Dysfunction in mesolimbic dopamine functioning is associated with disorders such as ADHD, depression, and substance use disorder. As is historically common in neuroscience research, thedata collected in studies on the neural underpinnings of these disorders has been conducted mostly on males. Generalizing findings to females could be problematic, as some recent studiessuggest that aspects of the mesolimbic dopamine system functioning may be sex-dependent. The purpose of the current project was to investigate potential sex effects related to phasic dopaminerelease. The mesolimbic dopamine system consists of dopamine cell bodies in the ventral tegmental area that project to limbic nuclei, most notably the nucleus accumbens (NAc). In thisstudy, we used in vivo fixed potential amperometry to measure specific aspects of NAc dopamine functioning (dopamine release, the synaptic half-life of dopamine, dopamineautoreceptor sensitivity, the neuronal supply of dopamine, and the dopaminergic response to cocaine) in male and female C57BL/6J mice. No differences were observed in the synaptic half-life of dopamine (a measurement of dopamine reuptake and dopamine transporter functioning), dopamine autoreceptor functioning, or the neuronal supply of dopamine. However, female micedisplayed greater dopamine release and an increased dopaminergic response to cocaine compared to male mice. These results fit with behavioral studies in which female mice acquirecocaine self-administration at a faster rate than males. These findings have implications for not only substance use disorder but also a number of psychiatric disorders related to dopaminefunctioning and/or treated with dopaminergic drugs.

Abstract Name: **Android and Alchemist in the Garden of Eden: An Analysis of the ﷺPinocchio Syndromeﷺ Character Type as a Guide to Our Humanity**

This paper will examine the morality, philosophy, and humanity of a few characters in pop culture who find themselves uniquely situated outside of the common human experience yet, through the depiction of their virtuous character and their quests to attain their humanity, are positioned to act as guides for their audience's personal development. The characters I have chosen to analyze are the android Data from "Star Trek: The Next Generation," Alphonse Elric from "Fullmetal Alchemist: Brotherhood," who is a boy whose soul has been bonded to a suit of armor following the loss of his physical body in an alchemical accident, and the synthezoid Vision from Marvel Comics. These characters fit into the trope called Pinocchio syndrome, which I will be defining as the desire of nonhuman characters to attain humanity in what they see as the meaningful elements of human existence and for formerly-human characters to regain what they have lost of their humanity. Critics have judged the quest of the Other for humanity as unrealistic and opposed to self-actualization when characters of this type often in fact possess superhuman abilities. However, viewing these characters as created by humans for a human audience, I want to demonstrate the value of these characters as representatives of an ideal vision of humanity with consequent potential to present a unique perspective and example to inspire their human audience. I will be analyzing scholarly articles on the characters I have chosen in relation to their identity formation, self-actualization, and humanity as well as comparing and contrasting the origin stories of each character with the narrative of humanity's beginnings from the Biblical book of Genesis to complete this study.

Abstract Name: **Effects of Brachial Plexus Birth Injury on Structure and Composition of Biceps, Supraspinatus, & Subscapularis Muscles**

Brachial Plexus Birth Injury (BPBI) occurs in about 0.9 out of every 1,000 births when the nerve bundle innervating the shoulder is damaged due to excessive stretching of an infant's neck. About 30-40% of affected infants suffer lifelong shoulder impairment including paralysis, reduced range of motion, and musculoskeletal deformities. Deficits vary by injury location, affecting muscle mass and contracture, but the effect on underlying muscle composition is unknown. We hypothesize diminished muscle growth resulting from BPBI is related to increased collagen content, causing impaired muscle function. Altered passive muscle loading and active functional loading can both contribute to collagen buildup between muscle fibers, so their effects will be examined across four different surgical groups. Sprague Dawley rats (n=8 per group per timepoint) underwent surgery on one forelimb at 3-6 days post-birth: preganglionic neurectomy, postganglionic neurectomy, forelimb disarticulation, or sham. Contralateral limbs served as added controls. Biceps, subscapularis, and supraspinatus muscles were dissected at various developmental stages (2, 3, 4, 8, or 16 weeks post-injury), snap-frozen, cryosectioned longitudinally, and stained using Masson's trichrome. Muscle sections were imaged and analyzed as a ratio of collagen (stained blue) to muscle tissue (stained red). Groups were compared using ANOVAs and Tukey posthoc tests (GraphPad Prism, α=0.05). Preliminary data indicate that injured biceps and supraspinatus muscles from postganglionic neurectomies tend to be more fibrotic at 4 weeks post-injury than contralateral uninjured muscles. The opposite was true for biceps taken from the disarticulation group. Subscapularis muscles tend to be more fibrotic for postganglionic neurectomy compared to disarticulation for both injured and uninjured limbs. Analyses are ongoing to understand the progression of altered muscle architecture throughout development following BPBI. This study is the first to characterize fibrosis progression of the supraspinatus, subscapularis, and biceps muscles after BPBI, which may inform treatment planning.

Abstract Name: **Effect of embryonic cortisol exposure on neuronal cell marker gene expression in zebrafish larvae**

Exposure to prenatal stress is known to correlate with additional health outcomes later in life, including neurodevelopmental disorders. Cortisol is the stress hormone thought to mediate the effects of prenatal stress. However, how changes in cortisol impact neuron development is not well understood. We tested how early cortisol exposure affects mRNA gene expression of different neuronal cell markers in zebrafish using quantitative polymerase chain reaction (qPCR). Zebrafish embryos were treated with either a 5uM cortisol solution or vehicle solution at 3 hours post fertilization (hpf). Treatments were refreshed every day until 5 days post fertilization (dpf). RNA was then extracted from pools of larvae per treatment, converted to cDNA, and then analyzed using gene-specific primers with qPCR. These genes include markers for both neurons and glia. Differential expression wascalculated by comparing cortisol-treated samples with vehicle-treated samples using standard methods incorporating primer efficiency values. We hypothesize that there will be selective regulation of certain cell marker genes by cortisol, and we will discuss the implications of our findings in the context of understanding neuron development and cortisol signaling.

Abstract Name: **Role of Cytoskeleton in Zea mays Stomatal Complexes**

Plants regulate water loss to grow as well as resist drought. Guard cells are epidermal cells that surround and form a stomatal pore. Guard cell regulation is essential for plants to resist drought. Drought impactsZea mays, a significant agricultural crop. Several studies have established the importance of cytoskeletal reorganization in guard cells as essential for guard cell function inArabidopsis thaliana, but the role of the cytoskeleton in grasses has yet to be determined. The cytoskeleton consists of microtubules and actin filaments that may play a part in the movement of guard cells in grasses. Latrunculin B (LatB) is a cytoskeletal disrupting drug that inhibits the polymerization of actin filaments. Disrupting the cytoskeleton ofZea maysguard cells to test if there is an impact on the function of the guard cells could elucidate the purpose of the cytoskeleton in grasses. Inhibiting actin proteins with LatB did not trigger stomatal pores to close during light-induced opening.LatB did not stimulate pores to remain open during dark-induced closure but trended towards significance.

Abstract Name: **The Impact of Familismo on Latinx Millenial Caregivers**

Background: Familismo, or familism, refers to the cultural ideology typically shared by central Hispanic/Latinx individuals which encompasses loyalty to one's family, communalism, reciprocity, and interdependence between nuclear and extended family networks. Familismo perpetuates the collectivist expectation of caring for one's family members during times of need, such that an individual may feel obligated to take on the caregiving responsibility at the cost of unfulfilling their individual financial, emotional, and physical needs.Purpose: To explore the experiences of Latinx millennial caregivers to better understand the effect of familismo on their caregiving and their needs for the development of culturally appropriate interventions focused on stress management.Methods: This report focuses on the first phase of a three-part qualitative descriptive study of LMCs. Participants were recruited through professional contacts, national caregiving groups, and online means to participate in online focus groups held by the researcher through Zoom. During the focus groups, participants were asked open-ended questions regarding their experiences as LMCs. Following the completion of the focus groups, participants were sent a demographic survey through REDCap featuring open and close-ended questions pertaining to their demographic background and caregiving experiences. Focus groups underwent thematic analysis after being recorded and transcribed.Results: Analysis reveals four general themes- Challenges of Family Caregiving, Social Support Dynamics, Rewards of Caregiving, and Coping Strategies, with an overarching theme of the Latinx Experience. The Latinx Experience encompasses gender roles as marianismo and machismo, familismo, immigration, minority stress, and the importance of community.Discussion: The caregiving role resides at an intersection of layered identities for LMCs that is often maintained by cultural expectations associated with familismo. These findings should be taken into consideration when developing interventions for LMCs to ensure that the support they receive is both culturally appropriate and applicable to their experiences.

Abstract Name: **Behind the Scenes of Dark Triad Traits: A Study of Neurocognition and Emotional Processing**

The Dark Triad consists of personality traits of Machiavellianism, narcissism, andpsychopathy. These traits have been found to be negatively correlated with empathy.Machiavellianism and psychopathy traits have also been demonstrated to be associated withpoorer self-control, whereas narcissism and psychopathy traits have been linked to impulsivity. However, still little is known about the relationships between Dark Triad traits and other aspectsof neurocognitive processes. This ongoing study examines a broad scope of neurocognitive processes (i.e., self-control, inhibition, impulsivity) and emotional processing (i.e., emotionalawareness, and empathy) to determine specific predictors of Machiavellianism, narcissism, andpsychopathy traits in university studentsData are currently available on 53 university students. Participants' personality traitswere assessed using the Short Dark Triad questionnaire.Neurocognitive functioning wasmeasured using the Tangney Self-Control Scale, Stop-It Inhibition Test, and The BalloonAnalogue Risk Task (BART). In addition, participants' emotional awareness was assessed usingthe Toronto Alexithymia Scale, whereas empathy was measured using the Empathy Quotient.For the interim analyses, traits of Machiavellianism were regressed on the five neurocognitive predictors (self-control, inhibition, impulsivity, emotional awareness, andempathy), using a simultaneous multiple regression procedure. The regression analyses revealedthat among the predictors, response inhibition (Beta = -0.001; t = -1.975, p = .05), emotionalawareness (Beta = -0.011; t = -2.113, p = .040), and empathy (Beta = -0.026; t= -4.603, p = .0001) were significant determinants of Machiavellianism traits, whereas only empathy (Beta = -0.025; t = -2.785, p = .008) was the strongest determinant of psychopathy traits. However, none of the neurocognitive processes were significant predictors of traits of narcissism.Preliminary findings from this study could potentially expand our understandingthe specific roles of neurocognitive functioning in individuals with the Dark Triad traits.

Abstract Name: **Panel discussion: Creating a developmental curriculum to build research skills**

In this panel discussion, moderated by Abby Hemmerich, four panel members will share examples of undergraduate research embedded across the curriculum and within individual courses. These examples will highlight principles of research woven through progressive courses in chemistry, psychology, kinesiology, and natural sciences, helping students build skills developmentally from their first year to graduation.David Durkin (co-author, Darion Isom) will discuss a series of integrated labs to grow research skills throughout the middle years of the chemistry major, culminating in an independent, problem-based learning project. Details about the final "Special Project" will be presented; this project requires students to utilize all of their skills to independently design the experiment, request materials, perform of the experiment, and write the research report.Nicole Depowski will present a case study of a psychology program with research introduced at the introductory level, integrated practice across the curriculum, and a capstone senior thesis project. Early exposure to scholarship focuses on locating and reading research, while students gain skills in research ethics and design at the next level. The third year requires use of primary sources, with synthesis and analysis, culminating in a senior thesis project in which students produce their own research.Brian Wallace will discuss the process for building evidence-based practice and research principles into the kinesiology curriculum to prepare students for graduate school or health and fitness professions. Changes to student engagement in research and outcomes related to faculty-mentored research will be discussed.Chimdimnma Esimai (co-author,George Ude) will present a series of course-based research experiences that engage a whole class of students in a research question or problem. Although individual projects are restricted to a single course, students experience multiple opportunities for these projects across the curriculum, providing complementary content and developmental progression in skills.

Abstract Name: **Epstein-Barr Virus Reactivation Mediated in-vitro by Short-Chain Fatty Acids**

Epstein-Barr Virus (EBV) causes infectious mononucleosis and was one of the first human viruses linked to a variety of cancers. EBV lives in two lifestyles, a latent and a lytic life cycle. Expression of the viral immediate-early gene BZLF1 triggers the latent/lytic switch in the virus. Targeting this switch is important for preventing spread by keeping the virus from reactivating. Sodium butyrate (NaB) activates the expression of BZLF1 gene and serves as an HDAC inhibitor in the cells. We have observed that short-chain fatty acids, propionate and valerate, also induce BZLF1, but not as potently. However, branched medium-chain fatty acids such as valproate and valpromide inhibit BZLF1 expression in Burkitt lymphoma cells. Asource of naturally occurring short chain-fatty acids can be found in the metabolic pathways of amino acids. To determine the effects of other short chain-fatty acids, leucine metabolite 4-methyl-2-oxovalerate was tested for effect on EBV-positive Burkitt Lymphoma cells. Using RT-qPCR, the effects of these molecules on BZLF1 expression was measured both accompanied by NaB and without. The administration of 4-methyl-2-oxovalerate had no observed activation of the viral lytic cycle. When introduced with NaB, this metabolite showed a slight increase in activation of BZLF1 compared to NaB alone. Investigations of the effects of other short-chain fatty acid metabolites on EBV reactivation and histone acetylation are compared. Discovering regulators of EBV will aim to understand the natural viral life cycle and to promote the development of clinical solutions for EBV related diseases.

Abstract Name: **An EEG Investigation of the Discrepancy Between Auditory and Visual Memory**

Previous research has indicated that visual recognition memory has a much larger capacity than auditory recognition memory. The purpose of this study was to investigate the disparity between the two memory systems by examining the neural circuitry involved in accurate recognition of visual and auditory stimuli, to examine the size of the discrepancy between auditory and visual memory across the lifespan, and to measure the relationship between working memory ability and recognition memory. In Experiment 1, participants completed a recognition memory task while neural responses were recorded with a 32-channel Brain Vision EEG system. Participants received a study phase with pictures/sounds, followed by an immediate recognition memory test. During the memory test, participants were presented with pictures/sounds that were old (presented during study), new (not presented during study), or exemplars that were variants of objects presented during the study phase. Participants were instructed to classify each picture/sound as “old” or “new” by pressing a corresponding key. In Experiment 2, participants ranging from 18 to 65 years of age completed a working memory assessment, followed by the recognition memory task from Experiment 1. The data analyses have the potential to indicate whether the discrepancy between visual and auditory memory is related to changes in gray matter density of the prefrontal cortex as we age. The results of this study will also improve our understanding of the connections between auditory memory, visual memory, and general cognitive ability and will allow a better understanding of the relationship between memory and general cognitive decline.

Abstract Name: **Computational Analysis of A Potential Inhibitor affecting Amyloid Beta Aggregation relevant to Alzheimer's Disease**

Alzheimer's Disease (AD) is a neurodegenerative disorder that impairs cognitive functions and memory retention of brain tissue and its symptoms can hinder the ability to perform daily activities. With the use of computational methods, this project looks for a molecular cause of AD. A chemically adhesive protein called Amyloid β (Aβ) aggregates and aids the development of AD by forming plaques in the brain. This protein consists of 42 amino acids that form Aβ aggregates, which are stabilized by intermolecular interactions, a rigid hydrophobic effectand hydrogen bonding within the backbone atoms of peptides gathered in the brain.We aim to discover a drug that disrupts these interactions. We investigate the efficacy of several polyphenols, which are associated with modulation of AD pathology. A polyphenol has aromatic carbon rings and hydroxyl groups that interact with Aβ which can destabilize itsstructure. We hypothesize the polyphenols form hydrogen bonds and π-stacking with aromatics and prevent Aβ aggregation. We use computational chemistry techniques, such as molecular docking and molecular dynamic simulations, to model interactions between Aβ and these polyphenols. Such molecular dynamic simulations can locate where a ligand binds to Aβ and predict how such ligand interacts with Aβ in human physiological conditions. From our previous work, thepotential inhibitors known as Purpurogallin (PUR) and Calebin A (CAL) werefound to help disrupt the Aβ aggregates. An analysis of binding free energies, root mean square deviations, root mean square fluctuations, hydrogen bonding and β-sheet percentages on PUR bound to Aβ and compared to Aβ by itself were perfomed to investigate the effectiveness of the polyphenols. Based on the results, PUR serves as a possible treatment for AD as the polyphenol displays a reduced β-sheet content compared to the protein on its own while CAL shows a reduced content of backbone hydrogen

Abstract Name: **Repurposing Nutrient-Rich Sediment from a Eutrophic Reservoir**

Lakes Menomin and Tainter are reservoirs within the Red Cedar Watershed, Wisconsin. They experience harmful algal blooms (HABS) due to high nutrient loading from agricultural and residential areas. Phosphorous and nitrogen runoff into the aquatic systems, fueling the HABs. Wetland restoration is not a common management practice within lakes and reservoirs; it can be a viable solution for disposing of nutrient-rich, dredged sediment. Organic matter in the sediment, is vital for plant growth and a source of atmospheric methane; these could be a valuable resource if harnessed. Chinampas are an indigenous Mesoamerican wetland structure for growing crops implemented in Mexico. There are few studies on traditional Chinampas; they have proven to support biodiversity and water quality. A fixed Chinampa-style raised bed was constructed to monitor Lactuca sativa Lettuce growth over 16 days within a hypereutrophic reservoir compared to an ex-situ location. Lactuca sativa was planted in various ratios of sediment to sphagnum moss: 25, 50, 75, and 100 percent sediment mixtures. The Chinampas Lactuca sativa 100 percent lake sediment grew significantly taller than the rest of the seedlings (0.05). Methane was captured, and the volume collected was used to estimate methane gas release in areas shallower than 3 meters across the reservoir. Methane ebullition over two days during the summer was 1.22 x 10-4 kg m-2 day-1. There is a source of methane production in the reservoir. Methane gas is a potent greenhouse gas that heats up the atmosphere to a higher degree than carbon dioxide. Finding a way to capture the gas emitted from the lake and convert it to carbon dioxide would reduce the impact of the lake's gas emissions. Lettuce growth within the lake supports Chinampas as a potential nutrient remediation strategy and other harvestable wetland species should be studied.

Abstract Name: **Psychoactive Treatments in a Mouse Model of PTSD**

Post-Traumatic Stress Disorder (PTSD) can be characterized as a complex mental disorder by its complications in cognitive functioning and behavioral deficits often onset by a traumatic event in one's life. Due to the limited efficacy of therapeutic interventions, the current treatment for this disorder includes psychotherapy, exposure-based therapy, and medications such as selective serotonin reuptake inhibitors (SSRIs) cultivated for the treatment of anxiety disorders. In recent years, different psychoactive substances with known psychotropic and hallucinogenic effects have been reviewed as novel treatments for acute stress disorders. Within the field of behavioral neuroscience, fear-eliciting paradigms are used to evoke and represent the acute stress symptoms that facilitate post-traumatic stress disorder. Within this study, sixteen C57 adult male mice were exposed to aversive shock stimuli within a novel operant chamber context. Four hours after the aversive stimuli, half of the mice were injected with Ketamine 30 mg/kg intraperitoneally and the other half received a saline injection. Twenty-four hours after the aversive stimuli, the mice were placed back into the chamber to monitor for symptoms of distress. The mice who received the saline injection associated the chamber with the aversive stimulus and exhibited freezing behaviors. Two weeks after the chamber exposure, all the mice were placed into an open field apparatus to assess for symptoms of generalized anxiety disorder. The mice treated with Ketamine had reduced fear generalization. This research concluded that Ketamine serves as a promising therapeutic treatment for anxiety and acute stress-related disorders.

Abstract Name: **?It?s Everything. Absolutely Everything?: Stage Management for The Revolutionists**

In an art form as reliant on vulnerability, communication, and connection as theatre is, a stage manager brings a sense of clarity and insight to all facets of the production process. However, when tasked with leading and guiding an incredibly small cast tasked with answering questions about intersectional feminism and creating art amidst catastrophe, the relationship-building and insightful abilities of a stage manager reach new heights. The stage management team augments, brightens, and guides ensemble work through analysis and active communication, and is central to shaping the rehearsal room and production team's mentality and communication of creative vision.This winter, I served as the stage manager for Hope College Theatre Department's production of The Revolutionists by Lauren Gunderson. I spearheaded the stage management team, which was responsible for coordinating production needs before rehearsal began, served as a point of contact, connections, and advocacy for the director, designers, and actors, and called light and sound cues during every performance, leading the show and preserving the director's vision following opening. By approaching The Revolutionists from the perspective of stage manager, I was able to strengthen relationships and solidarity with other femme performers and theatre artists in my department, and contribute to further intersectional forms of storytelling for my campus community.

Abstract Name: Identification and Characterization of a Soil Isolate Utilizing p-hydroxybenzoate as a Sole Carbon Source

The present study is aiming to identify and characterize a strain of soil microbe. The microbe was selected by its ability to utilize p-hydroxybenzoate as a sole carbon source when grown on minimal media. The goal of this study is to identify and characterize the microbe through the microbiologic and genetic analysis. The microbe will also be grown on a larger scale and harvested in order to begin testing for enzymatic activity of metabolizing the p-hydroxybenzoate carbon source. Since the microbe is grown aerobically, the metabolic pathway is expected to contain a hydroxylase and a dioxygenase. The crude cell extracts generated from the cell paste will be tested for this activity. Results from this work will be presented.

Abstract Name: A Deep Learning Approach to Automate the Analyses and Prediction of Function for Poplar Stomata

In plants, stomatal pores regulate the intake of carbon dioxide that enables and powers photosynthesis and the loss of water from the surface of leaves. Variations in stomatal size and density can thus reflect novel strategies that balance water loss with photosynthetic capacity. Poplars are an emerging model system for studying adaptation to climate change in tree species and exhibit variation in stomatal characteristics. Currently, many approaches used in collecting stomatal morphometric data require the manual measurement of microscope images of stomatal imprints by a trained individual using software such as ImageJ.The process can be extensive, inaccurate, and slow down long-awaited results after collection. Our process follows similar methods shown in Gibbs et al. (2021) but differs in the deep learning processes used. This study implements a deep learning method to automate the process of morphometric data collection. Images collected for our approach are accurately labeled using open-source software to identify stomatal pores and guard cells. The preprocessed images along with the generated segmentation masks are fed into the deep learning model. For our study, we will use UNet to segment and measure pixel values that correspond with measurements of stomatal cells and image region properties to measure the stomatal density from prediction. All experiments will be conducted on the University of Wisconsin-Eau Claire BOSE supercomputing cluster. These measurements can be combined with additional climatic data to understand quantitative measures of plant health and viability across geographical and environmental scales.

Abstract Name: The Christianization of Norse Mythology and Its Ties to White Supremacy

Norse mythology has become the plaything of white supremacists. Between its use as a propaganda tool by the early 20th century Nazi and völkisch movements and its current use by neo-Nazi extremists, ancient Norse paganism has taken on the role of the "black sheep" of scholarly mythological study. In this paper, I make an apology for not only the study of Norse mythology but of Norse mythology itself. I will also seek to explain the ways in which neo-Nazi movements have unfairly co-opted a culture diametrically opposed to many of the beliefs intrinsic to their own white supremacist movements. Lastly, I will attempt to explain how this misalignment came to be in the first place. In doing so, this paper touches on four different elements of white supremacy–nationalism, racial purity, sexism, and eugenics–and methodically debunks their supposed relationship with the ancient Norse. This includes discussions of the genetically diverse DNA found within Viking remains, the way in which ancient Nordic people set up their civilizations, their complex sex-gender system that made biological sex largely irrelevant, and the way in which the ancient Nordics worshipped an ideal of physical deformity and disability. Finally, after presenting evidence put forth by experts in a variety of fields, ranging from archeologists to anthropologists to biologists, I will argue that the origin of Norse mythology's misappropriation lies within its original recording by Snorri Sturluson in the Prose Edda and his interjection of western Christian values onto a society that did not follow the same beliefs.

Abstract Name: Effects of Tea Tree Essential Oil on Escherichia Coli & Staphylococcus Aureus

Melaleuca alternifolia (tea tree) leaves have been used throughout many cultures around the world to help heal wounds and injuries because of its anti-inflammatory and anti-microbial properties. Some essential oil companies claim that tea tree essential oil contains purifying capabilities for air and contaminated surfaces. Essential oils are synthesized by many methods, the most popular being steam distillation. The essential oils, once purified, are sold to customers so they can use the oil to benefit from the plant's physiology and metabolic processes. In attempts to inform the scientific community about the antibacterial properties of the essential oil, we tested whether tea tree oil possesses the ability to fight common infections to any significant degree. We grew Escherichia coli; Staphylococcus aureus and measured the zones of inhibition in response to different concentrations of the essential oil. We also tested two different brands of tea tree oil, dōTERRA and Lagunamoon. We found that dōTERRA tea tree oil exhibited antibacterial properties while the Lagunamoon oil did not.

Abstract Name: **High School Gateways: An Intervention Introducing Underserved High School Students to Healthcare Professions**

Objectives: This intervention targeted high school students in Flagstaff, Arizona to introduce them to various healthcare professions available through higher education with the long-term objective of reducing the healthcare provider shortage in rural northern Arizona. The Center for Health Equity and Research at Northern Arizona University reports that individuals living in rural areas in Northern Arizona lack opportunities for education and employment and experience a lack of proximal providers and specialty services (Sanderson et al., 2017). This intervention aimed to increase participants' knowledge about and interest in healthcare careers and increase self-efficacy regarding college applications. This program also aimed to increase college admission and enrollment rates for participants. Methods: This intervention was implemented over three days at an alternative education high school in rural Arizona. Participants attended 1.5-hour workshops each day, covering topics such as health professions and college applications. Intervention activities included mock college applications and interactive healthcare career roadmaps, which were designed around the Transtheoretical Model of Behavior Change. Results: This intervention was evaluated via pre- and post-surveys. This intervention was successful in meeting two out of three impact objectives: 67% of participants were able to explain the core components of at least three healthcare careers and 38.56% of participants expressed increased confidence in applying for higher education programs. Conclusions: Evidence-based initiatives, such as the one described for this project, can be replicated and utilized across rural high schools to increase interest in healthcare professions and address future healthcare provider shortages. Significance: Rural Arizona communities often lack opportunities for higher education and are strongly affected by provider shortages. Working with younger generations to increase access to higher education and encouraging students to pursue healthcare careers can help bridge this gap and improve healthcare access in these communities.

Abstract Name: **Defining Domains of a Recruitment Protein in Tombusviridae Essential for Viral Replication Organelle Formation**

Tombusviridae is a family of positive sense, single-stranded RNA viruses that infect a wide variety of vegetation, including food sources such as tomato and cucumber plants. Due to the relatively small genomes of these viruses, a master regulatory protein (p33) recruits a plethora of co-opted host factors to form viral replication organelles (VROs). The VROs are considered viral-induced membranous organelles, which protect the viral replication complexes (VRCs) from host RNases. The formation of VROs depletes the cell of resources essential for vital metabolic processes. Exhausting cells can lead to leaf mottling and eventually result in plant death. As the global population continues to grow, the demand for food will increase. Investigating the interaction between p33 and host factors will provide information necessary to develop targeted antiviral agents. These agents will aid in decreasing cell exhaustion and increase the yield of crops necessary to feed a demanding population. This project focuses specifically on the interaction between p33 and peroxisomes. The transmembrane domains of p33 insert into the membranes of peroxisomes; causing a series of events leading to an irregular aggregation of said organelles within the cytosol. Directed deletions of different domains of p33 can help determine which specific amino acid sequences are necessary for co-opted recruitment of peroxisomes. It is anticipated that any deletion in the ORF gene (ORF encodes the master regulator) that results in knocking out amino acid sequences located in either of the transmembrane domains of p33 will result in failed VRO formation. Much previous literature has confirmed the necessary dimerization of p33 proteins. Thus, introducing a mutant p33 (incapable of forming VROs) to cells infected with a virus within the family of Tombusviridae may prevent wildtype master regulators from aggregating peroxisomes in the cytosol. Without the formation of VROs, progeny viral RNA cannot be synthesized.

Abstract Name: Soil Carbon on Campus

Soils have been identified as a potential major carbon sink, and as carbon emissions continue to increase around the world, attention is being turned to soils as a possible way to offset these emissions. Healthy soils may be able to sequester carbon from the atmosphere in a variety of different compounds, storing it underground for many years. College campuses are a unique place to study soil carbon sequestration because they typically have ample green space that can be closely monitored and maintained by the university. While prior research on college campus soil carbon sequestration has focused on the role of land cover, the call to further investigate the role of soil compaction is based on related research in agricultural environments. This study seeks to examine whether land cover or soil compactness has a greater effect on soil carbon sequestration on a college campus. The study area is the Historic Neighborhood of Elon University in North Carolina which is the oldest area on campus, established in 1889. This part of campus features many different types of land cover with varying soil compaction levels. Areas of different land covers have been mapped using GIS software and will be ground-truthed in order to provide error estimates throughout analysis. Soils of low, moderate, and high compaction have been identified and GIS will be used to select random points within each land cover and soil compaction classification for sampling in order to mitigate the potential for researcher bias. Soil samples from each point will be analyzed using an automated soil carbon analyzer to determine the total amount of soil organic carbon (SOC) present. The results of this study will inform best management practices for university landscaping crews to promote soil carbon sequestration on Elon's campus.

Abstract Name: Construction of chimeric proteins to characterize the functional specificity of the post-transcriptional regulator RsmE in Pseudomonas fluorescens

RsmE is a post-transcriptional regulator in the bacterium Pseudomonas fluorescens that forms a heterodimer to sequester multiple mRNA and repress their translation. P. fluorescens also harbors two RsmE paralogs: RsmA and RsmI. Although Rsm paralogs are generalized to be functionally redundant, we have recently demonstrated that RsmE exclusively represses the production of extracellular secretions that collectively function to create remarkable spatial structures in a densely populated colony. The core peptide sequence of Rsm paralogs are highly conserved, with the same set of predicted secondary structures. In contrast, the C-terminus tail region of the paralogs does not appear to encode any secondary structures and varies greatly in sequence. Deleting the tail region of RsmE abolishes its repressive activity, we thus hypothesize that the C-terminus tail specifies RsmE's unique function from its paralogs. We constructed three chimeric proteins, RsmE core fused to the tail of RsmA, RsmE, or RsmI, with the expectation that only the RsmE core and RsmE tail construct (RsmE/E) will restore the repression of extracellular secretions in an rsmE knockout strain. Indeed, we observed that RsmE/E restores the repressive function while RsmE/A fails to do so. However, RsmE/I also restored repressive activity, indicating that the tail of RsmI could functionally complement that of RsmE. We are now in the process of constructing additional chimeric proteins to comprehensively decode the functional differences and similarities among the Rsm paralogs. The C-terminus tail sequences of individual orthologs appear to be highly conserved among Pseudomonas species, suggesting that the functional specificity assigned by the tail of Rsm homologs manifests across diverse environmental niche.

Abstract Name: **Magnetic field assisted alleviation of fast-charging induced damage in Li-ion batteries**

Lithium-ion batteries are the predominant energy storage technology for electric vehicles and mobile devices. One limitation of this technology is the deposition of lithium metal on the anode during fast charging, which reduces battery capacity and increases the risk of thermal runaway. My research explores the effect of an externally applied magnetic field on interfacial anodic degradation when charging at high C-rates in lithium-ion batteries. Lithium deposition occurs because of non-uniform ionic flux through the battery's separator. A magnetic field applies magnetohydrodynamic forces on the lithium ions and homogenizes the ionic transport, which can reduce the deposition. Our group has demonstrated that magnetic fields can reduce lithium deposition and used electrochemical impedance spectroscopy (EIS) to monitor the lithium deposition and stripping during fast charging. We expand on these results by charging and discharging for several cycles while performing EIS measurements to monitor the influence of a magnetic field on plating and stripping of deposited lithium. We perform charging experiments at C-rates ranging from 0.1C to 5C under a magnetic field and compared the EIS results to experiments with no magnetic field. We use 20, 50, 250, and 300 mAh capacity pouch cells with a graphite anode and a lithium cobalt oxide cathode in our experiments. Findings so far show insignificant effects of the magnetic field when slow charging at 0.1C over 5 cycles. This supports our hypothesis because lithium deposition doesn't occur at very low C-rates, so the results from the cycles with the magnetic field and without should look similar. After analyzing results at higher C-rates, we will perform post-mortem analysis of the anodes to see if the differences in performance relate to differences in lithium deposition.

Abstract Name: **The Adoption of Music Therapy in Child Vaccination Procedures: Reducing Anxiety Levels in Children and Parents to Increase Vaccination Rates**

The anxiety felt by children surrounding vaccinations has contributed to a decrease in pediatric vaccination rates within the past two decades. Though, using distraction methods during pediatric vaccination procedures has shown the tendency to decrease anxiety and improve the overall experience. Previous studies have explored the effect of music therapy as a method of distraction on anxiety during various medical procedures, such as dental and cardiac procedures, however pediatric vaccination procedures have not previously been explored. This proposed study aims to develop a protocol for music therapy to be implemented into pediatric vaccination procedures to decrease the anxiety experienced by patients and eliminate the resurgence of preventable illnesses. In pediatric patients, needle anxiety is common, especially surrounding vaccinations. The possible implementation of music therapy would not only be a cost-effective method of distraction compared to other methods, but it may also allow for reduced anxiety, as music may be used to cope with feelings of anxiety. The implementation of music therapy in vaccination procedures may be conducted by enabling pediatric patients to use a tablet device with the capability to play music off of a music database, in which patients are able to choose the genre and songs they will listen to throughout the procedure. Within this study, there are two key pieces: 1) developing a protocol for music therapy to be implemented into pediatric vaccination procedures and 2) exploring the effect of music therapy on anxiety levels in pediatric patients. This study would expand research on decreasing anxiety in patients with needle anxiety, provide a basis for a more calming procedure to be further developed, and examine the effects of potentially increased vaccination rates on the resurgence of preventable illnesses.Keywords: pediatric patients, vaccinations, needle anxiety, anxiety, music therapy, parental anxiety, vaccination rates, dopamine, calming, relaxation, trypanophobia

Abstract Name: The Priming Effects of Gratitude on Hope Among COVID-19 Vaccine Clinic Patients

COVID-19 has had an enormous impact on society, but can practicing gratitude make us more hopeful amidst adversity? The onset of the pandemic fostered newfound fears of death and increased general anxiety for the future. Previous research on the positive effects of practicing gratitude, such as the facilitation of hope and relationship reinforcement, serve as pathways for fostering healthy outlooks and coping mechanisms in light of adversity. The purpose of this study is focused on the priming effects of gratitude on hope. This research, distributed by survey, was conducted at a vaccine clinic where patients who received their first or second dose of the COVID-19 vaccine were in their 15 minute waiting period post-injection. Our findings yielded a small effect with no significant relationships between gratitude and hope aside from an association between age and levels of hope. The results of the research are analyzed and expanded upon in the discussion portion of the study. Ideally, the findings of this research study would provide enlightenment in regard to the positive effects of gratitude and its facilitation of hope within the context of hardship.

Abstract Name: Environmental Justice from the Ground(water) Up: Coping with Contamination in Tallevast, Florida

This research explores the history of groundwater contamination in Tallevast, Florida and how community residents have responded with coping strategies and environmental justice organizing. Tallevast is an historically segregated African American community in central Florida where residents discovered groundwater contamination from a local manufacturing plant. Since then, studies have documented high rates of cancer and other diseases. Using oral history interviews, we document the social, political, and economic strategies community residents developed in response to the contamination and health outcomes. These strategies focus on environmental justice activism that emphasizes community organizing, local citizen science efforts, and university-community partnerships.

Abstract Name: **Nuclear Fuel Remediation: A Computational Study**

Increased global attention on sustainable energy initiatives sparked renewed, global interest in nuclear energy. However, asignificant pitfall of nuclear energy is the production of high-level nuclear waste (HLW) with an extensive half-life. HLW waste storage poses a significant environmental and security risk. Remediating spent nuclear fuel (SNF) using nitrogen and sulfur-based chelation agents is a promising venture for recycling HLW into usable fuel or stable, nonradioactive compounds. This research paper aimed to perform computational studies on various nitrogen and sulfur chelation agents to determine if such agents are viable options for SNF remediation. The 6-31G(d) and MWB60 basis sets were used with Gaussian simulation software to perform computational simulations on viable chelation agents. Of the various agents studieddimercaperol, diethylenetriamene pentaacetate, and ethylenediaminetetraacetic acid appear to be the most promising in producing stable compounds from SNF byproduct. Thermodynamic and thermochemical properties of independent molecules were analyzed and documented to determine if stable compounds are possible. Lanthanide and actinide molecules were analyzed and documented for future research. Current simulations indicate promising results for dimercaperol in producing stable compounds for remediation; future research on this topicshould aim to understand if newly discovered compounds are applicable to industrial waste treatment processes.

Abstract Name: **Tapering Before NCAA Division I Cross-Country Competition Reduces Plasma HDL-C But Has No Effect on Structural HDL Apolipoproteins**

Exercising has shown to increase HDL-C levels in most populations, however it is uncertain if it has an effect in structural apolipoproteins such as apolipoprotein A1(Apo-A1) expression and secretion. Cross-country athletes undergo a period of tapering before competition resulting in reduced physical activity. The purpose of this study was to determine if the changes in physical activity that cross country athletes experience during the season and in preparation for competition affects their HDL-C. We hypothesize that the tapering period will result in reduced HDL-C and its structural apolipoproteins.Twenty seven D-I cross-country athletes, ages 19 to 25 years old, were followed for one season (four months). Blood was collected at the beginning of the season and analyzed for HDL-C levels through enzymatic spectrophotometry using the Alfa Wasserman Ace Axcel® biochemistry analyzer. Apo-A1 and Apo-CIII were measured through Luminex® MAGPIX® multiplex assays. Paired-samples t-test comparing the preseason (pre) vs postseason (post) values was performed using IBM® SPSS Statistics 25.HDL-C levels decreased significantly from pre = 64.2 ± 2.7, vs post = 60.7 ± 2.5 mg/dL p = 0.03. Apo-A1, 92.3 ± 6.5 vs 88.8 ± 6.8, p = 0.23 and Apo-CIII 13.8 ± 0.1 vs 13.3 ± 0.5, p = 0.37 showed no statistical difference from pre vs post.Our study shows that HDL-C levels are decreased by a period of time as short as 4 months. However, we did not observe a change on apolipoproteins A1 or CIII. These findings suggest that although exercise can modulate lipidation of the HDL particle through the process of cholesterol esterification in the reverse cholesterol transportation (RCT), Apo-A1 expression and secretion may be modulated independently of this process as we did not observe any changes in apolipoprotein concentrations.

Abstract Name: Circadian Rhythm Impact on Blood Pressure Dipping in African American Adults

Blood pressure (BP) exhibits a diurnal rhythm, wherein BP decreases during sleep and increases just prior to waking up. Elevated systolic BP (SBP) levels and SBP that does not decrease by at least 10% (“non-dipping BP”) are associated with increased cardiovascular morbidity and mortality, particularly among African American individuals. The objective of this study was to determine the contribution of the endogenous circadian system to nighttime SBP levels in African American adults. We used a 30-hour constant routine (CR) protocol, which is considered the gold-standard method for examining circadian rhythms in humans. In a CR protocol, activity, light, and meal timing are held constant by keeping the participant sitting upright in bed, keeping the room dark (<10 lux) while also blocking blue light exposure using filters on electronic devices, and giving the participant hourly iso-caloric snacks. During the CR protocol, we measure BP every 30 minutes and continuous core body temperature via ingestible thermometer. Recruitment is ongoing, but 20 normotensive African American adults with an average age of 37 years, have completed the study. Based on 24-hour ambulatory BP monitoring, 12 out of 20 (60%) participants had non-dipping SBP at baseline. The average clinical SBP for dippers and non-dippers was 113 mm Hg and 114 mm Hg, respectively. The average clinical diastolic BP for dippers and non-dippers was 68 mm Hg and 69 mm Hg, respectively. The average percent dipping was 17.2% and 5.7% for dippers and non-dippers, respectively. During the CR protocol, there was an absence of BP dipping during the nighttime period. However, both dippers and non-dippers exhibited a robust rhythm in core body temperature. These data suggest that the contribution to BP dipping may be minimal and that lifestyle and behavioral factors, such as meal timing, sleep, and physical activity levels, more strongly influence nighttime BP levels.

Abstract Name: Fake News Detection using Machine Learning Approaches

In this research, we focus on creating an automated fake news detection system using natural language processing of news texts. We investigate different machine learning-based classification techniques to predict whether a text is real or fake news. We also perform a comparative analysis of the accuracy of the different applied techniques. For our experiments, we implemented several white-box machine learning models, e.g. logistic regression, decision trees, multinomial naïve Bayes classifier, and black-box machine learning models, e.g. support vector machine (SVM)and neural networks-based multilayer perceptron(MLP). Additionally, we implemented an ensemble technique called stacking,which utilizes the previous models as base models for prediction and uses a meta-model for the final classification.

Abstract Name: Perceptions of Social Media's Educational Value in Relation to Evidence Based Practice

This project evaluates the educational value of social media platforms including TikTok, Instagram, and Twitter as course-based learning supports in an online graduate-level aphasia course. Components of evidence-based practice (EBP) in each of the three social media platforms are analyzed against student posts. These components include client perspectives, clinical expertise, and internal/external evidence (ASHA, n.d.). Additionally, student perceptions regarding the utilization of social media in course-based assignments are analyzed.Individually, TikTok (Escamilla-Fajardo et al., 2021), Instagram (Carpenter et al., 2020), and Twitter (Hull; Dodd, 2015) indicate a positive response among students and faculty in higher education. Social media in a classroom setting can help co-create knowledge, facilitate different learning styles, promote experiential learning, and enhance collaborative skills (Stathopoulou, 2019). Though each of the platforms are continuously rising in popularity, there is a substantial absence of conducted research studies that evaluate them holistically. A course-based assignment requiring use of each of the three social media platforms was assigned to 24 graduate students in an online aphasia-related course. Six prompts were presented every two weeks, and students used their assigned social media platforms to explore and develop answers to the prompts. Platforms were rotated across all students, so each student used each platform twice.The social media relics submitted by students were categorized based on the three components of the EBP triangle. Frequency counts for the presence of EBP domains within submissions for each platform will be presented. Additionally, student perceptions of each platform, their learning benefits, and their comparative value to the other course assignments will be discussed. Results will be discussed and applied to potential course-based pedagogical applications using social media platforms.

Abstract Name: The Associations between Belongingness, Trust, and the Willingness to Donate to One?s Alma Mater

Donations are a vital part of keeping universities up and running across the globe. Thus, it makes sense that universities have a vested interest in fostering relationships with students that will generate future donations. This study examines the degree to which feelings of belongingness, trust, and engagement in campus activities affect an individual's willingness to donate to their alma mater. The 72 participants in this study represent a diverse group of students at the University of Wisconsin-Eau Claire. The findings indicate that feelings of belongingness with the university and the belief that one can trust the university are more strongly associated with a willingness to donate. Engagement in campus activities was not significantly associated with a willingness to donate. Thus, we learned that while it is important for a university to provide opportunities for students to engage in campus life, the university should spend equal time fostering a sense of belongingness and trust with their students.

Abstract Name: **Pride Versus Prejudice: A study on the approach to race and sexuality by faith affiliated counselors and counselors in training**

Despite training inmulticultural counseling, counselors demonstrate a gap in integrating what they have learned into clinical practice (Owen et al., 2011; Rutherford et al., 2012). The purpose of this mixed methods study is to examine the responses of religiously affiliated counselors torace and sexuality. Thirty-five participants completed the following scales measuring religious affiliation and multicultural competency: Quest scale (Baston; Schoenrade, 1991), I/E-R Scale (Gorsuch; McPherson, 1989), Revised Religious Orientation Scale (Gorsuch; McPherson, 1989), Multidimensional Cultural Humility Scale (Gonzalez et al., 2021) and The Lesbian, Gay, Bisexual, and Transgender Developemnt of Clinical Skills Scale (Bidell, 2017). Participants answered open ended questions addressing theirbeliefs and clinical training. Themes emerged wherein participants described issues of race and sexuality within their training; some demonstrated prejudice while others demonstrated open-mindedness, both groups used faith to justify their ideas. We found significant positive correlations between counselors' self-assessed competency in their LGBTQ+ clinical skills and quest orientation (N=35, r=0.348, 0.05), self-awareness and fundamentalism (N=29, r=0.416 0.05), as well as significant negative correlations between extrinsic religiosity and supportive interactions (N=35, r=-0.336, 0.05), and intrinsic religiosity and LGBTQ+ clinical skills (N=35, r=-0.418, 0.05). This suggests that quest oriented participants, who allow themselves to wrestle with their religion,had higher self-assessed competencein providing care to the LGBTQ+ community as opposed to those who are more traditionally religious.Dataalso suggests that those who have rigid religious beliefs had more self-awareness. Overall the data suggest that a counselor's faith influences their ability to work with issues of race and sexuality. By having a clearer understanding of the relationship between religiosity and multicultural competency, counselor training can foster integration of multicultural principles in counselor practice.

Abstract Name: **The Influence of Dunstan on Monastic Reform in 10th Century England**

Christianity has been an integral part of the development of England, particularly the establishment of its legacy of scholarship and literacy. However, the advances made in these areas were disrupted by the Danish invasions during the eighth and ninth centuries. The Danes targeted the churches and monasteries in their raids because the monks were craftsmen and produced fine items of great value. These raids were detrimental to the stores of religious literature and artwork accumulated in monasteries across the country. Religious education and the fine arts associated with the church were lost after the attacks. Saint Dunstan was an accomplished scholar and gained prominent roles in the Catholic church. He used his authority to institute monastic reform to rebuild and revive what had been lost. The basis for this reform, called Benedictine Reform, was modeled after the work of Saint Benedict of Nursia. Saint Benedict established monasticism's values and practices in the sixth century. The tradition of scholarship and artwork in England was restored with the return to those standards. The work of these monks was key to the preservation and reinstitution ofliteracy and authorship. Saint Dunstan's monastic reform affected the whole nation because it was through the institution of the church that much of life was organized. Education became more widely available due to this revival of scholarship in the church. Dunstan's efforts brought immediate change and set the foundation of English scholarship.

Abstract Name: **How Women Communicate and Fulfill Sexual Desires**

Sexual desire has been recognized as the most universally experienced sexual response by men and women (Regan; Atkins, 2006), while also being one of the most subjective aspects of human sexuality (Mark et al., 2009; Meana, 2010). However, most of the research on sexuality is from a narrow lens that rarely highlights the positive aspects of women's sexual pleasure and desire (Jones, 2019). Additionally, there is no consensus on how to properly conceptualize and operationalize women's sexual desire (Brotto et al., 2009; Meana, 2010). Past research has assumed that women's sexual response cycle, and the ways they experience desire were identical to men (Brotto et al., 2009). Therefore, much of the research on sexual desire is through a heteronormative, male-centric lens, placing an emphasis on behavioral and physiological arousal responses to sexual desire. This has created a gap in the literature where women's individual and complex experiences with sexual desire may be overlooked or dismissed (Chivers; Brotto, 2017; Meana, 2010). Additionally, there is scant research on how women communicate desire to partners, which may be important in understanding how and if desires are fulfilled. The present study aims to understand women's lived experiences with desire through qualitative interviews. We are recruiting a diverse sample of 20-25 self-identified women.Using semi-structured interviews, women are beingasked about theirexperiences with sexual desire and the ways in which they communicate and fulfill desires. Through a feminist lens, we will be using thematic analysis to interpret the data. This study aims to offer new insights into women's desire and combat stigmatization around women expressing their desires.

Abstract Name: **The doubtful therapist: Can self-doubt be induced into therapists?**

The reason certain therapists are more successful than other therapists is paramount and largely a mystery. This study served the purpose to better understand the role of self-doubt (SD) in therapists by assessing the efficacy of a novel method for experimentally inducing SD in therapists. the therapists were randomly assigned to name different amounts of instances in therapy they felt confident, which meant to induce either high or low levels of SD and complete measures of SD and anxiety. This method of SD induction could be used by future researchers as it allows SD to be induced and studied in a laboratory setting. As expected, therapists in the high SD condition experienced higher levels of doubt and anxiety than those in the low SD condition. However, the degree of change caused by the manipulation was not drastic enough for statistical significance.

Abstract Name: Effect of Central Ghrelin Receptor Signaling on Avoidance Behavior in Wistar-Kyoto and Sprague-Dawley Rats

Behavioral inhibition (BI) is believed to be a genetically determined trait which causes individuals to respond to stressful situations differently than their non-behaviorally inhibited (NBI) counterparts. This research has been extended to the rodent population wherein the Wistar-Kyoto (WKY) rat models BI anxiety-like behavior, and the Sprague-Dawley (SD) strain serves as a control. We have previously demonstrated that a single overnight fast can enhance avoidance responses in SD rats to the level of avoidance exhibited by WKY rats. Overnight fasting elicits a variety of physiological changes that might directly or indirectly contribute to avoidance and anxiety-like behaviors, including reduced levels of gastric distention, reduced circulating levels of glucose and leptin, and increased circulating levels of ghrelin and corticosterone. Here we sought to investigate potential mechanisms that contribute to the fasting-induced increase in avoidance behavior we observed in SD rats. Since fasting increases circulating levels of the hunger hormone ghrelin, we hypothesized that central ghrelin signaling may contribute to the observed behavioral effect of fasting. We tested this by examining the effect of central ghrelin receptor activation on our signaled lever press avoidance task in female WKY (n = 8) and SD (n = 8) rats. All rats were implanted with cannulas targeting the lateral ventricle (LV) and receivedintra-LV injections of ghrelin or saline 45 minutes prior to the signaled lever press avoidance session. Ghrelin did not affect avoidance in SD rats. Surprisingly, intra-LV ghrelin significantly reduced avoidance performance in WKY rats, which resulted in a significant increase in the number of shocks that WKY rats received following intra-LV ghrelin relative to saline treatment. These findings suggest that central ghrelin may have an anxiolytic-like effect in WKY rats. Additional studies are necessary to further elucidate mechanisms by which central ghrelin signaling affects mood-related behavior in both NBI and BI models.

Abstract Name: Just Another Pretty Face? How Physical Attractiveness Affects Memory of Same-race and Other-race Faces

Undoubtedly, we have seen somebody casually going by and instantaneously determining whether they are attractive or not. Intuitively, attractive faces draw attention; thus one would expect they are memorable. Past studies have shown that faces outside of one's race are more poorly remembered than faces within one's race, a phenomenon called the cross-race effect (CRE). However, if attractive faces have a memorable quality, perhaps highly attractive other-race faces are remembered just as well as same-race faces. Thirty-four White female students studied 48 faces that were White, Latino, Black, and Asian and were classified as High attractiveness, Average attractiveness, and Low attractiveness. Afterward, their memory of those faces was tested by intermixing the studied faces with 48 new faces. Each face was presented one at a time alongside survey questions where they responded via mouse click whether they remember seeing the face. Additionally, we used an eye-tracking device to determine whether attraction or race influenced how long they looked at a face while taking the memory test. The results were rather surprising in that we discovered that more participants tended to recall faces low in attractiveness more accurately than faces high in attractiveness. Unsurprisingly, White faces were more accurately recalled than all other-race faces. Moreover, there was an interaction effect between race and attractiveness in that the CRE occurred among faces low in attractiveness, but not faces average or high in attractiveness. While this result was predicted, it was expected to be due to improved memory for other-race faces. However, it was largely due to poorer memory for same-race faces. As for the eye tracking data, participants visually fixated more often on high-attractiveness than low-attractiveness faces during the test phase. This behavior is either a sign of highly attractive faces' alluring quality or participants' uncertainty about their memory.

Abstract Name: **The Peculiar Intuitions of the Hard Problem of Consciousness**

All contemporary theories of consciousness must contend with the hard problem of consciousness. According to Chalmers, the hard problem is that if every physical function of the brain were to be described, the reason why these functions are accompanied by conscious experience would not be explained. I intend to undermine the hard problem by showing that it is a flawed intuition. Many have proposed theories that attempt to solve this problem, yet all non-physical accounts of consciousness encounter similar and peculiar issues. Substance and property dualism cannot adequately explain the causal relationship between mind and body, while panpsychism cannot explain how many small consciousnesses create a unitary, greater consciousness. In response to the hard problem, these theories propose something non-physical but cannot adequately explain how their non-physical something functions and relates to the physical world. The arguments that support the hard problem, such as Mary's Room, the Chinese Room, and philosophical zombies, exemplify a flawed intuition that underlies the hard problem and the theories of mind that ascribe to it. Human beings possess a flawed intuition that subjective experience is incompatible with physical explanation because experience seems incompatible with physical explanation. This is the flawed basis of the hard problem, and it manifests in the peculiar issues that each non-physical theory of mind faces. Scientific discoveries have proved repeatedly that intuitions mislead us, and a conclusive theory of mind cannot be based on a flawed intuition. The only way to solve the hard problem is to reconsider it, and reexamine our intuitions about experience.

Abstract Name: **Cardiac Fibroblast GSK-3? Aggravates Ischemic Cardiac Injury by Promoting Inflammation**

Myocardial Infarction (MI) is a leading cause of death worldwide. Glycogen Synthase Kinase-3 (GSK-3) has been identified as a promising therapeutic target for cardiovascular diseases. The GSK-3 family has 2 isoforms, α, and β. Previously, our lab identified fibroblasts (FB) GSK-3β as a negative regulator of fibrosis in the ischemic heart. However, the role of FB-GSK-3α in the ischemic heart is not well defined.To determine the role of FB-GSK-3α in MI-induced cardiac damage, GSK-3α was deleted in activated FBs using the tamoxifen (TAM)-inducible Periostin promoter-driven Cre recombinase. At 12 weeks of age, mice were fed with the TAM diet. After 1 week of the TAM diet, control and KO mice underwent MI surgery. Serial echocardiographic analysis revealed that KO mice were protected from MI-induced systolic dysfunction and dilative remodeling. To investigate the role of FB-GSK-3α in MI-induced chronic inflammation, hearts were harvested at 4 weeks post-MI and the expression of inflammatory genes was examined. Surprisingly, inflammatory gene expression was remarkably low in the KO group. To delineate the underlying mechanisms, we examined the effect of GSK-3α deletion on the key proinflammatory signaling, NF-κBpathway. WT and KO FBs were treated with TNFα. Western blot analysis showed a significant reduction in NF-κB activation in TNFα treated KO FBs.Additionally, co-culture experiments demonstrated that inflammatory gene expression was downregulated when immune cells were co-cultured withKO FBs. Our findings suggest that FB-GSK-3α plays a critical role in pathological cardiac remodeling and heart failure. Thus, it could be therapeutically targeted for future clinical applications to reduce post-MI complications.

Abstract Name: **Yoga Flow Class Impacts on Test Anxiety in University Undergraduates**

This study investigated how participation in introductory yoga flow classes offered by a university campus recreation department might reduce test anxiety and general anxiety levels more broadly in first and second year university undergraduates. Anxiety is an unfortunately common component of the undergraduate student experience in the U.S. Test anxiety, an increased state of emotionality and worry regarding examinations and schoolwork, affects undergraduate student populations. Behavioral approaches to anxiety management, such as yoga classes, can be advantageous within higher educational settings and can play an important clinical role in managing anxiety symptomology in undergraduate populations without the potential drawbacks of pharmacological intervention. This project attempts to contribute to the study of yoga as an economical, efficient, and accessible method of anxiety treatment for students in the United States. In this study, participants completed six survey questionnaires measuring resilience and anxiety before taking their first or second yoga class and then again after completing five classes within a span of sixty days. In this presentation, the observed statistical changes in self-reported test anxiety following participation in introductory yoga classes will be discussed. In conclusion, this study examines the efficacy of yoga as a means of managing anxiety symptoms in undergraduate populations. Yoga flow classes and similar interventions should be explored as potential alternatives to help students cope with the threat of test anxiety and stress.

Abstract Name: **Quantifying Benefits of Bridge Maintenance, Research Project for Minnesota Department of Transportation**

To improve decision-making standards based on life cycle cost-effectiveness, the goal of this research is to quantify the advantages of bridge preservation. The State Departments of Transportation (DOTs) have often used models developed by expert opinion to quantify bridge maintenance and preservation data. Due to data shortages, DOTs have conducted little prior study, making it difficult to accurately estimate the impact of bridge preservation efforts. The variation in performance for structures with various attributes, including as age, material, traffic volumes, and environmental conditions that they are exposed to, presents another difficulty in evaluating the influence of maintenance and preservation strategies. Additionally, because diverse characteristics result in different performances from bridge structures, it is challenging to recommend solutions for other bridges. To determine the efficiency of the various existing procedures in the state, it will be helpful to examine Minnesota DOT's history of bridge maintenance and bridge performance throughout time. Decision-makers will be informed on the best timing and kind of maintenance activities that will be the most cost-effective by a set of decision trees based on actual MnDOT project history. In this presentation, we will focus on District 8, which has additional data on maintenance activities that they have gathered. This is a sample of a larger MnDOT data collection that is currently under investigation, and it includes some extra information on work history.

Abstract Name: **The Effect of Varied Printing Parameters on Mechanical Properties of 3D Printed Materials**

Additive manufacturing builds 3D models from computer files by depositing layers of materials to create the part. This process of manufacturing has advantages over traditional subtractive manufacturing techniques, and to further utilize it, the materials need to be better understood. This study characterizes mechanical properties of multiple 3D printed materials. Additionally, parameters at which they were printed are varied to determine the most efficient and best-suited filament for different projects. For each material, PLA, PolyMax PC, Nylon, ABS, PETG, and Tough PLA, dog-bone specimens were printed at 0°, 30°, 45°, 60°, and 90° and 0.1mm, 0.15mm, and 0.2mm layer height (10 samples at each combination, for 150 total per material). Each specimen was tested in a Stress-Strain Apparatus by pulling the dog-bone away from the fixed end, thereby either breaking or stretching the specimen to completion. PolyMax PC had the highest average tensile strength of the 6 materials at 7.8 MPa, while Nylon had the lowest average tensile strength of 1.88 MPa indicating a significant difference in strengths of these materials (t-test, 0.05, PC vs. Nylon). The layer height showed that for half of the 6 materials, 0.1mm was the strongest and 0.2mm the weakest (t-test, 0.05, 0.1mm vs. 0.2mm PLA). PLA demonstrated the most brittle behavior (100% broke) while PETG was the most ductile (87% did not break). A ratio of tensile strength to time was defined, termed the efficiency ratio, to find the most efficient parameters for needed strength when considering print time. To provide a reference for future projects, this research characterized and analyzed materials by strength and relative ductility.

Abstract Name: **Digging Deeper: An Exploration of Supportive Strategies and Resources Faculty and Student Research Teams Deploy When Researching Emotionally Difficult Topics**

In higher education settings, cultivating high-impact research experiences led by faculty in partnership with students is of high importance. The collaboration between the two is very important in training the next generation of researchers as well as providing critical research experiences that can be carried into their professional endeavors. As universities continue to encourage more interdisciplinary research among faculty and students, special attention is needed to create supportive and relevant research collaborations. As a faculty mentor, to a team of undergraduate and graduate student researchers, I have been intentional in fostering such collaborations through experiences that include but are not limited to data collection, extensive mentoring, writing workshops, and methodological guidance and training. Further, given the nature of faculty and student collaborations, the focus of our research topics has evolved over time. Currently, we are researching grief in higher education to better understand the types of support and resources needed to address the emergent mental health concerns rising on college campuses in our student body. As the lead faculty researcher, I have been especially intentional in thinking through what types of support my student researchers themselves may need when engaging in the research of an emotionally laborious topic such as grief. As a team, we have identified key strategies that have been instrumental in providing the supportive structures needed to engage in grief and trauma-related research. This short talk will provide an opportunity to speak with other faculty who may be studying emotionally difficult topics alongside their student researchers and would like to learn some of the strategies we have deployed to protect the mental well-being of our student researchers while they are engaging in noteworthy investigations to expand the knowledge base in our field.

Abstract Name: **Socioeconomic Vulnerability and Environmental Inequalities: a Case Study of Climate Change Impacts in Egypt's Delta Agricultural Sector**

Egypt's Nile Delta has historically had a significant impact and drawn a sizable population because of its abundant resources and trading opportunities. The Nile Delta faces a significant risk of being severely damaged due to flooding brought on by extreme climate change. Temperature increases, unpredictable rainfall patterns, and increasing sea levels are some of the effects of climate change on these cities. When we start to look deeper at the impacts of climate change on different groups of people, a question begins to pose itself. How are the effects of climate change distributed, and is it proportional to the level of contribution to emissions? The objectives of this research are to identify the detrimental effects and threats of climate change on farmers in Egypt's delta agricultural sector and the vulnerability of farmers. A hybrid methodology and system mapping were used to accomplish these objectives. Farmers and other internal and external stakeholders, including professionals, government officials, and NGO representatives, were also interviewed. The results of this study show and prove that farmers in Egypt's delta region are highly vulnerable due to ineffective practices and weak and inadequate government communication. The study also demonstrates that households with lower incomes and less access to natural resources are more vulnerable to the risk of flooding and sea level rise. Income disparities and asset distribution at the community level tend to be greater at higher risk exposure levels, suggesting that households with higher individual vulnerability also have higher collective vulnerability.

Abstract Name: **Discovery and Extinction in a Biodiversity Hotspot**

Accurate species delimination and descriptions are a fundamental prerequisite for biological research. We are currently in the midst of the 6th mass extinction, with background extinction rates measuring 1000 times faster than species that the majority of life forms on Earth are facing. Conservation biology often aims to assess and protect existing biological diversity and is concerned with the sustainable use of natural resources over the long term. The assessment of biodiversity is the first step to the successful design of any conservation strategy. Identification of the organisms and the extent of morphological and genetic variability between them are the essential components of any biodiversity assessment. Amongst these, the identification of individual organisms via taxonomical and/or molecular means is vital for designing any conservation strategy. The patent leather beetle,Odontotaenius disjunctus and O. Floridanus,are easily recognized saproxylic (dead wood dependent) beetles with distributions extending across the eastern United States and restriced to the highlands of central Florida, respectively. recent studies inferred four well supported lineages that diverged during the Pleistocene and replaced each other geographically across the eastern United States. However, it has been shown that reliance on a single gene may be misleading because of asymmetrical gene flow, introgression, and other stochastic processes that affect mtDNA disproportionately. In this study, we use multilocus coalescent-based species delimination methods and multivariate analyses of morphological data to examine whether the phylogroups merit taxonomic recognition as species in light of multiple lines of evidence under the general lineage concept.

Abstract Name: Racial-Ethnic Identity and Academic Success B

There is immense discussion on what helps or hinders academic success. A person knowing who they are, no matter who, tends to know what they want and how to get it. This is not different in the academic setting. There are many different levels of understanding who we are within the culture from which we come. This study aims to connect several components of identity development with the resulting success in college. The aim is to see how the level of connection with one's racial-ethnic group, awareness of the perceptions by others and how one's racial-ethnic group is seen through the lens of academic achievement will impact the overall success in college. Other areas of interest in this study include college experience and how it impacts the motivation to attend classes and involvement in on campus activities connecting the student to the college leading to academic success. The final area that will be considered in this research is the level of college preparedness of the student and how the family or culture contributed to that preparedness. Correlational analysis will be completed through data collection in the spring semester of 2023.

Abstract Name: Cellular Model for Assessing Dermal Cell Response to Direct Soil-Arsenic Exposure as an Environmental Contaminant

Arsenic (As) is a carcinogenic metalloid with numerous routes of exposure. Exposure symptoms include gastrointestinal, neurological, and other health complications. The WHO and EPA have set exposure limits for air and drinking water. However, there are no guidelines for contact exposure. The baselines established in this research can serve as a springboard for safety protocols and establish guidelines for exposure via skin contact and provide insight into cell-As interaction. Conventional experiments studying environmental exposure use arsenic salts dissolved in water. This approach cannot represent the environmental conditions where the bioavailable Arsenic is affected by the soil conditions. Thus, the extraction of Arsenic from the soil is a crucial aspect.Therefore, As was obtained from soil samples using sequential extraction. Healthy Human Immortalized Keratinocytes (HaCaT) cells and healthy adult Human Dermal Fibroblasts (HDFa) cells were treated with four different concentrations based on 10-year accumulation of arsenic in soil (45, 225, 450, and 900 ppm of As), creating a cell model to assess arsenic exposure. In-cell Western/In-Cell ELISA was used to quantitatively assess cell responses. Preliminary data indicates that higher As concentrations lead to decreased cell proliferation and differences in cell migration among the cell lines tested. Higher concentrations of arsenic showed altered protein expression of Actin, CD44, and Zeb1, and displayed toxic effects. Arsenic uptake methods, localization of As within the cells, and long-term impacts of exposure will be explored to understand Arsenic uptake and cellular damage. The outcomes of this research will contribute to assessing damage from exposure to soil-As (high concentration or long-term exposure), provide guidance on exposure limits, and establish a safer environment for human settlements. These findings will create a better understanding of the hazards of exposure to heavy metals. The studies will inform new public health measures and provide guidelines for regulatory agencies.

Abstract Name: **Single-Hop Parallel Algorithm Comparison**

To address the need for high performance parallel communication algorithms for full-core nuclear reactor neutronics simulations, Idaho National Laboratory (INL) developed the Scalable Massively Asynchronous Ray Tracing (SMART) algorithm. This algorithm performs sparse communication of data structures while overlapping communication and computation, a key to achieving efficiency. This scalability study compared the computation time of 6 sparse data exchange algorithms in both strong and weak scaling experiments to determine the limitations of single-hop SMART algorithm; multiple single-hop algorithm parameters were independently scaled and analyzed. Extensive testing revealed the effectiveness and limitations of the single-hop SMART algorithm in both overlapping and non-overlapping communication models. Observed bottlenecks in single-hop implementation are discussed, and recommendations for further study are provided.

Abstract Name: **Role of Gap Junction Proteins on left-right axis development in zebrafish.**

Directional nodal flow initiated by motile cilia in the left-right (L-R) organizer of developing embryos is required for proper establishment of L-R asymmetry. Previous work in zebrafish has shown that morpholino knockout of the gap junction (GJ) protein, connexin43.4 (gjc4b), causes disruption of the L-R organizer, Kupffer's Vesicle (KV), and correlated randomization of L-R asymmetry (Hatler et al., 2009). Interestingly, Zygotic indel mutants of connexin43.4 (gjc4b) do not disrupt L-R development of the heart, but maternal zygotic mutants do. Here, we present phylogenetic analysis of proteins related to gjc4b and various approaches for generating mutant lines in these genes. Guides generated for injection of inconnexin52.8 (gjc1) and connexin47.1 (gjc2) use the Geneweld method for integrating acassette with a primary and secondary marker into an exon of this gene. Whole gene knockout guides were also generated for connexin44.2 (gjc4a.1) and it's tandem duplicate gjc4a.2 involving the deletion of both genes and the ~65kb region between them. Injection of a gRNA targeting gjc1,homozygous embryos for gjc4band mutated gjc1 caused defects in L-R asymmetry. This indicates that loss of function in gjc4b is compensated or has overlapping function withother related genes.

Abstract Name: **Addressing Body image in Child Actors**

Today's headline reads about another former child actor who was admitted for an eating disorder. The abnormally frequent occurrence of this challenged whether this was a consequence of fame, or if other external factors triggered concerns about body image. To address this curious pattern, I would like to ask and answer whether the history and experience of child actors can explain why these children could be at risk for developing severe mental disorders related to body image, such as eating disorders and depression. To understand how participation in the performing arts industry at a young age could influence future development, potential influencers of body image and self-concept in children are sought by looking at social comparison factors (such as relationships and social media). Additionally, to understand and apply the unique experiences of child actors to psychological well-being, their general psychology, testimonials, and origins are traced. While the investigation of this topic explains why former child actors are found at an increased risk for decreased psychological well-being, this does not mean direct involvement will cause psychological disorders related to body image during adult development. Given the high-stress nature of the performing arts industry, it is vital to consider how children generally respond to stress and use that information to equip them with the tools needed to adjust to adulthood.

Abstract Name: **Evaluating Plasma Vitamin A and E Concentrations in a Mature Horse Herd Housed in a Dry Lot or Pasture**

Vitamin A and E are adequately supplied to horses when they consume fresh pasture. However, horses in the Upper Midwest often become deficient during the winter months which can be detrimental to horse health. Considering the prevalence of deficiency has not been widely documented, this study aims to evaluate plasma vitamin A and E concentrations in the UWRF horse herd related to pasture versus dry lot housing conditions. Twenty-seven mature adult horses were used in the study. Thirteen horses were housed in a dry lot with hay-only access while fourteen horses had pasture access during the summer. All horses had access to a free-choice mineral and vitamin mix. Blood samples were taken in February (winter), May (spring), August (summer), and November (fall) and sent to Michigan State Veterinary Diagnostic Laboratory for analysis. Data were analyzed using PROC MIXED in SAS with significance set at P≤0.05. Adequate vitamin E was classified as 2.0 to 4.0 µg/ml and adequate vitamin A was classified as 175 to 300 ng/ml. In the winter and spring, 70 to 74% of horses were deficient in vitamin E with an average concentration of 1.83 µg/ml. Plasma vitamin E concentrations remained inadequate in dry lot horses in the summer at 1.43 µg/ml (P 0.05) while concentrations rose in pastured horses to 2.4 µg/ml (0.05). When evaluating vitamin A, 81% to 85% were deficient in the winter and spring, respectively, with an average concentration of 145 ng/ml. While pastured horses exhibited an increase in plasma vitamin A in the summer compared to dry lot horses (0.05), 64% of pastured horses remained deficient. These results demonstrate the prevalence of vitamin A and E deficiency in an Upper Midwest horse herd on a hay-only diet.

Abstract Name: **Race and Radon Hotspots are Correlated in African American Pennsylvanians with Racial Disparities in Lung Cancer Incidence**

Background Lung cancer has the 3rd highest incidence in Pennsylvania (PA). African Americans (AAs) have higher incidence rates than European Americans (EAs), despite smoking less. Radon is the second leading cause of lung cancer. Radon, race, and AA lung cancer incidence varies by PA county. The majority of PA counties are in EPA Radon Zone 1 (4 pCi/L), significantly elevatinglung cancer risk.HypothesisRadon exposure is correlated with higher lung cancer incidence in AAs compared to EAs in PA zip codes. MethodsCompared lung cancer incidence by race across three counties using PA Department of Health EDDIE Database. Selected PA counties with three largest cities according to the 2020 US Census. Used US Census Data Tools Advanced Search to tabulate every zip code and AA and EA population % by county. Integrated basement and first floor radon exposures by zip code from PA Department of Environmental Protection. Performed Pearson's correlation analysis for Variable A (zip code population by race %) and Variable B (first floor and basement radon levels).ResultsAAs had higher early and late stage lung cancer incidence across Allegheny, Northampton, and Philadelphia counties. Allegheny County (Pittsburgh City) had 113 zip codes (Radon Zone 1 zip codes: 9% AA, 91% EA), Northampton County (Allentown City) had 48 zip codes (Radon Zone 1 zip codes: 15% AA, 85% EA), and Philadelphia County (Philadelphia City) had 26 zip codes (Radon Zone 1 zip codes: 0% AA, 100% EA). In Allegheny and Northampton County zip codes, the AA population % can explain 33% and 31% of first floor radon levels (R2 = 0.33, R2 = 0.31). This correlation is significant (Allegheny: P = 0.004; Northampton: P = 0.01).ConclusionAAs living in Allegheny and Northampton radon hotspots should be targeted for lung cancer screening, early detection, and radon testing initiatives.

Abstract Name: **Exploration of Variables Associated with Reluctance to Speak in College Classrooms**

Controversial topics are important parts of discussion in many college classrooms. Due to the nature of these topics, students may feel reluctance in their desire to speak freely about them in an academic setting. Today, students may feel polarized as a reflection of the world outside of college campuses. The aim of this study is to explore the reluctance to speak about the controversial topics of gender, politics, race, religion, and sexuality. More specifically this study looks at what external forces may be influencing this reluctance. The Campus Expressions Survey is a nationally distributed survey created by the Heterodox Academy that asks students about their reluctance to speak about each of the five controversial topics. If they indicate that they are reluctant, they are then prompted with potential reasons for their reluctance to speak, which they answer with whether or not they agree with the statement. The sample consists of 207 UMR undergraduate students. A McNemar's Chi-Square test was used to analyze the results of the survey to determine if students were more concerned about criticisms from their peers, criticisms from their professors, or of their opinions being posted on social media. The results show that for the topics of Politics, Race, Religion, and Sexuality, students were significantly more concerned about their peers than about their professors or being posted on social media. This means that students are more concerned about how their peers perceive them directly than how their professors perceive them or how others perceive them online. This may be due to the fact that peers influence behavior more than professors and how social media affects in-person behaviors.

Abstract Name: **A Pilot Study Exploring Veteran Identity Using Lyric Analysis in a Qualitative, Community-Based Participatory Action Research Framework**

Researchers attempt to define what it means to be a Veteran, but it is rare for that question to be directly asked of Veterans. Traditionally, experimenters define variables and ask the community of interest (CoI) to provide responses without the CoI being included in the research process or reaping any direct benefit from participation. There is a high degree of distrust and disenfranchisement reflected in Veterans towards the mental health care system and the scientific community. We aim to use the CbPAR model to amplify their voices and focus on what is important to them. We are seeking to allow Veterans to define their identity in their own words. Researchers serve as messengers to help amplify Veteran voices and disseminate their stories to the larger community. In the current study, we asked Veterans to identify songs that answered the question, "What does being a Veteran mean to you?" This study is part of a larger research project using both photovoice and lyric analysis to help define the "sights and sounds" of Veteran identity. Veterans worked individually with researchers through the process of lyric analysis, which is a music therapy intervention in which the client and therapist listen to a song together and discuss the connection the lyrics have to the client's life experiences. Transcripts of interviews will be analyzed to uncover common themes and elements that help researchers understand how they conceptualize their community identity as Veterans. External validity is addressed through member checking, in which participants will review transcripts, discuss identified themes, and choose representative songs to present as a part of an immersive, interactive gallery experience for the community to allow for their stories to be told. We assert that more research should be done with the Veteran community, not to them.

Abstract Name: **Feeding the Spark of Creative Inquiry Through Community-Engaged Practices: A Developing Model**

Problem and Background: First-generation college students and students from lower socioeconomic backgrounds and under-resourced communities continue to report that socioeconomic and sociocultural pressures remain high and interfere with their ability to fully achieve academic success and prepare for a professional career. Some undergraduates become disillusioned and disheartened when they have limited financial ability or time to participate in unpaid extracurricular activities. Some undergraduates believe that students with greater financial means hoard university leadership positions and are over-represented on faculty research projects. Current evidence suggests that underrepresented undergraduate students can benefit from (a) individualized faculty mentorship giving strong support for applied learning, (b) academic support services that facilitate student-led initiatives for equity and inclusion, and (c) involvement in service-learning pedagogies that provide multiple opportunities to engage with under-resourced communities in efforts to "give-back" and bring new approaches to community problems. Proposal: This presentation proposes a developing model for undergraduate scholarship that is student-led and faculty-guided. This proposed model responds to students' wishes to serve as change agents and social justice advocates in local communities by combining what they experienced in their personal lives with what they learned in college. The model is grounded by evidence from discipline-based service learning and community-based research that suggests a more student-responsive model of learning that supports the expansion of participation of underrepresented undergraduates in creative inquiry. This developing model is based upon (a) two years of conversations with students who completed various community-based service projects, (b) three years of analyzing final reports from 975 total hours of discipline-based service learning in Augmentative and Alternative Communication (AAC), and (c) one retrospective pre-post AAC service-learning course outcomes analysis. This model may feed undergraduates' spark of creative inquiry and holds promise for advancing science in the sub-specialty field of AAC for and with underrepresented populations.

Abstract Name: **The Case for the Prioritization of Highspeed Rails in the United States**

The residents of the wealthiest (and most unwalkable) country in the world are relegated to 3 main modes of transportation: flying, driving, or underfunded public transportation. All modes have become increasingly inefficient and inaccessible in recent years. Projected increases in the US population indicate that we are creating mega-regions that will not prosper unless they can be freed from the stranglehold of highway and airport congestion. At the same time, the United States cannot build enough highway capacity or airport runways to meet demand. Highspeed Rail systems are far more efficient in land use than road and even air.The long list of benefits that come from Highspeed Rails ranges from decreasing our dependence on foreign oil to introducing the world's greenest form of transportation into the US ecosystem. This would transform our transportation to carbon-free which is an urgent task, and the single most important thing we can do to lessen the dangerous effects yet to come from climate change. Our country is in danger with many of our major cities located in low-lying land along our coasts. Most of our transportation and energy systems (powered by fossil fuels) continue to add to the climate problem by cranking out tons of carbon every day, locking in worse climate effects in the coming decades. The time for a Highspeed Rail initiative is no doubt here, we just have to be willing to act.

Abstract Name: **"FGF2 is Required for Early Morphogenesis of Bovine Vascular Endothelial Cells in the Angiogenic Process"**

When an injury occurs, there is a process of healing referred to asangiogenesis. Angiogenesis is comprised of a matrix of complexrebuilding from preexisting cells and contributes to the formation ofvascular endothelial cells (VEC). These cells are a crucial role in theprocess of angiogenesis. The main storage of adipocyte cells can befound in fat tissue which consists of mature adipocytes that aid in the regeneration of cells. In this quantitative study fat tissue from threeBrangus male cattle was collected and the mature adipocytes (MA) werethen isolated from the stromal vascular fraction (SVF)of the tissue. SVFwere cultured for 24hrto promote plate adhesion. MA were added after 24hr withfibroblast growth factor-2 (FGF2) polyclonal antibody (1:50or 1:100 dilution) or without antibody and cultured for an additional 24hr. Blocking endogenous FGF2 reduced (P=0.01) early morphologicalprogression of VEC in the angiogenic process.

Abstract Name: **Government Assistance Programs and Health Insurance Coverage in a Predominantly Hispanic Community in the United States**

How do government assistance programs affect the likelihood of having health insurance in the United States? Previous studies demonstrated that Hispanics are less likely to have health insurance than non-Hispanic whites. This study examines the relationship between government assistance programs—including the Supplemental Nutrition Assistance Program (SNAP) and housing and utility assistance programs—and health insurance coverage in a predominantly Hispanic community (El Paso, Texas). Our central argument builds on the policy feedback approach and emphasizes that government assistance programs free up financial resources for the consumption of private health insurance. Using data from an original representative survey and generalized linear models, we will estimate the effects of government assistance programs on possessing health insurance in El Paso. The empirical analysis will reveal the role that policy-based factors play in decisions to obtain (or not obtain) health insurance among Hispanics, and whether government assistance for food and housing propel recipients to acquire private health insurance coverage. The results will have important implications for public policy and public health, given the strong connection between having health insurance and positive health outcomes.

Abstract Name: **Developing Synthetic Methodology to Optimize a Series of Novel Anti-Malarials**

The human parasite,Plasmodium falciparum, kills nearly 500,000 people a year, with the most fatalities occurring in tropical areas that disproportionately affect sub-Saharan Africa. All clinical symptoms of the disease result from the intraerythrocytic development of parasite. During this part of the life cycle, the parasite expresses an array of proteases (enzymes that degrade other proteins) to carry out many essential processes, such as host cell protein degradation, host cell invasion, and parasite protein export. Previous studies developed a piperazine-based hydroxamic acid scaffold, and we are currently testing a diverse alcohol substituent at the N4 positions. We decided to use an array of alcohols since it is inexpensive, commercially available, and structurally diverse. To achieve this goal, we developed a synthetic methodology that uses shvo's catalyst for amine and alcohol coupling. Throughout the optimization, we determined that temperature, solvent, and equivalence of the alcohol, are factors for a good starting material conversion.

Abstract Name: **Panel discussion: Creating a developmental curriculum to build research skills**

In this panel discussion, moderated by Abby Hemmerich, four panel members will share examples of undergraduate research embedded across the curriculum and within individual courses. These examples will highlight principles of research woven through progressive courses in chemistry, psychology, kinesiology, and natural sciences, helping students build skills developmentally from their first year to graduation.David Durkin (co-author, Darion Isom) will discuss a series of integrated labs to grow research skills throughout the middle years of the chemistry major, culminating in an independent, problem-based learning project. Details about the final “Special Project” will be presented; this project requires students to utilize all of their skills to independently design the experiment, request materials, perform of the experiment, and write the research report.Nicole Depowski will present a case study of a psychology program with research introduced at the introductory level, integrated practice across the curriculum, and a capstone senior thesis project. Early exposure to scholarship focuses on locating and reading research, while students gain skills in research ethics and design at the next level. The third year requires use of primary sources, with synthesis and analysis, culminating in a senior thesis project in which students produce their own research.Brian Wallace will discuss the process for building evidence-based practice and research principles into the kinesiology curriculum to prepare students for graduate school or health and fitness professions. Changes to student engagement in research and outcomes related to faculty-mentored research will be discussed.Chimdimnma Esimai (co-author,George Ude) will present a series of course-based research experiences that engage a whole class of students in a research question or problem. Although individual projects are restricted to a single course, students experience multiple opportunities for these projects across the curriculum, providing complementary content and developmental progression in skills.

Abstract Name: **The Influence of Prior Exposure to Weapons on the Weapon Focus Effect**

The proposed study aims to further investigate if ownership of firearms decreases the weapon focus effect (WFE). When a weapon is present during the commission of a crime a witness is less likely to accurately remember details, specifically peripheral details, about the perpetrator’s appearance compared to when no weapon is present. It is hypothesized that having prior experience with weapons, through ownership, decreases the WFE compared to no prior experience with weapons.The proposed study will be a 2(Gun Familiarity: gun ownership vs. no ownership) x 2(Weapon Presence: present vs. absent) between subject's design. Participants will come to a lab in groups of 1-10. After receiving and signing an informed consent, participants will watch one of the two mock crime videos that are approximately 42 seconds in length. Both videos depict a mock robbery in the woods where a young woman carrying a backpack is approached by a man who robs her. The robber either only uses his words while holding a backpack to demand her belongings (weapon absent condition) or holds a rifle to demand her belongings (weapon present condition). After watching the mock crime, participants complete filler activities for 20 minutes. Then, participants complete a survey about what they remember about the perpetrators' appearance, select from a 6-person target-present line-up, rate their confidence for the selection, and complete demographic information. Students will be thanked for participating and community members will receive $10.00.The accuracy of participants descriptions will be calculated (total correct details/(total correct + incorrect details)).A series of 2X2 factorial ANOVAs will be used to see if Weapon Presence and Gun Familiarity affected the accuracy, the number of correct details, and the number of incorrect details reported. We expect that those who own firearms will have higher accuracy compared to those who do not own

Abstract Name: **The United Kingdom- A Future AI SuperPower's Effort to Mitigate Algorithmic Bias**

This research investigated the United Kingdom's role in addressing algorithmic bias. This type of bias is rampant in many different types of technology that the public uses, ranging from shadowbanning on social media platforms to facial recognition technology misidentifying non-white faces in public spaces. During the summer of 2022, data regarding algorithmic bias legislation, public opinion concerning legislation, and the history of algorithmic bias was collected from British government websites, articles, and three U.K.-based workshops focusing on artificial intelligence ethics and machine learning algorithms. With the data provided, a qualitative analysis was conducted on the legislative efforts made to contain algorithmic bias. Results showed that while the U.K. is making efforts toward countering bias, like implementing laws such as the General Data Protection Act of 2018 and the proposed Artificial Intelligence Act of 2021, current policies continue to be vague and difficult to understand. Significant revision to policies that address algorithmic bias is needed in order to prevent ethics washing and promote a more equitable outcome for all. This thesis concludes with recommendations of my own and from the Ada Lovelace Institute, a research institution based in the UK, to make practical use of algorithmic bias legislation.

Abstract Name: **Child Maltreatment and Adolescent Outcomes: Analyzing the Effects of Control and Learning Theory Variables as Mediators**

A number of studies have identified a strong relationship between a history of child maltreatment and later negative life outcomes, such as engaging in crime and delinquency. This study explores two potential mediating mechanisms from opposing criminological theories to promote our understanding of how this relationship unfolds. Social Bond Theory (Hirschi 1969) suggests that parental abuse and neglect results in weakened parental attachment, proposing that the weakening of an adolescent's social bonds removes constraints and allows the adolescent to engage in deviant acts. Differential Association Theory, on the other hand, suggests that early life experiences can influence individuals' self-selection into deviant peer groups and this, in turn, results in increased levels of crime and deviance (Sutherland 1947).Differences among adolescent outcomes are measured by self-reported delinquency, while using a binary measure of child maltreatment as the predictor. The effects of each mediator are analyzed using data from the "Adolescent Outcome of Physically Abused Schoolchildren'' study (N = 153) and the Pathways to Desistance Study (N = 1354). Preliminary results from a Poisson Model revealed that the relationship between child maltreatment and adolescent deviance is partially mediated by both intervening variables. Decomposition results suggested that the mediating effect of parental attachment was larger than that of peer delinquency.

Abstract Name: **I Am My Own: A Cross-Cultural Examination of Contradiction and Personal Identity**

The philosophical question of personhood seeks to define the essence of a person, and its potential answers have been explored by Eastern and Western traditions alike. However, the notions from the East and West oppose each other, revealing significant differences in their respective logic systems. Western logic excludes truths found in Eastern philosophy, creating a cross-cultural tension. This research argues that dialetheism, the view that there exist some true contradictions, proves more effective than classical logic in determining truth, thus presenting a solution to this cross-cultural tension. Firstly, the study presents an overview of the history of personhood, referencing Western philosophers, such as Socrates, Descartes, and Leibniz, and Eastern religious thought, including Buddhism and Taoism. Each region's claim is then translated into formal logic and viewed through the lens of classical logic, the logic system originating in the West. Classical logic utilizes the Law of Noncontradiction (LNC) which rejects all contradictions, yet Eastern perspectives actively employ contradictions, highlighting classical logic's inability to handle Eastern philosophy. From this point, this analysis argues in favor of dialetheism as an alternative logic system because of its ability to accept some true contradictions, and therefore, Eastern logic. The argument addresses common criticisms of dialetheism, analyzes formal logic within the personhood argument, and emphasizes the importance of context in truth. The research concludes by articulating the need for an inclusive standard of truth, which dialetheism upholds. Through the application of the personhood argument, this analysis asserts that both Eastern and Western schools of thought prove valuable.

Abstract Name: **Analysis of Cu2xZnxP2O7 towards Negative Thermal Expansion**

A variety of materials seen in ordinary life scenarios display the unusual behavior of negative thermal expansion (NTE), which is the counterintuitive physical phenomenon in which a material decreases in volume as heat is applied. Materials that exhibit NTE can act as thermal compensators when added to conventional positive thermal expansion (PTE) materials. This can allow for control of a material's size as temperature is varied, and can be advantageous for various fields trying to overcome the problems associated with PTE materials. Investigating the contributing chemical and structural factors that influence NTE in various structures will play a role in developing design principles that can be applied in rational design. These developed design principles may provide the ability to obtain desired thermal expansion properties like positive, negative, or zero thermal expansion in certain materials. Solid-state synthesis and structural characterization of the solid solution Cu2−xZnxP2O7 with varying x values is carried out to understand the effects compositional tuning and slightly positive chemical pressure have on thermal expansion. The results of the synthetic optimization of Cu2−xZnxP2O7 from $0 \leq x \leq 1.5$, its X-ray diffraction data, and Rietveld refinements will be presented to highlight the changes seen as the x value is varied.

Abstract Name: Examination of Listeria monocytogenes Protein p60 for Deubiquitination Activity

Listeria monocytogenes is a Gram-positive bacteria that causes the foodborne illness listeriosis. L. monocytogenes infection in mouse liver cells has been observed to lead to a decrease in ubiquitination sites. To determine if L. monocytogenes expresses secreted effectors responsible for this effect on host cells, previous work in the laboratory sought potential deubiquitinating enzymes and identified the protein p60 as a putative deubiquitinating enzyme. Deubiquitinating enzymes (DUB) remove ubiquitin from host and bacterial proteins to evade the host immune response. In order to assess whether p60 demonstrates DUB activity, we purified p60 and examined its DUB activity using a ubiquitin protein engineered with a tag that would fluoresce after being cleaved by a DUB. Our assay was performed at 25°C; 37°C at high (10μM) and low(0.1μM) p60 concentrations. We found that regardless of the assay conditions, p60 did not display DUB activity, in contrast to our positive control. Taken together, our study suggests that p60 either does not have DUB activity, that it could have weak DUB activity that was not detectable in this assay or could require a cofactor in order to cleave ubiquitination sites.

Abstract Name: In-silico Characterization of Potential SRF Inhibitors in HCT116 Colorectal Cancer

SRF (Serum Response Factor) is a transcription factor that is activated by growth factor stimulation and mitosis, leading to the expression of genes that influence growth and the cytoskeleton. Additionally, HOPX, which is associated with reduced cell proliferation and tumor suppression, inhibits the binding of SRF to DNA. Additionally, SRF in gastric cancer is associated with an aggressive phenotype and a poor outcome due to the downregulation of E-cadherin which promotes the epithelial-mesenchymal transition. Furthermore, in colorectal cancer, SRF is overexpressed in metastatic tissues, leading to increased cell motility and invasiveness. Based on this, we decided to look for potential SRF inhibitors. We are currently working with chemical similarity algorithms and clustering techniques, like Tanimoto similarity and UMAP, to determine SRF inhibitor candidates based on limited existing inhibitors. Those candidates will then be docked to the target using Autodock Vina. Molecules with high binding affinities will be tested for drug-induced liver injury (DILI) and toxicity in cells (DeepCDR). Furthermore AutoGrow, an open-source program which uses a genetic algorithm to 'evolve' known ligands based on binding affinity to the target, will be used for de-novo drug design. Preliminary results reveal several inhibitors with better binding affinities than our positive controls from the ChemBL dataset along with preliminary drugs from Autogrow with even better binding affinities. We anticipate that these drugs will eventually be tested in-vitro on colorectal cancer cell models, such as the HCT116 cancer cell line.

Abstract Name: A comparison of high- and low-powered pulsed electromagnetic field therapy (PEMF) equipment on mechanical nociceptive thresholds and behavior in horses

Evaluating components of stress or discomfort is an important step when working with new modalities of therapy equipment involving animals, in this instance horses. This ongoing study will be using behavioral and factors involving mechanical nociception to evaluate and compare both pulsed Electromagnetic Fields Therapy (PEMF) and Bio-Electro-Magnetic Energy Regulation (BEMER) therapeutic modalities. Eight horses over a period of eight weeks will be used in the University of Wisconsin River Falls equine herd that have never been exposed to either stimulus before. Intensity of stimulus will be dependent on each horse's individual needs. Prior to the initiation of treatments, a baseline mechanical nociceptive threshold (MNT) will be taken along 8 locations of the dorsal aspect of the thoracolumbar region. Pressure will be applied using an algometer until an avoidance response is observed, this could include moving away from the applied pressure, skin twitching, or localized muscle fasciculations. Horses will be randomly assigned to a treatment order. Magna wave will be applied every other day for 30-minute sessions on the front, middle, and hind region of the horse for 10-minutes in each section. BEMER will be applied twice daily for 3 consecutive days. On the first day the application will last 5-minutes for both sessions, the second day both applications will last 10-minutes, and on the final day applications will last for 15-minutes. During each treatment session, behaviors will be documented including licking and chewing, sighing, yawning, lowering of the head, decrease in locomotion, and a decrease in pawing. Following the last treatment session a post MNT will be taken using the procedure described above. After data has been collected for the first 4 weeks, horses will be switched to the opposite treatment. All data will be analyzed via a crossover study where statistics will be run at 0.05.

Abstract Name: Spirituality as a Buffer Between Traumatic Experience and Posttraumatic Stress

According to the American Psychiatric Association, trauma can be defined as exposure to actual or threatened death, serious injury, or sexual violence, involving direct exposure, etc. As a result of experiencing trauma or a traumatic event, it can lead to symptoms consistent with a formal diagnosis of PTSD. PTSD can then arise from stressful events or situations “of exceptionally threatening or catastrophic nature, which is likely to cause pervasive distress in almost anyone” (WHO, 2016). Anxiety buffer disruption theory (ABDT) suggests that posttraumatic stress disorder (PTSD) is a result of the disruption of one’s anxiety-buffering mechanisms. This disruption can lead to overwhelming emotions, hyperawareness of one’s mortality, and wide-ranging reactions to traumatic events. However, the anxiety-buffer system mitigates the effects of potential terror, promotes posttraumatic growth (PTG), and is comprised of three components: cultural worldviews (e.g., spirituality), self-esteem, and social support. In some cases, depending upon the threshold of the PTSD, traumatic experiences can lead to one experiencing a spiritual awakening. A spiritual awakening is a term given to describe a subjective experience in which an individual’s ego transcends their ordinary, finite sense of self to encompass a wider, infinite sense of truth or reality (James, 1902/1985). Moreso, it has been seen recently within research that although trauma has been experienced there is still a relatively low prevalence of PTSD in some due to “natural resilience”, often related to a survivor’s spiritual resources (Feurerstein, 1989; McClintock et al., 2016). A sample of N=300 individuals with above-threshold PTSD symptomology (PCL-5 scores 34) will be recruited via a research panel to examine the relationship between spirituality, PTSD symptoms, and posttraumatic growth. Thus, we expect that individuals who have experienced a traumatic event and who report higher spirituality will report lower PTSD symptoms and exhibit higher posttraumatic growth.

Abstract Name: **Development of Antiviral Peptides as Therapeutic Leads Targeting the Spike Protein of SARS-CoV-2**

Despite widely available vaccines, the potentially fatal disease Covid-19 remains pervasive throughout the world. Moreover, emerging variants of the virus can evade acquired immunity, leading to a persistent healthcare crisis. While some medications have received emergency approval, small molecule drugs have low target specificity and potentially high toxicity. Large biomolecules are designed to overcome these challenges as they are highly target-specific and show less toxicity. Because of this, peptide therapeutics are gaining increasing popularity as they are easy to synthesis, highly selective, and have fewer side effects. The causative agent of Covid-19 is SARS-CoV-2 which is a positive-sense single stranded RNA (ssRNA) virus. This virus translates four structural and many non-structural proteins. One of the most important structural proteins is the spike (S) protein which allows the virus to attach itself to the host cell surface by interacting with human angiotensin-converting enzyme-2 (hACE2). Recently, our group computationally screened over 700 antiviral peptides, that were known to work against SARS-CoV-1 and other viruses, targeting the spike protein. Several candidate peptides were chosen from the computational screening. These peptides were synthesized using standard Fmoc-based synthesis protocol, characterized by mass spectrometry, and assessed in a competitive ELISA to determine effectiveness at disrupting the formation of the Spike-ACE2 complex in-vitro. Peptides AH33, AVP1701, P1, and P2 had their inhibitory effectiveness determined to be 40%, 13%, 8%, and 8% respectively at 100μM. AH33 was the strongest lead peptide due to it achieving an inhibitory effectiveness of 30% at 20μM. These results suggest that further development of peptide-based antivirals targeting the spike protein of SARS-CoV-2 could yield effective therapies for Covid-19 treatment.

Abstract Name: **A Pilot Study Investigating Veteran Identity Using the Photovoice Technique in a Qualitative, Community-Based Participatory Action Research Framework**

Veteran identity has been defined as a Veteran's self-concept that derives from their military experience within a sociohistorical context. Reintegration into civilian life can be difficult, experiencing a "reverse culture shock" that can negatively impact many interpersonal relationships and result in experiencing negative feelings such as helplessness, isolation, and emotional disconnection. Understanding how Veterans define themselves in their civilian lives can give us insight that could bridge the gaps between them and their available support systems. We utilized a qualitative, community-based participatory action research (CbPAR) model where Veterans are empowered to use their voices to tell their stories and researchers serve to help communicate their stories to the community. We are using the photovoice technique where Veterans take pictures that represent the answer to the following prompt: What does being a Veteran mean to you? This study is part of a larger project using photovoice and lyric analysis to help define the "sights and sounds" of Veteran identity. Our Veterans will then be interviewed individually where they are asked questions to help the researchers understand the symbolism of the images relating to the prompt for them. Transcripts of the interviews are being analyzed to uncover common themes and elements that represent a definition of Veteran identity. Preliminary results of these analyses will be discussed after completion of our member-checking process, which helps establish external validity within the community. Our next aim is to present the images and our results in an immersive, interactive gallery experience to allow for the Veterans' stories to be told. We argue that without more emphasis on qualitative, CbPAR methodologies, research with special and/or marginalized populations, like Veterans, will continue to be more exploitative than beneficial and will further reinforce the distrust in scientists and clinicians already experienced by many in these populations.

Abstract Name: **TRENDS AND VARIATIONS OF NO2 POLLUTION (2005-2019) OVER TEXAS: VIEW FROM THE GROUND AND SATELLITE**

Nitrogen oxide (NOx = NO + NO2) is a widely occurring air pollutant that impacts atmospheric chemistry and human health. NOx is formed from various sources, such as lightning, vehicle emissions, and various geological activities. In this study, we present the NO2 variations and trends from 2005 to 2019 over Texas using measurements from an Ozone Measuring Instrument (OMI) abroad, the NASA Aura satellite, and compare with in situ surface NO2 measurements from US Environmental Protection Agency (EPA) Air Quality System (AQS) network. Both OMI and AQS datasets display distinct emission reduction rates from 2005-to 2020, including the COVID-19 lockdown.

Abstract Name: **Real-Time Shape-Changing DNA Origami**

DNA origami is the art of folding DNA molecules into prescribed nanostructures that may be used as nanocarriers for various applications such as drug and vaccine delivery. These DNA origami structures are assembled with two different types of DNA strands: one long single-stranded DNA scaffold strand, and several short oligonucleotides, called the staple strands. While there have been many advancements in this field, with notably the synthesis of actuatable nanoparticles, little is known on how to design shape-changing DNA origami. This type of structure could be used to trigger specific biological mechanisms by releasing or presenting biomolecules upon specific stimuli such as pH, biomolecules (e.g., RNA or cytokines), or temperature. This research focused on applying DNA origami design concepts to construct multiple DNA nanoparticles with the same single-stranded scaffold strand. These nanoparticles would only have a few variations in the staple strands used to allow quick shape changing by replacing only a few strands. Complex structures of DNA nanoparticles can be assembled with multiple smaller origami structures that act as building-blocks pieced together and can be reorganized to provide fast shape-changes. As such, before designing the final nanoparticle structures in TIAMAT, a tetrahedron was designed to serve as their building-block, allowing for a more cohesive build and transition between each nanoparticle. Through this method, two different nanoparticle structures were designed, each containing three of the tetrahedron structures: a triangular structure and a crescent structure. Both were made using the same 1,632 nucleotides scaffold strand, demonstrating that designing multiple structures from the same strand is possible. This allows for a better understanding towards the development of real-time shape-changing DNA origami, and the designed structures will be folded to observe their ability to transform from one shape to the next, using strand displacement as proof of principle for the occurrence of shape-changes.

Abstract Name: **Representation of Afghan Women in Western Media**

My journey for this research project started within a Literary Method class in the Fall of 2021 as I watched Chimamanda Ngozi Adichie's ted talk on "The danger of a single story" for the first time. Listening to her speech and hearing how she was personally affected by the projection of "different variations of a single story" in western literature and mainstream media about Africa and how it had limited the understanding and imagination of the people she interacted with when she came to the US as a college student, was an eye-opening moment for me to understand some of the interactions in the American society. The repetitive line of questioning about Afghanistan's Security, the Taliban, and my English Proficiency are a few of the many examples that signify the existence of a single story for an Afghan woman. In the last two decades, after 9/11 and with the United States' involvement in Afghanistan, the western media has been active in showcasing stories about Afghanistan, especially the ups and downs of life for Afghan Women. The United States government used the restoration of Afghan women's freedom and rights as part of its rhetoric to justify invading Afghanistan and overthrowing the Taliban's government at the time. From the cover of National Geographic highlighting Afghan women wearing a Blue Burqa showcasing the restrictions on "The Right to Fashion in the age of terrorism" to the front cover of Times magazine with an Afghan women's mutilated face, are variations of a single story that depict the challenges of women in that part of the world yet limit the understanding of Afghan women to just their challenges. In this research, I will focus on exploring variations of a single story in the case of Afghan women and ways in which it can be dangerous.

Abstract Name: **A mathematical perspective of Utilitarianism with emphasis on the ethic of social media**

This research focuses on a discussion of Utilitarianism from a mathematical perspective. The language and rigor of mathematics are used to create a representation of the essential aspects of this philosophical doctrine which, in the own words of its most important proponents, Bentham and Mill, states that societies ought to cause "the greatest amount of good for the greatest number." The purpose of this study is to develop an axiomatic framework for a more accurate treatment (from the perspective, language, and rigor of mathematics) of these topics. In spirit, the independent contributions of Hutcheson and Bentham are the most significant influences of this work, as the former proposed some mathematical algorithms intended to quantify the morality of actions, thus establishing the fundamental basis for the hedonic calculus of the latter. The ideas of ethic philosophers like John Gay, David Hume, and William Paley, have as well been valuable influences in our study. We pursue to expound on a system of measures that serves to gauge the overall happiness of a society, according to the definition of happiness given, which, particularly, prepares the ground for making comparisons among certain societies at specific instances of time. Additionally, because social media constitutes a significant part of modern life, we will exemplify our notions relevant to utilitarianism through the domain of social media. Especially, we consider Facebook as a society (according to our definition) and evaluate the implications, under the utilitarian lens, thatthis virtual network with its rules, tendencies, and interactions have for the rest of the world.

Farmer, Avery

Abstract Name: **Political Alignment and Activism of Free Black Men in Post-Revolutionary New York (1790-1830)**

The American Revolution turned a colony into an experimental sovereign nation with new ideals inspired by Lockean philosophy, the chief amongst them being freedom. Paradoxically not all Americans were free, black peoples in America posed an interesting question as to how this new form of democracy and rights laid out by the Constitution would apply. Northern states beginning in 1780 began to emancipate slaves, unsure what their role in the American political life would be. However, New York which grew to become the largest urban mecca in the United States was reluctant to emancipate slaves while hosting some of the largest freemen communities. The period known as the Early American Republic between 1790 and 1830, for this paper's purposes, in New York was a microcosm for how freemen fit into the American equation of citizenship and political power. Uncovering the stories of freemen in New York during this time and their role in creating progress towards equality is a key tool in understanding the American identity.

Abstract Name: **Viability of Trypanosoma cruzi in RBCs at cold storage temperatures**

Chagas disease (American Trypanosomiasis) is caused by the protozoa Trypanosma cruzi. Chagas disease affects approximately 10 million people in Latin America, manifesting in pyrexia, malaise, splenomegaly, and cardiomyopathies. T. cruzi is commonly spread through the infected feces of the 'kissing' bug. After insect bites, blood transfusion is the second most frequent mode of transmission. The Center of Disease Control (CDC) estimates in the US, around 300,000 individuals are infected with T. cruzi, causing a considerable disease burden. The goal of this research will be to study the viability of T. cruzi in packed red cell aliquots stored at various cold temperatures to study parasitemia. If successful, storage of packed red cells in cold temperatures will show reduced viability of infectious T. cruzi; creating a simple adjustment to current prevention methodologies furthering the reduction of transfusion-transmitted American trypanosomiasis. Warming temperatures can shift the distribution of triatomine insects, allowing the spread of the disease to non-endemic areas such as the United States as climates become more favorable. Pollution, insecticide resistance, and tourism are additional factors that may contribute to this threat. Means to prevent trypanosomiasis from blood products will become pertinent with this change. Routine screening of blood-donors using a questionnaire has reduced the incidence of contracting trypanosomiasis in non-endemic areas. Serological testing is not mandatory outside endemic areas because it is suspected that the number of T. cruzi-infected donors is small, and screening each donor would not be cost-effective. Although the questionnaire has been effective, it fails to screen asymptomatic carriers resulting in transfusion-transmitted infections.To mimic organ-donor tissue, cultures stored at low temperatures have shown a reduction of trypanosomes. Past research has explored cold storage on the viability of Babesia in blood bags. Minimal research has been conducted on the viability of T. cruzi in blood stored at cold temperatures.

Abstract Name: **Investigating the Effect of Varying Biochars in Controlling Seedling Root Rot in Soybean Plants Inoculated with Pythium sylvaticum.**

Pathogenic fungi and fungal-like organisms can greatly damage soybean yields leading to economic and social consequences. One possible solution is the use of biochar in mitigating the effects of these pathogenic organisms. An important waterborne pathogen to soybeans is Pythium, which causes root rot in young seedlings. We hypothesized that if we vary the types of biochar added to soil infested with Pythium sylvaticum, the soybean plants will have varying degrees of root rot depending on the presence and source of the biochar. Different biochar source materials lead to differing structure, which can change the way water is held in the soil and possibly mitigate the spread of the waterborne P. sylvaticum. Our secondary hypothesis is that the biochar with higher volumetric water content will have more severe root rot. We will test four different biochars from different sources. Each biochar will be added to pasteurizedsoil and soybean plants will be grown, in cups, in these amended soils. For each of the four biochars, there will be 10 replicate soybean plants inoculated with P. sylvaticum and 10 plants without P. sylvaticum. There will also be a control group in which there will be no biochar added with 10 replicate soybean plants inoculated with the P. sylvaticum and 10 with no pathogen present. We will use soil moisture probes to measure volumetric water content. Approximately threeweeks after emergence, the seedlings will be removed, roots will be washed, and we will record % root rot, root length, root dry weight, and shoot dry weight. After obtaining the data, it will be analyzed through SAS to look for statistically significant relationships between biochar, soil moisture, and seedling root rot. This research offers a potential alternative to fungicide to enhance agricultural productivity.

Abstract Name: **The Accuracy of Gluten-free Labeling in European and Middle Eastern Food Products Compared to Samples from the United States**

Gluten is a protein complex found in wheat, barley, and rye, and even in foods that do not normally contain these grains. Previous work in this lab has shown that 29.8% of labeled “gluten free” products made in the United States (n = 248) have significant amounts of gluten in them (20 ppm). The current study was designed to investigate the reliability of “gluten-free” food labels in the international consumer marketplace. This research helps to inform and potentially caution those with gluten intolerance, especially with Celiac disease, to avoid gluten cross contamination and be skeptical of the gluten levels in food products advertised as “gluten-free”. A total of 49 samples labeled “gluten-free” were obtained from grocery stores in Europe and the Middle East; samples were manufactured in 18 countries there. A Nima Gluten Sensor (antibody based colorimetric assay) was used to determine if gluten content was <20ppm, the maximum allowed by the European Commission and local Middle Eastern countries, for a product labeled “gluten free”. Of the 49 samples tested, 41 of them were confirmed to be “gluten free” (0 ppm), with only 8 (16.3%) having significant levels of gluten. When European and Middle Eastern samples are compared to those from the US, it appears that the food from these countries are more accurately labeled than in the United States; the percent of samples with measurable gluten is approximately half of that for products produced in the US. While gluten-free labeling can be trusted in most cases, the risk of cross contamination with gluten is still possible and continues to pose some risks to those who are gluten intolerant.

Abstract Name: **Radiation dose studies in fruit flies with 350keV electrons**

The effects of beta radiation on fruit flies (Drosophila Melanogaster) were studied using the Applied Nuclear Science lab AN400 accelerator modified for electron acceleration and extraction. Dose-dependent effects up to 800 Gy have been observed, with significant effects well below the LD-50 dose for 2-day old larvae. These effects include reduced larvae and aborted development to adulthood. The goal of establishing a population of viable adults in samples showing clear radiation dose effects to study inherent radiation resistance has now been met. The data gathered in the process of this experiment will be used to further calibrate the accelerator for future research.

Abstract Name: **The Effects of Anxiety on Vision Related Performance Among Collegiate Athletes**

Anxiety is an intense feeling of worry or fear and can often be overwhelming, taking over someone's everyday activities. Often times, individuals who have feelings of anxiety or are in stressful situations that are anxiety-inducing, they can get physical symptoms such as increased heart rate, sweating, fatigue and rapid breathing. Anxiety can also affect an individual's quality of vision. In circumstances that are highly stressful, individual's vision can start to diminish temporarily, affecting the peripheral vision as well as making central vision blurry. This study examines the effects of anxiety and vision quality on athletic performance among collegiate athletes. It compares the impact of being in stressful situations among athletes with and without vision disorder during athletic events. By conducting a study focusing on collegiate athletes and non-athletes at the University of Central Florida and comparing their anxiety levels, as well as any changes in their eyesight/perception, we can assess the association between stress and eyesight, and whether this correlation has an impact on their performance. The objective of this study is to assess a potential relationship between athletes' performance, with and without vision-related disorders, during highly stressful situations. 31 participants, both male and female, between the ages of 18-27 participated in this study. Using UCF Qualtrics and incorporating the State-Trait Anxiety Survey into an online modality was sent out to all student athletes. By comparing the data collected in SSPS and One-Way ANOVA, there was no significant data between the variables of what sport they played, the type of refractive errors they have, if they wear corrective lenses, and the anxiety they experience during stressful situation.

Abstract Name: **Synthesis of Lanthanide-Binding Peptides and Cyclical Absorption/Release Strategies**

Lanthanides are metals widely used in the production of technological components. Lanthanides do not occur naturally in the US, and we are dependent on the import of these metals for use in a variety of economically important applications. Meanwhile, disposal of lanthanides represents an environmental concern. We aim to address both concerns by recovery and separation of lanthanides from industrial waste streams. In this poster, we present the synthesis of solid supported lanthanide-binding peptides using solid phase peptide synthesis techniques. We present progress toward establishing their coordination selectivity and efficacy, pH dependent binding, and reusability.

Abstract Name: **Skunked.**

Skunked is a story about darts. I started writing the script almost two years now in my script writing class. It was during both the height of the pandemic, and the middle of winter, So I was able to dedicate a lot of time to wriitng this story. It was designed to be the type of project I could realistically shoot once I was finished, or close to finished with college. Alot of me and my colleagues are enraptured with high concept sweeping cinema and we all really want to learn how to produce that kind of stuff. But I wanted to actively seek out a subject matter that could be realistically produced in a college town in north Wisconsin, on a college budget. And that lead me to movies like Better Luck Tomorrow, Lock, Stock and Two Smoking Barrells, and Dodgeball: A True Underdog Story. All these movies are low scale stories without much in way of grandiose spectecale. I wanted to capture the youthful complexity of Better Luck Tomorrow and the special blend of drama and comedy that movie brought. I wanted to aim for the quick wit and sharp direction of a Guy Ritchie move like Lock, Stock. Finally the absurdism of dedicating a feature length movie to a game nobody cares about came from Dodgeball. I was able to experemint with this style and tone last semester with Folded, a spiritual prequel and proof of concept for Skunked chronicalling a poker game. And now I have the oppurtunity to shoot an exert from my script this semester and hope to share it with others. Skunked started as a goofy idea but morphed into a story of freindship, finding confidence, and making your mark before its too late. Hope you all are interested in the final product.

Abstract Name: **Impact of Sugar Substitutes on the Metabolism of Probiotics**

Non-nutritive sweeteners are commonly used in a variety of food and beverage products. They are primarily used to manage weight loss and diabetes by preserving a sweet taste without increasing calorie intake. While non-nutritive sweeteners are generally thought to be harmless, there is considerable evidence that they contribute to metabolic dysfunction and can impact body weight, glucose tolerance, hunger, and taste sensitivity. We investigated the influence of non-nutritive sweeteners (aspartame, mannitol, saccharine, stevia, and sucralose) on the metabolism and growth rates of Bifidobacteria sp. and Streptococcus stearothermophilus. The two microbes (Bifidobacteria sp. and Streptococcus stearothermophilus) were grown in five different sugar substitutes in a litmus milk medium. The cultures were incubated and checked repeatedly for growth. After 48 hours of incubation, aspartame, stevia, saccharine, and sucralose showed an increase in metabolism and growth. However, in Mannitol, Streptococcus stearothermophilus metabolic activity was similar to the control group when compared to the metabolism and growth of Streptococcus stearothermophilus that was cultured in glucose. In Bifidobacteria sp. cultured in aspartame, saccharin, and stevia showed a decrease in metabolism when compared to Bifidobacteria sp. cultured in glucose after 48 hours of incubation. The metabolism of Bifidobacteria sp. in mannitol was increased after 48 hours of incubation, while sucralose did not affect the Bifidobacteria sp. metabolism. In conclusion, our findings reveal that non-nutritive sweeteners can alter the metabolism of Bifidobacteria sp. and S. stearothermophilus.

Abstract Name: **Risk Factors for Suicidality in Black American Youth: A Narrative Review**

Objective: The purpose of this study was to identify risk factors of suicide ideation and suicidal behavior in black American youth.
Background: Research has shown that school aged and pre-adolescent black youth in America have higher rates of suicide deaths than their white counterparts. It is a leading cause of death in black youth in the 10 to 19 year old age group. Alarmingly, black American youth as young as 5 years old have shown trends of increased suicidality, but the risk factors and the causes driving this trend remain largely unknown.
Methods: The database searched was PubMed. The search terms used were “risk factors” AND “black youth” AND “suicide”. The search yielded a total number of 386 results. Of those, only 30 articles were eligible to be used in this review.
Evaluation: Several risk factors were commonly identified among the studies included in this review. Most of the articles noted an association between poor parent-child relationships or a complete lack of a quality parent-child relationship and increased suicidal ideation and behavior. Socioeconomic disparities, such as access to quality education and safe spaces, as well as historical disparities also played key roles as risk factors for black youth suicide attempts.
Conclusion: More research will need to be done on this topic to determine exactly how we can reverse these rising trends in suicidal ideation and behavior in black youth. However, by addressing and removing disparities, we can create situations of equity, potentially resulting in a downward trend to the disproportionate rates of reported suicidal ideation and attempts for black adolescents in America.

Abstract Name: **Political Divide**

The current political climate in the US is more than contentious. The current state of the us verses them attitude divided along the political lines is ever worsening. What information is fact and what is political rhetoric? How can the divide be bridged? What are the potential dangers of such a divide in a powerful country? This research is designed to study how the political attitudes across the US are shaped by unfriendly dialog and news media bias. The goal is to understand how the varying forces around the political disconnect predict the perspective of adults in the US. This research will focus on political knowledge, willingness to connect with people of differing views, commitment to current political views, and news seeking behaviors when identifying underlying reasons for the unwillingeness to accept others with different viewpoints and what can be done to mediate the negative behaviors creating an even wider divide between the groups. How does having friends with widely different political views impact inter-political discourse? What communication skill sets can be cultivated to foster necessary listening and dialogue techniques? Data analysis will be completed in the spring semester of 2023.

Abstract Name: **Modeling Cannabinoid Withdrawal With Anxiety and Depression-Related Behaviors in Long Evans Rats**

Cannabinoid withdrawal plays a role in maintaining the use of a drug, thus influencing a substance use disorder (SUD). The symptoms associated with withdrawal in humans, including depression and cravings, interfere with efforts to achieve cessation of drug use. I will characterize the behavioral profile of cannabinoid withdrawal in rats using models that measure multiple endophenotypes of cannabinoid dependence that may contribute to withdrawal and craving. Initial studies will be performed using adult male and female Long Evans rats receiving twice daily infusions of the synthetic cannabinoid agonist WIN55,212-2 or vehicle via jugular catheter starting at 0.2 mg/kg and increasing to 0.8 mg/kg over 4.5 days. This model produces dependence such that somatic signs of spontaneous withdrawal are observed. Here I used open field, marble burying, and elevated plus maze to measure anxiety related behavior and sucrose preference, forced swim, and the social novelty test to evaluate depressive-like behavior following spontaneous withdrawal for 1 or 2 weeks (between-subjects). The open field test and elevated plus maze are measures of exploratory nature. Marble burying measures repetitive and anxiety like behavior. The sucrose preference test is a measure of anhedonia, the forced swim test measures behavioral despair, and the social novelty test measures sociability of a rat. I expect to see an increase in depression and anxiety-like behaviors in rats treated with WIN55,212-2 and spontaneously withdrawn in comparison to the vehicle group. By solidifying the relationship between depression and anxiety and withdrawal from cannabis, I hope to better understand the influence of these symptoms of withdrawal on craving and relapse.

Abstract Name: **Synthesis of Substituted Isatins as Potential Antibacterial Agents**

The decline in the development of new antibiotics, combined with their over prescription against bacterial pathogens, has resulted in an increase in the antibiotic resistance cycle and accounts for much of the hospitalized-infection rates. Therefore, this represents an urgent health priority in the synthesis of novel antibiotics. Our research focuses on the expansion of substituted indole-1H-2,3-dione derivatives, most commonly known as isatin. Isatin is a heterocyclic compound with significant synthetic versatility for its highly reactive C-3 carbonyl group and N-1 amino group, whose derivatives can serve as a precursor for potential antibiotics and pharmaceuticals. The unique properties of isatin's structure lend it to perform a broad variety of structural modifications to synthesize structurally diverse derivatives and yield a large spectrum of biological activity that are dependent on the substituent properties. Many of the synthetic routes involve substitutions at positions C-3, C-5, C-7, and N-alkylation reactions. Previous studies have observed the greatest antimicrobial activity when substituting electron-withdrawing groups at the C-3 and C-5 positions due to the increase in the overall lipophilic character to facilitate transport across the hydrophobic membrane. We synthesized a library of substituted isatin derivatives to investigate how substitutions on the C-3 carbonyl and the bromination of the aromatic moiety at the C-5 and C-7 positions can affect the antibacterial properties. These derivatives involve Henry reactions, Grignard reactions, Hydroxyalkylation, and Schiff base formations through modifications on the C-3 carbonyl of isatin, 5-bromoisatin, and 7-bromoisatin. Each compound's identity was verified through NMR to ensure the success of the synthesis. We have successfully synthesized and identified 13 isatin derivatives, with product yields ranging from 51% to 90% yield. The synthesized compound library will be screened against E. colito measure the potential antimicrobial activity.

Abstract Name: **Undergraduate Researchers Activities and Autonomy: Strategies for Tracking and Assessing Student Engagement**

Empirical research has outlined the benefits and outcomes associated with engagement in undergraduate research broadly (i.e., student retention and persistence, intention to pursue post-baccalaureate studies, university belongingness). Fewer studies have aimed to understand students' research activities and the degree of student autonomy anticipated with sustained engagement in undergraduate research.
To better understand the research activities of students participating in the Research Apprenticeship Program (RAP), a two-semester multi-disciplinary research experience for underclassmen, biweekly reports were developed to track student engagement and activities. In reports, students provided narratives of their weekly research activities and reflected on beneficial tasks. Initially, biweekly reports served as a useful programmatic tool for administrators to ensure students were regularly participating in research as required by the program. While still a useful programmatic check-in, additional assessment of students' self-reported text data within biweekly reports provided rich descriptions of student activities and learning across time. To understand a) what day-to-day activities students were engaging in and b) how those activities may have changed across the duration of the two-semester program, we utilized a mixed-method approach. Specifically, we applied a topic modeling algorithm (HDBSCAN + tSNE) and conducted qualitative content analysis to understand how student activities and autonomy changed over time. Results from qualitative analysis were used to supplement and inform the output of topic models to provide an overview of student activities across time.
The aim of the current presentation is threefold. First, we will provide an overview of the biweekly reporting system for tracking and assessing undergraduate research participation. Second, based on the results of our mixed method analysis, we will report activities students engaged in and how they shifted across time. Third, we will outline resources and approaches that may be utilized for assessing text-based data at other institutions.

Abstract Name: **SYNTHESIS AND ISOLATION OF CANNABINOIDS**

The Cannabis plant produces a variety of molecules that interact with the human endocannabinoid system. These molecules, named cannabinoids, are drugs with many benefits ranging from pain relief to appetite stimulation. The most popular cannabinoids currently used for medicinal and recreational purposes are Δ9-tetrahydrocannabinol (Δ9-THC) and cannabidiol (CBD). These two substances are the primary cannabinoids found within the cannabis plant, but there are many more cannabinoids that can provide possible therapeutic benefits that occur in minor quantities. One of these cannabinoids, cannabinol (CBN), has promising potential as a sleep aid. Our project aims to find a unique method for creating synthetic CBN from CBD in high yield and isolation efficiency. If such a method could be derived, it could be applied to industrial settings, specifically within the hemp industry, to provide more CBN of higher quality to the general market at lower costs. Our project will compare existing synthetic routes to CBN to our own. Our synthetic route begins with CBD as it's readily available in large quantities within the hemp plant. We then use existing methods of converting CBD into Δ8-THC at a high yield. After this intermediate step, the Δ8-THC is finally converted into CBN. The last step requires a workup and efficient isolation of our product.The current isolation method used is column chromatography, but we intend on experimenting with thermomorphic systems to improve efficiency.

Abstract Name: **Characterization of novel genes that mediate serotonin-dependent effects on behavior**

Brain-targeting drugs and their actions have been an intensive area of research as potential therapeutics for neurological disorders. Despite the use of an array of pharmacological therapeutics for targeting neurological mechanisms associated with depression, understanding of the mechanisms underlying these processes and the exact targets of each drug is still not fully understood. More recently, there has been a focus on understanding novel mechanisms that mediate modulatory effects from key biogenic amines including serotonin, neuropeptides and electrical junctions in mood, emotion and reward. We are currently investigating the effects of serotonin on intracellular pathways and sensori-motor networks. We use Caenorhabditis elegans, to investigate the effects of serotonin on key worm behaviors utilizing genetic mutants that lack gene families encoding neurotransmitters, neuropeptides, intracellular signaling and electrical junctions for possible roles in serotonin effects on worm egg laying and movement. Many C. elegans genes share significant conservation with humans, which provides a potential avenue to identify the effects of human targeting compounds that are still not fully understood. We have begun to characterize the role of novel intracellular neuronal signals, synaptic and non-synaptic information flow that is required for serotonin-dependent stimulation of egg laying and inhibition of movement. We have identified multiple neural signaling molecules that mediate the serotonin-dependent effects, synaptic transmission and select neurotransmitter genes, neurosecretory signal encoding genes, and, heterotrimeric G-protein signaling mechanisms that are required or interact with serotonin-dependent effects on egg laying and movement. We propose using C. elegans as a platform for continued study of serotonin mechanisms.

Abstract Name: **Adjustment to College: The Role of Parental Reciprocity and Gender**

Purpose: The role of parental reciprocity on college adjustment was examined. Parent-adolescent reciprocity promotes attachment (Bowlby, 1980) and enhances college adjustment (Agliata; Renk, 2008). Males report better adjustment than females (Enochs et al., 2006). Based on past research it is hypothesized that better adjustment will be reported by those high on parental reciprocity and by males.Procedure: First-year undergraduate students (18 males, 27 females) completed the Perception of Parental Reciprocity Scale (Wintre et al., 1995) and the College Adjustment Scale (Anton; Reed, 1991).Results: 2 x 2 ANOVA procedures were performed with gender and high/low reciprocity as the independent variables and the nine adjustment scales as the dependent variables. Low scale scores indicate better adjustment. High reciprocity resulted in better adjustment onthe depression scale (M=16.76, SD=2.08) than did low reciprocity (M=23.29, SD=6.03), F (1, 33) = 2.92, p = .048. Similar findings were obtained for suicidal ideation. No effect of gender was obtained. Gender and parental reciprocity interaction on anxiety was significant, F (1, 32) = 3.22, p = .04. Among females, high reciprocity resulted in better adjustment. Conclusions and implications: High reciprocity resulted in better adjustment on depression. The study hypothesis and findings of Agliata; Renk (2008) were supported. The hypothesis and past research (Enochs et al., 2006) for gender was not supported. Regarding interaction effects, high reciprocity resulted in better adjustment on anxiety among females. Findings suggest that parental reciprocity results in better adjustment regardless of gender on certain subscales and helps female college students adjust to college on others. Educating parents on the importance of reciprocal and quality communication with their children helps them become more independent in the transition. Future research should examine the role of family structures in the parental reciprocity-adjustment relationship.

Abstract Name: **Animals' Impact on Stress**

The majority of today's students are stressed in some way, and research suggests that animals are a good way to manage stress levels. With anxiety and depression on the rise, programs are seeking support for students in the stress-filled school life. Some researchers have found that bringing in therapy animals has been a good way to lift the spirits of the students. Animals have been used in therapy as early as the 18th century (Chu et al., 2009) and have been shown to ease isolation. Over 98% of full-time students are stressed, and 86% of students find improvement in domestic animals. Animal-assisted programs are still being researched, but evidence shows that there is a positive influence towards stress in many students. This research attempts to disclose the relationship between pet interaction and the level of stress the person feels. The results show that a majority of students have reduced stress after interacting with a domestic animal.

Abstract Name: **Identification of Biomarkers For Nonalcoholic Steatohepatitis Diagnosis Using Fourier Transform Infrared Spectroscopy**

Nonalcoholic steatohepatitis (NASH) is a progressive type of nonalcoholic fatty liver disease (NAFLD) characterized by hepatocyte inflammation and ballooning, as well as fibrosis. Common symptoms include fatigue or vague abdominal pain, however for many the disease may progress asymptomatically. Complications of NASH can lead to cirrhosis, end stage liver disease, and liver transplant. Currently, NASH is diagnosed through a liver biopsy, which then undergoes hematoxylin and eosin staining before being examined by a pathologist for diagnosis and staging. Diagnostic criteria includes the presence of hepatic steatosis (>5%), hepatocyte ballooning degeneration, and hepatic lobular inflammation. Additionally, alcohol consumption is considered to differentiate the diagnosis from alcoholic steatohepatitis. This method is limited by pathologist experience, which can result in later diagnosis andlead to discrepancies in interpretations of samples. Infrared spectroscopic imaging (IR) has been shown to rapidly image human tissue biopsies and to identify biochemical signatures that are associated with disease diagnosis and outcome in a label free manner. IR presents a possible new diagnostic approach that is more standardized since it does not rely on staining or a pathologist interpretation of the stain which can lead to errors and discrepancies. In this study we applied Fourier Transform Infrared (FTIR) Spectroscopy Imaging to biopsies from patients previously diagnosed with NASH, and to liver resections of patients without NASH, in order to identify biomarkers expressed in NASH. Using FTIR we were able to determine different stages of fibrosis based upon the spectroscopic signature using multivariate data analysis. With this information we hope to explore and better develop FTIR as a diagnostic method for other diseases that have similar complications with traditional diagnostic methods.

Abstract Name: **Physiology and Training for Single-Day Ultramarathons**

In the form of a detailed and highly annotated training document, which the author completed in his preparations to run a 100-kilometer race, as well as a thoughtful explanation of its background training principles based in human physiology, this project attempts to find the most efficient and effective strategies leading to success in this grueling distance. It includes specific and detailed workouts acting as examples of the different training practices and theories proven to work best for the experienced endurance runner, as well as having clear explanations as to why those workouts were performed and their greater role in the training process. The paper also defines several relevant physiological adaptations of the Cardiovascular, Musculoskeletal, and Nervous systems that serve as more specific goals of training. All methods of exercise are succinctly noted, defined, and put in their larger contexts. In general, the types of exercises performed consist of slower runs designed to build and maintain the cardiovascular engine, a variety of faster runs to increase oxygen consumption and vVO2max, and strength building exercises meant to develop and enhance muscular endurance. Each workout has its own specific purpose, and the subject in this self-case study attempted to perform them as closely as possible to what has been prescribed as to render the best conclusions. As a whole, this project aims to serve as an anecdotal and clinical standard for other experienced athletes wishing to run an ultramarathon lasting roughly 8-15 hours, as well as a thoughtful application of scientific research.

Abstract Name: **The Relation Between Sensory Input and Alcohol Drinking Patterns in College Students**

According to a national survey, almost 53% of full-time college students ages 18 to 22 drank alcohol in the past month and about 33% engaged in binge drinking during that same time frame. Unhealthy drinking habits are on a rise and despite the efforts implemented by schools, just under 2,000 college students die a year from unintentional alcohol-related injuries. Findingwhat leads students to binge drinking will help find apreventive solution to college student drinking rates. This study is focused on finding the relationship between sensory input during the drinking event and drinking patterns in college students. It is established that sensory properties influence food choices and behaviors, “a food sensory appeal is largely determined by the physical and chemical properties that are sensed before and during consumption, which informs initial acceptance and the degree to which a food will be consumed.” There is a gap in the literature about how sensory intake impacts alcohol choices, habits, and blackout (alcohol-induced amnesia) tendencies. By breaking downaspects of a person’s environment, it may be possible to find a connection betweensenses and drinking habits. This study collects data from college students at a midsized, midwestern college through an online survey called the Student Health Survey. The data will be qualitative, asking students about a recent heavy drinking experience, and surveying them about the senses they remember experiencing. This data will also be compared to questions about their drinking habits such as how often and to what extent they drink alcohol. Responses will review each sense individually to see what is most mentioned. The expected findings are that people experiencing specific sensory inputs also have heavier drinking habits and are more prone to blacking out. This study is important to understand how impactful sensory input is on drinking choices and health.

Abstract Name: **Skeletons of Algebraic Surfaces in Grasshopper**

Algebraic surfaces can be difficult to understand from a 2D view, such as on a screen, and creating an accurate physical model comes with many inherent problems, specifically at points of singularity which cause the model to break easily. Past attempts to solve this problem have included global and piece-by-piece solidification. This ongoing project attempts to create printable models piece-by-piece and place a plug and socket connection at connecting singularities, allowing the model to be taken apart and snaped back together. We previously used OpenSCAD, but it was unable to perform the necessary Boolean operations, so we opted to change tools. Related work done in Summer 2022 focused on porting code to Rhino3D and Grasshopper. The current project extends upon this work and aims to compute and print the skeleton of algebraic surfaces, incorporate the plug and socket connections, and add shells, allowing for the printing of larger and more intricate models of algebraic surfaces.

Abstract Name: **Comparing Growth Rates of Somaliland and Namibian Cheetah Cubs**

Cheetahs (Acinonyx jubatus) are classified as endangered species by the IUCN, facing major threats of habitat loss, illegal pet trade and human-cheetah conflicts. With approximately 7,500 individuals left in the wild across Africa, research is significant to understanding and ensuring the species' survival. At Cheetah Conservation Fund (CCF), located in Namibia, research has been ongoing since its establishment in 1990, and was once known as the cheetah capital of the world. CCF also has a campus in Somaliland, where currently 86 cheetahs of the "Tanzanian cheetahs" (Acinonyx jubatus raineyi) are being cared for, while 29 "South African cheetahs" (Acinonyx jubatus jubatus) are at Namibia's facility. Caretaking of young cheetahs is critical to their survival and one of the goals of the Namibia and Somaliland facilities is to facilitate the healthy growth of captive cheetah cubs. This project investigates the comparison of growth rates between Somaliland and Namibian cheetah cubs. Through CCF's data of cheetah cubs rescued between 2006-2022 within Somaliland and Namibia, weights, meat and milk consumption has been recorded from 0-6 months and organized in a new Excel Spreadsheet. 19 individuals are recorded from Namibia, and 46 are recorded from Somaliland. Through preliminary results, we found that growth rates of cubs 0-6 months old indicate males have a higher growth rate than females, and Somaliland has a lower growth rate than Namibian cheetah cubs. As research in this field has not been done, these results could indicate important information to improve caretaking skills and in the long-run, the species' conservation. Further statistics will be conducted to understand more about growth rates and what affects it, as well as the difference between Namibian and Somaliland cheetah cubs.

Abstract Name: **Ground-dwelling invertebrate assemblages are influenced by plant traits in deciduous forests, but not in evergreen-dominated forests.**

Ground-dwelling invertebrate (GDI) community composition is an important but often underrepresented part of forest ecology. GDI communities are crucial for breaking down leaf litter and recycling nutrients in forest ecosystems. Plant functional traits can affect leaf palatability and decomposition rates.Even so, little is known about how plant functional traits influence the composition of ground dwelling invertebrate communities. In addition, the relative importance of tree canopy traits and understory vegetation traits has not been investigated.We placed three pitfall traps in 40 locations in Northern forests (i.e., mainly evergreen conifers) and Southern forests (i.e., mainly deciduous trees) across a strong gradient in soil moisture. We used the vegan package in R to ordinate the GDI composition in the two forest types and investigated how GDI composition varied with moisture and vegetation composition and traits. We found that the North and South GDI community compositions did not respond similarly to environmental variation. Some taxa did not covary consistently. Hymenopterans (ants) were mostly located in dry forests in the North, but they were found in areas with more moisture in the South. Path analysis showed that moisture effects were mediated by vegetation in both Northern and Southern forests, however the in the North, understory trait composition had no effect on GDI composition, while tree canopy composition had nearly twice the effect of tree trait diversity.In the South, understory trait composition had moderate effects on GDI composition, while tree canopy composition had a stronger effect.Overall, vegetation effects were about twice as strong in the Southern forests.

Abstract Name: **An examination of mainstream media's treatment of female guitarists**

The music press in the United States has historically marginalized and under represented female guitarists in rock and blues, especially Black women. This phenomenon can be traced back to widespread gender inequality and racism in white, male-dominated rock'n'roll culture and the masculinization of electric guitar. Previous research about the music press examines how itplayed an important role in reinforcing the gender-based status quo of rock by systematically denying women artistic credibility in various ways. Focusing exclusively on female guitarists,this study uses quantitative and qualitative analysis of 565 articles from 10 publications about 43influential female guitarists. Overall, these findings provide evidence to support the lack ofmedia coverage, resulting in symbolic annihilation. By portraying female guitarists as women first and musicians second, the music press denies them credibility and reinforces traditional stereotypes of the guitar as a masculine instrument.

Abstract Name: **Reflections on how alternative grading strategies can aid in increasing meaningful student interactions and opportunities**

Recently there has been a growing interest in moving away from traditional grading strategies in favor of alternatives that allow faculty to increase the number of meaningful interactions with their students; primarily research engagement. This short talk will introduce two alternative grading strategies, Equity-Based Grading and Specifications Grading, and discuss the effects implementing these strategies had on undergraduate research in both Computer Science and Mathematics courses. The data and observations to be discussed have been collected from nine sections of five unique undergraduate courses across two semesters including both introductory and upper-level courses. While some strategies do not reduce the amount of time required for the evaluationof students' work, they do shift the evaluations away from traditional 'isolated'grading to interactions with the students. With this increased contact time with thestudents, we are afforded the ability to integrate research into our courses. Having more research experiences in our courses will help foster the skills and expectations needed for our students to be productive in research activities outside of the classroom. In addition to the flexibility of assignments and increased interactions with the students, we have noticed a shift in the focus of our students. From our observations, students seem to be more invested in understanding the problem at hand and somewhat less focused on the steps needed to be taken for a particular grade; thus leading to better skills and understanding of their research activities.

Abstract Name: **Evaluation of the Effects of Molecular Crowding on the Enzyme-Substrate Binding Using Saturated-Transfer Difference NMR**

The in vitro studies with enzymes are conventionally performed in dilute conditions containing mainly the desired buffer and salts. However, these conditions do not accurately reflect the in vivo crowded environment of a cell that can impact the structure, function, and dynamics of an enzyme. The present study focused on Escherichia coli Prolyl-transfer RNA synthetase (ProRS), a multidomain enzyme that is involved in catalyzing the ligation of proline to tRNAPro during protein biosynthesis. According to previous studies, molecular crowding affects the catalytic efficiency of ProRS. However, the molecular mechanism of the crowding and confinement on enzyme catalysis has remained elusive. In this study, the binding affinity of ProRS to its substrate, adenosine triphosphate (ATP), was probed in the presence of synthetic crowder molecules like ficoll 70, Dextran 40, and PEG 20. Saturation Transfer Difference-Nuclear Magnetic Resonance (STD-NMR) spectroscopy was used to analyze the binding affinity of ProRS for ATP, both in the presence and absence of crowder molecules. In parallel, computational docking study was performed to assess the crowding-mediated changes in substrate-enzyme interactions. The results of this study are expected to further our understanding of the molecular mechanism of crowding and advance structure-based drug design. Preliminary results of the study will be presented.

Abstract Name: **Exposing Sperm to Thalidomide Prior to Fertilization Results in Abnormal Embryogenesis in Sea Urchins**

Thalidomide, originally introduced in the 1950s for off-label treatment of hyperemis gravidarum, resulted in birth defects in approximately 10,000 children exposed in utero (1957-1962). Due to its anti-inflammatory properties and non-addictive nature, the U.S. FDA approved thalidomide in 1998 for treatment for leprosy and other diseases with inflammatory components. Clinical pharmacokinetic research indicated that thalidomide can be found in semen. Whilst the FDA classified thalidomide as unsafe for use by pregnant females, little work focused on the effects on embryos exposed to thalidomide through either sperm or semen. The FDA Thalidomide REMS program recommends males using protection for pregnancy prevention while taking the drug and for 4 weeks after stopping treatment. Sea urchin embryos serve as good model organisms for studying early embryogenesis. They are also sensitive to thalidomide. Previous research in this lab noted that sea urchin embryos fertilized with thalidomide pretreated sperm exhibit five times more abnormalities than controls. To examine this in more detail, we will generate a dose response curve for sperm pretreatment and observe embryos at 24-hours (gastrula), 48 hours (blastula), and 72 hours (pluteus) for malformations and other abnormalities. To evaluate teratogenesis compared to toxicity, we will evaluate cell viability and apoptosis comparing treated embryos to controls. We expect to find that higher concentrations of thalidomide sperm exposure will yield a higher percentage of malformations in embryos compared to controls. In addition, immunofluorescent cell dyes will be used to evaluate cell viability and apoptosis. We anticipate that embryos resulting from thalidomide pretreated sperm will exhibit differences in cell viability and apoptosis induced cell death compared to controls. This research addresses broader implications about the potential paternal contributions to teratogenesis.

Fisher, Anna

Abstract Name: **Impact of Fat Studies Course on Body Image**

Body image is how someone sees themselves in the mirror or in their mindIt affects mental,physical and emotional health, specifically in quality of life, psychological distress, and the prevalence of unhealthy behaviors. Because of fatphobia, diet culture, and social media, young adults and adults in their early 20s to 30s are especially affected by body image and people's perceptions on their bodies.For this project, we are seeking to answer the question whether exposure to an upper level, semester-long, undergraduate course on fat studies has an impact on students' body image and their relationships with their bodies.We are using data that was collected over a three-year period between January 2019 and December 2021. Content analysis will include written student assessments (N=78) completed at the beginning and end of the course from students who took Fat Studies and Body politics and follow-up interviews (N=17) with students from the first cohort.We believe that after being exposed to a fat studies course,the students' perceptions of their body and body image will overall improve and thatit will also increase their awareness on how fat is a social justice issue. The purpose of Fat Studies and Body Politics is to explore the social construction, medicalization, and pathologization of fat bodies in the United States. Fat is examined as a social justice issue that intersects with race, class, gender, sexuality, and ability status. This course explores the body politics behind attempts to redefine fat identity, including body positive and fat positive movements.

Abstract Name: **Alliance Dilemma: Decreasing State Compliance with Nuclear Treaties and Increasing Useable Scenarios of Nuclear Warfare**

Since the rapid development of nuclear weapons in the 1940s, many international laws have been put in place to combat these dangerous weapons. Many treaties created by the international community seek to limit the use, stockpiling, threat of use, production, and sharing of nuclear weapons, including the Treaty of Non-Proliferation of Nuclear Weapons (NPT) and the Treaty on the Prohibition of Nuclear Weapons (TPNW). State compliance is crucial for international security regarding the success of nuclear treaties. Some assumed that because of the destructive nature of nuclear weapons, states are interested in ratifying and complying with treaties that work to eliminate these weapons. However, as time has progressed, states have been less willing to be a party to nuclear treaties as seen with the lack of state support for TPNW. Similarly, members of the international community fear that state compliance could decrease and lead to the possible use of nuclear weapons. This project asks, what is preventing progress on eliminating nuclear weapons? This research argues that the existence of an alliance dilemma interferes with state compliance related to nuclear treaties. Despite the fact that these treaties and alliances are established to increase state security, alliances actually increase the possible scenarios for and chances of nuclear warfare.This result occurs because nuclear alliances bring nuclear states and non-nuclear states together under one umbrella, meaning that these weapons could be engaged as a result of conflict between states that do not possess nuclear infrastructure themselves.This argument creates a new way of examining the success of nuclear treaties beyond simply looking at compliance by nuclear states.

Abstract Name: **Developing A Community-Engaged Design Framework for Community Environmental Justice Efforts**

Due to information accessibility and lack of technical resources, disenfranchised communities risk being spoken over by protective agencies in environmental justice (EJ) efforts. However, academics can use community-engaged research methods to understand the afflicted population's needs and vision for remediative action. In previous academic-community collaborations, methods emphasizing stakeholder participation have shown to encourage residents to think creatively about their needs and potential solutions by allowing participation in the design process. This study evaluates the benefits of allowing community members greater control in design decisions by collaborating with a community in Garland, Texas concerned with their neighborhood's history of industrial pollution and possibly-related epidemiological concerns. Over the course of the study, the research team developed a new design framework geared towards enabling citizen autonomy after short-term community-academic partnerships. This framework modified the traditional design thinking (DT) process by increasing the frequency of "choice points" which allow stakeholder feedback to alter the product during all stages of the design process. Ethnographic interviews were used to collect community perceptions as site conditions evolved. Then, insights derived using qualitative data methods were used to drive the design process. By the end of the study, use of the framework resulted in multiple product prototypes for community use and a positive relationship with the citizens involved in the EJ effort. Moreover, retrospective stakeholder feedback It is expected that applications of the design framework in other EJ sites and disciplines will contribute to continuing research efforts to establish ethical and equitable methodologies for community-engaged and community-based work.

Abstract Name: **Prescribed Burn Effects on Animal Species in the St. John's Abbey Arboretum**

We investigated the impacts of prairie prescribed burns on small mammal diversity in the Saint John's Abbey Arboretum, Collegeville Minnesota. We hypothesized that there would be a correlation between burn age and degree of diversity. Based on this hypothesis, we predicted that older burns would have greater diversity. During June and July of 2022, we placed 18 traps on each of three different burn age plots (four, two and one years). Traps were placed 15 meters apart and were opened in the evening and checked early morning on the next day (H.B. Sherman live traps, model 3310A). Traps were baited with peanuts, oats, and raisins. Data collected for each trapped animal was plot name, trap ID, species, weight, gender, reproductive status, total body length and left hind leg length. Captured animals were released at their trapping site. A Chi-square goodness of fit was used to analyze data. Our mammal diversity among plots was not as expected – we trapped only house mice (Mus musculus). There was a difference in number of animals trapped on the three plots ($\chi 2 = 22.65$, $df = 2$, $p = 0.0001$). More animals were trapped on the plot with a one-year burn. One factor that might contribute to trapping only one species is an extremely wet spring and summer. The ground was frequently saturated, and the vegetation density was hard for even us to walk through. We plan on continuing this study in 2023. We think that this research is important because today less than 1% of prairies remain in North America and are fragmented and scattered around.

Abstract Name: **Efficacy of Social and Physical Support for Cancer Patients**

Cancer is the second leading cause of death in the United States. In addition, cancer treatments provoke harsh side effects that demand extra strength from the patient. Cancer causes lifestyle modifications that can be detrimental on the patients' health; however, healthy habits can potentially increase the chances of a positive prognosis. Additionally, physical, and social support has proven to help patients in their fight against cancer. Since the lack of physical and social activity in patients with cancer has been shown to correlate with mental and cognitive decline, ultimately reducing quality of life, the purpose of this study is to examine the relationship between physical activity and quality of life in patients with cancer And increase their overall quality of life.This project included eight female participants that are currently struggling with cancer, or the cancer is in remission. The program consisted of group discussions, fine motor movements, and various physical activities twice a week for three weeks. Using pre/post intervention questionnaires and a dependent t-test, the significance of social and physical activities amongst the participants were analyzed. The dependent t-test showed a significant difference (t=-3.729, p=0.007) in the overall quality of life between pre and post program. These preliminary results imply that implementing a support group such as Healthy Habits that includes the use of physical and social activity, improves the overall quality of life of patients with cancer. In conclusion, the program created an additional outlet for individuals with cancer to find a relatable support group that can aid with daily struggles. Further analyses in a larger sample and with longer duration will provide stronger evidence about the relationship between physical activity and quality of life in patients with cancer.

Abstract Name: **Understanding Multi Cathode Blend Strategy for Non-flammable Extreme Temperature Li-Ion Batteries**

Issues of rechargeable lithium-ion batteries at high temperatures are a constant problem that affects our society in different ways. This is due to the instability and limited knowledge of the electrode-electrolyte interface, especially cathode electrolyte interphase (CEI) for Li-ion cathode materials at high temperatures. Sustainable rechargeable lithium-ion batteries with a high capacity, a good cycle life, and high thermal stability are necessary to combat environmental, economic, and social problems around the world. Therefore, in this study, possibilities for low cobalt and high-temperature stable cathode materials using a multi cathode blend strategy in thermally stable ionic liquid electrolytes are explored. LiNi0.5Mn0.3Co0.2O2 (NMC532), a material with high electronic conductivity, energy density, and low thermal stability, was blended with LiFePO4 (LFP), which is a thermally stable material with a low energy density and electronic conductivity. This was done to combine the properties and characteristics of both materials and get a cathode material with improved performance for extreme temperature Li-ion batteries. Electrochemical characterization at 100 °C was performed on the blended cathode material and individual ones, NMC532 and LFP, fabricated using coin cell test structures and Li-metal anodes. Electrochemical studies indicated that the blended NMC532|LFP cathode material has a stable lithiation-delithiation reaction after few initial electrochemical cycles and the obtained specific capacity is between the specific capacities of the two individual cathode materials. Besides, from the first to the fifth cycle, the particles of the blended cathode material experience in situ activation to provide good interfacial properties. With this understanding, we believe that the fundamental understanding on high temperature cathodes using low cobalt materials is of paramount importance to transform the ambient temperature Li-ion technology to high temperature applications.

Abstract Name: **Dreaming In Isolation: The Effects of Dreams During the Pandemic**

The COVID-19 pandemic introduced extreme levels of panic from being forced into isolation from loved ones, fearful that there would be no food on the table for dinner, and feeling that there would be no end to the rising death rates. The world was in a collective state of mayhem, both mentally and physically. Furthermore, even when individuals looked forward to resting at the end of the day, the feeling of dread lingered and snuck into their dreams. Visual imagery reported by people during the pandemic explained how their dreams ranged from being absent to being extremely vivid. This study explores the relationship between nightmare occurrence and the COVID-19 pandemic. Peer-reviewed articles were gathered to collect information on the types of dreams and the effect COVID had on dreams. An 11-question survey comparing sleep quality, stress levels, dream frequency, and nightmare frequency before, during, and after the COVID-19 pandemic was completed by 69 participants. A One-way Analysis of Variance (ANOVA) and T-test was used to examine the data collected from the survey. The ANOVA tests revealed that there was no difference in stress level, dream frequency, nightmare experience, and sleep quality before, during, and after the COVID-19 pandemic. From the 71 participants, 46% tested positive for COVID-19 at one point and were asked questions about their dreams and 30% of them stated to have had nightmares while they were sick. The vividness of dreams were also measured for each participant to better understand aphantasia and hyperphantasia. Aphantasia is characterized by an absence of visual imagery, whereas hyperphantasia refers to vivid visual imagery. Future data needs to be done on the correlation between sickness and dreams to better understand parasomnia as well as dream vividness.Keywords: COVID-19, dreams, sleep quality, aphantasia, hyperphantasia

Abstract Name: **Repurposing FDA-approved drugs to re-sensitize TP53 mutant Diffuse Intrinsic Pontine Glioma to radiation therapy**

Diffuse Intrinsic Pontine Glioma (DIPG) is a pediatric brain cancer that forms in the brainstem, mainly affecting children aged 4-11. The survival rate of children with DIPG has not changed in more than 50 years, and remains <1%. While there is no cure for DIPG, radiation therapy has shown to be beneficial in providing temporary symptomatic relief. However, all DIPG will become resistant to radiation therapy. Most DIPG has inactivation of the p53 pathway, mainly through mutation of the tumor suppressor protein p53 (TP53). TP53 plays an important role in regulating apoptosis, cell cycle arrest, metabolism, senescence, autophagy, and aging. A common phenotype that is associated with TP53-mutation is resistance to apoptosis induced by radiotherapy. We hypothesized that TP53 mutation in DIPG contributes to radio resistance of the tumor, and by reactivating the pathway, we could resensitize the cells to radiation therapy. In prior research, the Blackburn lab completed a screen of 1,400 FDA-approved compounds to find drugs that could be repurposed to sensitize a TP53 mutant zebrafish line to apoptosis after irradiation, but did not induce apoptosis in the animals when no irradiation was given. The top 9 hits from this drug screen were further tested in radioresistant human TP53 mutant DIPG cells. To date, two of the hits, Tamibarotene and Veliparib, show good efficacy in resensitizing DIPG to radiation, resulting in a 1.35-fold reduction of cell viability at the most efficient concentration when given with radiation, than when cells were treated with radiation alone. Future studies will test the remaining drugs and determine the mechanisms by which the top hits reactivate apoptosis in the irradiated cells.

Abstract Name: **P(NIPAM-co-MAA) Macrogels as Wound Dressing Biomaterials**

The goal of this research is to investigate potential biomedical applications of hydrogels by characterizing the properties they demonstrate when synthesized with various combinations and concentrations of organic or inorganic polymers. We have chosen to explore the effectiveness of hydrogels as wound dressings in terms of maintaining a sterile microenvironment to prevent biofilm formation in flesh wounds. To do this, we are testing the capability of macrogels derived from N-isopropylacrylamide (NIPAM) and Methacrylic acid (MAA) to retain and release the drug gentamicin sulfate in both a liquid and solid medium through stimuli-dependent behavior.

Abstract Name: **The Influence of Surgical Stress and Inflammatory Biomarkers on the Occurrence of Postoperative Delirium**

Research focusing on hypothermia has established a relationship between surgical stress and inflammatory biomarkers on delirium incidents in critically ill non-cardiac surgical patients. Unfortunately, postoperative deliriumis a common complication after surgery and results in acute brain failure. Though the cause of delirium is still relatively unknown, systemic inflammation with neurological involvement is one of the leading etiologic theories. Another common complication in surgical patients, is the occurrence of unplanned hypothermia during non-cardiac surgeries. For our study, we will be looking at two inflammatory biomarkers: C-reactive protein (CRP), and Interleukin 6 (IL-6). CRP is produced in the liver and is an index of overall inflammation in the body and is found elevated in postoperative delirium. IL-6, a pro-inflammatory cytokine, promotes a variety of cell functions that stimulate end enhance inflammation and is also known as a brain-active interleukin. IL-6 is a biomarker identified as a predictor of postoperative delirium when compared to those that do not experience postoperative delirium.Delirium assessments, surgical temperatures, and blood samples will be obtained from at least 100 non-cardiac surgical intensive care patients at a local hospital for the first three postoperative days.) Our role in the project is to separate the serum from the blood and perform enzyme-linked immunosorbent assays (ELISAs) for CRP and IL-6. We will be assaying the separated serum to identify the levels of the two previously established inflammatory biomarkers. Through the comparison of inflammatory biomarker levels and surgical temperatures in non-cardiac patients with and without postoperative delirium we hope to establish the influence of inflammatory stress and unplanned hypothermia on postoperative delirium. It is hoped that the findings from this study will further the understanding of how to assess, treat, and prevent postoperative delirium. Presently, this is a work in progress and our findings will be shared at the conference.

Abstract Name: **Pet Insurance: Changing the Veterinary-Client-Patient Relationship for the Better**

The risk of suicide for veterinarians is disproportionately higher than the average population. Burnout in the profession is soaring. Pet owners are frustrated with veterinary costs and often have to put loved pets down because they cannot afford treatment. I wanted to explore if pet health insurance, which works somewhat similarly to human health insurance, could resolve the problems within the veterinary-client-patient relationship (VCPR). Tension in the VCPR can make clients distrust veterinarians, resulting in poorer care for pets and burnout for veterinarians. I researched three topic areas to find an answer to my research question: First, I focused on reviewing existing research about the relationship pet owners and veterinarians have with pet insurance. Second, I looked into exactly how the pet insurance industry works, including the actuary science behind creating monthly payments and estimating risk. Finally, I researched what pet owners and veterinarians expect from the VCPR, and how breakdowns in communication can occur. Compiling the details together, I found sound evidence to support the argument that more pet owners using pet insurance can help mend the VCPR, leading to better care for animals due to less financial strain. Most veterinarians favor greater use of pet insurance, and many pet owners who do have pet insurance are pleased with their choice. Certain aspects of pet insurance, like coverage for pre-existing conditions and increasing premiums for some breeds, need to be re-evaluated. There is also increasing concern among veterinary doctors over the direct pay model, which many fear could begin to dictate their medicine. Despite these concerns, the model for traditional pet insurance is still well-received by pet owners and most veterinarians. More research to increase the awareness of pet owners about the option of pet insurance is a positive first step to better care for our pets.

Abstract Name: **Estimating Settlement of Strip Footings on Soft Clay Stabilized with a Granular Trench**

Research on foundation systems has brought increasing opportunity in the building construction sector for greater efficiency and accuracy in design. Available research development shows exploratory opportunity with a focus on quantifying the improvement offered by ground reinforcement through granular trench support in clay soils. Settlement analyses will be performed for a continuous strip footing placed on soft clay soil stabilized with a granular trench. The analysis software PLAXIS and LimitState:Geo will be used to develop models for evaluation and provide ultimate bearing capacity the along with settlement for considered configurations. Results from the theoretically developed model will be compared with published research for physical modeling and numerical method results in literature. The results will help the engineer to estimate the settlement when considering the inclusion of a granular trench beneath the strip footing. Design parameters such as trench depth, trench width, footing width, and friction angle of the granular material in the trench will be varied in this study to investigate their influence on the foundation settlement. Phase 1 of this research, which focused on quantifying the ultimate bearing capacity, was completed and concluded that these design parameters influence the design significantly. The current research (Phase 2) continues the investigation efforts of the various design loading parameters based on a set settlement. The models being used in the settlementevaluated used ratios of trench width to foundation width and then increasing the trench depth to width until the loading needed shows a plateau. With the addition of settlement, the engineer will be able to create a comprehensive foundation design for the problems in hand byaddressing the maindesign constraints: strength and settlement. As an availableresource, the results will provide progression in ability to accurately design reinforced foundation supports in building projects.

Abstract Name: **An Analysis: Self-Narrative in Toni Morrisonðs Sula: Abstract**

Self-narrative is a widely studied and discussed concept of psychology that affects everyone's thoughts, actions, and lives. This concept illustrates an internalized process where individuals formulate a narrative about themselves and their lives inside their minds. These narratives follow the structure of a story narrative. They contain a plot, characters, setting, themes, and a timeframe consisting of a past, represented by memories, a present, and a perceived future based on past and present experiences. Throughout Toni Morrison's "Sula", we meet a wide array of people, and we follow them along their journeys as they make their way through life. We watch as bystanders as they try to make sense of, react to, and cope with an abundance of extremely complicated and individually distinct experiences. We formulate opinions on the world and characters that Toni Morrison created, and we pass judgment on the characters' actions and the choices that they make. However, we carry with us our own preconceived notions, life experiences, personality traits, world views, and many other contributing factors that dictate how we formulate these opinions and judgments. All these factors are what help us to build our self-narrative. The characters that we observe in "Sula" also have their own inimitable self-narratives. They are the narratives that they have constructed in their minds about who they are and how they should interact with the world around them. These self-narratives, not their actual aspirations or desires, are what dictate the choices they make.

Abstract Name: **Dusting off the Archives: Digital Curation & Information Justice**

In the age of information, tension exists between information quantity and accessibility. Digital curation is the process of collecting, selecting, organizing, storing, and displaying items with the respective information using technology. It is also a strategy to address this conflict; it reduces the quantity and refines the quality of digital products on the internet. While this strategy may sound ideal, curation requires 'intermediation' which allows for the information to be displayed, but may cause erasure, skewing, or insertion of bias such as "whitewashing" for archived items. Technology is not a neutral entity; information systems perpetuate the social systems in which they are created. Intermediation, therefore, has the potential to replicate all of the social injustices present in society. Without acknowledging these inequities, archivists may unintentionally reinforce these power dynamics. However, curators are also well-positioned to increase information accessibility through praxis. This project introduces an open-source digital archive and archival workflow for a small academic institution, exploring curators' ability to address these injustices. To understand the intricacies of practice, I conducted a paired literature review and scoping review of established archives to reflect both theoretical best practices and current practicalities of technological implementation. Then I tested the digital system and workflow against a case study: the curation of a donated wooden sculpture. This work illuminated a number of difficulties that were not highlighted by the literature alone. Disciplinarity is heavily reflected through the intermediation of curation to the point of creating terminology barriers. Another barrier is the technical expertise required to create and maintain an accessible archive. Even though this work is an opportunity for interdisciplinary collaboration between experts, faculty, staff, and students, sustainability and continuity of work cannot be achieved with current practices.

Abstract Name: **Identifying the impact of environmental influence on XRF analysis; implications for Mars sampling**

X-ray fluorescence (XRF) sampling is a common method used for geochemical analysis of rocks on Mars. Many rover and lander missions have employed drilling or abrasive tools to remove the external face of rock samples to mitigate inaccuracies in geochemical analysis due to weathering. The objective of this project is to test for a potential sampling method that could yield predictable geochemical analysis of a rocks' interior based on readings from altered external surfaces when the rock cannot be physically sampled by rover or future manned missions. For this study we are conducting XRF analysis of basalt samples to see if external surfaces that have been exposed to weathering yield predictable geochemical patterns of departure from internal geochemistry. Basalt samples will be collected from Houghton Michigan because it is a common rock type on Mars and because many minerals in basalt weather rapidly. We predict that the exterior surfaces of rock will yield consistent XRF geochemical departures as compared to the internal control data if environmental weathering is truly a contributing factor. If a consistent pattern of geochemical alteration is identified, it may be possible to make reasoned predictions about the nature of unaltered internal geochemistry for some rocks that cannot be physically sampled.

Abstract Name: **Assessing Lupine as an Environmental Conservation Tool in Iceland**

Iceland's environment is highly prone to erosion and has conditions that make plant growth challenging. The plant lupine is a divisive solution to soil erosion and reforestation that has been found successful in some regions of Iceland but not all. We researched the issue through extensive document research, expert interviews from different perspectives, and surveys of native Icelanders, to get as complete and unbiased a picture of the issue as possible. We used this to create a decision guide that gives a comprehensive account any person in Iceland can use in order to choose what they would like to do to address soil conservation and reforestation issues on their land. Key issues the decision guide covers are soil conservation, reforestation, and removal of lupine. Along with the decision guide, we include a decisional balance sheet to show the pros and cons of lupine usage in Iceland and a plant infographic to teach about the plants in the decision guide. These tools can be used by land owners in Iceland to make decisions about restoration and reforestation on their land.

Abstract Name: **Parental Perceptions of Physical and Outdoor Activities in Their Adult Child with Autism and Intellectual Disability**

Background: Adolescents with autism spectrum disorder (ASD) have been found to have lower levels of physical activity than their typically developing peers (Stanish et al., 2017). This concerning degree of physical activity is likely to continue into adulthood (Pan; Frey, 2006), causing unfavorable health concerns, and even premature death (Tomaszewski et al., 2021). Adults with ASD and an intellectual disability (ID) are at higher risk of being physically inactive due to various barriers. Purpose: The purpose of this study is to investigate parental perception on benefits, challenges, and needs of physical and outdoor activity participation in their adult child with ASD and an ID. Methods: Up to seven families will be interviewed in a 1-2 hour session to find their perceptions of physical and outdoor activities regarding their child. Interviews will be audio-recorded and later transcribed for qualitative analysis. My observation and field notes will also investigate the perceived feelings or attitudes of adults with ASD and ID regarding their previous and current outdoor and physical activity participation. The interview data will be combined with field notes and analyzed using NVivo data analysis software. Common code and themes will be emerged across the interviews and field notes for thematic analysis. Expected results: I anticipate there will be common themes throughout the interviews, including parents feeling like getting their child active and outdoors is a burden, a lack of accessibility for adults with ASD and ID to get active, and outdoor physical activities having more positive results than indoor physical activities. The findings of this study will be beneficial to inform the benefits of regular outdoor and physical activity and potential strategies to meet the unique needs of this underserved population.

Abstract Name: **The Future of Plastic Waste: A Multi-Disciplinary Approach**

Approximately 300 million tons of plastic waste is produced every year worldwide; only ~7-9% is recycled. The result is harmful plastic waste accumulation that negatively impacts ecosystems and communities around the world. Polyethylene terephthalate(PET) is one of the most abundant plastics due to its transparency and chemical strength. While naturally occurring PET-degrading bacterial enzymes have been identified (i.e., PETase and MHETase), their physiological requirements make them ill-suited for industrial use. We attempted to address this problem by bioengineering a chimeric PETase::MHETase protein for enhanced PET degradation. Review of recent literature revealed a collection of PETase and MHETase-optimizing mutations shown to enhance temperature and pH tolerance. Building from this work, our approach was to combine these nucleic acid changes into a single modified open reading frame (ORF) to support even greater PET degradation capabilities. The synthetic plasmid DNA construct was transformed intoE. coliand expressed to produce a novel chimeric protein. The biomanufactured product was purified by nickel column chromatography and quality-tested using standard assays. Finally, functional assays allowed us to measure PET plastic degradation. Recognizing that typical practices in life science laboratories are part of the plastic waste problem, our team explored and implemented ways to make our laboratory—and others like it—more sustainable. Additional methodologies from the field of STS (Science, Technology and Society) were used to consider, imagine, and develop greater understanding of the implications of plastic waste and how a bioremediation-based solution might be implemented in the future.

Abstract Name: **Analysis of Commercial Extraction Methods for Removal of Phytocannabinoids from Hemp Biomass**

Phytocannabinoids are produced from a plant called cannabis sativa (hemp) for protection from insects, UV light, and winds. Phytocannabinoids are extracted to produce products with alleged medicinal benefits. Phytocannabinoids that are of particular interest were cannabidiol (CBD), cannabidiolic acid (CBDA), Δ-9-tetrahydrocannabinol (THC), and Δ-9-tetrahydrocannabinolic acid (THCA). Single-pass ethanol, multi-pass ethanol, and supercritical CO2 extraction were the extraction methods examined to improve yield, throughput, and product quality. The extraction process is started by passing a solvent (ethanol, carbon dioxide, hexane, etc.) through hemp biomass. The solvent is removed through evaporation to produce crude oil. The oil is further refined by the operator to sell as medicinal products. The analytical methods used to determine concentrations were High-Pressure Liquid Chromatography Ultraviolet Detection (HPLC-UV) and Gas Chromatography Flame Ionization Detection (GC-FID). Single-pass ethanol extraction had the most CBD percentage in the crude oil product after extraction. Multi-pass ethanol extraction was the most effective for the throughput of the product. For multipass ethanol extraction, the fifth cycle was the maximum amount able to be extracted but the third cycle was the point of diminishing returns. During multi-pass ethanol extraction, CBDA was preferentially extracted compared to the other phytocannabinoids measured. The supercritical CO2 extractor removed the most CBD and THC percentage at 89% and 73%. While single-pass ethanol extraction recovered the least CBD and THC at 66% and 59%. A thorough analysis of the extractor would allow commercial operators to reduce time, labor, and expenses for commercial extraction.

Abstract Name: **Stopping the Spread: An Autoethnographical Examination of Intergenerational Transmission**

Expectations for the performance of US American masculinity and femininity highlight the bind in which individuals are placed. Modern conceptions of masculinity and femininity both expect that individuals embody and transcend stereotypic gender norms (Wood, 2011). Gendered norms and expectations, as with most societal expectations, are first learned and reinforced within the family (Bandura, 1971). How do we change our communication so that individuals and families can transcend these learned behaviors? This paper is an autoethnographic examination of how learned and repeated communication behaviors perpetuate family trauma(s). Using my lived experiences, I will articulate how societal, familial, and intergenerational influences have affected communication behaviors within my family of origin. After contextualizing my lived experiences in the literature, I will offer researched-based solutions for breaking the cycle.

Abstract Name: **The effects of restoration projects on phosphorus concentrations throughout Manitowoc County streams and Lake Michigan**

Phosphorus poses an ongoing challenge to Lake Michigan. Excess levels cause algae blooms resulting in degraded water quality in near-shore waters. As local tributaries serve as important phosphorus sources to Lake Michigan, we analyzed phosphorus levels in two streams in Manitowoc County, WI—Centerville Creek and the Little Manitowoc River.These streams have historically exceeded Wisconsin DNR surface water phosphorus standards of 0.075 mg/l phosphorus. Each stream has undergone restoration near where they enter Lake Michigan in order to slow stream flow and reduce phosphorus loading into Lake Michigan.Each creek showed a different trend in phosphorus concentration along its length.Centerville Creek showed lower phosphorus concentrations within the restoration area compared to the upstream branches, although all significantly exceeded the WDNR threshold. North branch averaged 0.510 mg/L phosphorus, and the south branch averaged 0.430 mg/L.Sites within the restoration project averaged 0.307 mg/L. In contrast, no difference in phosphorus concentration was noted between the upstream and restoration sites in the Little Manitowoc River.This may be because this restoration was more recently completed (2020 vs 2012), or due to the surrounding land use as the Little Manitowoc River runs through the city of Manitowoc, while Centerville Creek goes through agricultural land.However, overall concentrations across the Little Manitowoc River were lower than any of the Centerville sites, with an average concentration of 0.071 mg/L, below the WDNR threshold, and rain events did not increase phosphorus as much as in Centerville Creek. Future work will focus on identifying future sources as well as continued monitoring to evaluate the success of these restorations and inform land use decision-making.

Abstract Name: **On Building a Mind: Replicating a Neural Network Model of a Neuron**

The future of AI depends on making our systems more like biological brains. Current technology and understanding are far from emulating an entire brain, but advancement canstart with their building blocks- neurons. Our research consists of two parts: the first is areplication of work by David Beniaguev, et al. entitled “Single cortical neurons asdeep artificial neural networks,” and the second is generating a new data setfor testing the model. The paper describes the authors’ creation and training of a temporal convolutional deep neural network (TCN) to accurately model a singleL5PC neuron. Our replication begins with code written by the authors and posted to publicrepositories, pre-trained Keras models, and original training data. Determining the structure of the neural network is accomplished by selecting one model and examining thefiles used to train and test the models. To generate a new data set for testing, we turn to aprogram created to simulate biophysical models of neurons called NEURON. The base of this model is provided through the ModelDB online database and is modified using the hoc language to approximate the one used by Beniaguev to generate a similar data set with inputs and corresponding outputs. Data is consolidated into a form readable by the TCN model, tested,and the prediction and accuracy values are recorded. Given the difficulty in recreating the NEURON model faithfully, the results show that the TCN model can accurately replicatethe results of a neuron simulation given the same inputs, yet the model may not beable to classify input patterns different from what it was trained on. The model performs well, but may not represent all possible neuronal states. This, however, leaves an exciting avenue for future research.

Abstract Name: **Preventing NicoTEEN Addiction Through Nurse-Led Education on Vaping**

The aim of this research project is to develop, present, and evaluate an educational intervention on electronic cigarettes (e-cigarettes) and vaping for non-school staff adults who have influence on adolescents, such as coaches, counselors, and parents. The U.S.Surgeon General reported that the use of e-cigarettes continues to be a public health concern among adolescents. Additionally, according to the Centers for Disease Control, there is evidence that adolescents who use e-cigarettes are more likely to smoke regular cigarettes in the future. While there is a growing body of research on the short and long-term health effects associated with e-cigarettes and vaping, less is known about how we might best prevent adolescents from engaging in use of these products. This project targets adults that spend large amounts of time with adolescents and have the ability to influence them on the dangers of e-cigarettes and vaping. It involves the delivery of an interactive and evidence-informed presentation. The efficacy of the intervention is then studied by comparing pre- and post-test results. Results are forthcoming, but it is predicted that the educational intervention would improve participants' knowledge about vaping and e-cigarettes.

Abstract Name: **Ideologies of Production and the Environment: A Case Study of Local News Coverage Surrounding Enbridge Line**

Enbridge Line 3 is a crude oil pipeline running from Canada through the Great Lakes region. During its construction, it was heavily opposed by the Anishinaabe tribe and environmental groups, both for its use of fossil fuels and its route near Indigenous agricultural lands. This case is especially unique as a type of wild rice, Manoomin, on the lands, had recently been awarded legal personhood (influenced by the legal paradigm, "Rights of Nature"), obligating the government to protect Manoomin's well-being in ways that are analogous to the ways it would protect a human's. This conjecture of events provides an opportunity to critically interrogate discourses surrounding "development" and how groups of people come to see themselves in relation to non-human nature. Drawing on a systematic discourse analysis of the Star Tribune, I address the question of how "production" and the "environment" were conceptualized and prioritized during this period of increased salience; articles were chosen based on a keyword search of any article published between 6/28/2018-10/31/2021 that contained the words "production", "productivity", or "environment". I then coded the articles in NVivo, using a codebook of my own design, demonstrating how ideas of production and the environment were framed by the newspaper. This content analysis was contextualized with press releases from Enbridge and the Anishinaabe. Overall, the newspaper presented production as taking precedence over everything else. Some articles did prioritize things like health over production, but the articles never critically interrogated productivism as an ideology. More environmentally-focused articles were often presented as political think-pieces or tended to be more qualitative. Environmental concerns were often presented as external to production. While productivism was often explicitly endorsed, the newspaper used rhetoric that distanced it from alternative views of production and the environment, carefully not endorsing these positions.

Abstract Name: **Microbiome Derived Metabolites and Their Potential Protective Benefits During Sepsis and Immobilization Induced Muscle Dysfunction**

Background: The Covid-19 pandemic has uncovered major limitations in healthcare practices and presented major challenges to clinical nutrition support in the intensive care unit (ICU). Patients suffer from increased muscle breakdown, which exacerbates the body's ability to recover from the viral infection. The impact of the microbiome on enteral nutrition support for critically ill patients is not well understood. Research has focused on the pre-biotics (i.e. dietary fibers, simple/complex sugars, and amino acids/peptides/proteins) and pro-biotics (i.e. bacterial species of interest) improving patient outcomes, but other studies fail to find such benefits. Many bacterial derived metabolites (post-biotics) are absorbed into systemic circulation and taken up by peripheral tissue. Thus, the impact of the post-biotics are equally, if not more, important for the host compared to pre- and pro-biotics. We hypothesize that post-biotics, such as short chain fatty acids (SCFAs) and succinate, will contribute to attenuating the catabolic effects of sepsis and immobilization on peripheral tissue such as skeletal muscle.Methods; Results: Sepsis was induced in mice through intraperitoneal injection of anaerobic bacteria mixture. Antibiotics and fluids began 12 hours post sepsis induction and continued BID for 3 days. Immobilization was achieved using 3D printed casts and taped onto the mouse hindlimb unilaterally. Muscle function was assessed on day 4 post sepsis or immobilization by measuring plantarflexion in vivo using isometric force measurements. Mitochondrial function was assessed using high resolution respirometry, and reactive oxygen species production was measured using AmplexRed fluorescence. Short chain fatty acids and succinate are either provided with the fluids during resuscitation post sepsis or through drinking water ad lib. Conclusions: SFCAs and succinate may be required for protecting peripheral tissue during ICU-like conditions. Although more studies are required to confirm these findings in human patients, changing standard enteral and/or parenteral nutrition may help reduce ICU mortality.

Abstract Name: **Determining the Functional Role of Short Open Reading Frames in Mycobacterium smegmatis**

This study examines the roles of a subset of short open reading frames (sORFs) in M. smegmatis using targeted mutagenesis and subsequent examination of the phenotypes associated with sORF absence or overexpression. sORFs are defined as stretches of nucleic acid encoding a protein with a maximum of 50 amino acids. Genome annotation pipelines overlook sORFs encoding small proteins (sproteins) and, thus, sproteins in bacteria have gone unnoticed, even those that are expressed at levels similar to larger proteins. Recent advances in ribosome profiling, mass spectrometry, and RNA-sequencing capabilities have identified hundreds of previously unannotated sORFs, increasing the number of annotated genes in both the M. tuberculosis and M. smegmatis genomes. Previously studied sproteins have been found to carry out diverse functions within the cell, ranging from modulating enzymatic activity to stress-response signaling. In the present study, sORFs were inspected using a JBrowse genome viewer that displays RNA-seq and Ribo-seq data mapped to mycobacterial reference genomes to determine active gene boundaries. The sORFs chosen for study are thought to be physiologically relevant based on their high expression level and conservation within the M. smegmatis genome and across other mycobacterial species. Utilizing targeted mutagenesis protocols, mutant sORFs were created and assayed for a reproducible phenotypic effect. The assays utilized aim to accurately address the function of the synthesized sprotein itself, as well as examining the potential of the sprotein to participate in fundamental cellular processes. Studying sORFs and their encoded sproteins has the potential to provide insight into how they modulate biological functions, and to identify novel functions not previously considered due to their seemingly negligible size. Therefore, a multifaceted approach was developed through targeted mutagenesis and studying the associated phenotype in response to gene mutation and overexpression to address the challenge of determining functional roles for small proteins in mycobacteria.

Abstract Name: **Racial and gender differences in individual sleep health dimensions among adults with poor sleep and excess weight**

Purpose: To explore the associations between sociodemographic factors and sleep health, both individual dimensions and overall composite score, among adults with perceived poor sleep and excess weight. Context: Sleep health is multidimensional and may vary based on sociodemographic characteristics. Previous research focused on a single dimension of sleep e.g.,. quality or duration. However, it is important to examine overall (composite) sleep health and individual dimensions.Methods: As part of the screening process for a larger study, individuals provided sociodemographic information and answered the RU-SATED questionnaire. RU-SATED is a six-item, self-report questionnaire that assesses the six sleep dimensions (regularity, satisfaction, alertness, timing, efficiency, and duration) through a scale of rarely/never (0), sometimes (1), and usually/always (2). Individual dimension scores were summed to calculate the composite sleep health score. Chi-squared and Oneway ANOVA tests were used to examine differences in sleep health by sociodemographic factors.Results: Participants (N = 52) were predominantly white (n = 38, 73.1%) and females (n = 41, 78.8%). The average age was 43.6 years old (standard deviation [SD] 17.0, range 20-76), and the body mass index (BMI) was 34.4 kg/m2 (SD 5.3, range 27.1-48.4). While composite sleep health scores did not differ by race or gender, results showed that females had better sleep efficiency (P = .009) than males. Also, those who were White had better sleep duration (P = .045) than those who were Black/African American, Asian, or American Indian/Alaska Native. There were no statistical significant differences with regularity, satisfaction, alertness, or timing with either gender or race.Conclusion: This study demonstrated that individual sleep health dimensions can produce differing results based on gender or race. Therefore, it is important to evaluate composite sleep health and individual dimensions when addressing poor sleep health in an intervention.

Abstract Name: **Playful Learning: The disposition of architecture as the pedagogy**

Education is a vital foundation of a society. The standard of today's school environment is built upon the pedigree of the factory schools from the nineteenth century. However, elementary age children require a flexible, engaging, and creative learning environment that the standard school environment does not provide. Learning is a dynamic and innovative action. Architecture should mirror the learning that it supports through providing spaces that allow for flexibility, engagement, accessibility, and attraction. Children are transformed by the spaces they are in, spaces that will leave lasting impacts on the cognitive development of the children, spaces that can be playful and imaginative for learning. By looking at how play is beneficial in children's cognitive growth and the crucial role that architecture plays in supporting the learning processes, this research aims to explore the architecture of play as a means to support the children's learning processes and cognitive growth. What are design strategies to create architecture that facilitate dynamic learning and pedagogy? What are ways that the physical space can stimulate playful learning through the senses, tactics, and imagination of the children? Constructivist psychological theorists Piaget and Vygotsky argued that children's cognitive development occurs within physical and social environments. In relation to the notion of learning by doing, promoted by Froebel, Dewey, and Montessori - the benefits of learning-by-doing are refined physical motor skills, improved bonding within relationships, confident self-expression, communication, language, greater independence, and creative problem-solving and thinking. Learning-by-play predisposes a child with the practice of learning-by-doing at an early age, curating a life-long impact. Besides researching pedagogical approaches and theories, this research examines examples of successful designs of school for children. Architecturally, learning-by-play allows children to explore their environment freely, enjoying the physical and temporal space through senses and imagination.

Abstract Name: **Understanding Male Student Athletes of Color Perception on Mental Health and Stress**

The college-to-professional league sports pipeline is a breeding ground for stress. Men of color are susceptible to being pulled into this pipeline system. Given the existing intersection between race and gender in athletics, when you combine being a man of color and being an athlete, there is an overwhelming risk for this specific population to experience declining mental health and mental disorders. The purpose of the research is to understand the college-to-professional sport pipeline system and identify athlete-specific and culturally/racially relevant risk factors for declining mental health. I interviewed four athletes of color from different institutions (and I am currently trying to increase my sample size). Iaskeda mixture of demographic and open-ended/closed-ended questions to identify the various areas of stress and gain perspective on mental health. Iobserved each participant for a day to gather a sense of what they experience. I discovered how mental health is affected by a system where college athletics is the “pipeline to the pros”, and how various institutions are advocates for mental health but lack a solid framework that offers whole-person support and considers all aspects of an athlete.My findings shed light on the pressure to do well in sports from a young age up until adulthood. While pressure and stress increase, there are limited mental health frameworks within sports programs specifically to deal with this stressFindings from this research will facilitate the development of frameworks for the psychological needs of athletes, and increase the availability of existing resources.

Abstract Name: **How Gen Z Views Incentive and Productivity in the Context of Continuous Improvement (CI)**

This study examines how Generation Z views incentive and productivity in the context of continuous improvement (CI). Many industries have successfully identified CI factors that have improved overall productivity. However, applying previously found CI factors may not extend the longevity of CI. Continuous improvement is an ongoing improvement of a process, technique, or product that can be judged against its effective use of resources (productivity). As such, the question of what incentives drive a specific population of potential workforce leaders, such as Generation Z, remains. This research aims to identify the factors that impact the support for CI initiatives among college students. Specifically, the study examines how incentives encourage productivity and promote job growth and satisfaction among Generation Z students who concurrently study and work. Two hundred undergraduate junior and senior student participants will complete a survey on whether an educational process (including educational resources), an embedded incentive system, has encouraged productivity both in academics and in their current jobs. The data collected will be run through regression analysis to investigate the relationship between the current incentive system and job environment incentives toward productivity. The results of this study will add to the previous research in understanding the correlation between academic performance and what incentives motivate students to be productive in their studies and their motivation to continue working during their studies. Research on this subject is needed to build a complete understanding of the correlations between undergraduate employment in relation to academic success and workforce productivity orientation in the context of continuous improvement orientation.

Abstract Name: **Retroactivity of Judicial Override Ban in Alabama**

Alabama consistently has the highest per-capita rate of capital sentencing and one of the highest execution ratesin the United States. This is largely attributed to the fact that Alabama, prior to the 2017 abolition of judicial override in capital sentencing, was one of three states in which the jury's sentencing verdict in capital cases was subject to judicial override (the others being Delaware and Florida), and the only state in which the practice was habitually utilizedin favor of death penaltiesrather than life sentencing. In 2017, United States Supreme Court ruled this practice unconstitutional under the Sixth Amendment, inHurst v. Florida.However, amended Alabama statute does not apply retroactively, andof the 166 inmates currently on Alabama Death Row, 31 face execution as a result of judicial override. The vagueness of Alabama statute does not address whether defendants charged but not convicted prior to the 2017 ruling may still be subject to judicial override in their capital cases. Toprove the unconstitutionality of upholding death sentences resulting from judicial override and of using the practice in any and all cases, this study will: examine to what extent racial bias and political gain influence the practice; evaluatecommonalities amongst aggravating factors and expressed judicial bias; examine the number of Alabama death-row convictions later overturned due to proof of innonence or prosecutorial misconduct; and compare the Alabama statute to relevant Delaware and Florida law. The result will be a legislative proposal to the Alabama Supreme Court and Department of Justice to abolish judicial override in its entirety, to amend the currentAlabama statuteto clearly dismiss of all loopholes permissing the practice, toamend the statute to retroactively apply, andto reverse the sentences of the aforementioned 31 Alabama death row inmates.

Abstract Name: **The effects of restoration projects on phosphorus concentrations throughout Manitowoc County streams and Lake Michigan**

Phosphorus poses an ongoing challenge to Lake Michigan. Excess levels cause algae blooms resulting in degraded water quality in near-shore waters. As local tributaries serve as important phosphorus sources to Lake Michigan, we analyzed phosphorus levels in two streams in Manitowoc County, WI—Centerville Creek and the Little Manitowoc River.These streams have historically exceeded Wisconsin DNR surface water phosphorus standards of 0.075 mg/l phosphorus. Each stream has undergone restoration near where they enter Lake Michigan in order to slow stream flow and reduce phosphorus loading into Lake Michigan.Each creek showed a different trend in phosphorus concentration along its length.Centerville Creek showed lower phosphorus concentrations within the restoration area compared to the upstream branches, although all significantly exceeded the WDNR threshold. North branch averaged 0.510 mg/L phosphorus, and the south branch averaged 0.430 mg/L.Sites within the restoration project averaged 0.307 mg/L. In contrast, no difference in phosphorus concentration was noted between the upstream and restoration sites in the Little Manitowoc River.This may be because this restoration was more recently completed (2020 vs 2012), or due to the surrounding land use as the Little Manitowoc River runs through the city of Manitowoc, while Centerville Creek goes through agricultural land. However, overall concentrations across the Little Manitowoc River were lower than any of the Centerville sites, with an average concentration of 0.071 mg/L, below the WDNR threshold, and rain events did not increase phosphorus as much as in Centerville Creek. Future work will focus on identifying future sources as well as continued monitoring to evaluate the success of these restorations and inform land use decision-making.

Abstract Name: **Predicting Vape Usage Among Young Adults**

Peer pressure has been demonstrated to be one reason why young adults are using e-cigarettes (Wallace; Roche, 2018). However, there is little research looking into how attitudes of masculine norms might influence personal vape usage. Masculine norms might influence individual's vape usage through peer pressure (Iwamoto; Smiler, 2013). Evidence explains that individuals who follow masculine norms more closely may be more likely to engage in risky behaviors, and using vape products could fall under this category (Iwamoto; Smiler, 2013). This study examined the impact that masculine norms and peers' vape usage have on individuals' personal vape usage. Data was collected from 1 non-binary, 51 female, and 13 male participants (n= 65) attending the University of Wisconsin-Superior and nearby colleges and universities. This study demonstrated that participants' attitudes about masculine norms did not influence personal vape usage. However, along with previous research, this study demonstrated that peers' intention to vape was correlated with participants' potential to vape. Future research could utilize a larger sample size, in which gender is more evenly distributed.

Abstract Name: **Detection of Low Concentration of Bifenthrin and Esfenvalerate using Molecularly Imprinted Polymers**

Molecularly imprinted polymers (MIPs) were prepared for selective detection at trace levels of pesticides, including bifenthrin and esfenvalerate. If traces of these pesticides reach environmental waters, even in low concentrations, they may be harmful to aquatic life.The goal is to develop imprinted polymers that can be used either in a solid phase extraction for concentration of eachpesticide from dilute environmental samples, or for direct analysis of the compounds via HPLC. MIPs were prepared in dry chloroform with template (bifenthrin or esfenvalerate), monomer (methacrylic acid), and crosslinker (ethylene glycol dimethacrylate) in the ratio of 1:8:40. The initiator2,2'-azobisisobutyronitrile was added and polymerization was completed by ultraviolet radiation (365 nm) for 24 hours at 6 °C followed by placing polymers in an oven at 80°C for 2 hours. Polymers with no template were also prepared as controls for comparison. Recovery of the template after grinding each polymer was 93.1% for bifenthrin and 25.4% for esfenvalerate, so washing to remove template continues for esfenvalerate. For bifenthrin, the polymers were sieved to collect particles between 38 and 63 µm, which were packed into empty stainless steel HPLC columns for evaluation of their ability to selectively retain the pesticide for which they were prepared. For a first evaluation, acetone was used for comparison of the void time on each column and acetonitrile was used as mobile phase. The polymer showed a slight increased retention of bifenthrin on the test column compared with the control column.Evaluation continues with different mobile phases.

Abstract Name: **Does Gender Equality Improve Health Outcomes?**

Research on women's role in global health focuses on disparities in women's health, but often overlooks the contribution that women make to improving global health outcomes. In response to this gap in research,this paper proposes to explain variation in health outcomes between countries using gender equality as the primary independent variable of interest. The analysis is conducted through cross sectional large-n style multiple linear regression analysis of national-level data in 74 countries. Health outcomes are operationalized as under-5 mortality rates in 2019, while gender equality is operationalized as gender parity index in secondary school enrollment and percentage women in national government in 2018 and 2017, respectively. This study found that gender equality indicators have a statistically significant relationship with under-5 mortality rates. Plausibility probes using process tracing in Rwanda and Bangladesh indicate that as gender equality indicators improve, health outcomes do as well, despite recent instability and low GDP per capita rates. Possible policy implications of this study include the consideration of women's participation in public health initiatives.

Abstract Name: **The New Eden: How Faith and Folklore Shaped Appalachian Culture**

In the region of Appalachia, a confluence of Old-World cultures (mostly Scottish, Irish, Germanic, and British), Native beliefs, and Early Colonial Christianity blend together to create a web of intermingled faiths and beliefs that are able to coexist and thrive well into the modern era. The Appalachian Mountains are not only unique for theirage and biodiversity, but also for the range of faith held by those who call the mountains home. Due to having its feet in both Christianity and animistic traditions, the region has become home to a beautifully unique system of beliefs that make up a wholly exotic way of life compared to the rest of the continent. By combining protestant evangelical beliefs with the Old-World mysticism of its European settlers,as well as Native American traditions and rituals, the mountains host a wide array of peoples who are able to coexist between worlds of spiritualism and biblical faith. Whether it be in Pentecostal churches or in the homes of "Granny Witches", the people of Appalachia search for faith and salvation from different, yet not exclusive, sources. This presentation seeks to examine the historical roots and roles that the concepts of Religious Faith and Regional Folklore play in shaping Appalachian culture and its continued relevance in the lives of Appalachia's population.

Abstract Name: **Evaluation of assessment data collected by nursing staff and assistive personnel in a simulation environment**

Accurate clinical assessment by nursing staff, including nurses, certified nurse assistants (CNA), and unlicensed assistive personnel (UAP), plays a critical role in the early detection of patient deterioration. Obtaining accurate vital sign data, timely documentation, and the implementation of clinical bundle protocols for patient deterioration requires education preparation, clinical experience, and sound nursing judgment. UAP delegated the task of collecting and documenting vital sign data may lack the education and clinical judgment necessary to appreciate the need for accuracy and recognize abnormal findings on a per-patient basis, delaying the implementation of clinical deterioration bundles. Therefore, the objectives of this study are to determine: 1) if vital signs are assessed; 2) if vital sign data is accurate when collected; 3) if vital sign data obtained by licensed nurses has higher accuracy rates than UAP (including CNAs); 4) if there is a potential correlation between the respondent's attitude toward the data and the accuracy of the data collected. We will employ a two-part model to identify assessment techniques and accuracy in a simulated environment, followed by a post-simulation vital sign attitude survey. Part one will utilize high-fidelity mannequins in a simulation environment to assess the method of collection and accuracy of vital sign data collected by licensed and unlicensed nursing staff. Part two will utilize the V-Scale to measure the respondent's attitudes toward vital sign monitoring in clinical deterioration to identify potential knowledge, attitude, and skills deficits.

Abstract Name: **Effect of Climate Conditions on Leaf Traits in Sunflowers**

Plants are sensitive to their environment and are phenotypically plastic, meaning that individuals are able to adjust their morphology in response to external factors. Thus, patterns of plasticity in plants are great indicators as to how our climate is changing. We are determining the effects of climate conditions, such as precipitation and temperature, on specific leaf traits in 3 species of sunflowers. These effects can help us predict and understand how sunflowers grow and acclimate in response to these climate conditions and help us understand how other plants might also change.We conducted a common garden experiment using approximately 225 plants from three species of sunflowers, Helianthus maximiliani, H. grosseserratus, and H. giganteus, planted at a site in Eau Claire, Wisconsin. We harvested leaves of each plant in July to measure a suite of traits. We focused on specific leaf area, leaf water content, and leaf thickness because these traits are often correlated and all exhibit associations with the amount of precipitation and the temperature of the environment. We are examining how these traits were affected by varying temperature and precipitation rates over the past three years and will determine if variation in trait values may be driven by environmental differences across years. These results will tell us a great deal about how sunflowers and plants in general may respond to climate change.

Abstract Name: **Analysis of Muons Produced by Electron-Positron Collisions in the Belle II Experiment**

Belle II is an ongoing experiment intended to explain the differing amounts of matter and antimatter in the universe by analyzing the products of high-energy electron-positron collisions in the SuperKEKB collider. The experiment focuses on potential differences in the decay of the B meson and its antiparticle. The SuperKEKB collider accelerates electrons and positrons to appreciable fractions of the speed of light, then slams the particles together at a predetermined interaction point inside a ring of concentric detectors. The high amounts of energy involved in these collisions leads to the formation of new particles rarely found elsewhere, including B mesons and muons. High-energy muons are ideal for calibrating and aligning the detector, and are the focus of this project. The K-Long and Muon detector, or KLM, consists of a “barrel” and two “endcap” sections, which surround the electron-positron beam pipes. These sections are divided into a meshwork of layers and strips, each of which can detect the position of a muon passing through them. This data is compared with extrapolations from the inner detector layers to determine the “efficiency” of different parts of the KLM. A set of histograms made at the beginning of the semester revealed an unexplained gradual falloff in the efficiency of strips in the endcaps. The endcaps contain two planes of strips: one with the strips laying horizontally and one with the strips arranged vertically. In both planes, the strips close to the center of the detector have a higher efficiency than the strips on the outside. This anomaly is not present in simulated data. Through analyzing more data, we hope to determine the source of the anomaly, and to increase the KLM efficiency for muons. Such an improvement would benefit Belle II’s measurements of B mesons, which often involve muons in their decay.

Abstract Name: **Enhancing STEM identity among women through participation in community STEM activities: An ecological systems theory approach**

Alverno College is a designated HSI women’s college serving primarily first-generation, and low-income students. Several lines of research strongly support the recommendation that community engagement can increase STEM retention for underserved students (Lozano, Franco, Subbian, 2017; Estrada, et. al., 2016). In addition, Estrada et al. 2016 found that showing students how to creatively link their STEM training to the needs of their communities is an effective strategy for increasing URM students’ success in STEM. We extended this research by applying Brofenbrenner’s model of human development to enhance STEM identity among women STEM majors. Our approach has been to place the individual student in a pro-social STEM community ecosystem to promote development and maintenance of their STEM identity (Miller, 2011). Alverno College’s Truchan STEM Community Impact Program (T-SCIP) program funded by NSF IUSE HSI (award #2122903) applies evidence demonstrating that women and underserved students in STEM are motivated by directly experiencing ways STEM benefits the communities where they live. Specifically, the T-SCIP program provides multifaceted community based activities involving STEM peer mentoring, STEM faculty support, engagement with STEM community partners, the social support communities for the student (such as, family and friends), STEM alumnae, and the STEM professional community. We will report program organization and preliminary findings of the impact Alverno College’s T-SCIP program has on STEM identity, sense of belonging, interest in pursuing research opportunities and graduate school study in STEM. Using a quantitative and qualitative study design, preliminary data suggests participants discuss the benefits of learning from each other, as well as having opportunities to develop personal leadership skills in science. Survey questions indicate participants gained confidence for doing science and being a scientist. We will also report retention and persistence to graduation rates in STEM.

Abstract Name: **Stratigraphic Analysis of Paired Vegetated Linear Dunes in the Nebraska Sand Hills Using Ground Penetrating Radar**

There are three models of linear dune formation, and there is no agreement on which theory best explains their formation. The research focuses on the stratigraphy, the internal sediment layering, of the Nebraska Sand Hills' paired linear dunes in north-central Nebraska to determine how the dunes there were formed. Sand dunes are given their shape by wind velocity and sand supply. Therefore, the shape of dunes and the internal layering of sediment within them are indicators of the former wind regimes and dune movements during formation and can be used to determine the correct formation model.
The ground penetrating radar (GPR) data was collected in herringbone-shaped transects centered in the trough between paired linear dunes, extending over the crests. The pattern maximizes the visible internal layering within the dune. Sensors and Software's Pulse EKKO Pro GPR system was used as a non-invasive, high-resolution means of viewing stratigraphy. Topographical data was collected every 2 meters using Topcon RL-H4C laser level. The GPR data was collected using a frequency of 100 MHz antenna frequency, maximizing image depth while maintaining image resolution. The GPR transmitter and receiver were separated 1 meter apart and traces collected every 0.25 meters. The transects varied from 45 meters to 150 meters long. GPS points were plotted at the beginnings and ends of transects to accurately record GPR data locations. Results show some dune stratigraphic layers being superimposed over dune's, which indicates different periods of deposition. This would support a bimodal wind theory over windrift or helical roll vortices theory. The southern dune of the pairs compared to the northern are larger, suggesting two separate formational periods for each dune. Further GPR investigation and Optically Stimulated Luminescence (OSL) dating on sediment cores should be conducted to confirm ages of stratigraphic layers to provide further evidence of our results.

Fricks-Gleason, Ashley

Institution: *CO - Regis University*

Discipline: FAN Abstract

Author/Contributors:
Ashley Fricks-Gleason

Abstract Name: **Increasing access to mentored research and creative inquiry opportunities through the creation of an Undergraduate Research Certificate**

Undergraduate research is a high-impact practice that deeply engages students with the university. In order to stimulate undergraduate research and creative inquiry at Regis University, we created an Undergraduate Research Certificate to officially recognize students who engage in significant, mentored undergraduate scholarly activity. The goal of the certificate is to make research opportunities more transparent and accessible to a diverse student population. While some students arrive at Regis knowing they might like to pursue undergraduate research, many more – especially first-generation college students and historically marginalized populations – do not discover research until they are in college. As such, programs that enroll students in their first semester (e.g. our Honors Program) unintentionally exclude our most marginalized students. This Certificate aims to engage a diverse population of motivated undergraduates in collaborative research or creative inquiry with a faculty mentor by combining research-specific coursework with disciplinary courses and transcripted research credits. A slate of newly-created courses allows for the big-picture research training, teaching of communication skills, professional development training, and vocational discernment to occur within full cohorts. This learning is then supplemented in disciplinary-appropriate ways through individual mentorship pairings. By formalizing the process, the Certificate provides research training, mentorship, and a line on the transcript/CV for students who may discover the joy of research and scholarship later in their academic career, or who may not otherwise fit the requirements (GPA, etc.) for other programs. The addition of the Certificate to our curriculum has provided a novel avenue for students to deeply engage with their faculty. By making this high-impact, valuable experience available to all students who desire to perform undergraduate research, we have lowered a barrier and increased support for some of our most marginalized student populations. This presentation will speak to the lessons learned during the program's initial two years.

Friedman, Lucy

Abstract Name: **Safe communities Safe Schools presentation**

Safe Communities Safe Schools (SCSS) is an adaptive model for school safety in community engagement, capacity building, and data-based decision making. This research based model is designed to create a school that promotes social, emotional, and physical safety. Current STOP School Violence funding through the Bureau of Justice Assistance (BJA) has given SCSS an opportunity to work with 40 schools across Colorado. To recruit schools for this partnership, I am supporting the development of a database to share information about the project and assess schools' potential needs (e.g., alignment with current improvement plans, level of state-funded support, culture, and climate data). By April, I will be able to share information about considerations for recruitment of school participants for this kind of project, along with an analysis of potential factors that increase the likelihood of schools' choosing to collaborate. Once schools are recruited, SCSS members will facilitate meetings to identify needs and gaps in school culture, climate, and safety (e.g., information sharing, SEL MTSS, mental health referrals, bullying prevention), using survey tools developed by the SCSS team. Data from these tools will help prioritize needs and develop action plans, and I will complete a comparison of school needs identified during the recruitment process with current local data. In summary, I intend to cover strategies that SCSS relies on to help translate research into practice regarding recruitment, school engagement, existing versus more recent data, and strategies for being responsive and adaptive to unique needs in the school environment.

Abstract Name: **Effects of Well Opacity, Well Shape, Length of Light-Dark Stimulus Time, and Larval Age on Zebrafish Larvae Swimming Behavior Development**

Zebrafish are an excellent model organism for high-throughput behavioral analysis. Measuring development of simple behaviors such as swimming can provide insight on underlying neurodevelopment of zebrafish larvae. Dark-induced hyperlocomotion is a common stimulated movement used to assay swimming behavior. Video tracking software allows analysis of swimming patterns in response to cycles of light and dark stimuli in a controlled environment to be conducted. However, the methods used in such zebrafish behavioral studies vary in the literature, and some intrinsic and extrinsic factors have been shown to significantly affect fish behavior. We investigated whether four additional factors (well opacity, well shape, length of light-dark stimulus time, and larval age) influence swimming behavior in larval zebrafish. 5 day post-fertilization (dpf) zebrafish in 96-well plates were exposed to an alternating light-dark protocol and tracked for movement using a commercial motor tracking system (Noldus DanioVision). 5 dpf fish in opaque wells showed higher average velocity compared with 5dpf fish in clear wells. Fish in square wells also showed higher average velocity in all lighting conditions compared to fish in circular wells. Fish exposed to differing lengths of light-dark stimulus time showed no difference in swimming behavior. Varying the age of zebrafish larvae tested also showed no effect on swimming behavior. Our results emphasize the importance of internal normalization per experiment and reporting protocol details to enable informed comparisons between these kinds of behavioral studies.

Abstract Name: Food Environments and Healthy Communities: An Assessment of the Food Environment on the University of Wisconsin-Eau Claire Campus

The foods we eat are a determinant of health and wellbeing, with nutrition as a key factor in the most prevalent chronic diseases in the United States including heart disease, obesity, and diabetes. Food environments, the physical, economic, and socio-cultural settings that play a role in what people choose to eat, are associated with diet-related health outcomes. In the university setting, campus food environments are an important determinant of what students eat which influences their quality of diet and nutrition status. To examine the food environment at the University of Wisconsin-Eau Claire (UWEC), students enrolled in a course titled “Food Environments and Healthy Communities” measured the availability and accessibility of healthful food options on campus using University of Pennsylvania’s Nutrition Environment Measurement Surveys. In a student-led approach, sampling boundaries were determined to include food outlets on campus and in the surrounding community. Survey data was collected and scored to provide quantitative data regarding the affordability and nutritional value of food fromvending machines, cafeterias, grab-and-go shops, restaurants, and stores. The data gathered will enable researchers to provide evidence-based recommendations to student senate, university administration, and city council, with the overall goal of improving the campus food environment such that students have equitable access to affordable and healthy foods which is key to health, quality of life, and educational success.

Abstract Name: Variations in System Parameters at Low Energy Input on Thermosiphon Collector Efficiency

A thermosiphon is a system of components that passively generates a closed cycle of flowing water wherein solar energy is stored as useful thermal energy. Systems used in real-world applications contain no mechanical or electrical components, making it useful in areas lacking capable infrastructure. Flow starts in the collector by heating the water, decreasing its density, and creating a buoyant force, which drives the fluid through a hot leg pipe into a raised tank. This heat contained in the tank could be extracted for domestic hot water heating or building supplemental heating applications. The water cools, increasing its density, and sinks down the cold leg pipe and re-enters the collector where the process continues cyclically. Thermistors, located at the collector inlet and outlet pipes, measure system temperatures and an open-bore flowmeter measures flow through the system. During steady-state, a period where flowrate, inlet and outlet temperatures remain relatively constant, collected data is used to calculate the instantaneous efficiency of the system. The discreet efficiency values are then used to calculate overall efficiency. Components of the system allow the ambient temperature around the device to be controlled, a parameter overlooked by most thermosiphon research projects. These components include insulated, removable walls enclosing the device, a fan to circulate the air inside the enclosure, and a space heater and AC unit to control the temperature. Previous research has used high-power input to the collector simulating sunny-days, but current research conducted low-power tests simulating cloudy-days to compare trends across both conditions. The base parameters that are varied and researched are collector angle, hot leg height, cold leg height, hydraulic resistance, and input power. By conducting a range of diverse test series, each investigating the effect of altering a single parameter, the team explored the effects of each system parameter on overall efficiency trends.

Abstract Name: **Mapping of spinal dorsal horn interneurons associated with the lower urinary tract in mice**

Precise coordination between sensorimotor systems of the lower urinary tract (LUT) is required for normal micturition function. To date, the intraspinal circuitry of the lumbosacral spinal cord (SC) with respect to regulating the LUT remains unclear. Interneurons (INs) within the dorsal horn of the SC receiving input from urinary bladder (BL) primary afferent neurons are critical to the coordinated, but opposing, function of the LUT (e.g., BL detrusor and external urethral sphincter). An increased understanding of how IN circuitry changes in the context of LUT dysfunction, particularly spinal cord injury, would enhance the development of therapeutic strategies for functional recovery. The goal of this study was characterizing the location and number of SC INs receiving input from BL afferent neurons. GFP-conjugated pseudorabies virus (PRV-512; CNNV, Princeton University) was microinjected into the BL wall (10 ul total volume in 3-4 sites) of anesthetized male and female C57Bl/6 mice (JAX). At either 3, 4, or 5 days after injection, animals were humanely euthanized and lumbosacral SC tissue was harvested and processed for immunohistochemical labeling of PRV-512 and photographed (Leica LMD6 and DFC3000G). Transsynaptically labeled SC INs were identified and quantified using a thresholding strategy in NIH ImageJ and Adobe Photoshop, focusing on what were thought to be primary INs making direct synaptic contact with afferent axonal input. Results demonstrated that day 4 was optimal for PRV-512 visualization in the lumbosacral SC, the L6 superficial dorsal horn contained the most primary INs, and that the L6 dorsal commissure contained the fewest primary INs. These results suggest IN population discrepancies in rat and mouse SC architecture within LUT-associated regions.

Abstract Name: **3D Printing to Improve Patient Outcomes for Mini-Thoracotomy Aortic Valve Replacements and Mini-Mitral Valve Repairs**

Aortic valve replacement (AVR) was established in the 1960's and has become a routine therapy to treat patients with severe aortic valve dysfunction. AVR is usually performed using a full sternotomy and cardiopulmonary bypass support. Since the late 1990's, minimally invasive procedures have been developed for aortic valve surgeries, such as the mini-thoracotomy AVR. These less invasive procedures claim reduced postoperative complications, shorter lengths of stays in the hospital, and lower mortality. However, the minimally invasive nature may provide challenges in the viewing of patient anatomy during the procedure. This project will provide the 3D printing capabilities needed to investigate if using 3D printed anatomical models for pre-operative planning and/or patient education will result in better patient outcomes for mini-thoracotomy AVR surgery, particularly in those with thoracic abnormalities. For selected patient cases, the Mayo Clinic Luther Campus will provide UWEC researchers with DICOM files for segmentation and 3D printing. The UWEC research team will perform the segmentation and provide the physical 3D anatomical model with initial feedback on accuracy from Mayo physicians. Ultimately, the Mayo Clinic collaborators will evaluate the effectiveness of using the 3D models in patient outcomes as well as patient education on the procedure.

Abstract Name: **Effects of Stress on Corrosion Behavior of Additively Manufactured 316L Stainless Steel**

Laser powder bed fusion (LPBF) additive manufacturing (AM) is a relatively new manufacturing method in which metal parts are manufactured layer-by-layer through rapid heating and cooling of the powder bed. Consequently, complex geometries can be produced to simplify assemblies and reduce material wastage. These benefits make adopting additive manufacturing enticing, however mechanical and electrochemical properties of AM metals are significantly influenced by their unique microstructural and defect features that are highly dependent on the build parameters. In this paper, we will investigate the interplay between mechanical and electrochemical effects on additively manufactured stainless steel 316L (SS316L). Tests are designed to perform corrosion characterization on AM coupons in stressed and stress-free conditions. Corrosion properties such as pitting potential, corrosion potential, and corrosion current density will be characterized under both stress conditions. Results of the AM samples will be compared with the results of the wrought SS316L to understand the effects of microstructure and defects on corrosion properties. Conclusions will be made about how significant the impact of additive manufacturing is on key properties of this material and if there are any relevancies to its microstructural characteristics. This increase in insight will reveal how to implement AM SS316L safely so its previously mentioned benefits can be realized when appropriate.

Abstract Name: **In-House Development of Sensor and Motor shields for Utilization on Robotic Systems**

In this work, the low-level (LL) hardware for sensor collection, motor input, and networking with a high-level (HL) controller is presented for robot systems which utilize linear series elastic actuators (LSEAs) for joint actuation. In multi-joint robotic systems, LL controllers rely on sensor readings to control each joint and communicate the obtained information to the HL controller. This research outlines the hardware design of two printed circuit boards (PCBs), as well as the use of an EasyCAT PRO board for communication. An in-house sensor interface shield is designed as an extension of the TM4C123GXL TIVA microcontroller launchpad and another in-house shield connects to the AZBDC12A8 analog servo drive, or rather, the motor controller. These PCBs allow for sensor integration with circuits that route, filter, or manipulate data obtained from the sensors. The goal of the sensor interface shield is to interface between sensors and the microcontroller. The sensor board takes readings from a force sensor, absolute encoder, quadrature encoder, as well as adjusting the pulse-width modulation (PWM) signal that is sent to the motors. The sensor shield also includes Controller Area Network (CAN bus) capabilities to allow for additional sensors to be included. The main purpose of the motor shield is to supply power, route the PWM input, and filter the current output of the motor. The final designs for both the shields are built in the PCB design software Eagle. Overall, these boards will allow for better sensor integration for LL controllers which interface with LSEA driven multi-joint robotic systems.

Abstract Name: COMMUNICATION DISORDERS GRADUATE STUDENT SKILLS IN THICKENING LIQUIDS

Previous research has reported inconsistent and inaccurate production of thickened liquids used as a treatment for those with dysphagia,which can have major health implications for individuals who ingest these liquids. The International Dysphagia Diet Standardisation Initiative has been created to help provide consistent terminology and a method for testing these liquids, but the liquid production and use of this method by future speech-language pathologists (SLPs) must be examined to ensure the liquid range is accurate and that they use proper protocols. This research examined 16 graduate students to determine the effect of clinical placements that required them to thicken liquids on their performance of this task. This study also examined confidence levels and familiarity with IDDSI to determine their effect on liquid performance. The examination included an analysis of the classification of the level of thickened liquid and the procedures associated with production. Overall, this study found that there was no association between clinical placement and the performance of two thickened liquid tasks. This study also found that the majority of participants (80% forMildly Thick; 66% forModerately Thick)did not prepare a liquid that was the directed consistency. In addition, no participant correctly used the IDDSI flow test. The researcher informally observed delayed application of gloves or incorrect attempts of the IDDSI flow test.Ultimately, these future SLPs areexpected to correctly thicken liquids that follow their swallowing course, so it can carry over to future clinical practice as a speech-language pathologist. These results indicate that changes or improvements should be made to the thickened-liquid education and training received by graduate students at the university.

Abstract Name: Development of a Wound Infection Detection Device

An infection within a wound is a devastating circumstance that can potentially turn a simple graze to a multi year long healing process. The latest methods for wound infection detection are cumbersome and time consuming. These practices often need to undress the wound and leave it exposed for a few seconds or up to an hour. Undressing a wound is counterproductive to the healing process and this small window of exposure can possibly result in an infection in itself. There is a need for a tool that allows for active infection detection that causes very little to no compromise to a wounds healing environment. The device we propose is placed amongst the gauze whenever a wound is initially dressed and implements an array of sensors to collect a wide range of data. The type of data we plan to collect is pH, pressure, moisture, and temperature. We also want to have an integrated RFID or WIFI module so that this data can be wirelessly collected from the device. The specific methods involved for this developmental project start with designing and testing the responses of multiple sensors in an infected wound environment compared to a healthy environment. This is done so that a reference point can be made when a healthy wound transitions to an infected wound. Currently, progress is being made towards gathering preliminary data and calibration of our sensors for our design. Although the project is still in its early stages, It will be beneficial to observe the outcomes from the system in simulated wound environments to provide a baseline for further research and applications.

Abstract Name: **How Gen Z Views Incentive and Productivity in the Context of Continuous Improvement (CI)**

This study examines how Generation Z views incentive and productivity in the context of continuous improvement (CI). Many industries have successfully identified CI factors that have improved overall productivity. However, applying previously found CI factors may not extend the longevity of CI. Continuous improvement is an ongoing improvement of a process, technique, or product that can be judged against its effective use of resources (productivity). As such, the question of what incentives drive a specific population of potential workforce leaders, such as Generation Z, remains. This research aims to identify the factors that impact the support for CI initiatives among college students. Specifically, the study examines how incentives encourage productivity and promote job growth and satisfaction among Generation Z students who concurrently study and work. Two hundred undergraduate junior and senior student participants will complete a survey on whether an educational process (including educational resources), an embedded incentive system, has encouraged productivity both in academics and in their current jobs. The data collected will be run through regression analysis to investigate the relationship between the current incentive system and job environment incentives toward productivity. The results of this study will add to the previous research in understanding the correlation between academic performance and what incentives motivate students to be productive in their studies and their motivation to continue working during their studies. Research on this subject is needed to build a complete understanding of the correlations between undergraduate employment in relation to academic success and workforce productivity orientation in the context of continuous improvement orientation.

Abstract Name: **Role of Regulatory mRNA Structures in the Expression of Cancer-Related Genes**

Messenger RNA (mRNA) translation, the synthesis of proteins based on genetic code, is an essential process in gene expression. Translation is often inhibited when cells are under stress, but there are mechanisms that allow certain genes to bypass stress-induced inhibition. Prior studies have identified a list of genes that disregard stress signals to continue mRNA translation using regulatory RNA structures to hijack the translational machinery. We hypothesize that stress-signals must alter the RNA structure to trigger structure-mediated mRNA translation. Our target genes include oncogenes HIF1A, FGF2, and tumor-suppressor gene TP53. We aim to amplify regulatory mRNA regions previously reported for each gene from A549 lung carcinoma cell lines. Next, we will build and compare structure models for regulatory regions under three conditions: (a) cell-free, (b) in-cell unstressed, and (c) in-cell stressed. For structure modeling we use SHAPE-MaP, a chemical-probing strategy analyzed using next-generation sequencing (NGS). We have successfully extracted, probed, and amplified the target regions using gene-specific primers, reverse transcription (RT), and polymerase chain reaction (PCR). We analyzed PCR products using gel electrophoresis. Here we describe our experimental workflow along with data from NGS library preparation. Applying NGS using the Illumina MiSeq platform on target mRNAs, we will build RNA secondary structures with Shapemapper2 and SuperFold software packages. Our long-term goal is to describe structure-based mechanisms by which translation of cancer-causing mRNAs can be blocked, and how translation in cancer-fighting mRNAs can be reengaged.

Abstract Name: **The Apple Doesn?t Fall Far from the Tree: an Examination of the Mother-Daughter Relationship in 2000's Sitcoms**

In modern television, there has been an increase in the tension between mother and daughter both in the real world and on television. This representation must be studied to better understand both its origin and effect on said relationship as a whole. To research the portrayal of the mother-daughter relationship on modern sitcoms, I examined the complexity of this relationship with post-second wave feminism ideals in modern sitcoms and compared the factors leading to a beneficial relationship and a toxic one. Research suggests that strong mother-daughter relationships follow a more traditional pattern, where a daughter accepts her mother's lifestyle as a viable path and chooses to model hers after it. It also suggests that weak mother-daughter relationships can follow a more modern pattern where a daughter tries to forge her own path and abandons the typical cycle of mimicking one's parents. With this in mind, the relationship between mother and daughter is psychoanalyzed in both Jane the Virgin (2014) and Arrested Development (2003), and the two opposing relationships are compared in order to better understand what specific social factors contribute to the differences. From Jane the Virgin, I found that the main factor contributing to a healthy mother-daughter relationship is the daughter's ability to learn from her mother's mistakes and communicate with her mother in order to utilize maternal wisdom. From Arrested Development, I found that toxic mother-daughter relationships stem from the refusal of mother's advice by the daughter, where the mother creates an unsafe or unpleasant environment around the daughter, leading the daughter to reject maternal wisdom. It is necessary for those that value familial relationships in third-party contexts, such as television, to understand what differentiates healthy and unhealthy relationships to be able to assess their own mother-daughter relationships and implement strategies for improvement where necessary.

Abstract Name: **Exploring the Contextual Interference Effect Using a Bimanual Coordination Task**

Stroke, amyotrophic lateral sclerosis (ALS), and other movement disorders result in loss of upper limb function, thus impairing bimanual coordination. Motor imagery is an effective clinical intervention for accelerating recovery; however, the cognitive and neurophysiological parameters that inform effective strategies remain elusive. The study aims to explain the neural dynamics that underlie bimanual coordination during real and imagined movement. Healthy young adults (n=13) learned a visuomotor tracking task using either one or both hands in a single session. Two dials control the movement of an on-screen cursor. The left and right dials correspond to vertical and horizontal cursor movement. The participants were tasked with tracking a moving target using the left and right dials with the appropriate speed and direction. Before the session, each participant was fitted with a 40-channel EEG cap (Compumedics, Neuroscan). Two phases were tested: unimanual and bimanual control. The first phase consisted of unimanual control using the left hand to draw a vertical line and the right hand to draw a horizontal line. The second phase consisted of bimanual control in a 3:1 pattern followed by a 1:3 pattern. The pattern notation represents the ratio of left-hand turns to right-hand turns. Trials were 10 sec in duration, elapsed time from target origin to target endpoint; the intertrial interval (ITI) was 5 sec. Each trial block was followed by a mental imagery condition (MI) where participants were asked to imagine performing the task they had just completed with their eyes closed. Mental chronometric data were collected, and vividness ratings were assessed by self-report immediately after each trial block. The results indicated learning in a single secession; [F(1,10)=19.43, .001]. EEG analyses of active vs. rest conditions, and real vs. imagined conditions, are underway. These results may inform neurorehabilitation strategies for patients recovering from movement disorders (upper limbs).

Abstract Name: **The Ethical Flaw of American Conservation Theory**

American environmental conservation is typically associated with the 'progressive' era and the likes of Theordore Roosevelt, Gifford Pinchot, and John Muir. The aforementioned figures are all remembered for their parts in setting aside large amounts of land for the benefit of the public as opposed to the private land owner. In the words of Pinchot, the first U.S. Forest Service Chief, "conservation means the wise use of the earth and its resources for the lasting good of men." While setting aside large swaths of land for the purposes of public interest has beneficial impacts on the environments that are conserved, the intention is to benefit humans rather than the animals or the general ecosystem in question. In turn, this creates an ethical dilemma in which beneficial effects occur from an ethically and morally skewed philosophy. It could be argued that conservation should take place as it is society's responsibility to regenerate habitats and ecosystems that are affected by human activity such as pollution, deforestation, and climate change. While the old adage 'if it's not broken don't fix it' often impedes change, there is a clear flaw within domestic conservation theory as the American landscape is still both decimated and conserved for human benefit. Although past theories of conservation act as guidelines for present activity, the issues of drought, wildfires, and other human attributed disasters display that the current system is not perfect and is in need of alterations. That being said, if locations are set aside for non-human reasons, the general public will still receive the benefits of an environment-first conservation theory through the ability of visitation and increased safety from natural disasters. A conservation theory that emphasizes environments and ecosystems before public benefit has the potential to create a more sustainable country as a whole.

Abstract Name: **Screening Marine Extracts for Antibiotic Potential against Staphylococcus aureus and Methicillin-Resistant Staphylococcus aureus**

Antibiotic resistance is a public health emergency that continues to worsen due to the misuse of existing medications and the lack of novel treatments. A potential source for new antibiotics is marine environments. Marine soil and bacterial extracts seem to be promising in their ability to fight human bacterial pathogens, including those that have evolved resistance. For this screening, extracts were prepared using organic solvents from the secreted products of marine bacteria by the UNCW Drug Discovery Lab. They were then sent to the van Hoek lab to test for antibiotic potential against dangerous bacterial pathogens, specificallyStaphylococcus aureusand the methicillin-resistant strain (MRSA). The antibiotic potentials of the marine extracts were determined through Kirby Bauer assays and Minimum Inhibitory Concentration (MIC) assays. In the Kirby Bauer assays, the zones of inhibition for each extract were compared to the zones created by the negative control (blank disk) and positive control (cefotaxime) to see if there was any antibiotic activity. This was done for bothS.aureusand MRSA for a total of 13 compounds. DSK-226 was determined to be the most promising hit for bothS. aureusstrains, with zones of inhibition of 26.5mm (S.a) and 8mm (MRSA). A MIC assay was performed to determine the concentration at which the extract could effectively be used. A precise MIC value could not be determined, indicating that the minimum inhibitory concentration is 64 ug/ml. A more concentrated sample would be needed to precisely determine the MIC. Of additional interest, a thickening in bacterial culture was observed during this test. Ultimately, one extract, DSK-226, was identified that was able to inhibit growth of S. aureus and methicillin-resistant S. aureus. This suggests the potential of identifying a new antibacterial compound in the extract mixture with further fractionation and study.

Abstract Name: **The Development of ZnO Ultraviolet All-Optical Switches**

The pursuit of faster communication has driven the development of new optical communication components, such as all-optical surface-normal switches constructed of semiconductor thin-film heterostructures. In such a device, strong control pulses and weaker signal pulses are spatially overlapped in the thin-film heterostructure and tuned to the band edge of the active semiconductor layer. The control pulse modulates the transmission of the weaker signal pulse by altering the absorption properties of the semiconductor. Zinc oxide (ZnO) is a promising switching material for all-optical switches that operate in the ultraviolet (UV) spectral region. It has a bandgap in the UV spectral region (~3.4 eV) and is less toxic than other materials with similar bandgaps, such as gallium nitride (GaN). The structures we are studying are thin, polycrystalline heterostructures composed of alternating layers of ZnO and zinc magnesium oxide (ZnMgO), where the ZnO serves as the active semiconductor layer. Our structures are grown by DC sputter deposition. In my presentation, I present the results of experiments that demonstrate control-induced modulation of 120-ps signal pulses using ZnO/ZnMgO heterostructures with varying layer thicknesses. I will show how the modulation varies depending on the energy of the control pulses and the time delay between the control and signal pulses. Moreover, I will discuss the physical mechanism that is responsible of the modulation.

Abstract Name: **Investigating the Biocompatibility of Poly(N-isopropylacrylamide)-based Nanoparticles**

Poly(N-isopropylacrylamide) (PNIPAM) hydrogels are thermoresponsive polymers which exhibit a lower critical solution temperature at approximately 31°C. The dramatic swelling and collapsing behavior of such stimuli responsive polymers enables them to be used for various applications in tissue engineering, drug delivery, and biosensing.For this reason, PNIPAM nanoparticles were synthesized using a precipitation polymerization. Briefly, N-isopropylacrylamide and N,N'-methylenebisacrylamide were combined in a round bottom flask with water, purged with nitrogen, and heated to 70°C. Then, the solution was initiated with ammonium persulfate and left to react for 4 hours, after which the nanoparticles were purified by dialysis, lyophilized, and stored at room temperature for future use. The nanoparticles were characterized using dynamic light scattering to determine their zeta potential, polydispersity, and hydrodynamic diameter. After successful synthesis and characterization of PNIPAM nanoparticles, the materials were evaluated for their biocompatibility. Specifically, murine fibroblasts were cultured under standard cell culture conditions in standard growth media and exposed to varying concentrations of nanoparticles (0.25-1.0 mg/mL) for up to 24 hours. Controls were cells cultured in parallel under similar conditions but not exposed to nanoparticles. At the prescribed time point, cell viability was determined using the CellTiter 96 Aqueous One Solution Cell Proliferation assay. Dynamic light scattering results revealed that in 0.1X PBS PNIPAM nanoparticles are slightly negative in surface charge, monodisperse, swollen at room temperature, and collapse at body temperature. Cell viability results under the conditions tested revealed >75% viability under all nanoparticle concentrations examined. The results obtaineddemonstrate the potential of these nanoparticles to be used for various applications in tissue engineering, drug delivery, and biosensing.

Abstract Name: **Atomic decomposition of partitions and the Cayley's formula**

A partition Pof a finite nonempty set Xis a collection of disjoint nonempty subsets ofX, called theblocks of the partition, whose union is X.The set of all partitions of the set X, denoted by Par(X), is endowed with the refinement of partitions. The partitionP is said to refine the partitionP' ifand only ifevery block ofP' is the union of some blocks ofP. If a partitionP refines P', then we say that Pis finer than P', or, equivalently, P' is coarser than P. For any partitionsP and P'there are partitions that are refined by both. The finest partition that satisfies this property iscalled the join ofP and P'. The partitions of X that cannot be but trivially decomposed as the join of other partitions of X are called the atomsof Par(X).It is well-known that every nontrivial partition P of X admits a decomposition into atoms.An atomic decomposition of a partitionP is a subseta(P)of atoms ofPar(X) whose join results in P. An atomicdecomposition of a partitionP is said to be minimal if it contains no other atomicdecomposition of a partitionP strictly.We investigate the function NfromPar(X) to the nonnegative real numbersthat assigns to every partitionPof X the number of minimal atomic decompositions of P. An analytical expression forN is given, as well as various interesting properties that describe its behavior in a great extent. We prove a strong relationship between thenumber of minimal atomic decompositions ofpartitions and the Cayley's formula for labelled graphs.

Abstract Name: **Field of Study Stereotypes: Are They a Reality?**

This project examines whether the stereotypes about people in specific fields of study reflect actual demographics within those majors, and data was collected by surveying and interviewing UW-Stout undergraduate students. The variables I looked into are gender, race, political affiliation, potential salary, parents' occupation, parents' level of education, and how these variables overlap. I asked students to indicate what they believe to be true about the demographics of majors such as the breakdown by gender and race, the typical political views of people in those majors, and to what degree students choose those majors based on salary. I analyzed the data by comparing views about major demographics to actual demographics, and by asking students about their own major and how they are feeling about the stereotypes associated with their major. Results show that perceived stereotypes closely align with the actual demographics and views of students within college majors.

Abstract Name: **Exploring the effects of tRNA-carrying mycobacteriophages on Mycobacterium tuberculosis infection**

Multi-drug antibiotic resistant bacteria represent a serious worldwide health-related problem. As a consequence, many types of bacterial infections in the human population are becoming increasingly difficult to treat with antibiotics. The use of bacteriophages, also called phages, brings hope and many advantages, as phages infect only bacteria and are generally harmless to people. The goal of our study was to characterize cluster A mycobacteriophages that infect various mycobacterial hosts, including Mycobacterium tuberculosis. Cluster A, which contains mostly temperate viruses, is the largest cluster of phages published to the NCBI GenBank database. Cluster A is divided into 20 sub-clusters with the largest, A1, containing 189 members. The total number of discovered phages in the A cluster is currently reported as 727. These bacteriophages have relatively large genomes with 90.5 genes and 1.5 tRNAs per genome on average. The phages utilize either lytic or temperate life cycles, with the temperate phages being able to integrate their DNA into the bacterial host as a prophage. We comparatively analyzed the 471 sequenced genomes of mycobacteriophages in accordance with their shared gene content and the occurrence of tRNA genes in their genomes. We found that thirty-two tRNA genes, coding for four amino acids, were observed among cluster A phages. These data support the notion that the presence of tRNA genes in mycobacteriophage genomes is beneficial for successful phage infection via down-regulation of host transcription, enhancement of phage replication and expansion of its ability to infect a broader range of hosts. We conclude that phages which carry tRNA genes make better candidates for the successful infection of M. tuberculosis for the purpose of combating antibiotic resistance in these bacteria.

Abstract Name: **Effective intercalation of 2D-Bi on an epitaxial graphene and silicon carbide interface**

Previous research has demonstrated the energy saving potential of quantum spin Hall materials due to dissipationless spin current characteristics. While efforts to stabilize such materials as 2D-Bi have been achieved through intercalation of epitaxial graphene on silicon carbide, growth is limited to nanoscale regions not effective for energy saving devices. This project aims to establish a process property relationship for larger scale, uniformly intercalated 2D-Bi through confinement heteroepitaxy applicable to device function. This process was optimized through adjustment of temperature, H:Ar gas flow ratios, and growth time, and results were analyzed through Raman spectroscopy, scanning electron microscopy (SEM), and x-ray photoelectron spectroscopy (XPS). It was found that maximum intercalation of Bi while minimizing extraneous Bi2O3 occurred at 900° C and 4% H2 to Ar at 500 Torr. Next steps include transmission electron microscopy (TEM) characterization of nanoscale sample structure.

Abstract Name: **Contesting Confucian Moral Paradigms in Seventeenth-Century China: A Study of Idle Talk Under the Bean Arbor**

The story Idle Talk Under the Bean Arbor is a collection of stories by the late Ming dynasty writer Aina Jushi (Aina the Layman, whose actual name is not known). Characterized by its novel narrative framing and storytelling strategies, the text boasts unconventional perspectives on paragons in heroic tales and orthodox values of the time period. In this collection of twelve chapters, participants act as both storytellers and audience members, bringing with them a diverse range of age, experience, and perspectives. This essay examines the author's capitivating strategies in creating this multi-layered and multi-perspectival retelling of classic tales by drawing from vernacular traditions. As a result, one cannot be too sure if this unidentified author could have been the sole penman of this story. Although that is a separate possibility to discuss, another one would be the idea that this narrative framing and storytelling set a precedent in the form of written works and their ability to spread information and ideas in imperial as well as modern and contemporary China. Additionally, I examine how the text challenges the conventions and traditions of their time and revolutionize the status of the common civilian to a degree. Through the use of unique setting, diverse narration methods, and directing the audience through morally ambiguous situations, the author of Idle Talk was able to shed new light onto a previously insignificant tradition of storytelling and comradery among the common folk of 17th century China. And this influence expanded into modern times as well.

Abstract Name: **Secession in Texas: Division Amongst the People**

In early 1861, following the election of Republican Abraham Lincoln, a special Texas convention voted overwhelmingly, 166-8, to secede from the Union. Yet, the decision to secede was more contested than it appears. This research analyzes the ideas of leading secessionists and anti-secessionists who tried to influence the state in making that decision. Methods used to conduct this research were analysis of primary sources such as letters, speeches, newspapers, and documents from events and individuals during secession. Secondary sources were also analyzed that included books, articles, and academic journals about events and specific groups of people in Texas. Results indicate that secessionists in Texas, like most other states, used speeches, letters, clubs, and newspapers to motivate citizens to withdraw. However, it was found that Texas secessionists also used fear to bring the vote in favor for secession. With a population consisting primarily of Whites, Blacks, Germans, and Tejanos, secessionists ultimately succeeded as Blacks had no rights, and both Germans and Tejanos were in fear of persecution. Moreover, spreading narratives of possible uprisings from anti-secessionists, the abolishment of slavery, the destruction of states' rights, and desegregation instilled fear in White Texans causing them to feel resentment towards the already prosecuted anti-secessionists. For this reason, it is believed that the scare tactics employed by secessionists is what ultimately influenced voters to opt for the secession of Texas.

Abstract Name: **Wishful Thinking: An Original Play for New Audiences**

The exploration of new age performing arts has begun with the introduction of innovative theatre that challenges audiences to observe stories in an unique style and format. The presenter wishes to stage and perform the original written play, Wishful Thinking, to inspire new audiences to reach towards a hardly touched part of theatre named the fantasy realm. This realm allows audiences to perceive mythical realities and feel the essence and energy manifested by the production in a stage setting. Fantasy is a genre rarely ever explored in straight plays due to the technical limits and directorial interpretations of the production crew. However, the script Wishful Thinking allows the production to ether be inexpensive or upscale because the essence of the fantasy realm lies within the written lines and the actors as the spoken word of the fairiesalgins with the fantasy world they live in. The performance will be approximately 10 minutes performed by UWEC actors, featuring a scene of a flower fairy, Ollie Petal, and a human, Holly Nova, who have a conversation about their own struggles of finding out who they are now and who they will be in the future. The setting is Holly's dream state, a lost garden with an abandoned burned down house and a graffitied wall expressing her inner struggles with coming out. Ollie enters in torn up clothing matching the wall with beautiful wings on his back. The cast requires Holly's appearance be closer to high school age while Ollie's appearance is closer to graduate college age.

Abstract Name: **Immigrant Communities in the Urban Reconstruction Era South**

This research paper aims to uncover and analyze the experiences of European women who immigrated to the southeastern United States during Reconstruction. Specifically, it focuses on the experiences of German, Irish, and British immigrants to Nashville and other southern urban centers. Nashville will act as a case study as similar patterns of immigration occurred in several of the major cities in the South. In the 20 years between 1860 and 1880, the percentage of the United States population that was foreign-born rose from 13.2% to 15.6%. This represents an increase of over two million people. The United States was perceived internationally as a land of opportunity, and the Reconstruction South needed low-wage workers to compensate for the labor of the millions of previously enslaved Black and Brown individuals. Directly after the Civil War, plantation owners pushed for immigration to the South in order to fill the need for agricultural workers, and in 1866, state-subsidized immigration campaigns picked up heavily. The majority of immigrants were not interested in the agricultural work the post-war South offered; some were even warned to stay away from the back-breaking work of the agricultural industry in the South. In turn, the Reconstruction Era South received a disproportionately low number of immigrants compared to the rest of the country. European immigrant women found work in the urban setting as maids, seamstresses, and domestic servants. Immigrants tended to settle in communities made up primarily of other people from their home country. This resulted in ethnic enclaves such as 'Black Bottom,' Edgehill, and Germantown. This research utilizes census records, death and marriage certificates, immigration records, newspapers, city-planning documents, and official immigration pamphlets put out by the southern states to uncover and analyze the experiences of immigrant women in the urban Reconstruction Era South.

Abstract Name: Preparing Communication Disorders and Sciences Students to Collaborate with Interpreters: The Power of Interdisciplinary Experiences

Nearly 25% of children in the United States currently speak a language other than English at home (Ann Casey Foundation, 2022). Despite the clear and compelling need for competent and linguistically responsive assessment and intervention practices, practicing speech language pathologists (SLPs) frequently report feeling underprepared to accurately work with interpreters when serving dual language learners (DLLs) (Guiberson; Atkins, 2012; Santhanam; Parveen, 2018). However, collaborative training experiences can provide SLPs and interpreters with the opportunity to converse about their roles, discuss ethical problems with interpretation, and merge their shared thoughts to ensure best practices for clients (Zhang, 2020). The purpose of this research project was to understand the ways in which an interdisciplinary simulated training experience and interdisciplinary immersion screening experience compare and contrast in relation to communication sciences and disorders (CSD) and interpreter students' feelings of preparedness for working collaboratively within their future professions. Researchers gathered data through reading, analyzing, and then qualitatively coding CSD and interpreter student summaries written post- simulated experience and post-screening. Student reflections included overall perceptions of the experience as well as perceptions regarding the ways in which the experiences influenced their feelings of preparedness. Student reflections and interviews were analyzed using inductive coding procedures as described by Merriam and Tisdell (2016). Codes, categories, and subcategories were revised and operationally defined during the coding process, until a final set of codes, categories, and subcategories was developed. Findings highlight the similarities and differences in CSD and interpreter perceptions, as well as the similarities and differences in student perceptions of an interdisciplinary simulated experience as compared to an interdisciplinary immersion screening experience. Findings will inform future pre professional and professional training experiences designed to increase SLP confidence and competence for working with interpreters and to increase the quality of interpreter and SLP practices for DLLs.

Abstract Name: Nondimensional Wind Shear Over West Texas Terrain

Nondimensional wind shear was computed using high frequency wind measurements obtained on a 30 meter tower located near Big Spring, TX. The three components of the wind, along with temperature, were sampled at 32 Hz using sonic anemometers positioned at five height levels on the tower. Coordinate rotations were performed to produce longitudinal, transverse and vertical components of the winds and turbulence statistics were generated for the different measurement heights. These statistics allowed inter alia for the determination of u_star velocity scales, nondimensional wind shears, and Monin-Obukhov stability parameters. Because of limitations due to a significant roughness sublayer and finite fetch, two middle height levels were used in the analysis. Parameterizations found from previous studies are compared to results from this analysis.

Abstract Name: Identities of Adoption

As an adoptee myself, my body of work is about adult adoptees and their self-identity formation; along with the conditions that can cause an adoptee to have a nomadic self-identity. Or, a shift in their identity based on who they are with or their surroundings. This can stem from traumas that most adoptees seem to face in some way from being taken away from their biological family and raised by adopted families. At times, these adoptions take place with families that have a different race or cultural background from the adoptee, which can add to the chance they will face identity challenges. Adoption creates complicated familial relationships that can be hard to navigate, as most adoptees are never taught about the effects adoption could have on them, and the resources they can use to seek understanding.I use black and white medium-format film to make portraits with adult adoptees after we have talked about their adoption, and their self-identity. In some instances, double exposures of the film are used to help convey the possibility of a nomadic self-identity, wavering identity, or other marks being an adoptee can have on an individual. In these instances of double exposure, one exposure is taken in focus, while another is taken out of focus, which accounts for what can appear as a glowing or softening of an image. Final photographs are printed as large high-contrast images that convey mood, and a larger-than-life scale that forces the viewer to be confronted with these identities of adoption, and to make them think deeper into the practice of adoption, and its effects on those involved.

Abstract Name: How Minority Students Turn into Tokens: An Analysis of the Diversity Regime and Tokenization

Major Purpose While historically higher education institutions (HEI) have adopted diversity policies under the guise of correcting social wrongs, the reasons for diversity in HEIs have changed. HEIs have shifted toward a desire for diversity based on perceived social capital gains and potential economic benefit. Though diversity policies have evolved, minority students still report negative campus racial climates and tokenization. Thomas (2018) finds that these effects are indicative of an institutional construct: the diversity regime. In the diversity regime, Thomas (2018) describes a “benign commitment to diversity” among HEIs. Using the diversity regime framework, I will show how students from universities are tokenized by HEIs. Methodology The university I attend fits the criteria for having a “benign commitment to diversity.” To investigate its effects on students, I will recruit students from my university from primarily Latino/Latina backgrounds. Using Constructivist Grounded Theory, I will conduct semi-guided interviews to question roughly 30 students. Next, I will code interview content into themes related to tokenization experiences and the diversity regime. This project has been approved by the IRB. Expected Results Through qualitative coding, I expect to find consistency with the original diversity regime framework. Also, I expect that tokenization will play a key role in minority students’ experiences. In addition, I expect to find evidence about the mechanisms which might influence becoming a token. Lastly, I expect the data will show students feel a pressure to reify their identity as a result of their college experience. Conclusion and Implications This project can provide universities with feedback to change their practices surrounding diversity and make active commitments to equity and inclusion. More directly, it will inform universities how to amend their diversity, equity, and inclusion policies to inhibit tokenization. It may also provide new insights into how tokenization works at an institutional level.

Abstract Name: Seniors on the Move

The Hispanic population is the first largest racial/ethnic group in the city of El paso Texas, accounting for 81.5% of the total population. Evidence has shown an increase in diabetes and multiple other preventive health conditions in this specific population. Many of these health conditions can be associated with sedentary lifestyle and lack of motivation to be active. Therefore, the purpose of this program was to improve the quality of life of male and female Hispanic seniors (age 65+) through physical activity and social interactions.Participants were asked to complete quality of life assessments at the beginning and the end of the program to compare the improvement of physical activity, mood, and social aspects of their life throughout the course of the program. In addition, participants were asked to complete questions regarding the impact of the study on their daily lives. Participants engaged in 45 minutes of physical activity including: walking, stand in place exercises, and range of motion (ROM) while being in partners or groups to help improve daily function and social interactions. The program was integrated through a 3-week span of 2 days per week. The program began with 17 participants (1 male, 16 female, age= 65+ years) and finished with 6 consistent female Hispanic participants. Parametric and nonparametric statistic results have shown a non-significant difference between pre-evaluation and post implementation of service-learning project (p > 0.05). Even though, the results of this study provide evidence that there was no significant difference in improving the physical activity in the Hispanic senior population, participants were grateful for the opportunity and did see improvements in daily activities and overall quality of life. Further analysis is needed in a longer program and bigger sample size to identify the potential effect of physical activity and social interactions in the Hispanic senior population.

Abstract Name: The Effects of Energy Drinks On The Human Body

In today's society, energy drink consumption has increased. It is important to know what ingredients are in energy drinks and what we are ingesting due to them being linked to multiorgan failure and acute liver injury. While the energizing effects only last approximately 1 to 2 hours, the negative damage to one's health can last a lifetime. This research focuses on the hidden ingredients in energy drinks that are not found in nutrition labels. The purpose of this research is to analyze how these unmentioned ingredients affect the human body and the different ways they could potentially be toxic to us. The research concentrates on three major ingredients: Guarana, Ginseng, and Niacin. Since previous study has been done on other energy drinks, this research focused on energy drinks that have not been studied like Bang, Celsius, and Ghost. These three energy drinks have been recently growing in popularity due to them being considered as a healthier option for consumers. A Vernier Labquest®2.0 (Beaverton, OR 97005 USA) and Vernier pH Sensor (Beaverton, OR 97005 USA) were used to gather information on the pH of the energy drinks. Hence, the results gathered were relevant to determine how acidic these drinks are. The energy drinks all had a pH lower than 4 which meant they are all acidic. A 14 question survey was distributed to the public to gather data on possible symptoms experienced by consumers. Common physical symptoms reported by participants include : Energetic 50%, nauseated 12.5%, alert 12.5%, jittery 25%, and 25% did not experience symptoms. Mental symptoms felt by participants were: anxious 50%, relaxed 12.5%, drained 12.5, and 25% of participants experienced no symptoms. This data shows how dangerous these drinks can be to the human body.Keywords: Guarana, Ginseng, Niacin, Toxic, Acidic

Abstract Name: **Mortality Salience and Political Attitudes: The Implications on Queer Politics and the LGBTQIA+**

Terror management theory (TMT) suggests that we utilize cultural worldviews and self-esteem to reduce our anxieties about our mortality. Previous research on TMT and politics shows when people are presented with mortality salience (MS), reminders of death, it leads them to make decisions according to their political beliefs (Burke et al., 2013). MS also results in worldview defense, making decisions that are most positive towards in-group members and are more negative towards out-group members (Burke et al., 2013). Historically, when the human immunodeficiency virus (HIV) and acquired immunodeficiency syndrome (AIDS) had a rise in cases, there was a need to reduce the MS it caused. The queer community was largely affected. Politically driven prejudice impacted how people viewed these illnesses and treatments. Currently, we are facing a rise in cases of monkeypox, and the criteria an individual must meet to receive a vaccination for monkeypox includes disclosing types of sexual partners, how they identify themselves, and in what settings sexual acts may take place in (Centers for Disease Control, 2022). This has led to a large misinterpretation that monkeypox is only affecting the queer community, similar to what was first thought about HIV when it was referred to as gay-related immunodeficiency syndrome (GRID). This study will investigate how MS and political ideology impact worldview defense and attitudes toward people with illnesses that largely affect the queer community. Participants will be grouped by political ideology and primed with MS or control. Participants' attitudes toward the queer community and a fictional character with monkeypox will be measured. We hypothesize that participants in the MS condition who are conservative will express more negative attitudes toward the fictional character, than participants in the MS condition who are more liberal. We will explore how these results can inform current reactions to monkeypox in the US.

Abstract Name: **Investigating the Role of the RNAi Pathway in Pericentromere Silencing in Stem Cells**

In the eukaryotic genome, a large portion of DNA includes non-coding repetitive regions that undergo RNA transcription. One specific region is the pericentromere, which contains tandem satellite DNA repeats and is proposed to be silenced by heterochromatin. However, in some circumstances, pericentromeres are transcribed, leading to increased cellular levels of satellite RNA. Previous studies indicate that aberrant pericentromeric RNA levels drive tumorigenesis of different cancers. Thus, it is important to understand the mechanisms of pericentromeric RNA transcript regulation.We hypothesize that Argonaute (Ago) proteins of the RNA interfering pathway (RNAi) play a direct role in the repression of pericentromeric RNA at specific stages of the cell cycle. This hypothesis was tested in mouse embryonic stem cells (mESCs) using three central aims. First, we evaluated the impact of depletion of key RNAi proteins Dicer and Ago on pericentromeric RNA levels. Second, we tested whether the catalytic activity of Ago2 is required for repression by comparing pericentromeric RNA expression in Ago2- and Ago1-only expressing cells. Finally, we developed a cell synchronization approach to assess how pericentromeric RNA is regulated during the different stages of the cell cycle. Our experimental approaches utilize RNA and protein quantification in mESCs that have conditional Ago2 or Ago1 expression in an otherwise Ago1-Ago4 null background, and similar conditional Ago expression in Dicer knockouts.The mESCs were treated for wildtype Ago expression or depletion and following this, the RNA and protein levels were quantified. Upon RNA purification, the samples were resolved on gels for northern blots probing pericentromeric RNA and GAPDH, which serves as a loading control. To further support differential expression, quantitative PCR was used to measure RNA levels upon RNAi factor depletion. Finally, the standardization of cell cycle stage markers was characterized by northern and western blots to ultimately assess pericentromeric RNA with cell cycle synchronization.

Abstract Name: Transformation, Expression, and Purification of Formate Dehydrogenase Mutants

Formate Dehydrogenase (FDH) is a well-documented enzyme found in bacteria and yeast that catalyzes the reaction between formate and NAD+ through the transfer of a hydride ion. This project planned on the mutation of wild type FDH expressed in E. coli through the Gibson Assembly method which would be followed by expression and purification of wtFDH mutants. The resulting products were to be transported to the Cheatum lab at the University of Iowa where further analysis of the enzyme could be studied by 2D-IR Spectroscopy. Work on the purification of wt FDH was hampered by issues with the column purification steps, which led to a deeper analysis of the method used previously to purify wt FDH via affinity chromatography. This led to a move to modify wt FDH with a histidine tag using the Gibson Assembly. Overall there appeared to be success at placing a histidine tag on the C-terminal end of the wt FDH. Future work will include continued modification of the wt FDH protein and purification of the products for further study.

Abstract Name: The Development of Inhibitors used to Target Falcilysin (FLN) in the Human Parasite, Plasmodium falciparum

There are five species of parasites that are involved in malarial infection: P.knowlesi, P.malariae, P.ovale, P.vivax, and P.falciparum. The human parasite Plasmodium falciparum causes the most severe case of malaria and is common in the Sub-saharan region of Africa and South Asia. Our study focuses on developing inhibitors against falcilysin (FLN), and metalloprotease expressed by the parasite during infection of the human host. Selective chemical inhibition is a valuable tool for understanding the biological role of falcilysin. Our group previously reported the development of potent FLN inhibitors using a piperazine-derived hydroxamic acid scaffold. This study focuses on optimizing the N1 and N4 substituents of the piperazine ring. Synthetically accessible candidate structures were DOCKed against the FLN crystal structure, and a subset of 20 promising compounds were selected for synthesis and testing against FLN and cultured P. falciparum. These studies revealed that a variety of bulky aromatic groups were tolerated at the N1 and N4 positions of the piperazine core. Introduction of naphthalene, dibenzofuran, and various substituted benzene rings resulted in improved potency relative to the previous lead compound. Notably, we also observed a correlation between the binding affinity predicted in our DOCKing studies and biochemical inhibition FLN, indicating that virtual screening is likely to be an effective tool for optimization of this scaffold against FLN.

Abstract Name: Smartphone Use and Well-being

How has Smartphone use impacted the general well-being of people today? The Smartphone usage has certainly increased over the past generation. The use is so prevalent that nearly everyone from 9-99 has one. Questions regarding how this intense Smartphonne use is impacting the overall health and well-being of society has been discussed across many different aspects of research. This research intends to study how Smartphone use impacts the physical, psychological, cognitve and social well-being of individuals across the generations. Previous research tends to focus on one aspect or another of well-being, for exmaple sleep or academic performance (cognitive functioning) or anxiety (psychological functioning). The research is lacking when looking at the global health of an individual and its association with Smartphone use. Thisstudy will also examine the specific ways individuals are using the Smartphones as well as how much of their daily life is consumed by the use. A correlational analysis will be completed in the spring semester of 2023 to determine what factors are most impacted by Smartphone use.

Abstract Name: Indigenous Representation in International Organizations: How Arctic Indigenous Peoples Cooperate to Address Climate Change

Utilizing non- and pseudo- regional governmental cooperation, Arctic indigenous peoples (AIP) collaborate to produce frameworks that address the effects of rapidly diminishing Arctic sea ice. Some of these frameworks include theInuit Circumpolar Council's 2009 Declaration on Sovereignty in the Arctic and the Arctic Council's 2013 Agreement on Cooperation on Marine Oil Pollution Preparedness and Response in the Arctic.The international regional cooperation of low-level, previously disenfranchised AIP is significant in the evolving political, economic, and natural environment of the Arctic because they have a profound connection to the land and its resources. AIP are also extensively involved in regional inter-governmental organizations (IGO), forming a rare working relationship between low-level cultural or ethnic groups and high-level nation-state governments. This study analyzes the benefit of meaningful involvement by indigenous peoples in inter-governmental organizations, particularly in the context of climate change. A conclusion is reached through comparative studies of IGO work on climate change and governance structures. Although the role of indigenous peoples in the Arctic is unprecedented in the present system of International relations, AIP cooperation has proven to be consequential and useful in addressing climate change in the Arctic and improving IGO governance. Heightened AIP visibility in international relations generates questions about the sovereignty of indigenous peoples, the role of AIP in addressing climate change, and the ideal structure of IGOs. The findings of this paper cover a rising phenomenon in liberal international relations theory and provide insight into the impact that cultural minorities produce within international organizations.

Abstract Name: **3D Printing to Improve Patient Outcomes for Mini-Thoracotomy Aortic Valve Replacements and Mini-Mitral Valve Repairs**

Aortic valve replacement (AVR) was established in the 1960's and has become a routine therapy to treat patients with severe aortic valve dysfunction. AVR is usually performed using a full sternotomy and cardiopulmonary bypass support. Since the late 1990's, minimally invasive procedures have been developed for aortic valve surgeries, such as the mini-thoracotomy AVR. These less invasive procedures claim reduced postoperative complications, shorter lengths of stays in the hospital, and lower mortality. However, the minimally invasive nature may provide challenges in the viewing of patient anatomy during the procedure. This project will provide the 3D printing capabilities needed to investigate if using 3D printed anatomical models for pre-operative planning and/or patient education will result in better patient outcomes for mini-thoracotomy AVR surgery, particularly in those with thoracic abnormalities. For selected patient cases, the Mayo Clinic Luther Campus will provide UWEC researchers with DICOM files for segmentation and 3D printing. The UWEC research team will perform the segmentation and provide the physical 3D anatomical model with initial feedback on accuracy from Mayo physicians. Ultimately, the Mayo Clinic collaborators will evaluate the effectiveness of using the 3D models in patient outcomes as well as patient education on the procedure.

Abstract Name: **The Role of USF1 in Lymphocyte Responses to Double-Stranded DNA Breaks**

We are investigating the role of DNA break-induced activity of the Upstream Stimulatory Factor 1 (USF1) transcription factor in lymphocytes. Double-stranded DNA breaks (DSBs) are the most dangerous forms of DNA lesion. Most research on DSB repair has focused on early actions of the transcription factor p53. In contrast, steps that occur days after DNA damage as cells complete repairs are not well known. We found that DSBs alter USF1 activity for days after DNA damage. Lymphocyte cell lines that were engineered by RNA interference to lack activity from both USF proteins (USF1 and USF2) showed changes in the transcriptomic response to DSBs for days. To test the specific role of USF1, we used RNAi to knock down only USF1 expression, and then exposed USF1 RNAi cell lines to the topoisomerase inhibitor etoposide. We measured transcription of DSB response genes in USF1KD clones and controls that carry a scrambled RNAi at 1, 3, and 6 day time points. By three days, Trp53 transcript levels were induced in control cells, but this induction was blocked in USF1 RNAi cells. We also found that USF1 RNAi disrupted the profile of Cdk6 expression. When live cells were counted at each time point, we found that USF1 RNAi populations accumulated significantly faster between days 3 and 6 than controls, suggesting that loss of USF1 disrupts cell cycle control in the late stages of a DSB response. This work provides an essential stepping stone for further research on DSB response mechanisms and cell growth control.

Abstract Name: **Reimagining College Support: A Critical Exploration of the Impact of Grief and Loss on the Experiences of First-Year College Students**

Student attrition is a rising concern in higher education given the various challenges that have arisen over the past couple of years. The offset of the COVID-19 pandemic, the racial justice movements, and the current social-political climate have significantly impacted our college students like never before. Of growing concern is the rising mental health crisis that is sweeping through higher education which warrants an immediate and intentional response. Further, students are currently facing dire financial constraints, food and housing insecurities, and many other challenges that complicate their college experiences. As freshman students are now experiencing college for the first time, their experiences may vary drastically from their predecessors. Specifically, current first-year students' college transitions are muddied from their various high school experiences that may have been a remote, hybrid, or in-person with some variation of security measures. Further, the grief, loss, and trauma first-year college students have experienced during the pandemic warrant special attention as we are contending with the types of resources and support, they need to matriculate and complete their degrees. The remnants of grief and trauma from the pandemic still linger and are impacting the college experiences of first-year students and their abilities to navigate their academic and professional goals. Hence, through a qualitative research design, our research explores the lived experiences of first-year college students. Specifically, the research question explored in our study is: How or to what extent has grief and trauma from COVID impacted the educational journeys of first-year students? The aim of this research is to provide an important opportunity to investigate how to better support college students as they move through collegiate experiences.

Abstract Name: **The Effects of Climate Change on Papilio indra Lepidoptera**

Climate change may be responsible for the extinction of numerous plant and animal species. Recently, drought in the Western United States caused by climate change has raised concerns. Amongst these, it was hypothesized that climate change has had detrimental effects on the Indra Swallowtail butterfly and their host plants. This rare butterfly is endemic to the Western United States. This is concerning because these butterflies are pollinators with mutualistic symbiotic relationships such that its extinction will have a cascading effect on the environment. In this research study, 7 locations throughout Nevada, California, and Arizona were chosen to determine the fitness of the butterfly populations in drought conditions. This butterfly deposits eggs on a specific plant of family Apiaceae which serve as maturation sites for caterpillars. The locations were studied before the drought and had healthy plants with an abundance of caterpillars, meaning that the butterflies were reproducing and thriving. To determine the health of these populations, several factors were studied including plant health, egg numbers, and caterpillar activity. Drought caused decreased plant health, with reduced plant numbers. Moisture is important for Indra butterflies because they will not exit diapause until water has fallen. Under drought conditions they sometimes wait years before exiting diapause to reproduce. In all locations Indra swallowtails had not left their diapause for a substantial amount of time. In addition to not seeing Indra adults near host plant locations, there was no evidence of caterpillars or eggs on plants that in years past were filled with them. The data from the locations were compared with prior data when there was normal moisture. The findings were obvious: climate change had a negative effect on the Indra butterfly. Water is imperative for these populations, and evidence shows that the lack of moisture has severely reduced plant and butterfly fitness.

Abstract Name: **Effects of Protein Crowders on the Folding of DNA Repair Protein Using High Performance Computing**

Xeroderma Pigmentosum group A (XPA) protein, a key regulator of the nucleotide excision repair pathway and is essential for the repair of DNA damage due to platinum-based chemotherapy. Due to its intrinsically disordered nature, the structural dynamics of XPA likely play a major role in the activation/inactivation or changing functions of the protein. However, being disordered the protein is difficult to crystallize and hence lacks a X-ray crystallographic three-dimensional structure. Thus, little is known about the folding dynamics of these proteins and the role that other biomolecules or crowders play in the process. However, Alphafold (1), the artificial-intelligence-aided protein structure database offers three-dimensional structural information of disordered proteins. To investigate the folding effects of XPA, a molecular simulation study was conducted in presence and absence of crowders using on-campus supercomputers. This simulation used molecular dynamics to probe protein movements and used Newtonian/molecular mechanical calculations to study the energetic changes produced due to the interactions between the protein and surrounding environment. Polyethylene glycol crowders (PEG), ranging from molecular weight of 600-20k, along with ethylene glycol (EG) crowders, water molecules, and various ions were added to simulate an intracellular environment. We hypothesize that the addition of these crowders will enhance the folding of XPA, allowing for a better understanding of intracellular XPA structure and the function of the intrinsically disordered protein regions. The effects of crowders on the structure, dynamics, and energetics of XPA using 50 ns simulation data will be presented.

Abstract Name: **The effect of ethanol and adipogenic differentiation on myogenesis & insulin sensitivity in C2C12 Cells**

In Type 2 diabetes skeletal muscle has a reduced sensitivity to insulin. Another characteristic of diabetic skeletal muscle is the presence of adipocytes within and between muscle fibers, which is implicated in altered insulin sensitivity. The effects of ethanol on the content of adipocytes within skeletal muscle and insulin sensitivity are not fully understood. In this study, we will investigate the effects of ethanol on adipocyte differentiation and insulin sensitivity using C2C12 cells.C2C12 cells (20,0000 cells/mL) were cultured in tissue-cultured 24-well plates with growth media (GM) composed of DMEM, 10% fetal bovine serum, 1% Pen-Strep (P/S), and 0.2% Mycozap (M/Z) for 3 days. Upon 70% confluency, samples were then separated into different treatment groups: (1) Differentiation Media (DM) +/- Ethanol (EtOH), (2) Adipogenic Induction (AI) and Maintenance Media (AM) +/- EtOH. Samples in the DM+EtOH Group were cultured in DM (DMEM, 2% Horse serum, 1% P/S, 0.2% M/Z) along with 0%, 0.5%, 0.75%, 1%, 1.5% concentrations of 200% proof EtOH. Samples in the AI/AM+EtOH Group were cultured in AI media for 3 days (DMEM/F12, FBS, 1% P/S, 0.2% M/Z, Insulin, Forskolin, and Dexamethasone) along with the aforementioned concentrations of 200% proof EtOH prior to switching to maintenance media for the addition of adipogenic factors. Samples in the AM+EtOH Group were exposed to the established concentrations of 200% proof EtOH at the point of Induction Media and Maintenance Media (DMEM/F12, FBS, 1% P/S, 0.2% M/Z + Insulin). After performing immunofluorescence staining with myosin heavy chain (MyHC) and DAPI, confocal microscopy will be used to quantify the number of C2C12 myotubes, as well as fusion index (nuclei per myotube), average myotube length, and average myotube diameter. It isexpected the Ethanol will significantly decrease fusion index, myotubes per field and total nuclei.

Abstract Name: **The Determinants of Income Inequality in Rural Wisconsin and Policy Implications**

Rural communities in Wisconsin are currently facing many economic challenges, namely high levels of poverty, declining population, lack of high-quality services, and poor infrastructure. These are issues that call for innovative and creative approaches and require prompt attention. This project is a collaboration of three faculty members at the Department of Economics at our institution. Our project has three main goals. First, we propose to measure regional, particularly rural, income disparities while identifying the main explanatory factors with American Community Survey data and quantile regression analysis. Second, we will examine and quantify the impact of entrepreneurship, growth of immigrant populations and access to broadband on rural incomes in Wisconsin. Third, we will offer insights and recommendations to Wisconsin policy makers. Our research findings will help assess economic needs and resources and provide policy options to address challenges facing rural communities.

Abstract Name: **The more you know: Knowledge about gender and sexual minority experiences as a tool to improve inclusive health care practices**

In current literature, healthcare providers' attitudes, the healthcare system, and biased health curriculums are some of the main bridges between creating inclusive, gender-affirming healthcare for sexual and gender-diverse (SGD) people. For SGD people, many unnecessary barriers exist that prevent them from accessing health care and receiving quality, affirming care. The burden of overcoming these barriers must not be prominently placed on SGD people, but rather on current and future healthcare providers. Education on SGD issues for undergraduate pre-health students is a first step toward shifting biased education and improving inclusive affirming patient care. In our previous research, we found that pre-health students express uncertainty and ambivalence on some issues related to sexual and gender diversity. Similarly, in other studies, medical and nursing students have expressed not having enough education and skills on LGBT and sexual health. Most health profession curriculums provide few hours of low-quality SGD health. Failure to understand and empathize with sex and gender differences and the interconnections of SGD identities and health have left the SGD community at risk for life-threatening and chronic health conditions. In response to the concerns and uncertainties about quality SGD education, I plan to cultivate a digital infographic booklet that can be readily accessible for pre-health students at the University of Utah that focus on gender, sex, and sexual orientation. Initially, the resource will help define gender and sexual identities. Pre-health students will also learn about health disparities, social determinants of health, minority stress, and social safety in order to understand SGD people's sensitivity to healthcare and their accessibility. Additionally, many pre-health pathways recommend patient exposure, so the booklet will also guide students on how to make social safety a tool for making SGD people more comfortable and safer to express their authentic selves in the healthcare system.

Abstract Name: **Interrupting the Discrimination-Distress Link: Religious Commitment and Racial Identity**

Racial discrimination is a universal experience for Blacks in America. Research has shown that racial discrimination is related to a host of difficulties, including higher levels of depression, race-based traumatic stress, and anxiety symptoms. Given this, it is critical for researchers to explore the potential protective factors that help to shield Black people from the effects of racism. Two prominent factors are racial identity and religious commitment. Despite the body of work examining the connection and history Black Americans have with racial discrimination, religion/spirituality, and racial identity, there is still an unexamined gap in understanding how these together can affect Black psychological well-being. The current study overcomes this gap by examining the role of religion/spirituality and racial identity in connection with discrimination and psychological distress. The purpose of this proposed study is to determine how both religious commitment and racial centrality (a dimension of racial identity) affect the relationship between discrimination and psychological distress. Specifically, I examine whether racial centrality and religious commitment moderate the hypothesized positive association between discrimination and psychological distress. I hypothesize that high religious commitment will moderate the relationship between discrimination and psychological distress. The sample will be comprised of 150 participants who will be at least 18 years old and self-identified as Black or African-American at a Midwestern Predominately White Institution. Participants will complete a survey. To test the hypotheses that religious commitment and racial centrality serve as moderators of the relationship between discrimination and psychological distress, I will conduct a hierarchical linear regression analysis. I will examine the two-way interactions between discrimination and racial centrality and discrimination and religious commitment and the three-way interaction of discrimination, racial centrality, and religious commitment. The findings will address the gap in understanding how religious commitment and racial centrality are associated with discrimination and psychological distress.

Abstract Name: **Decadal Variations of Six Criteria Air Pollutants Over Texas**

The Clean Air Act requires the US Environmental Protection Agency (EPA) to set National Ambient Air Quality Standards (NAAQS) for six common air pollutants (also known as “criteria air pollutants”). These six pollutants are carbon monoxide, lead, nitrogen oxides, ground-level ozone, particulate matter, and sulfur oxides. These pollutants are found all over the U.S. They can harm health and the environment and cause property damage. The EPA must designate areas as meeting (attainment) or not meeting (nonattainment) the standard in accordance to the Clean Air Act. States must develop a general plan to attain and maintain the NAAQS in all areas of the country and a specific plan to achieve the criteria for each area designated nonattainment for a NAAQS. This study presents in-situ surface measurements from the Air Quality System (AQS) EPA for six air pollutants from 2005 to 2022, as well as the weekly, monthly, and yearly trends for these pollutants over Texas’ major population centers. This study will analyze these trends for any correlation with petrochemical industry, vehicle usage, technological advancement, and natural events. Although the overall trend is that of a decrease in the concentration of these pollutants over time, it is worthwhile to explore more granular trends in an effort to identify their underlying causes.

Abstract Name: **Ties Between Social Media Use and ADHD, Depression, and Anxiety-Related Symptoms**

Social media has become a staple in the life of adolescents and young adults. In a recent study, 97% of teens reported using at least one social media platform (Anderson,; Jiang, 2018). With this increased use of social media platforms, psychologists are concerned about their potential impact(s) on people's experiences in life. One avenue of interest is the relationship between social media usage and mental health conditions. Studies have reported that high social media use is positively correlated with symptoms of ADHD (Baumgartner et al., 2017), anxiety, and depression (Hussain,; Griffiths, 2019). Through this study, we predict to find similar findings, hypothesizing that ADHD, depression, and anxiety-related symptoms in University of Wisconsin-Eau Claire college students will all be positively correlated with their time spent on social media. To collect this data, the research team developed a survey that asked participants to report their demographic information (age, gender identity, sexual orientation, and major), time spent using social media, and <a>mental health-relatedsymptoms using the PHQ-9, GAD-7, and ASRS-6 assessments. Participants will be recruited through WRIT 114-120 classes by asking the students to voluntarily participate in an online survey. To analyze the survey results, the researchers will conduct bivariate correlational analyses of the total time spent on social media in the last seven days and each set of mental health-related symptoms (ADHD, depression, anxiety). We perceive this research, and the findings, as important for furthering the understanding of the relationship between ADHD, depression, and anxiety symptoms and social media use.

Abstract Name: **Transcription and Translation: Challenges, Methods, and Lessons Learned from Translating Spanish Language Oral History Interviews**

Oral history interviews are a method of qualitative research that provide opportunity for stories to be heard that may otherwise be left unnoticed, in order to learn from these stories and enable change based on the perspectives that are shared. Voces del Campo/Rural Voices is a research project that aims to document and preserve the life experiences of people in Wisconsin, specifically in the Latinx community, by conducting oral history interviews. Given that Spanish is the primary language of many of the interviewees, transcription and translation of these interviews are key steps in the documenting and sharing of these experiences with a wide audience. Neither process is as straightforward as it may seem and can have crucial impacts on the integrity of the interviewee and the quality of data provided by the interview. This research first intends to explore methods of translation and transcriptions including naturalized versus denaturalized transcription and semantic versus contextual equivalence in translation. Furthermore, challenges such as accuracy, slang, word equivalency, figures of speech, and translator cultural competence and language familiarity will be examined. This will be accomplished by analyzing previous literature on these processes and offering a student perspective from the Voces del Campo project. Finally, a discussion of the lessons learned from transcribing and translating oral history interviews highlights the significance of the responsibility transcribers and translators have in accurately conveying the stories of the interviewees and the significance of the trust placed in them to do so in a respectful manner and offers practical advice for students performing interviews or oral history research in the future. The lessons additionally emphasize the importance of cultural understanding in these processes and the increased cultural understanding that comes with being a part of them.

Abstract Name: **Supervised Injection Sites (SIS): A Response to the Drug Epidemic in America**

The War on Drugs, “Just Say No”; D.A.R.E. programs were created in the 1970-80’s and focused on preventing drug use at an early age. However, these programs are outdated and ineffective. This can be shown through the increased rates of opioid use and opioid related deaths throughout the United States. According to the Center for Disease Control, in 2019-2020 opioid misuse has led to a 38% increase in opioid-related deaths and the rate continues to climb with the development of new synthetic-opioids. Since the 1990’s and early 2000’s, comparable countries have utilized a new approach; supervised injection sites (SIS). These sites are widely used by other nations abroad and have been expanding rapidly throughout Europe and Canada. The United States, however, only has two sites, both located in New York City. How can the establishment of a SIS benefit the La Crosse, WI community? By looking at peers abroad and domestically, the benefits and challenges of an SIS can be identified. This paper analyzes the history, political challenges, public opinions, and cost savings of supervised injection sites across the globe, specifically Insite in Canada, Uniting MSIC in Australia, and OnPoint in New York City. With drug use on the rise and La Crosse having the highest rate of opioid overdose related deaths and opioid related hospital visits in the Western region of Wisconsin, there is a need for the La Crosse community to establish a SIS. This SIS will not only save lives of drug users, but promote public health of the greater community, and provide costs savings in the governmental response to the opioid crisis that affects every community in America.

Abstract Name: **M. tuberculosis secreted effector protein, PE17, binds eukaryotic lipid droplets**

Mycobacterium tuberculosis (Mtb) is a pathogenic bacterium known for causing the respiratory disease, tuberculosis, which remains the second-most infectious killer behind COVID-19. With drug resistance of M. tuberculosis on the rise, treatments to combat Mtb infections have become less effective, escalating the urgency for research towards the development of new pharmaceutical treatments. The ability of M. tuberculosis to infect its host relies on its capabilities to invade alveolar macrophages, evade host cell defense mechanisms, and to utilize host cell nutrients to support its intracellular lifestyle. It is known that Mtb secretes a complement of proteins into the host cell during infection, which allow the bacterium to meet these goals. One such secreted protein, PE17 (Rv1646), belongs to the PE/PPE family of proteins, which have been linked to the pathogenesis and survival of other Mycobacterium pathogens. Despite this knowledge, no known function of the PE/PPE family proteins have been discovered to date. By using simple eukaryotic cell model systems, Saccharomyces cerevisiae, we now show that PE17 binds specifically to lipid droplets in both human lung epithelial A549 cells and yeast. Furthermore, we show that yeast strains expressing PE17 are exquisitely sensitive to the fatty acid synthesis inhibitor, cerulenin. As yeast must consume the neutral lipids stored within lipid droplets to survive treatment with cerulenin, we now propose that PE17-decorated lipid droplets are unable to be utilized by the host and may serve to increase the host intracellular lipid droplet population for consumption by M. tuberculosis during the infection. These findings provides vital insight on the pathogen's ability to infect and persist within host cells through the acquisition of lipid droplets.

Abstract Name: **A Novel, Unbiased 3D Region-Based Convolutional Neural Network for Hair Cell Detection, Electron Microscopy Based Hair Cell Image Segmentation and Deep Embedded Subspace Clustering for Prediction of Cochlear Hair Cells.**

Approximately 20% of the global population is affected by hearing loss, which is more than 1.5 billion people. In the United States, ~15% of American adults (37.5 million) aged 18 and over report some trouble hearing. Hearing loss most often occurs in the inner ear, where sound is transduced by inner hair cells (IHCs) and then converted into electrical signals that are carried by auditory nerve fibers to the brain. According to the WHO, unaddressed hearing loss creates an annual global cost of US$ 980 billion, which includes the cost of hearing devices, educational support, productivity losses, and societal costs. This project will develop a novel approach for auditory hair cell detection along the entire length of the cochlea using an innovative deep learning approach. Our deep learning model will use two main algorithms for analyzing microscopy images of cochlear hair cells: 3D iFS-RCNN for hair cell detection and EM-net for hair cell segmentation. To detect and classify cochlear hair cells, we will use iFS-RCNN which encompasses the cell using a box, a classification label, and a confidence score. For hair cell segmentation, we will analyze the fluorescent signal in hair cells along the length of the cochlea using EM-net and optimize spatial embeddings of cells for instance segmentation. We will also use Deep Embedded Subspace Clustering to calculate clusters of pixels for prediction of segmentation masks of missing cells. We envision that our segmentation analysis will be used with fluorescent markers to label the whole cell for volumetric analysis, or spatial distribution of fluorescence within a cell of fluorescently labeled structure (i.e., endoplasmic reticula, mitochondria, or fluorescent drugs). Our deep learning-based algorithms can also be used to validate the protective capabilities of oto therapeutic drugs designed to prevent hearing loss or rehabilitate the ability to hear.

Abstract Name: **Design and Experimental Results of Planar Antennas for Rocket Integration**

The ability of a rocket to transmit and receive data is critical for precise positioning, communication, and recovery; multiple antennas are required to receive satellite data, maintain communicationwith the ground controller, and broadcast its location throughout its apogee. In this research, three antenna structures were designed for transmitting and receiving telemetry, GPS, and radar signals. A meander line antenna was designed and fabricated for the ISM band (915-910 MHz), a standard patch antenna for the GPS L2 band (1227 MHz), and a corporate-fed two-element patch array antenna for C-band radar (5-6 GHz). The three antennas were fabricated on FR-4 glass-reinforced epoxy laminatematerial using an LPKF ProtoLaser S4 and terminated with printed circuit board (PCB) edge mount subminiature A (SMA) Radiofrequency (RF) connectors. The antenna return loss, VSWR (Voltage Standing Wave Ratio), and bandwidth of the three antennas were measured using an N9913 FieldFox Handheld RF analyzer. The additional characterization will be conducted in an anechoic chamber to obtain gain patterns and shall be presented at the conference.

Abstract Name: **Charactering Biohybrid Microswimmers as A Potential Targeted Drug Delivery System**

Guided drug delivery has evolved in recent years to allow for more effective treatment of diseases such as cancer. Cancer is often treated with intravenous chemotherapy which often involves a myriad of unwanted side-effects. In order to achieve reduced side effects and increased treatment efficacy, an innovative method would be desirable if it allows delivery of therapeutics to targeted regions instead of the body being infused with the medication. Chlamydomonas reinhardtii, biflagellate unicellular green algaes with strong positive phototaxis, may serve as a promising guided drug delivery system. The goal of this project is to utilize the phototactic properties of the algal cells that are loaded with therapeutic microspheres as cargos and direct these biohybrid microswimmers with a focused light source. We have developed effective procedures to bind microspheres to algal cell bodies. A large number of cells under various loaded or lighted conditions were recorded under a light microscopy. Their moving trajectories and velocities were tracked frame by frame using a particle image velocimetry (PIV) software. Our preliminary results showed that these algal microswimmers moved at relatively more consistent directionality towards the guided light source, compared with random moving orientation without the guided light. This study will pave the way for further characterization of the novel biohybrid microswimmers as a potential targeted drug delivery system.

Abstract Name: **Turning Telomerase Off: Computational Drug Discovery for Telomerase**

Cancer is not one disease: any tumor may be the result of one or many pathways that manifest in a dysfunctional cell cycle. One causative pathway includes the activity of the enzyme telomerase, which regulates the relative age of the genetic material within a cell. Telomerase is an active enzyme before birth, and its overexpression is related to cellular replicative immortality, a hallmark of cancer. Therefore, drugs that target telomerase may prove to supplement or enhance chemotherapeutic treatment. The first objective was to collect data on ligands that competitively inhibit telomerase function for chemotherapy drug design. Current telomerase inhibitors include BIBR1532, which is not readily bioavailable. Six thousand ligands from NCBI's Molecular Database were tested for telomerase active site binding using AutoDock Vina. The inhibitor candidates were analyzed for their ligand–enzyme interaction strength in Chimera, relative drug-likeness using SwissADME, and toxicity using the Toxicology Estimation Software Tool. BIBR1532 was used as a positive control throughout all calculations, and a scaled score was assigned to each tested ligand to determine the most promising inhibitor candidate. While most inhibitor candidates that bound strongly to the telomerase active site exhibited toxicity, ligand NCI2968 shows great potential due to its strong enzyme interaction and drug-likeness. Critical to overcoming the adaptive rewiring of cancer cells' survival response to drugs, the collected data may be used to develop new drugs that target alternative cancer pathways. The second objective was to inspire high school students interested in healthcare by educating them on this project's research. Arthur A. Benjamin High School students in Sacramento engaged in games, discussions, and informative illustrations to learn more about this project and the breadth of scientific research. As strides are made in cancer development, encouraging the future generation to approach large issues in healthcare through scientific research becomes an important goal.

Abstract Name: **The Influence of Restricted Abortion on Women's Mate Choices**

Reproductive rights have been fiercely contested over the past several decades. With the recent overturning of Roe v. Wade, women's liberty and bodily autonomy is once more at stake. The US Supreme Court's decision to overturn Roe v. Wade has taken away the constitutional right to seek abortion: a decision that has harmful and inequitable repercussions on the reproductive health of many Americans. Given the anxiety and confusion surrounding the removal of Roe v. Wade, it is even more precedent to examine how women's behaviors across of spectrum of disciplines change with the now limited rights. We investigated through an experimental study whether a reminder of the recent Supreme Court decision influences women's mating strategies in the online environment. From past research, we were able to conclude that women who were looking at pictures of men, for mating purposes, preferred faces that were more masculine in appearance.Thus, leading us to hypothesize that women remined of abortion restrictions would be more selective of men, and would exhibit greater interest in masculine-appearing men. Participants were randomly assigned to read an article reviewing the overturning of Roe v. Wade, or an article reviewing a recent Supreme Court decision on open-carry gun laws, or to read no article. They then examined several fictitious Tinder profiles, varying in facial masculinity, and rated their interest in the men.Data will be analyzed through an ANOVA test in SPSS to determine whether the priming of an abortion article has an effect on female college students mate selection. Considering the recency of the overturning of Roe v. Wade, this study is among the first to document how women's behavior might change in the post-Roe v. Wade landscape.

Abstract Name: **Analyzing the Radius of an Aerosol Droplet Using Enhanced Resonances from Raman Scattering**

The atmosphere contains tiny particles known as aerosols which play an important role in how the sun's rays interact with the Earth's surface. Aerosol droplets reflect the sun's rays to help cool down the surface of the Earth and keep radiation from getting to dangerous levels. Understanding the interaction between aerosol droplets and the sun's rays is going to play an important role in the future of science with concerns ranging from global warming to skin cancer. To better understand how light interacts with the molecules in the air surrounding us, an aerosol droplet made of salt water was caught in a chamber using an Argon laser. The droplet was held in place due to the laser exerting a gradient force which pulled the droplet to the most intense part of the laser beam. While the droplet was held in place, pictures were captured of the droplet and then analyzed using a LabView program.The images were used to get a range of values representing the radius' size, and the images gave position values to see the droplet moving in X,Y,Z coordinates. While the images were being captured, light coming off of the droplet was collected with an optical fiber and sent to a spectrometer. This light gavea spectrum with noticeable peaks. These peaks represented resonances from the droplet which were enhanced with the help of Raman scattering and a red LED. These peaks were then analyzed to find the wavelengths associated with them. The peak data was then sent to another program which looked over the data and gave values of the radius, dispersion, and refractive index of the aerosol droplet. This data could then be compared with the pictures captured from the LabView program to confirm the size of the droplet.

Abstract Name: **Synthesis of Diketopiperazines for the Synthesis of Novel Tryprostatin-Based Microtubule Inhibitors**

Trypotstatin A (TPS A) is a microtubule inhibitor that has anticancer properties. Unfortunately, TPS A is difficult to isolate in large quantities, and has lower activity than other microtubule inhibitors on the market. However, studies have shown that some analogs of TPS A have higher activity than the natural product. Our goal is to synthesis new analogs with higher activity and shorter synthetic pathways while reducing the hazardous chemicals previously used to synthesize TPS A. An important step in our synthesis of TPS A analogs is the creation of a diketopiperazine. This diketopiperazine can be modified in several ways, making it useful for producing new analogs. My work involves the creation of several types of diketopiperazine compounds that will be incorporated into the synthesis of TPS A analogs. Methods used to create these diketopiperazines include amide coupling, catalytic hydrogenation, thermocyclization, and column chromatography. Additionally, Thin layer chromatography (TLC) was used to verify reaction completion and Mass spectroscopy and Nuclear Magnetic Resonance were used to verify identification and purity. If successful, we will create a highly selective and active microtubule inhibitor that can later be used as a cancer treatment.

Abstract Name: **Potential role of miR-223 in regulating neuroinflammation through CCAAT-enhancer-binding protein beta**

Chronic neuroinflammation has been implicated in the pathophysiology of several brain diseases including traumatic brain injury (TBI). Inflammatory responses are complex and involve many mediators among which are microRNAs (miRNAs). MiRNAs are noncoding RNAs that negatively regulate gene expression by preventing translation through binding to mRNAs. MicroRNA-223-3p (miR-223) is an X-chromosome residing miRNA that regulates various proinflammatory pathways. Previously, we reported that miR-223 exhibits sexually dimorphic inflammatory responses in brain following controlled cortical injury (CCI). Here we provide evidence that miR-223 regulates neuroinflammation via its validated target CCAAT-enhancer-binding protein beta (CEBPβ), an important transcriptional factor for inflammatory gene expression. In this study, we isolated bone marrow derived macrophages (BMDMs) and brain CD11B+ cells from female and male wild type (WT) and miR-223 knockout (KO) mice. Inflammatory markers from these two cell populations were then quantified using RT-qPCR. BMDM cells grown in culture also were analyzed for CEBPβ and inflammatory marker major histocompatibility complex II (MHCII) using immunocytochemistry. Finally, tissue homogenates from naïve animal brains were used for Western blot analysis. Our results revealed that miR-223 deficiency results in enhanced levels of CEBPβ and MHCII proteins and a concomitant increase in the inflammatory markers NLRP3, TRAF6, TNFα, NFκB, and ITGAM.

Abstract Name: **COVID-19 Mitigation Efforts and Psychological Health Outcomes in Adolescents Residing in the Deep South**

The impact of COVID-19 and its resulting mitigation measures (e.g., shelter-in-place orders, social distancing, suspension of in-person school and extra-curricular activities) may have had serious consequences on adolescents' psychological health. Early reports of short-term effects suggest that COVID-19 led to lowered social activity and outcomes took a much greater toll on particular subgroups (e.g., Black/African Americans, those of lower socioeconomic status). This project investigated the differential impact of COVID-19 on adolescent psychological health as a function of age, race, SES, and gender over time. It was hypothesized the impact of COVID-19 on depression and anxiety would vary by age, minority status, SES, and gender. Drawn from a larger, longitudinal study, adolescents (n=190, Mage=17.12 years, SD=1.98; 73% Black/African American, 53% female) reported depression on the Center for Epidemiologic Studies Depression Scale (CES-D) and anxiety through the General Anxiety Disorder-7 (GAD-7) before and during COVID-19 mitigation efforts. Mixed effects regressions estimated COVID-19's effect on depression and anxiety and if change was a function of age, minority status, SES, and gender. Participants reported change in depression over 18 months (b = .11, t = 2.52, p = .02). There was no recorded change due to COVID-19 or demographic factors. Anxiety was shown to have no effect by COVID-19 when accounting for demographics, but some evidence of an effect of Gender on overall GAD (regardless of time, covid, etc.) with males having lower anxiety compared to females (b -1.58, t = -2.65, p = .01). The long-term consequences of COVID on adolescent social health should be further investigated.

Abstract Name: **The effects of chronic mild stress on traumatic brain injury recovery**

Traumatic brain injury (TBI) is a debilitating condition which results from a concussive blow to the head and can produce epilepsy, mental health issues, and cognitive and behavioral impairments. The long-term impacts of TBI include brain edema, hypoxia, as well as damage to neural processes, the effects of which may compromise blood-brain barrier function and promote inflammatory responses. It is not clear if prolonged exposure to stress exacerbates symptoms associated with TBI thus the current experiment addresses the impact of chronic mild stress (CMS) on anxiety-like and depressive-like behaviors in a mouse model of TBI. The current study also assesses the combined effect of CMS and TBI on gliosis, the process through which glial cells respond to central nervous system damage. Using S100β staining, we quantified the extent of gliosis in the cortex and hippocampus of mice exposed to CMS, TBI or a combined treatment of both CMS and TBI.

Abstract Name: **Phenotypic and Transcription Analysis of the Effect of Lactic Acid Bacteria on Carbapenem-resistant Acinetobacter baumannii**

Acinetobacter baumannii is a gram-negative, non-fermenting bacteria, notable for its antibiotic resistance, and in some strains, pan-drug resistance, thus limiting the effects of therapeutics. Therefore, we evaluated the potential of probiotic lactic acid bacteria (LAB) as an alternative therapy to antibiotics by observing the interactions between LAB and A. baumannii that mitigated the virulence expression of the pathogen. Agar overlay and agar well diffusion methods were conducted, respectively, to exhibit the inhibitory effects of LAB on A. baumannii A118 (antibiotic sensitive). Inhibition halos were categorized as “intermediate” or “strong,” particularly in Lacticaseibacillus casei BL23, which also inhibited A. baumannii strains AB5075, AMA16, AB0057, ABUH702, and AYE. A series of RT-qPCRs were conducted to quantify the transcriptional response of A. baumannii AB5075 and A118 when co-cultured with BL23, which showed significant effects on A. baumannii’s virulence-related genes, such as biofilm, motility, iron-utilization, metabolism, quorum sensing, T6SS secretion system, transcriptional repressor, Zn utilization, and resistance and efflux genes. In addition, the antagonistic activity of BL23 on AB5075 was evaluated in healthy human fecal material—a medium with complex microorganisms—resulting in a 35% decrease of viable AB5075 and 50% decrease in total microbial MF. LAB exhibits antagonistic and antimicrobial effects on A. baumannii, as it inhibits the growth of the pathogen by targeting its virulence genes, thus making them a great candidate to study for alternative treatments against the infectious pathogen.

Abstract Name: **General Microbiology Students Searching for Antibiotics in Minnesota's Wetlands**

As antibiotic resistant pathogens continue to emerge, there is a dire need for the discovery and development of new antimicrobial agents. In Fall 2021,University of Minnesota Crookston General Microbiology students collected soil samples from wetlands of Northern Minnesota. They isolated and characterized the microbes to see if they have antimicrobial activity. Nineteen students were able isolate cultures that showed antimicrobial activity against the safe relatives of the ESKAPE pathogens. The current aim of the research is to conduct a longitudinal study to isolate and identify antibiotic-producing bacteria from bogs and fens collected from the previous student work. We hypothesized that some of the pure culture isolates would produce antimicrobial substances and show inhibition against the ESKAPE safe relative pathogens.Procedures followed the general protocols of the Tiny Earth-Studentsourcing Antibiotic Discovery Initiative. Soil samples were further analyzed using standardized techniques to identify the presence of potential antibiotic-producing microorganisms. Bacteria from these samples were transferred to isolates and tested against ESKAPE pathogens to show signs of antibacterial activity. Streak plates were created for all isolates showing antibacterial activity and incubated at room temperature to further separate the microorganisms to purity. This process was repeated until cultures reached purity. Pure isolates were then tested against ESKAPE pathogens to demonstrate inhibition. Pure isolates that showed inhibition underwent chemical fixation using acetone. Further testing is needed to isolate and extract the antimicrobacterial component. Further characterization of the twelve pure isolates that have antimicrobial activity will be reported. Findings from this research could aid in the development of antibiotics with new antimicrobial properties that can fight off pathogens resistant to current medications.

Abstract Name: **Correlates and predictors of recidivism among adult incarcerated offenders**

The purpose of this study is to investigate psychological predictors of recidivism among adult incarcerated offenders. We examine mental health information among offenders to test the Criminalization Hypothesis. This hypothesis argues that people with mental illness become trapped in the legal system due to a lack of mental health resources in their community. We also examine perceived social support, openness to treatment, and self-regulation. Previous research found that high levels of perceived social support and self-regulation are negatively related to institutional infractions. Our research builds on this evidence by examining how these variables predict recidivism and by analyzing how open to treatment inmates are based on their perceived social support and self-regulation. We gathered data from 108 male and female adult incarcerated individuals (Mage = 39.29; 76.32% males) from four correctional facilities in North Carolina. Recidivism data is currently being collected and entered. Coding of recidivism will be completed by the end of 2022. Analyses will be conducted in February 2023, and the poster will be completed in March 2023. We measured psychological predictors via self-report and recidivism from criminal public records. This is a longitudinal study with recidivism being gathered three years after predictors. Based on prior research of these variables, we hypothesize and expect to find that (1) inmates who have been diagnosed with a mental health disorder will have more encounters with law enforcement (i.e., Criminalization Hypothesis), (2) inmates who report higher perceived social support and higher levels of self-regulation will also report higher levels of openness to treatment, and (3) inmates who report higher perceived social support and higher levels of self-regulation will be less likely to recidivate. We discuss implications for working with at-risk children to equip them with social supports and self-regulation tactics before their criminal behavior increases in frequency and severity.

Abstract Name: **Exploring the Raman Scattering Response of Meteoritic Fragments**

Raman spectroscopy is a technique that has been used extensively on different kind of samples (carbon allotropes, semiconductors, polymers, microplastic particles, microorganisms, cells, etc.) since it is a nondestructive tool that provides information about their structure and material composition. In particular, it has been employed on meteoritic samples which in general are mainly composed of micro/millimeter sized inclusions, surrounded by a matrix of microparticles, that date from around the time of the formation of our solar system. The study of the physical properties of these relics using Raman spectroscopy can help to understand how planets formed since they can give evidence of the conditions (e.g., thermal, temporal and barometric) in which the materials found in the meteoritic samples developed in our solar system. However, not all the constituents of meteoritic samples have a Raman signal with a high signal-to-noise ratio, or other phenomena present in those materials (e.g., fluorescence) can hide some Raman features. In this work, we examine several meteoritic fragments that have recently been acquired by our group, such as carbonaceous chondrites Northwest Africa (NWA) 7184 and Aguas Zarcas, using this experimental technique. We explore the surface of these samples carrying out Raman spectroscopy measurements on numerous inclusions and surrounding matrix to find materials with high signal-to-noise ratios to analyze the mineralogical composition of the fragments. We correlate these results with other experimental techniques (e.g., optical microscopy, scanning electron microscopy, energy dispersive X-ray spectroscopy and/or atomic force microscopy) to look for signatures of the physical processes that drove the formation of these meteorites.

Abstract Name: **Embedding Undergraduate research in AI and Cybersecurity Courses**

Artificial Intelligence (AI) and Cybersecurity are driving rapidly in many industrial, commercial, and academic disciplines, ranging from autonomous cars, health systems, and robotics to personalized shopping and recommendation systems. Of late, both fields have demonstrated very successful applications in different healthcare challenges, such as improved patient privacy protection, safer operation of medical devices, precise diagnosis, timely detection of diseases, personalized medicine, and robot-assisted surgeries proposing to name a few. There is thus a pressing need to bring together a powerful research platform and educational capability to develop a highly skilled workforce for AI and cybersecurity-powered healthcare development. The current panel will offer a professional forum to mainly discuss hopes and hypes in high-quality undergraduate research in AI-powered healthcare and cybersecurity. In particular, we will discuss four different AI and cybersecurity areas in healthcare; medical image analysis, clinical natural language processing, AI-assistive devices, and security and privacy in healthcare. Inspired by these four AI topics, the presenters will discuss practical methods and tools to implant undergraduate research and creative inquiry into computer science, AI, computer engineering, and cybersecurity courses and curricula. The methods and tools can have different intensities and forms, such as class-based activities, class research projects, and capstone projects. Moreover, the discussion will focus on the barriers and obstacles to incorporating research activities in undergraduate curricula.

Abstract Name: **Assessment of At-Home Genetic Testing Kit Consistency Between Identical Twins**

Since their arrival on the market in the early 2000s, direct to consumer (DTC) genetic testing kits (at-home kits) have exploded in popularity. As the industry has continued to grow, questions have emerged over the accuracy and consistency of the results of these ancestry reports. Despite claims by all companies studied here of over 99% accuracy, previous research in this lab has shown significant inconsistencies between the results provided by each company. Of 42 individuals previously tested, 39 had large discrepancies in their genetic ancestry categories from company to company; results varied by up to 40% for some participants. The goal of the current study was to examine the DNA of identical twins to determine if these testing discrepancies exist within companies (since the DNA of identical twins should be the same) or only between them. The same three genetic testing companies that were previously studied were used here - Ancestry, 23&Me, and MyHeritage. To date, five sets of identical twins have received full results, and several additional sets of twins are in process. Results have remained consistent with the previous study, with discrepancies between ancestry categories reported by each company. Surprisingly, in addition to the discrepancies between companies, differences were found between twins in data reported by the same company. No set of twins had results that completely matched. In some twins, one individual was noted to have an ancestry category that the other didn't have at all. Given the claims of near-perfect accuracy reported by the companies, and the fact that some of them also market genetic health screenings for certain diseases and health conditions, these inconsistencies raise serious ethical concerns about the way on which they market and report data to under-informed consumers.

Abstract Name: **How can ponderosa pine seedlings be propagated to improve drought resistance in the field?**

Ponderosa pine, a widespread species in the western US, is a valuable species economically and environmentally. The preservation of this species is important for the ecological health of many forests due to increased temperatures, drought, and frequency of forest fires. Reforestation efforts following fire and timber removal often fail because seedlings propagated in greenhouses are not resilient to stressful field conditions. To increase seedling field survivorship, drought resistance, and to decrease mortality rates, we implemented a number of treatments in the greenhouse during the initial propagation. The treatments were a manipulation of water supply and different types of fertilizer, tested with seeds collected from varied elevations. After threemonths of growth in the greenhouse under these treatments, we measured height and both shoot and root biomass of the seedlings. We also measured days to mortality on a subset of the seedlings. Seedlings subjected to drought treatment and amino fertilizer grew shorter but survived longer. These seedlings allocated more biomass below ground, which likely contributed to their longer survivorship in the days to mortality test. However, despite the potential benefits these treatments conferred to seedlings in the greenhouse, all seedlings experienced nearly 99% mortality after they were outplanted to a nearby field site. We suspect that most of this mortality was due to frost-heaving, a process whereby seedlings can be pushed out of the ground during frost-thaw cycles that occur in soils in the winter, and is exacerbated by the creation of bare patches of soil around the seedling during planting.

Abstract Name: **Investigating the Function of RECQL in Herpes Simplex Virus Type-1 Infection**

Herpes Simplex Virus Type-1 (HSV-1) is a prevalent human pathogen, infecting over half of the U.S. population. While the most common symptoms of infection are cold sores, more severe cases can cause genital herpes, herpes keratitis, or encephalitis. While HSV-1 is a common and potentially deadly virus, we do not fully understand the infection process. We do know that HSV-1 utilizes both viral and cellular factors during infection and replication, several of which have been identified. Through previous studies in our lab, we discovered that human RECQL, a helicase protein involved in the DNA damage response, associates with the HSV-1 genome during DNA replication. In uninfected human cells, RECQL plays a role in restart of stalled replication forks, homologous recombination, and base excision repair. However, the role of RECQL in HSV-1 infection has not been studied. To determine the effects of RECQL knockdown on HSV-1 infection we created an inducible shRNA knockdown cell line. We found that in the absence of RECQL protein, the amount of virus produced per cell increases. Other proteins involved in the DNA damage response are seen to act in an intrinsic antiviral defense against incoming HSV-1 genomes. We hypothesize that RECQL may be part of this antiviral response. Some proteins are degraded by HSV-1 protein ICP0, a ubiquitin ligase that allows the virus to evade the host cell's antiviral defenses. In the future we will investigate a potential relationship between RECQL and ICP0 and determine the effects of RECQL overexpression on HSV-1 infection.

Abstract Name: **Welcoming The Dear Neighbor: The Catholic Interracial Council Twin Cities**

Conversations surrounding racism both on individual and systemic levels continue to be at the forefront of American society. Our research aims to understand the tensions between individual and systemic solutions to racial change in the context of the Twin Cities during the 1950s and 60s. Though implications of racist thought have permeated the country for centuries, the 2020 murder of George Floyd and subsequent recent racial unrest in Minnesota has increased conversations concerning systemic change. To understand how systemic change will look in the future, we must first understand the efforts of the past. Our research centers on one national organization striving for change during the mid 20th century, the Catholic Interracial Council, also known as the CIC. The Twin Cities chapter of the CIC (CICTC) made great headway with community action and education during the beginning of the civil rights movement, but fell short of lasting systemic change. Though many efforts were made within the community, no legislature was passed to further their mission of racial equity. To understand CICTC contributions in conversations surrounding discrimination, inequality and needed change, we conducted an oral history interview with CICTC founding member, Patricia Caponi. Following the interview, we examined some of her personal documents from her time in the CICTC which included newsletters, correspondence, and informational pamphlets. Through analyzing these sources, we were able to see the challenges in working to alleviate systemic racism, such as the lack of supportive legislature and community push-back to anti-racist policy. Analyzing the CICTC's work demonstrates the possibilities and limits of individual efforts in anti-racist efforts and the importance of systemic change.

Abstract Name: **Does Revenge Toward Genocidaires Mediate the Relationship Between Exposure to Genocide Events and Traumatic Stress in Survivors of the 1994 Genocide Against the Tutsis?**

As the 30th anniversary of the 1994 Genocide Against the Tutsi looms, adverse mental health outcomes and disrupted relationships remain, despite considerable progress in rebuilding communities and work in mental health. Many studies have indicated that adverse mental health outcomes, such as posttraumatic stress disorder remain elevated in survivors of the genocide. Understanding factors that may maintain adverse mental health outcomes may be beneficial in fostering healing amongst survivors of the genocide. Previous research has documented the dose-effect relationship between exposure to potentially traumatic events and traumatic stress symptoms. Additionally, previous literature has indicated that revenge could be one avenue in which traumatic stress symptoms could be maintained. Specifically, past work has found revenge to be associated with higher levels of traumatic stress symptoms. Conversely, forgiveness, a distinct but related concept to revenge, has been found to mediate the relationship between exposure to traumatic events and traumatic stress symptoms. The aim of the current study is to investigate the relationship between feelings of revenge, exposure to genocide events, and traumatic stress symptoms in Rwandan genocide survivors. We hypothesize that feelings of revenge will mediate the relationship between exposure to genocide events and traumatic stress symptoms. Specifically, we hypothesize that higher levels of exposure to genocide events will berelated to higher levels of feelings of revenge and that higher levels of revenge will be related to higher levels of traumatic stress symptoms. To test this hypothesis, we will analyze previously collected data from a community survey of over 300 genocide survivors. Results could inform future interventions addressing adverse mental health outcomes in Rwanda.

Abstract Name: **Reconsidering Wisconsin's Northern Kettle Moraine: How a Novel Look at the Interlobate Zone Yielded New Glacial Age Constraints**

Modelling environmental responses to a dynamically changing global climate is critical to understanding the potential challenges humans may face in the near future. These models are limited by the accuracy and robustness of data that reflecthow past environments changed when Earth faced similar dramatic shifts in climate.Between 23,000-11,000 years ago, Wisconsin rapidly transitioned from a largely ice-covered landscape to one similar to today's. As the region warmed, flora and faunal migration would have necessarily kept pace with the melting ice or face losing their zonal niche. How rapidly this forcing occured, and how this reflects on future environmental responses, is not yet fully understood. Retreating continental glaciers left behind temporal markers in the form of moraines that have provided a cursory timeline of glacial retreat and floral advance. However, age constraints on glacial moraines are incredibly elusive andeven the best models of glacial retreat in Wisconsinare based on limited data. Using new cores from a lake in southeastern Wisconsin, this study obtained the first known series of robust radiocarbon dates that reflect glacial retreat, readvance, and final retreat in the corridor known as the Interlobate Zone. Furthermore, these new temporal markers reflect a previously unknown anomaly in local ice extentthat will significantly impactthe glacial models in this part of the state and may impact how retreating ice of the Greenland and Antarctic ice sheets are modeled. Ongoing study of the core is working to identify when diatoms, pollen, and phytoliths appear in the core to determine aqueous and terrestrial environments and their changes before, during, and after the readvance. These studies will overlap with previous research on local kettle lake fire history to create a continuous record of changefor the last 30,000 years.

Abstract Name: **Home Range and Habitat Selection of Rehabilitated and Released Female Black Bears in Northern Wisconsin**

The Eastern American Black Bear (Ursus americanus americanus) is a valued species among many for its biological, intrinsic, and cultural significance. Black bears are considered habitat generalists, taking advantage of the resources available to them. In the state of Wisconsin, previous studies suggest black bears select for habitats in northern hardwood forests and near beaver flowages. Habitat selection data from rehabilitated and released bears is lacking in Wisconsin, although this is a practiced management technique. The purpose of our study is to investigate the home range and habitat selection of rehabilitated and released female black bears in northern Wisconsin. The rehabilitated yearlings are fixed with GPS radio-collars prior to release, and location data is received every four hours. Habitat data from the received GPS points are compared to habitat data from random locations within the bears' home range (third-order analysis). Habitat data such as landcover type and distance to nearest road, stream, and open water source is collected. Understanding habitat selection of rehabilitated black bears in comparison to previously known black bear selection behavior is important for determining the impacts of rehabilitation and release as a management technique.

Abstract Name: Bayesian non-parametric learning of stochastic differential equations

Stochastic differential equations (SDEs) are potent tools to model real-world phenomena in various domains, including biology, chemistry, physics and mathematical finance. Accuracy of these mathematical models depend on their proper calibration according to the available data. This in turn requires employing statistical learning techniques to estimate the driving functions of the SDE from an observed trajectory. Previous work in this area has mostly focused on parametric estimation problems,where the underlying assumption is that the forms of the driving functions are completely known up to some finite number of real-valued parameters. While this simplifying assumption works in certain ideal cases, a vast majority of realistic systems require a data-driven approach where the entire driving functions are learnt from the given data. These are, however, infinite-dimensional learning or inference problems (in function spaces), and our work uses a kernel-based Bayesian approach to address them. An important aspect of this Bayesian approach is incorporation of low-cost sparse learning through proper use of various shrinkage priors, while allowing proper quantification of uncertainty through use of posterior distributions. Several examples with different SDEs illustrate the accuracy of our learning scheme.

Abstract Name: The effect that amount of video game usage has on maladaptive coping strategies

Previous studies found that more time people played video games, the higher their trait anger (Demirok, 2012). People play video games to assist emotional regulation and escape reality (Sarsenbayeva, 2020), but excessive video game use is associated with maladaptive coping strategies (Maroney, 2019). This study hypothesized that (1) amount of video game play (measured by hours/week) is positively correlated with maladaptive coping strategies; (2) amount of video game play is negatively correlated with cognitive reappraisal and expressive suppression, and (3) those who use games as a source of escapism will have a lower level of cognitive reappraisal and expressive suppression, and higher levels of anger expression. 290 undergraduates (62% females, 77.10% White, Mage = 19.07) answered online questionnaires of Game Addiction scale, Coping Strategies checklist, Difficulties in Emotion Regulation Scale, Emotion Regulation Questionnaire, Videogame use measure, and Anger Expression. Hours of video game use per week were positively related to escapism and expressive suppression positively, and negatively related to distraction-based coping strategy (allps < .01). There was weak evidence for a negative relationship between amount of video game play and avoidance coping strategy(p=.09) and no evidence of a relationship between amount of video game play and cognitive reappraisal. (p=.37). Escapism was negatively weakly associated with cognitive reappraisal and positively weakly associated with expressive suppression (allps < .05), and there was no significant relationship between escapism and anger expression(p=.25). Results show there is a relationship between video game usage, escapism and emotional regulatory processes that both support and present contrary evidence to the original hypotheses. Future research should evaluate the nature of these relationships and determine the direction of causality using experimental or longitudinal study designs, such as whether using video games as escapism can potentially cause maladaptive coping strategies.

Abstract Name: Embedding authentic inquiry in a first year environmental science course: Lessons learned on group work, student self efficacy, and being comfortable in your own teaching skin

Project management and cooperative group work are considered important parts of many ecological curricula but are often viewed negatively by students. Here, I focused on three components related to group work in UW-Stout's introductory Plant Biology class, the first class in the major taken by students in the Environmental Science program. Based on several years of comments recieved in student evaluations across multiple classes, I focused on three parts of the student experience (general attitudes toward cooperative learning, feelings and attitudes toward their group mates, and feelings of self-efficacy as scientists), while developing an authentic course inquiry project meant to introduce skills that would later be refined elsewhere in the curriculum (plant identification, Geographic Infomation Systems) while providing useful infomration for the campus (locations of populations of invasive plants). Working in teams, students identified and mapped populations of invasive species on campus and developed a short report their findings. For each segment of the project, students identified their "job" from a set of prescribed roles and completed a questionnaire related to their feelings toward their own and their peer's performance, their feelings about group work overall (SAGE assessment), and their feelings of self-efficacy (Baldwin's self-efficacy assessment). Generally, students felt an increasing sense of self-efficacy as the project progressed, and attained competency in the desired technical skills, but attitudes toward group work remained largely unchanged. In future offerings of the course, I will work with different group strategies to attempt to find a setup that is both beneficial to students while allowing me as the instructor to feel "comfortable" and "authentic" in leading learning activities.

Abstract Name: A Deep Learning Approach to Automate the Analyses and Prediction of Function for Poplar Stomata

In plants, stomatal pores regulate the intake of carbon dioxide that enables and powers photosynthesis and the loss of water from the surface of leaves. Variations in stomatal size and density can thus reflect novel strategies that balance water loss with photosynthetic capacity. Poplars are an emerging model system for studying adaptation to climate change in tree species and exhibit variation in stomatal characteristics. Currently, many approaches used in collecting stomatal morphometric data require the manual measurement of microscope images of stomatal imprints by a trained individual using software such as ImageJ.The process can be extensive, inaccurate, and slow down long-awaited results after collection. Our process follows similar methods shown in Gibbs et al. (2021) but differs in the deep learning processes used. This study implements a deep learning method to automate the process of morphometric data collection. Images collected for our approach are accurately labeled using open-source software to identify stomatal pores and guard cells. The preprocessed images along with the generated segmentation masks are fed into the deep learning model. For our study, we will use UNet to segment and measure pixel values that correspond with measurements of stomatal cells and image region properties to measure the stomatal density from prediction. All experiments will be conducted on the University of Wisconsin-Eau Claire BOSE supercomputing cluster. These measurements can be combined with additional climatic data to understand quantitative measures of plant health and viability across geographical and environmental scales.

Abstract Name: Analyzing the Ability of Astragalus Tennesseensis to Accumulate Selenium

Selenium is a metalloid and an essential micronutrient but is toxic in high amounts. This element is naturally occurring in many soils and can be accumulated by some plants. When accumulated in high amounts, generally considered to be above 1000 ug/g dry weight, the plant becomes toxic if eaten by animals and is called a selenium hyperaccumulator. A study by Ohlendorf et. al. showed that a diet high in selenium given to aquatic birds resulted in severe and fatal birth defects, often involving developmental deformities of various organs and external body parts. Plants that can accumulate selenium do so by replacing sulfur with selenium in the amino acids within their tissues. Astragalus is one of the largest genera of plants, with estimations of around 3000 species. This genus is known to have many selenium hyperaccumulators; among these, one of the most well-studied species is Astragalus bisulcatus, which is often used as an indicator plant to detect seleniferous soils. Astragalus tennesseensis grows in Tennessee and surrounding states and is often found in Middle Tennessee's unique cedar glades. The environments this species typically grows in contain low amounts of selenium, compared to A. bisulcatus growing in the western United States in highly seleniferous soils. This study aims to investigate whether A. tennesseensis can accumulate selenium. This species will be grown alongside A. bisulcatus to compare their reactions to varying levels of selenium treatment (0 mg selenium/kg dry soil, 1 mg/kg, 10 mg/kg, and 100 mg/kg). Sodium selenate (Na2SeO4) will be used for treatment. After treatment has been completed, the plants will be digested in nitric acid and analyzed by atomic absorption spectrophotometry to determine the selenium content.

Abstract Name: Goal Attainment Scaling and Use of Retrieval Based Practice

Using goal-attainment scaling to promote the effective use of retrieval-based learning strategies among college studentsBackground: Retrieval-based practice is a learning strategy built upon an extensive body of research demonstrating that frequent and intentional recall of information results in more robust learning and memory over time. (Agarwal et al., 2020; Carpenter; Agarwal, 2020). Unfortunately, retrieval-based practice is underutilized among college students (Pinheiro et al., 2022). Methods are needed that help students successfully incorporate retrieval-based practices into their study routines. Goal attainment scaling (GAS) has been found effective in facilitating skill acquisition by employing self-monitoring to promote goal attainment (Hoepner et al., 2021; Turner-Stokes, 2009). The current study investigated the effectiveness of GAS in supporting online college students' independent use of retrieval-based practice.Methods: Students in two online undergraduate courses in communication sciences and disorders were taught how to use retrieval-based practices and given weekly tips on how to apply them to specific course content throughout the semester. Additionally, all students from one course utilized GAS to track their progress in acquiring retrieval-based practice as a skill. Students from both classes completed start-of-course and end-of-course rating scales that assessed self-efficacy related to the use of retrieval-based practices and the likelihood of continued use of the strategy in future courses. Rating scales were then used to evaluate the effectiveness of GAS in promoting retrieval-based practices among college students.Analyses have not yet been completed. We expect both groups to improve in their knowledge of and use of retrieval-based practices, although we anticipate the GAS group to improve at a higher rate and be more likely to use the strategy in the future. Relationships will be discussed related to the variables being investigated in addition to applications of findings that may help college students effectively utilize retrieval-based learning strategies.

Abstract Name: The Life and Music of Florence Price

Born in Little Rock, Arkansas, Florence Beatrice Smith Price (1887-1953) was America's first significant African American woman composer. The purpose of this lecture-recital is to uncover how Price's compositions are a historic symbol for traditional black composers today, revisit her significance in music history, and provide a biographical overview of her life through the exploration of her piano compositions and experiences composing as a Black woman. Graduating with a double degree in solo organ and piano teaching from the New England Conservatory of Music in 1906, Price was deeply influenced by mentors who helped reinforce an African American identity in her music. While living through the Great Migration and the Great Depression, Price slowly gained recognition throughout her lifetime as a prominent figure in the black community by writing piano compositions that included the "juba dance" and other Afro-American characteristics. Linda Rae Brown's findings in The Heart of a Woman: The Life and Music of Florence B. Price, reveal Price faced issues with conflicting roles both as a woman and a composer. With increasing racial tensions in the late 1920s, Price was denied access to professional music organizations such as the Arkansas Music Teachers Association. Although she lived a moderately private life, analyzing gender and race-based marginalization through the lens of Black feminism illustrates how Price challenged prejudicial social structures and contexts. Price challenges these notions by advocating for herself as a Black woman composer, eventually paving the way by fusing Euro-American structures with elements of her own American cultural heritage by emulating plantation melodies and African American folk melodies in her music. This lecture-recital is part of a growing momentum to give further attention to Price's piano compositions and life, which deserve continued further attention from scholars, teachers, and pianists.

Abstract Name: Image Processing and Molecular Modeling to Understand Nanovaccine Release in Colitis and Colon Cancer

In a living cell/tissue Reactive Oxygen Species (ROS) can be produced in excess due to both environmental and endogenous factors. ROS target the mitochondria and can cause allergic reactions, damage DNA, cell death, and even cancer. This microenvironmental condition is known as oxidative stress. One major consequence of oxidative stress is ulcerative colitis and colorectal cancer. Using the ROS-sensitive thioketal chemical linker in an ROS sensitive nanoparticle (a lipid shell with drug inside) has been designed to deliver the drug only at the site of infection (i.e., diseased colon with high ROS). The linker breaks to release the drug only at the site of high ROS in the gastrointestinal tract (food pipe) due to colitis or cancer. By attaching a fluorescent molecule (IR-780 iodide) to the lipid shell (with and without drug) we collected experimental data on (a) the location,(b) rate and (c) effect of the drug release – in healthy and infected mouse. Image processing of glowing (infected)/ non-glowing (healthy) mouse colon at successive time points using Python3 scripts we correlated RGB values of each pixel to the epi- fluorescence scale – corresponding to rate of drug release. To gain deeper biophysical insights of the molecular mechanism of drug release in the colon, we will create an all-atom molecular model of the lipid vesicle with and without the drug contained in the cavity. To mimic the in vivo colon conditions, we will apply exact salt concentration around the lipid shell (nanovaccine), and then use molecular dynamics simulations (1000 nanoseconds) with the GROMACS force-field to simulate and predict the mechanism at work. Using the results from the simulation we can record time needed for drug release as a function of ROS concentration in the colon. This will help us quantify nanovaccine performance and design better nanovaccine drugs for personalized therapeutics.

Abstract Name: **BRAIN/BLOOD-BASED EXTRACELLULAR VESICLE BIOMARKER QUANTIFICATION FOLLOWING TRAUMATIC BRAIN INJURY AND PHOTOBIOMODULATION THERAPY IN MICE**

Of the 1.5 million people experiencing traumatic brain injury (TBI) in the US annually, up to 80% experience debilitating pain symptoms. TBI induces neuroinflammation and oxidative stress, which promote post-injury hyperalgesia. While opioid-based therapies are the most common treatment for post-injury pain, their chronic use can exacerbate pain symptoms, potentially due to enhancement of neuroinflammation and oxidative stress. Therefore, it is critical to identify non-opioid based treatment for post-injury pain treatment. Photobiomodulation (PBM) light therapy has shown promise in reducing pain sensitivity, oxidative stress, and neuroinflammation in our experimental TBI studies. However, mechanisms by which systemic exposure to PBM affects neural processes related to TBI and pain are unclear. We hypothesize that extracellular vesicles (EVs), cell-secreted, lipid-bound particles enabling cell-cell communication, mediate the antioxidant/anti-inflammatory effects of PBM, as EVs transport antioxidant/anti-inflammatory cargo. To test this, C57Bl/6 mice were given one closed-skull impact or sham (control) surgery. One day post-surgery, a subset of sham/TBI mice received PBM for 7 days using a handheld LED panel (670 nm, 50 mW/cm2, 90 sec/day). Brain tissues and serum were collected on days 7 or 30 post-injury. Using enzyme-linked immunosorbent assays (ELISA), levels of two EV surface markers, CD63 and CD81, were quantified to reflect EV quantity. TBI significantly reduced serum CD63 levels by 7 days post-injury, compared to sham, regardless of PBM exposure, with no effect of TBI or PBM at 30 days post-injury. No changes in CD81 levels in the prefrontal cortex or the dorsal hippocampus 7 days post-TBI were observed. Together, these data suggest that TBI reduces early circulating levels of EVs, but that neither TBI nor PBM affect brain biomarker levels at the time points examined. Further studies will examine EV content which may reveal potential mechanisms by which EVs may mediate oxidative stress and/or neuroinflammation after TBI and PBM exposure.

Abstract Name: **Animals' Impact on Stress**

The majority of today's students are stressed in some way, and research suggests that animals are a good way to manage stress levels. With anxiety and depression on the rise, programs are seeking support for students in the stress-filled school life. Some researchers have found that bringing in therapy animals has been a good way to lift the spirits of the students. Animals have been used in therapy as early as the 18th century (Chu et al., 2009) and have been shown to ease isolation. Over 98% of full-time students are stressed, and 86% of students find improvement in domestic animals. Animal-assisted programs are still being researched, but evidence shows that there is a positive influence towards stress in many students. This research attempts to disclose the relationship between pet interaction and the level of stress the person feels. The results show that a majority of students have reduced stress after interacting with a domestic animal.

Abstract Name: Smartphones, Attention, and Brain Electrical Responses

Given concerns about how distracting smartphones can be, we are interested in how they affect attention-related brain electrical activity. Previous research suggests that the mere presence of one's smartphone can negatively impact behavioral performance on an attention-related task. The aim of our ongoing study is to investigate whether simply having one's smartphone present and visible (although shut off) influences attention-related EEG (electroencephalographic) activity. We are assessing this in two ways. First, subjects perform an oddball task, which requires attention and responses to occasional target stimuli ("oddballs") among many task-irrelevant stimuli ("standards"). The P3, a late component of the event-related potential (ERP), is typically larger to oddballs (which receive more attention) than standards; we predict an attenuation of this oddball effect in the presence of one's phone versus a control non-phone object (tile). Second, we are looking at EEG power in the beta range (13-30 Hz) as subjects passively view their phone versus the control object. Since beta activity is positively correlated with alertness and attention, we predict greater beta power in the phone condition. Furthermore, we predict a correlation between beta power in response to one's phone and attenuation of the P3 oddball effect by one's phone; that is, the more attention is garnered by one's phone the more we think their phone will distract from a phone-irrelevant attention task.Preliminary data suggest increased beta activity in the presence of the phone and replication of the classic P3 oddball effect, but are unclear about an impact of smartphone presence on P3 amplitude.

Abstract Name: What are You Watching? Chinese Soft Power Influence Seen Through Taiwanese TV and Film Habits

China has attempted to increase soft power influence globally in recent years, largely through popular culture endeavors. This project will explore whether Taiwanese people perceive China positively or negatively by analyzing television and viewing habits. Many researchers have focused on how Chinese soft power influences Asian countries and their perceptions of China, but there has been little focus on how China influences Taiwan and therefore how Taiwan perceives China. The research will utilize the theory of soft power from a media standpoint. The data will consist of structured interviews and cross-sectional surveys with Taiwanese students and teachers from National Taiwan University (NTU). Upon finding commonalities in the data through thematic coding, the project will then discuss the likely reasons for these trends. The data could reveal Taiwanese people do not often watch Chinese television, therefore demonstrating they perceive China negatively. If Taiwanese people perceive China negatively, then these findings would indicate a need for change of focus in Chinese policy and advertising techniques to foster better relations.

Abstract Name: **Development of a Wound Infection Detection Device**

An infection within a wound is a devastating circumstance that can potentially turn a simple graze to a multi year long healing process. The latest methods for wound infection detection are cumbersome and time consuming. These practices often need to undress the wound and leave it exposed for a few seconds or up to an hour. Undressing a wound is counterproductive to the healing process and this small window of exposure can possibly result in an infection in itself. There is a need for a tool that allows for active infection detection that causes very little to no compromise to a wounds healing environment. The device we propose is placed amongst the gauze whenever a wound is initially dressed and implements an array of sensors to collect a wide range of data. The type of data we plan to collect is pH, pressure, moisture, and temperature. We also want to have an integrated RFID or WIFI module so that this data can be wirelessly collected from the device. The specific methods involved for this developmental project start with designing and testing the responses of multiple sensors in an infected wound environment compared to a healthy environment. This is done so that a reference point can be made when a healthy wound transitions to an infected wound. Currently, progress is being made towards gathering preliminary data and calibration of our sensors for our design. Although the project is still in its early stages, It will be beneficial to observe the outcomes from the system in simulated wound environments to provide a baseline for further research and applications.

Abstract Name: **Detecting Bias in Intelligent Autonomous Hiring Systems**

This project analyzed if artificial intelligence (AI) hiring systems demonstrate prestige bias, and how that bias may be mitigated. We chose to look at prestige bias since the quality of a candidate's education will naturally be reflected in their skills and experience; a school's reputation should not additionally be factored into a hiring decision. Of note, this project analyzed prestige bias against Historically Black Colleges and Universities (HBCUs). The majority of students attending HBCUs are people of color who are already marginalized members of society. We examined how hiring site Indeed utilizes AI to list candidate resumes by relevance and measured the relationship between a candidate's resume ranking and the university they attended. We expect to find a negative association between HBCU status and ranking, which is stronger than the association between ranking and other confounding variables such as experience type, degree level, field of study, etc. Subsequently, we will develop our own AI system, utilizing hiring decision data that we collected from Indeed, to observe if it will present a similar bias. If so, then we will apply debiasing techniques to our model to create a new AI hiring system that is not biased against HBCU applicants. With businesses considering AI as a tool for hiring, companies must understand that AI hiring systems can perpetuate the same biases found in human hiring on a larger scale.

Abstract Name: **Identifying the Customer and Purchase Motivations at the New Harvest Market**

Previous studies have observed consumer behavior patterns at various farmers' markets across the United States. However, this particular study focuses on the consumers at the New Harvest Farmer's Market in Knoxville, Tennessee. This farmer's market in particular is similar in size and location to other farmer's markets in the region, which makes the findings more applicable. The method used in this study was intercepting with a paper and pencil survey. We surveyed 49 New Harvest Farmers' Market customers out of a total of 246 attendants (during the time span we were there). The mean age was 38.9 years old. The respondents were white and both their education levels and income were greatly dispersed. Half of the respondents were from four main zip codes (37918, 37917, 37924, and 37931). Only 5 respondents answered that they are recipients of SNAP or WIC. The interpretation of the results is most respondents attended the market for the perceived quality of food rather than a sense of community. This was unexpected since we thought a small market would have a stronger sense of community. This research informs other markets in the region that an effective marketing strategy could be highlighting the quality and origins of the food in marketing efforts rather than trying to create a sense of community.

Abstract Name: **3D Printing to Improve Patient Outcomes for Mini-Thoracotomy Aortic Valve Replacements and Mini-Mitral Valve Repairs**

Aortic valve replacement (AVR) was established in the 1960's and has become a routine therapy to treat patients with severe aortic valve dysfunction. AVR is usually performed using a full sternotomy and cardiopulmonary bypass support. Since the late 1990's, minimally invasive procedures have been developed for aortic valve surgeries, such as the mini-thoracotomy AVR. These less invasive procedures claim reduced postoperative complications, shorter lengths of stays in the hospital, and lower mortality. However, the minimally invasive nature may provide challenges in the viewing of patient anatomy during the procedure. This project will provide the 3D printing capabilities needed to investigate if using 3D printed anatomical models for pre-operative planning and/or patient education will result in better patient outcomes for mini-thoracotomy AVR surgery, particularly in those with thoracic abnormalities. For selected patient cases, the Mayo Clinic Luther Campus will provide UWEC researchers with DICOM files for segmentation and 3D printing. The UWEC research team will perform the segmentation and provide the physical 3D anatomical model with initial feedback on accuracy from Mayo physicians. Ultimately, the Mayo Clinic collaborators will evaluate the effectiveness of using the 3D models in patient outcomes as well as patient education on the procedure.

Abstract Name: **Geochemistry and petrography of the volcanic stratigraphy and syn-volcanic intrusions at the Lynne Zn-Cu-Pb Deposit, Oneida Co., Wisconsin**

This project constrains the volcanic and tectonic setting at the Lynne Zn-Cu-Pb deposit in Oneida County, Wisconsin and improves regional metallogenic models in the Penokean volcanic belt. The Lynne deposit, discovered in 1990 by Noranda Exploration, is one of many volcanogenic massive sulfide (VMS) deposits located in northern Wisconsin. The VMS depositional environment of Wisconsin is currently interpreted as continental back-arc volcanism which formed as the Pembine-Wausau Terrane accreted onto the Archean Superior Craton during the Paleoproterozoic Penokean Orogeny (1.8-1.9 Ga). However, the extent of Archean basement and its influence on metallogeny of VMS deposits is poorly constrained. Samples of the least-altered volcanic and intrusive rocks were obtained while re-logging ~2900' of Lynne deposit drill core and were prepared for geochemical and petrographic analyses. The volcanic units at the Lynne deposit were previously divided into upper and lower rhyolite/dacite units based upon their stratigraphic position relative to the ore horizon. Major and trace element geochemistry and petrographic observations from these volcanic units reveal no petrochemical difference between the upper and lower strata indicating that VMS formation is not associated with transitioning geodynamic settings, but rather is a subsurface replacement of volcanic facies. Intersecting the Lynne deposit are fine grain felsic dikes and a large coarse grain granodiorite pluton at the bottom. These intrusive rocks are geochemically indistinguishable from the volcanic host rocks which suggests they are a part of the same magmatic system. Additionally, the geochemical similarities to the felsic volcanic rocks and lack of contact metamorphic aureole suggests the granodiorite is the syn-volcanic intrusion that helped drive hydrothermal circulation. Continued geochemical and geochronological analyses will allow for improved metallogenic models and tectonic interpretations of similar deposits across the Penokean Orogeny.

Abstract Name: **Sex Differences Exist in the Dendritic Complexity of Adult Born Hippocampal Neurons**

Following a traumatic brain injury (TBI), adult hippocampal neurogenesis is stimulated. Hippocampal neurogenesis is linked to memory and learning performance. Traditionally TBI studies have almost exclusively focused on male mice. Sex differences exist in the regulation of neurogenesis and need to be examined as a physiological variable in posttraumatic hippocampal neurogenesis. We used transgenic reporter mice to genetically label neural progenitor cells to examine sex differences in the regulation of adult neurogenesis and in neuron morphology. Naïve mice received tamoxifen injections at 8 weeks of age. After waiting 6 weeks to allow neurons to mature, mice were euthanized. Here we investigate the number of mature neurons in the dentate gyrus of male and female mice. There is no significant difference in the overall numbers of mature neurons between male (n=6) and female (n=10) mice. To assess dendritic complexity, Scholl analysis was used to examine dendrite length and branching complexity. Conclusions for this study, although there are no significant differences with overall granule cell counts, sex differences exist in dendritic complexity in naïve mice. Naïve male mice exhibit less dendritic complexity than naïve female mice at 50-100um from the cell soma. This is important to consider when examining dendritic complexity after TBI between sexes.

Abstract Name: **A Case Study Analyzing Climate Change Curriculum Implementation in Flagstaff Middle Schools**

Data explicitly supports that Earth is facing a climate crisis, yet Arizona Science Standards severely underrepresent and suppress climate change causes, severity, and solutions. These vague standards leave interpretation open to individual districts, schools, and teachers. This qualitative case study identifies what type of curricular implementation yields the deepest student understanding of climate change causes, severity, and solutions, and how successful it is in preparing middle school students to solve the future climate crisis. Data was collected in six sixth grade classrooms representing six different specialized programs in two Flagstaff Unified School District (FUSD) middle schools, and four field expeditions at Camp Colton, a four-day environmental camp offered to all sixth grade students in FUSD. Student surveys, semi-structured teacher interviews, focused observations, and curriculum comparison revealed differences in students' depth of climate change comprehension and teacher interpretation and implementation of Arizona Science Standards. Teacher surveys and observations at Camp Colton revealed that the preparation provided does support students in overcoming psychological barriers to climate mitigation. Iterative thematic coding analysis and statistical significance of results between programs have been conducted to quantify the results. In analyzing FUSD middle schools' application of Arizona Science Standards and delivery of climate change concepts, there is potential to reform curriculum and inspire other schools to do the same.

Abstract Name: **Relating Patterns in Mathematics & Statistics Tutor Center Use to Student Success**

Our research explores usage patterns of the mathematics and statistics tutoring services provided by a regional comprehensive university, and how these patterns relate to student success. Tutor service is available at no charge to students and supports 100- to 200-level courses and is staffed by undergraduate and graduate students. General trends are explored, and statistical models are built to identify connections between student success and frequency of attendance. Our data set consists of date and timestamp information per student visit to the mathematics and statistics tutoring center at a regional comprehensive university during the Spring 2022 semester. The visit information is joined by ID number to other details (class standing, GPA at the semester of interest, demographic information, major/minor, and overall grade in the class that they received support for). A comparison group of students in the same classes that did not attend the tutoring center during the semester was gathered. The same variables excluding timestamps were recorded for this group. Students are matched between tutoring and comparison groups by similar characteristics (e.g. GPA, major) and analyzed. Statistical models (ordinal and logistic regression) are created to relate student success to how often they attended tutoring. By including a comparison group, we can compare success rates between those who attend tutoring and those who do not. Our research provides a foundation for the university to continue monitoring relationships between tutor center use and student success. Our results highlight how student success metrics link to the tutoring center service provided by the university. Generalized student use patterns and metrics are shared to provide recommendations to better staff the tutoring center and answer other questions. Results will be reanalyzed each semester in the center with additional data. Similar methods can be applied to tutoring centers in other subjects or at other universities.

Abstract Name: Mental Health Impacts of COVID-19

Background:Previous research has been conducted that shows an array of opinions on vaccination against COVID-19. A qualitative study found that most participants had negating opinions on the reasoning behind vaccination status. The results showed individuals were fearful for possible side effects and concern regarding the reliability.We hypothesized: women would have a higher likelihood of being vaccinated and less likely to have contracted COVID-19. We hypothesized that vaccinated individuals would have worse mental health symptoms throughout the pandemic and, they would be less likely to have an optimistic outlook on the pandemic. We also hypothesized that individuals who contracted COVID-19 would report worsened mental health symptoms and lower optimism regarding the outcome of the pandemic. Last, we hypothesized that the effects of vaccination and contracting COVID-19 would be more pronounced in women.MethodsAn online survey was conducted utilizing an online crowdsourcing program, MTurk. Across the United States, there were n=1,351 participants, 635 men and 766 women. The data used in this study was collected between May 26, 2021, and June 25, 2021. Everyone that completed the main survey was compensated $1.50. ResultsWe examined whether more males or females:· Were more likely to get vaccinated,· Contracted COVID, and· Had an optimistic outlook on the pandemic.We discovered:· Women were less optimistic regarding the outcome of the pandemic.· No correlation between gender and the likelihood of getting vaccinated or contracting COVID.· Individuals who contracted COVID-19 were more optimistic on the pandemic.The relationship between vaccination and depressive symptoms, substance use, and feelings surrounding the impact of COVID was also explored. There's a significant correlation in vaccinated individuals and heightened levels of fearand substance misuse. Contrary to our hypothesis, the results yielded vaccinated individuals didn't have moreoptimism regarding the pandemics outcome.

Abstract Name: Congruence Subgroups of the Virtual Braid Group

Braid theory is a mathematical field that studies knotted structures in the world around us. For example, hair can be braided and DNA is braided. There are two categories of braids which are distinguished by crossing information. The standard braid group consists of braids with regular crossings (which can be thought of as two roads crossing at an overpass). The virtual braid group has braids with both regular crossings and virtual crossings (which can be thought of as two roads crossing at an intersection). A common theme within braid theory research is generalizing known theories about standard braids and extending those ideas to virtual braids. This project investigates a particular subsection of virtual braids which is well established for standard braids.Two braids are said to be congruent if they are indistinguishable after a translation process through the Burau representation. A useful analogy is to think of the Burau representation as an interpreter that translates braids into another language. Two braids are congruent if they get translated into the same word. For standard braids, the theory of congruent braids is well studied and understood. This project is the first of its kind to study when two virtual braids are congruent.This project is computation-based in nature, requiring an implementation of the Burau representation. Our approach uses computer computation to search for examples of congruent virtual braids. We expect to find that congruence in the virtual setting is much more generic than in the standard setting, which would spark a whole new avenue of investigation.

Golden, Mara

Institution: *NY - Siena College*

Discipline: Social Work

Mara Golden

Abstract Name: **Finding a Sense of Self Through Autoethnography**

This article explores finding a sense of self through an autoethnography. This autoethnography contains a lit review which explains and breaks down how to write an autoethnography. Many people choose their majors because they have a connection to it. There is some event or situation that occurs connecting a person to their major and or future career. This autoethnography will focus on my personal connection to the social work field. While exploring an abusive personal upbringing, I will connect a specific experience to social work theories. These connections will then be analyzed through my social work approach at Albany Medical Center, located in Upstate New York. The results of the research focus upon finding a sense of self in the social work field. The goal is to be able to identify emotions to patient situations, pinpoint specifically where these emotions stem from, and what true emotions I am feeling. The findings of this autoethnography will follow me throughout my time as a social worker. My hope is to leave a piece of work behind for both the Social Work department and the Bonner Program at Siena College. This work will be guidance in how to write an autoethnography for future capstones. For future Social Work students, this autoethnography will be guidance in finding their sense of self in their own social work practice.

Abstract Name: **Agent, Interlocutor, or Policymaker? The Glasgow Financial Alliance for Net-Zero and the Formation of Private Authority in Global Governance**

What explains the emergence of the Glasgow Financial Alliance for Net-Zero (GFANZ) within the constellation of climate finance actors? More importantly, how might its deepening or decline in private authority impact the global financial industry's mobilization toward systemic decarbonization? Although the current on-target climate finance gap of an annual $2.5 trillion presents a key global governance deficit, the prospect of GFANZ's private authority remains fragile without formal enforcement mechanisms. Moreover, this fragile stage of establishing private authority––and how an organization like GFANZ may possess agency to strategically mitigate challenges and accumulate legitimacy––remains an under-investigated process with implications for the integration of nonstate actors in global institutional architectures. Through a case comparison with the Institute of International Finance (IIF), I trace how this global financial association acquired authority over time, starting as a small data-sharing organization for sovereign debt market lending risk and evolving into a key governance player that harmonizes best practices for international regulatory compliance. I attribute the gradual embeddedness of the IIF's private governance role as a result of the strategic manipulation of its social network power, brokering between private firms and public entities as an interlocutor. Applying this analytical frame to GFANZ, I conduct a formal social network analysis of 81 nodes to visualize its network power and vulnerability vis-à-vis member firms, climate NGOs, UN bodies and initiatives, and other voluntary climate finance frameworks. Although GFANZ's anticipated exercise of authority has gravitated these actors to contribute to and possess a stake in its sophistication––similarly entrenching a broker role––I will trace and synthesize trends in the public climate finance regulatory sphere and GFANZ's private demand to consider how this network structure may transform, and subsequently impinge, its authority.

Abstract Name: **Hydraulic efficiency of 3d printed static mixers**

Drainage practices are commonly used in Midwestern states to increase crop yield. While this method is very feasible for crop production optimization, it has some unwanted environmental effects. Unfortunately, water that is artificially drained from agricultural sites carries large amounts of nutrients to receiving waters and creates a pollution problem.There are several experimental engineering practices that suggested decreasing nutrient concentration. One of them ison-site treatment filtration of drainage water. Fast and efficient mixing of drainage water with treatment material is the key to this practice. This goal may be achieved viastatic mixers.Static mixers are used incontinuous practices, where they homogenize fluids with no moving parts, making themkey componentsfor filtration processes. Therearedifferent types, but we will focus on them here in theinlinemixer. As they have for purpose to create turbulence that enhances the rapid mixing of the injected chemical into the water stream. We use them specifically for chemical treatment due to the fact they create an injection point for chemicals into water line. This research is devoted to determining the efficiencies of static mixers with different geometries.The goal is to improve filter efficiency by finding the adequate format of inline static mixer for the right task. Hence, every filtration process differs and needsa differentstatic mixer. For this, we are focusing on analyzing, characterizing, and designing a 3D line static mixer. In order to accomplish that we will be using a 3D printer to create models based on the design that we produced and test them based on specific criteria which are based on homogeneity and sediment retainment after mixing.

Gomez, Karla

Abstract Name: **Death and Grief Support in Nursing Homes**

Effective, high-quality end-of-life care should be holistic and encompass practical and emotional care and heightened family involvement. Nursing home staff make every effort to provide effective high-quality care that allows individuals to die with dignity. Effective care during the end of life is important for the individual and their families. The aim of this study is to examine burnout syndrome and grief in nursing home staff when caring for dying patients. Recruitment of the participants was a multi-step process. First, researchers utilized a convenience sampling technique, selecting from 38 nursing facilities utilized as administrative internship sites for students in the health care administration program at a Midwestern University. Next, stratified sampling was employed to select frontline workers from each nursing facility. From each site, in addition to assessing the administrative interns' perspectives, seven other stakeholders were selected (the nursing home administrator, the Director of Nursing, the food; nutrition director, a dietary aide, and three nursing assistants) completed a survey with demographic questions about the nursing facility and questions pertaining to grief support and burnout. Analysis is currently in progress. The data will be analyzed using a descriptive analysis, independent t test, correlation, and logistic regression tests.

Abstract Name: Understanding the Experience of Students of Color in Honors

Nationally and at UW-Eau Claire, honors programs are increasingly invested in attracting and serving diverse students, creating an environment where all students feel a sense of belonging. However, honors programs often face challenges in recruiting and retaining students of color for a wide variety of reasons, ranging from inequality in the K-12 school system, to the discriminatory effects of test scores and other commonly used admissions criteria, to challenges around social affinity. The Honors Program at UW-Eau Claire made great progress in improving inclusivity about ten years ago, when it moved toward a holistic admissions model— allowing for a more accessible program for students of diverse backgrounds. Building on this foundation, we are aiming to prioritize improved retention of students of color to graduation with University Honors through an equity, diversity, and inclusion structured lens. We use structured interviews to gain an in-depth, nuanced, context-rich account of how students of color understand their identity as honors students, how they experience their honors courses, and how their honors experience relates to their broader experience at the university. After coding the interview transcripts through an analytical and interdisciplinary approach, we have been able to identify main themes or experiences of honors students of color. Many of which are in relation to imposter syndrome, a sense of othering, and an obligatory feeling of sharing personal experiences due to race. We believe that it is due to these main themes, that students of color are not retained at a proportional rate in comparison to their white peers. We hope that this work will contribute to our knowledge of the experience of high-achieving students of color within the Honors Program and aid in the journey of becoming an increasingly equitable program for all current and future students..

Abstract Name: Energetic Pathways and Trophic Diversity Among Macroinvertebrate Communities in Saltmarshes

Saltmarsh food webs are some of the most productive and complex ecosystems because they sustain both pelagic and benthic communities. Macroinvertebrates are key consumers that link primary productivity in benthic and pelagic communities to higher trophic levels. The energy transfer among macroinvertebrates in saltmarsh food webs is not well understood. Nonetheless, the food web interactions at the macroinvertebrate level are less understood. The gap in knowledge suggests the need for additional research concerning the energetic pathways and trophic linkages macroinvertebrates contribute to saltmarsh food webs. Macroinvertebrates (amphipods, ants, beetles, copepods, midges, mud crabs, polychaetes,snails, springtails, spiders, ticks, and wasps) were sampled at six different saltmarshes in southern Louisiana. Of these, there are two restored and 4 natural saltmarshes. Stable isotope analysis (SIA) of δ13C (energy source) and δ15N (trophic position) was used to trace the trophic pathways throughout each marsh.The first objective of this study is to quantify the relative contribution of pelagic vs. benthic carbon energy sources among macroinvertebrate taxa. We anticipate that saltmarshes with differing abiotic factors will influence the food web structure through variation in carbon sources. The second objective is to determine the trophic level these taxa occupy. It is anticipated that predatory species will occupy higher trophic levels than herbivorous and omnivorous species. Organisms that occupy higher trophic levels have elevatedδ15N signatures. Understanding the contributions of macroinvertebrate communities is important because of the complex benthic and pelagic ecosystems they help sustain.

Abstract Name: **Medical Applications of Additive Manufacturing: Anatomical Modeling**

Additive manufacturing, also used interchangeably with 3D printing and rapid prototyping, is utilized in many industries to manufacture objects for consumer use. It is beneficial to the medical field as it can be applied to make educational tools for healthcare students and patients with life-threatening conditions. Insight is also provided with patient-specific medical aids such as implants, prosthetics, and bio-manufactured organs. There is a streamlined process in constructing patient-derived 3D models from DICOM (Digital Imaging and Communications in Medicine) files. The DICOM files were retrieved from The Cancer Imaging Archive (TCIA) through the NBIA Data Retriever and downloaded onto a device. There was, however, a challenge in converting DICOM files into rapid prototyping compatibles. With only basic anatomical knowledge and limited familiarity with radiographic scans, the segmentation portion proved difficult. The software used for conversion was Mimics Research 19.0 from Materialize. DICOM images were uploaded onto the software, and segmentation of a particular body part was performed. Following thorough segmentation, exportation as an STL (Standard Tessellation Language) file was accomplished. Once converted, a certain manufacturing method was applied, and the model was then printed using a selected material (e.g. polymers, ceramics, and metals) to be ultimately used according to one of the indications listed above. In this case, the prototypes are a spine (hard tissue), a kidney model (soft tissue), and an angiotensinogen protein model used for educational purposes.

Abstract Name: **Comparing Trajectories Toward Activism Amongst Asian American and Latinx Young Adults**

Following the murder of George Floyd, the Black Lives Matter movement inspired an increased awareness of social injustices and racism in America. In this research, we examine how the anti-racism movement that followed this historical event impacted Latinx and Asian American young adults and their social activism. We conducted in-depth interviews with Asian American (n=12) and Latinx (n=12) emerging adults who identified as activists. Utilizing Interpretive Phenomenological Analysis we examined recurring themes in participants' life stories that explained their involvement in activism. We found that both Asian and Latinx participants were motivated to join political-cultural heritage organizations to bridge and integrate their American and ethnic cultural identities. Prejudice against the Latinx community motivated Latinx participants to become involved in cultural-political organizations in comparison to Asian American involvement in organizations alike, which led to an increased awareness of anti-Asian racism. The rise of the Black Lives Matter movement motivated Asian American activists to advocate against Asian discrimination. In contrast, the Latinx participants were more motivated towards coalitional activism for people of color, specifically Black and Brown. This research illuminates the similarities and differences in trajectories toward activism for Latinx and Asian American young adults.

Abstract Name: **Estimating The Path of COVID-19 Using Phylogenetic Techniques**

Genetic data provide a wealth of information about the evolution of organisms and their unique features. When it comes to viruses, genetic data is crucial for surveillance and vaccine development efforts. The COVID-19 pandemic led to the collection of large amounts of genetic data on the coronavirus. With such data, the evolution of COVID-19 has been documented since the onset using phylogenetic trees. Strains that are sampled and sequenced can be placed as leaf nodes in these trees. These strains contain spatio-temporal data about where and when the strain was discovered. Internal nodes connecting each branch represent a relationship between the sample and its ancestor. Unlike leaf nodes, the location of internal nodes can never be known exactly. The goal of this research is to estimate the locations of internal nodes using ancestral character state reconstruction and find the full evolutionary path of COVID-19. We obtained genetic data through GISAID which is a large database focused on collecting and sequencing samples from viruses related to influenza and COVID-19. Our sample size is over 8 million, containing spatiotemporal data and other metadata. GPS coordinate data were extracted by processing the location names. To estimate internal node locations, we used ACCTRAN, a form of ancestral character state reconstruction algorithm that annotates internal nodes using characters from leaf nodes and the tree paths. The results provide a novel estimation of the locations of internal nodes and the full spatial path of the phylogenetic tree which will shed light into generating accurate phylogenetic trees from limited sample data.

Abstract Name: **Metal Speciation**

Metals in the natural environment exist in multiple forms or species including soluble organic and inorganic complexes, colloids, and free metal ions. According to the biotic ligand model, free metal ions are more bioavailable than other forms and are therefore considered to be more toxic. We studied the speciation of lead, copper, and mercury in the South Fork New River upstream and downstream of a wastewater treatment plant (WWTP) in northwestern North Carolina. Since WWTPs discharge dissolved organic matter (DOM), we expected metals downstream of the WWTP to be bound by DOM, making them less bioavailable but more likely to be transported throughout the environment. Anodic stripping voltammetry (ASV) with a boron-doped diamond electrode was used to quantify free metal concentrations. Surprisingly, in 2021, we found higher concentrations of free metal ions downstream of the WWTP, even though we expected the WWTP to discharge DOM capable of binding metals. More recent work in 2022, however, suggests similar free metal ion concentrations upstream and downstream of the WWTP. The complexing capacity of the South Fork, or its ability to bind free metal ions, is 5 parts-per-billion both upstream and downstream of the WWTP. We plan to study the seasonal variation in metal speciation and if pH or electrical conductivity impacts free metal ion concentrations and complexing capacity. We will also measure total metal concentrations using acid digestion and inductively coupled plasma-optical emission spectroscopy (ICP-OES).

Abstract Name: **Green against the odds: Overcoming institutional barriers to sustainability in cities with pragmatic and progressive needs**

If cities are to realize their potential as leaders of sustainability policy and innovation, they require both symbolic resources such as social networks and legitimacy and material resources such as financial and technical support. Although external support mechanisms, including those provided by diverse climate networks, seek to help cities overcome institutional barriers to urban sustainability, previous research on city networks has underestimated the importance of variations among member cities in terms of how serious they are, or can afford to be, about sustainability. We argue that cities taking sustainability more seriously have different material and symbolic resource needs from those that take sustainability less seriously. Drawing on qualitative data from 53 in-depth interviews with city officials across the sustainability-seriousness spectrum, climate network leaders, and other organizations supporting cities, we confirm this variation by identifying that cities tend to face one of two distinct sets of resource needs. Cities with pragmatic needs seek to push the boundaries of political feasibility, and look to peer cities for reassurance; cities with progressive needs aim to push the boundaries of technical possibility and broadcast their achievements to the world. We conclude that different sets of needs require different external support mechanisms, and we note that skewed attention towards cities that already take sustainability seriously limits our understanding of how cities can overcome institutional barriers to climate action, especially when these barriers are particularly high. Our findings offer contributions to literatures on cities and climate change, the institutional drivers of urban sustainability, and network governance.

Abstract Name: **Synthesis of Novel Bisamidoxime Compounds for Use as Potential Anti-Cancer Agents**

Novel bisamidoximes have been found to be effective against cancer cells by inhibiting histone modifiers, such as HDAC and HAT enzymes. This inhibitor targets the zinc ion in the histone enzyme'sactive site. In this study, we describe the synthesis of bisamidoximes using a three-step reaction sequence that can be used to prepare the target compounds in multigram yields. The first reaction converts commercially available aldehydes into oximes. The resulting oximewasthen converted to a hydroximoyl chloride, which washighly reactive toward an acyl-substitution reaction. Finally, the hydroximoyl chloridewasreacted with a diamineto form thebisamidoxime. Synthetic details and characterization via NMR spectroscopy will be discussed.

Abstract Name: **The Growth and Decay of Danchi Housing in Japan**

This study explores the changing functions of Danchi housing in post-World War II Japan. To begin is the examination of how post-WWII influenced political, social, and economic advances that lead to the construction of Danchi housing in the 1950s and 1960s is provided. To understand these changes, it is important to briefly introduce the Japanese political, social, and economic system that generated the need for public housing, including recovery from bombings that caused their housing crisis—as well as rebuilding their economy. By addressing these needs, Japan changed the concept of both Japan and its cities. While pre-WW II Japan harbored an Imperialist reputation, the results of WWII forced Japan to adopt themselves as a constitutional monarchy. In an effort of reflection, post-war Japanese housing served to construct a positive image of Japan and Japanese society. In the contemporary period, after the growth of the economy, Danchi was abandoned with the invention of living spaces within city limits. Danchi housing has become designated areas for citizens that are not easily accepted by the majority of the country. The finding, based on scholarly literature, is significant due to its demonstration of the changing notion in housing and cities generated by evolution of political, economic, and social conditions.

Abstract Name: **Sex and age estimation using CT images in Forensic Anthropology**

Forensic anthropologists reconstruct the biological profile (e.g., ancestry, sex, and age) of skeletal remains for victim identification at a crime scene. However, the preservation state of the skeletal remains may be compromised due to taphonomic factors, which requires alternative methods for assessing morphological features present on the bones. Bone mineral density (BMD) is known to be affected by sex and age of individuals. In this regard, sexual differences in BMD and its relationship with age have been studied. Recently, three-dimensional (3D) imaging technology such as computed tomography (CT) has been popularly used for forensic anthropological examination. The purpose of this study is to generate new methods for sex and age estimation from the Korean skeletal remains using CT data and related software. In this study, a new concept, digital bone loss (DBL), will be introduced. Whole body CT scan data from 240 Koreans (119 males, 121 females) were studied. Mean ages of the samples are 55.1 years and 53.6 years for males and females, respectively. Three open-source software (3D Slicer, Meshmixer, and CloudCompare) were used to calculate DBL. In this study, DBL is defined as the ratio of loss in the number of faces between two 3D models which are reconstructed using different thresholds in the Threshold tool of the Segment Editor module of 3D Slicer. Logistic regression models and linear regression models were generated for sex and age estimation, respectively. This study suggests that DBL can be possibly used as a proxy for BMD and thus, can serve as an indicator for sex and age estimation in forensic anthropology.

Abstract Name: **Learning to belong again: University belongingness in a post-pandemic society**

Belongingness refers to a feeling of connectedness and acceptance. In a university setting, feeling a sense of belonging can influence a student's attitude about their university and their experiences while enrolled there and is implicated in several factors related to student success. Many factors can influence university belongingness such as peer and faculty interactions. These factors were clearly disrupted during the height of the COVID-19 pandemic when classes abruptly went to an online format, which was shown to negatively influence belongingness. This current study aimed to understand how the return to in-person classes from online/remote classes has impacted belonging. Using the College Belongingness Questionnaire and the Expectancy-Value-Cost Survey of Student Motivation, students were asked to reflect on their experiences during the period of remote learning (2020-2021 academic year) and the year during which all in-person classes resumed (2021-2022). Using paired sample t-tests, belongingness and motivation significantly increased in the 2021-2022 school year from the year prior; however, none of the captured demographic variables were able to explain this increase (e.g., age, gender, living situation, university size, etc.). These results suggest that in-person classes are beneficial to student success, but more work is needed to identify the factors that mediate this relationship. Keywords:belongingness, university, COVID-19, remote learning

Abstract Name: **Empathy Development: Is maternal mind-mindedness rooted in other maternal traits and does it contribute to infant empathy?**

The construct of maternal mind-mindedness is the capacity to accurately perceive and talk about a child's mind. It predicts multiple social-cognitive outcomes for the child, such as fostering a secure attachment relationship and the development of theory of mind. However, whether mind-mindedness supports the development of important processes, such as empathy, is yet to be understood. Empathy can be observed in children at 17 months, through concern for others and hypothesis testing. It's a valuable quality for children to develop due to its positive associations with prosocial behavior. Despite sharing underlying perspective taking characteristics, there is little research examining the influence of maternal mind-mindedness on the development of empathy. This study will examine the effects of maternal mind-mindedness on the development of toddler empathy. Mind-mindedness was measured in a task where 90 low-income and women at risk for parenting problems were asked to free play with their 5-month-old infants. Transcripts were coded for frequency of attuned mental comments directed at their infant. At 17 months postpartum infants and caregivers participated in a task designed to elicit infant empathy. Recordings were coded for infant empathic behaviors. Additionally, as further research needs to examine the maternal factors that contribute to interactional mind-mindedness, this study will also examine the prenatal factors of self-reported perspective seeking in the relationship, maternal Alexithymia, personality, and how these variables might contribute to maternal mind-mindedness and infant empathy. It is predicted that these prenatal traits will contribute to postnatal maternal mind-mindedness, which in turn, will partially mediate associations with infant empathy. This research will further our understanding of how individual differences in empathy arise in infants and how individual differences in maternal mind-mindedness are influenced by other maternal traits. Findings will carry implications for the timing and design of interventions.

Abstract Name: Modeling Tryptophan/Indoleamine 2,3 Dioxygenase Activity with Water-Soluble Heme Superoxide Mimics

Tryptophan 2,3-dioxygenase (TDO) and indoleamine 2,3-dioxygenase (IDO) are two unique heme-containing metalloenzymes that catalyze the oxidative cleavage of the indole ring in essential, and energetically expensive amino acid tryptophan during the first and rate-limiting event of the kynurenine pathway. Moreover, these enzymes have been the focal point of numerous recent studies owing to their implications in multiple pathogenic conditions with paramount significance in human health. Despite the intense research and substantial developments in the field, designing bio-inspired model systems of such enzymes has continued to be a challenging endeavor. Such models could serve as powerful tools in shedding light on some of the yet obscure critical mechanistic details pertaining to TDO and IDO. For designing such enzyme model, it is important to consider the functional and structural similarity between the model and the active site of enzyme. However, previously reported synthetic models lack the structural similarity between the active site (heme) and these models with respect to the central metal and/or the ligand. This work depicts a synthetic heme model system that closely mimic the TDO/IDO (bio)chemistry, where a water-soluble iron-porphyrin (meso-Tetraphenylporphine-4,4′,4″,4‴-tetracarboxylic acid, Fe-TCPP) is shown to dioxygenate N-acetyl-L-tryptophan methyl ester substrate that serve as tryptophan model. Fe-TCPP has been synthesized and characterized using various spectroscopic techniques (UV-vis, NMR, MALDI-MS), while the oxygenated tryptophan product has been characterized by LC-MS, NMR, and FT-IR methodologies. In-detail insights into the mechanistic events, and relevance and properties of key reaction intermediates involved during Fe-TCPP mediated tryptophan oxygenation will be discussed in detail. Comprehensive understanding of such reactivity will benefit future attempts in the rational design of salient therapeutic agents, including next generation anticancer drug targets with amplified effectivity.

Abstract Name: Water Chemistry of the St. Mary's River, Virginia: Liming to Mitigate Acid Rain

St. Mary's Wilderness is a federally designated portion of the George Washington National Forest in Augusta Co., Virginia. The 10,000-acre Wilderness is drained by the St. Mary's River with five major tributaries: Sugartree Branch, Mine Bank Creek, Bear Branch, Chimney Branch, Hogback Creek and a small tributary, Dawn's Branch that drains a wetland. The river and its tributaries experienced loss of aquatic life in the late 1990s due to acid rain. In 1999, 2005, 2013 and March 2022, limestone was introduced into all of the streams in the Wilderness to neutralize acidity. Dosage was ~200 tons evenly distributed to 7 in-stream sites. Water samples were collected at the Wilderness boundary and throughout the Wilderness upstream and downstream of the liming sites. The frequency of sample collection has varied throughout the period of the project. Analytical data for these samples have been used to judge the initial effectiveness of the limestone treatment and estimate longevity. Key water chemistry parameters for the weekly samples showed average increase in pH from pH 5.87 to pH 6.48, increase in ANC from 9.6 to 45.4 μeq/L, increase in Ca / H ratio from 25.7 to 184.7 and decrease in Al from 13 to 7 ppb. The upstream and downstream data pairs for each liming site also showed improvement in water quality. Longevity estimates indicate the Wilderness will not need another limestone treatment for at least 7 years. Due to the Clean Air Act and improved rainfall water quality, it is possible that no future treatment may be needed.

Abstract Name: **Explaining the Domestic Factors That Led to German Dependence on Russian Natural Gas**

With the 2022 Russian invasion of Ukraine and the ongoing energy crisis, security analysts have criticized Germany's energy policies for their long-standing dependence on Russian natural gas. The flaws in Germany's energy policy approach became painfully apparent, with the consequences ricocheting globally. But where did those flaws originate? What domestic factors led to Germany becoming dependent on Russian natural gas?Using historical analysis, process tracing, and policy analysis, this paper analyzes how the lessons drawn from German history, post-Cold War foreign policy, social movements, business considerations, and individual political actors have shaped German energy policy for the past decades. Contemporary German governments believed that trade with the Soviet Union led to the end of the Cold War, reinforcing the belief in change through trade. The peace and anti-nuclear movements pressured German governments towards cooperation with the Soviet Union and prevented nuclear energy from becoming widespread. German companies heavily benefited from cheap Russian natural gas. Pro-Russian political actors, such as previous chancellor Gerhard Schröder, advocated for Russia as a viable energy partner.This study is significant for at least three reasons. First, the relationship between Germany and Russia has become hostile due to the war in Ukraine. Learning how Germany reacted to the previous souring in their relationship, such as Russian military operations in Georgia and Ukraine during the the 2000s and early 2010s, can establish explanations of how strained relationships evolve. Second, an analysis of a liberal-importer and authoritarian-exporter relationship, such as between Germany and Russia, can offer lessons to similar cases such as the United States and Saudi Arabia. Finally, conceptualizing how Germany and Russia were able to cooperate for so long, despite the complex and oftentimes tense political relations they had, is a useful guide toward interpreting economic cooperation between countries with competing geopolitical objectives.

Abstract Name: **A Community Partnership to Upcycle Textiles into Reusable Bags to Deliver Meals Prepared from Recovered Foods**

Background: The increase in fast fashion has decreased the lifespan of textiles, resulting in an increased amount of textile waste. In the US alone, only 13.6% of clothing is recycled. Additionally, 1 in8 people in Kentucky struggles with food insecurity while 40% of food is wasted. Based on a previous collaboration to address food waste and food insecurity, upcycled grocery bags could be a novel approach to simultaneously address textile waste and food insecurity.Purpose: 1) Evaluate the process of working with volunteers to create reusable grocery bags from upcycled textiles. 2) Evaluate the durability of reusable grocery bags to package and transport foods. 3) Evaluate the environmental impact of creating and using reusable bags.Methods: Volunteers from UK Cooperative Extension master-sewing quilt guilds were invited to use scrap materials to create two patterns and complete a 28-item survey about their experience. Students from a student-led recovery and meal delivery operation will package and deliver prepared meals using reusable bags to low-income seniors and will complete a survey. The environmental impact will be measured through the amount of fabric diverted from the landfill.Results: To date, 45 volunteers have completed surveys. The survey response rate was 60%. Preliminary findings suggest that volunteers were eager to participate, implying the acceptability to continue or expand this project. Preliminary analysis shows 5,169.25 g of textile waste has been redirected from landfills to be made into these bags. Currently, 10 student volunteers are testing the durability and acceptability of the bags and will complete surveys about their experience.Conclusions Initial findings suggest that this pilot project is feasible and effective due to a decrease in textile waste, volunteers' desires to continue making similar bags, and student volunteers' optimistic opinions on reusable bags being easier and more convenient to pack than paper bags.

Abstract Name: **How do painted nest boxes affect Eastern Bluebird nest temperature?**

The rise of global temperatures as a result of climate change has created the need for new practices to ensure the survival of many species. For birds, temperature is a primary factor in nest site selection and a driver of success, so successful management will require temperature mitigation techniques. Cavity nesting birds such as the Eastern Bluebird are particularly vulnerable because natural cavities and nest boxes can experience temperatures higher than the outside ambient temperature. If the interior temperature reaches 41oC, this can be lethal to eggs and nestlings. Additionally, temperature can drastically affect nesting bird physiology and behavior, which can also negatively impact nest success. The goal of this study is to determine if painting nest boxes white can reduce the interior temperatures. We monitored 50 Eastern Bluebird nest boxes, 25 were painted white and 25 were left unpainted, at Panola Mountain State Park in central Georgia. Each nest box contained two temperature data loggers, one inside and one on the underside, and recorded temperatures every hour from June 4th to August 15th, 2022. Throughout the whole season, the daily high temperature in control boxes remained approximately 2oC warmer than outside while the daily high temperature in painted boxes remained approximately 2oC cooler than the outside. Painting the boxes not only provides better conditions for nesting bluebirds, but provides a cooler environment than ambient temperature. Especially in hot climates such as central Georgia, cooling nest boxes will become increasingly important as global temperatures rise. Painting nest boxes colors that reflect solar rays may inform habitat management for this and other cavity-nesting species.

Abstract Name: **Electrical ring resonator: Experiments and program development**

Since the large-scale commercialization of fiber optics in the 1970s, there has been an explosion in research to find ways to optimize and further its applicability. Primarily applied in the field of optics, ring resonators have been found to haveincreasing potential in such areas as photonic switching, signal filters, and optical sensing. Similar in its applicability, electrical ring resonator can be created to serve a variety of functions. In this research, electrical filters made from ring resonators were created both experimentally and computationally. The filter was built in a physics laboratory byusing co-axial cables connected in various configurations with different numbers of cable rings join to a straight signal cable path. The filter properties were measured by an impulse method using a frequency generator and an oscilloscope. The extracted data from the oscilloscope are analyzed computationally to determine the characteristics of frequency transmission for each configuration.Additionally, the computational model developed allows us totest various configurations of ring resonator structures by employing the transfer matrix method. This allows us to compare the experimental values with expected computational values and enable future researchers to test increasingly complex resonator structures that are too difficult to create in the lab.

Abstract Name: **An Intersectional Analysis on Water Quality and Socioeconomic Status in America: A Scoping Review**

In the 1930's the federal government began redlining real estate, marking "risky" neighborhoods for federal mortgage loans on the basis of race and environmental factors. Many historically redlined communities and low socioeconomic status households currently experience significant disparities as a result of America's biased and racially motivated capitalistic system. Disparities such as water quality below that of the general population is a scope of investigation that is often neglected. Additionally, there is a lack of resources, studies, and data available that describes the connection between socioeconomic factors and water quality. A scoping review was designed to identify peer-reviewed literature that examined challenges related to water quality in the context of socioeconomic factors. The study was undertaken to identify the extent of the literature, summarize current reports, and identify research gaps and needs. Since scoping reviews are hypothesis-generating rather than hypothesis-testing, this review serves as a critical stepping stone for further research. Key search terms were developed and mapped on three bibliographic databases, Science Direct, National Center for Biotechnology Information (NCBI), and ProQuest. Review selection and characterization were performed by two independent reviewers and a senior reviewer. A total of 1,848 references were imported into CovidenceTM for screening published from 2012 to 2022. Of these, 26 studies were included in the final analysis. Preliminary results of this investigation show that research investigating the effect of socioeconomic factors on water quality is limited. There is an immediate need for more research funding, research initiative, and inquiry to inform policy decisions for improvements of water quality and health-related outcomes in low socioeconomic communities.

Abstract Name: **Considerations for Implementing Equity, Diversity, and Inclusivity Practices into an Elementary Classroom**

Recently there has been more literature regarding introducing equity, diversity, and inclusivity into elementary schools. In my project, I examine possible ways to implement these equitable practices as an aspiring elementary and special education teacher. I draw on my experiences and research to provide plenty of examples such as lesson plans and prompting questions. My project consists of three categories; Identities, Environment, and Content. In the first category, I ask guiding questions on how to support students in many different demographics including race, gender, socio-economic status, and more. For the environment, I question the inclusivity of culture in classroom decorations and the usability of the furniture layout. Lastly for content I inquire on topic delivery for students with disabilities and assignments for students who may not have a home life that allows for homework completion. Additionally, I created a discussion framework to assist with having difficult conversations. It follows a mnemonic that encourages critical thinking and taking action.The goal of this project is for this informationto be used by teachers as a short and simple document that can guide their addition of more equitable practices in the classroom.

Abstract Name: Religious Counselors and Cultural Competence: When Beliefs Collide

Individuals with a fundamentalist religious orientation respond defensively to challenges against their religious beliefs(Abeyta; Blake, 2020). Individuals who are intrinsically religiously oriented are internally focused and help others based on their own values, whereas quest-oriented religious individuals are altruistic and act based on the values of those they help, (Batson 1976, Batson et al., 1989). Researchers aim to understand the relationship between orientations of religiosity and counselors' perceived multicultural competence with clients. In this exploratory mixed-methods study, 35 counseling students and alumni from a small midwestern religiously affiliated college completed a survey with open-ended questions and scales. The short answer questions ask about faith, experiences in clinical training, and counseling practice. Participants completed the 12 Item Quest Scale (Batson; Schoenrade, 1991), Revised Religious Orientation Scale (Gorsuch; McPherson, 1989), Multidimensional Cultural Humility Scale (Gonzalez et al., 2021), Lesbian, Gay, Bisexual, and Transgender Development of Clinical Skills Scale (Bidell, 2017), and Fundamentalism Scale (McFarland, 1989). Researchers discovered participants who score themselves as fundamentally oriented and see religion intrinsically, score highly in self-awareness. Participants who score highly in quest orientation score highly in competence to work with LGBTQ+ clients. The results were: significant positive correlations between intrinsic and fundamentalist (N=29, r= 0.646, 0.000), fundamentalist and self-awareness (N=29, r= 0.416, 0.25), quest and LGBT DOCSL (N=35, r= 0.384, 0.04), as well as significant negative correlations between fundamentalist and quest orientations (N=29, r= -0.595, 0.001). Qualitative responses indicated that counselors who wrestle with their religious beliefs are more willing to engage clients' values. Conversely, religiously certain counselors displayed more internal conflict and less confidence when helping clients with differing beliefs. These initial results support Abeyta and Blake's (2020) findings that those who are more fundamentalist and intrinsically oriented help others according to personal values.

Abstract Name: Social Media and Self-esteem

Social media, what did we do before it existed? Were we better off before or are we now? The debates around social media use are endless. There are strong viewpoints on both sides. Some believe it is literally the demise of human society, contributing to the delinquency of minors and providing negative information that molds the minds of the young. Others believe it is entertainment and provides no harm to society and has no impact to the changing world we live in. Still others are cautiously in the middle. While social media has been around for some time now, we still know very little about the potential long-term impact. The population most influenced is the young. This research study explores the association between age of beginning use of soical media and the impact on various aspects of development.The key areas of interest are mental health, self-esteem, sexualization, achievement and addiction. Correlational analysis will be completed in the spring semester of 2023.

Abstract Name: **Building a Better Nanofiber Electrospinning Apparatus**

Electrospinning is a method used to create nanofibers, in which a voltage difference draws a solution or melt of a polymer into long, thin strands. With an appropriate apparatus, electrospinning could be used in rural areas without safe drinking water, to fabricate filters. I am developing that appropriate apparatus. The current basic setup involves a set of metal plates, with a voltage difference across them. The polymer fluid is drawn into “fingers”, or deformations of the surface, and then into cone-jets through which the polymer fluid exits at small diameters. Electrospinning is usually done with solutions rather than melts, but that is a slower process, with less potential for scaling up for industrial viability, and less adaptable for rural areas. Melt electrospinning is a promising alternative, but current attempts have involved blow-back issues, in which the nanofibers form a clump between the metal plates. In order to solve this blow-back issue, I have built a new prototype for the collector plate. By introducing a spinning collection device, the nanofibers adhere to the surface, and are pulled away from the area in which they could form a blow-back clump. That alone is sufficient for spinning solutions, but voltage must be applied to the collection device in order for it to be used with melts. There has been some success in testing this prototype, both with solution and melt electrospinning. The future development of this prototype could lead to a portable melt electrospinning device to be used in large- and small-scale operations.

Abstract Name: **How Do Animals Affect the Mental Health of College Students?**

Humans and animals often have a unique bond - animals can be a source of comfort and companionship, help us to perform the tasks we need to, and help us heal from difficult times in our lives. There has been research conducted about how the human-animal bond can influence both physical and mental health, but not many decisive conclusions have been drawn as to whether animals can directly influence our mental health for the better. This paper discusses findings of a study conducted at the University of Wisconsin-Stout investigating the influence of animals on mental health through a survey and follow-up interviews. A survey was sent to a random sample of 1,000 students who were asked questions about their previous experiences with animals, how those experiences influenced their mental health, and about their current mental health. At the end of the survey the students were given the opportunity to opt into an interview to discuss the topic of animals and mental health in further detail. Eight interviews were conducted wherein the researcher found overall positive experiences with animals, especially with pets. Although I did not find a significant impact on mental health, I did find that animal relationships play an important positive part in the lives of many college students. Given these findings, I recommend that college campuses consider hosting events featuring animals (such as de-stress puppy meet-ups) in order to help students deal with negative emotions and with the loneliness that college can cause. Providing animal-assisted therapy could also play a role in helping students and could be considered.

Abstract Name: **Screening Type III CRISPR Complexes for Enhanced Signal Amplification**

Type-III CRISPR-Cas systems are programable RNA-guided detection systems that recognize RNA targets by complementary base pairing. Target RNA recognition activates a polymerase domain that selectively polymerizes adenosine triphosphate (ATP) into cyclic oligomers of adenosine (cOA). In bacteria, target detection-dependent polymerization of ATP amplifies the cOA alarm signal during an infection, and we recently repurposed these systems for sequence-specific detection of SARS-CoV-2. However, the sensitivity of these new CRISPR-based diagnostics is still insufficient for clinical applications. To improve sensitivity, we are screening type III complexes from Thermus thermophilus, Streptococcus thermophilus, and Enterococcus italicus to determine the rate of cOA synthesis (kcat). Complexes that synthesize cOAs more rapidly will be incorporated into the diagnostic to increase overall sensitivity.

Abstract Name: **Animals and Autism in Middle-Grade Literature**

Middle-grade literature about nonhuman animals, children, and autists reveals how those three categories—which are associated with “inferior” mental and linguistic capacities—blend together in the cultural imagination. These stories form such a large and relatively monolithic body of work that they constitute their own “autism/animal” subgenre, which has yet to be examined by humanities scholars. The genre’s patterns of representation reflect how and why people envision autists as mentally and spiritually closer to nonhuman animals, a conception that has popularized animal therapy programs for autists and has justified the maltreatment of those on the spectrum. Stories in the autism/animal genre often act out translation fantasies that allow characters to overcome the frustrating communication barriers between autists and neurotypicals as well as between humans and animals. These translation fantasies, although responding to a natural desire to connect with others, can place unfair burdens on autists and animals and can engender unrealistic expectations about communicating with those of a different neurotype or species other than one’s own.

Abstract Name: **Gender Diverse Identity in Brazil: Resilience in an Epidemic of Violence**

Although the Brazilian LGBTQ+ community commands great influence in the nation's art and entertainment industry, more trans people are murdered each year in Brazil than in any other country in the world. While this is certainly an alarming statistic and an issue that deserves more attention than it currently receives, there is so much more to trans and travesti life in Brazil than death and violence. Therefore, it is the aim of this paper to reframe the idea that being trans equates death and emphasize the resilience, solidarity, and success of the Brazilian trans and travesti communities. However, it must first be acknowledged that anti-queer violence occurs at alarming rates in Brazil, and Black transfeminine people are especially targeted due to the confluence of racism and transphobia. Additionally, the recent anti-queer rhetoric and policy from the federal government has only perpetuated this violence. Despite these seemingly insurmountable barriers, though, thetravesti community, many of whom are sex workers, has managed to build networks of solidarity to promote mutual support, access to healthcare, and respectful recognition. Furthermore, many trans and travesti Brazilians have achieved national and international fame and have used their platforms to bring awareness to issues affecting their communities. Trans people have broken barriers in telenovelas watched by millions of people, graced magazine covers, and ruptured (trans)gender norms. Even though it is incredibly important to fight for an end to the violence against the queer community, it is imperative to highlight the incredible achievements of the Brazilian trans and travesti community to promote resilience and inspire hope in future generations of queer people.

Abstract Name: **Assessing Lupine as an Environmental Conservation Tool in Iceland**

Iceland's environment is highly prone to erosion and has conditions that make plant growth challenging. The plant lupine is a divisive solution to soil erosion and reforestation that has been found successful in some regions of Iceland but not all. We researched the issue through extensive document research, expert interviews from different perspectives, and surveys of native Icelanders, to get as complete and unbiased a picture of the issue as possible. We used this to create a decision guide that gives a comprehensive account any person in Iceland can use in order to choose what they would like to do to address soil conservation and reforestation issues on their land. Key issues the decision guide covers are soil conservation, reforestation, and removal of lupine. Along with the decision guide, we include a decisional balance sheet to show the pros and cons of lupine usage in Iceland and a plant infographic to teach about the plants in the decision guide. These tools can be used by land owners in Iceland to make decisions about restoration and reforestation on their land.

Abstract Name: Interstellar Travel: Reaching Alpha Centauri

Will mankind ever venture to the stars and become an interstellar space-faring civilization, like is often imagined in popular science fiction? With the recent deployment of the James Webb Space Telescope astronomers can now see farther and deeper into space than ever before. There can be seen vast countless galaxies, each containing millions of stars, and each star likely containing many of its own planets. The number of exoplanets in the universe must be beyond what can be fathomed in the human mind; it may even be infinite. Can we reach out to explore this endless universe or can we only gaze in wonder? The purpose of this project is to research both theoretical and cutting-edge space exploration technologies that may bridge the gap between the earth and interstellar space and to provide a brief compendium to compare these concepts side by side. To understand both the limits and potential of interstellar travel this study will reference theories, research, and development from organizations such as NASA and SpaceX, as well as the writings and research of prominent physicists, astronauts and aerospace engineers.

Abstract Name: From the New Mother to the Other Mother: An Intersectional Look at Age and Class in Neil Gaimanðs Coraline and Lucy Cliffordðs ðThe New Motherð

Discussion surrounding Neil Gaiman's novella, Coraline (2002), has foregrounded psychoanalytic and feminist theories, centering on the gendered antagonism presented as the titular character fights and defeats her supernatural "other mother." Scholars have often overlooked an underlying issue that Coraline faces: her family's lower-class status. My argument illuminates the heavy impact that classism has on the family dynamic within the novella, specifically the significance of working from home, which both of her parents do. Drawing upon social science research preceding and contemporary to Coraline's publication, I demonstrate how the text fits into the cultural zeitgeist around the "work from home" dynamic as it developed at the turn of the twenty-first century, especially the challenge it presents to the historical separation of "work" and "home." In doing so, I posit the acceptance of class hierarchy as the border that the story places between childish immaturity and readiness for adulthood. In addition to the novella, I examine one of its source texts, Lucy Clifford's "The New Mother" (1882), to facilitate historical comparisons of parent-child relationship dynamics as well as the relationship between "work" and "home" in the Victorian period, when the two were first teased apart, and the contemporary moment, when the two are once again blurring. As many Americans have found themselves having to work from home during the pandemic, discussion surrounding the experience of work and home in Coraline and "The New Mother" are more relevant than ever.

Abstract Name: First complete mitochondrial genome of the Saharan striped polecat (Ictonyx libycus)

The Saharan striped polecat (Ictonyx libycus) is endemic to Africa, inhabiting the edges of the Saharan Desert. Little is known about the biology or genetic status of this member of the weasel family (Mustelidae). We present the first complete mitochondrial genome of the Saharan striped polecat, assembled from data generated using a genome skimming approach. The assembled mitogenome is 16,549 bps in length and consists of 37 genes including 13 protein-coding genes, 2 rRNAs, 22 tRNAs, an origin of replication, and a control region. Phylogenetic analysis confirmed the placement of the Saharan striped polecat within the subfamily Ictonychinae.

Abstract Name: Student Perspectives on Sustainability at Iowa State University

Today's university students will face unprecedented environmental, economic, and societal sustainability challenges upon graduation. The Sustainability in Curriculum Change Project (SiC-CHANGE) employed focus groups and a student body survey to understand Iowa State University (ISU) students' perspectives on how well the curriculum and extracurricular activities are preparing them to address the various sustainability challenges that society faces. Although ISU has incorporated sustainability language into its strategic plans and actions over the years, we are not aware of any systematic efforts to assess the adequacy of the university's efforts to increase student knowledge and skills related to sustainability. This research project is a rigorous effort to learn from students about their interest in and their experiences with sustainability at ISU. Twenty-one students from select colleges participated in focus group discussions between October 2021 and December 2021, and 1,206 students responded to a web-based survey of juniors and seniors conducted between April 18 and May 16, 2022. Our sample represents all colleges offering undergraduate degree programs at Iowa State University. Most respondents placed high importance on addressing environmental, economic, and social sustainability outcomes articulated in the UN sustainable development goals. Students at Iowa State feel empowered to solve climate change issues in the future, but they want more courses that integrate sustainability into their curriculum. Additionally, students believe that public universities should be leaders in sustainability. Our results show that most students don't think Iowa State prioritizes sustainability in education or that they are leaders in sustainability. Survey and focus group participants suggested many ways that ISU could incorporate this topic into the ISU experience to better prepare students with the knowledge and skills needed to face present and future sustainability challenges.

Abstract Name: **Sex and Cuff Pressure Specific Hemodynamic Responses to Blood Flow Restriction Leg Extensions**

Background. Resistance training with blood flow restriction (RT+BFR) is a popular exercise prescription in populations including athletic and older individuals. However, there is limited data on the influence of cuff pressure on the exercise pressor reflex (EPR) and resulting blood pressure (BP) increase, especially in women. Therefore, our purpose was to investigate the cuff pressure- and sex-specific hemodynamic responses to RT+BFR.Methods. 33 young (24 ± 6 yrs) adults (16 male, 17 female) completed 2 randomized visits. The participants completed the exercise with 40% of the minimum pressure to occlude each femoral artery (AOP), whereas the other day participants exercised with 60% AOP. The exercise consisted of 4 sets (1x30, 3x15) of bilateral leg extension with 30% of their one-repetition maximum (1RM). Following each set, heart rate (HR) was recorded, whereas BP was recorded after the last set. Two, mixed-factorial ANOVAs (Sex×Cuff Pressure) were performed to examine mean differences in percent change of mean arterial pressure (MAP) and HR.Results. The ANOVA for MAP indicated that there was no Sex × Cuff Pressure interaction (p=0.480) or main effect for Sex (p=0.481).There was a main effect for Cuff Pressure (p=0.028). The 60% AOP provoked a greater increase than 40% AOP (23.2 ± 11.5% vs. 17.4 ± 10.9; Δ=5.8%, CI95%= 6.5 – 11.0). For HR, there was no significant (p>0.05) interaction or main effects, but every value was positive suggesting (as expected) HR increased indiscriminately during exercise.Conclusions. Our results indicated that a bout of RT+BFR likely elicited an augmented EPR such that the typically observed sex difference in increase of MAP was eliminated. Thus, prescribing BFR based ons ex is likely not needed. For special clinical populations, our results suggest using 40% AOP to mitigate changes in MAP

Abstract Name: **Mapping the Presence of Invasive Plants in a Temperate Forest Fragment.**

Biological invasions are a prominent contributor to the loss of biodiversity around the world. Introduced plants are common in fragmented forests, especially those used for recreation. My research sought to map the presence of invasive plants in the SUNY Brockport campus woodlot and relate the abundance to areas disturbed by the emerald ash borer (Agrilus planipennis). I hypothesized that there would be more invasive species along the forest's edge and in the areas disturbed by the emerald ash borer, where there is less canopy. I walked twenty transects through the entire site and established 318 15x15m plots along the forest's edge and within its interior. In each plot, I measured invasive species abundance using an ordinal scale, canopy cover using hemispherical photography, the total number and identity of all living and dead trees and recorded the GPS location. I used ArcGIS to create maps of the data to visualize trends between edge and interior and to identify high priority species. I performed t-tests to compare my results between the edge and interior and Spearman's rank to find associations between variables. My results did support my hypothesis, as invasive plants are most abundant on the edge and in the areas where ash was recently lost. I also found that one species in particular, Rosa multiflora, was indicative of higher invasive species richness. The emerald ash borer is widespread across the nation, so it is imperative that we understand its consequences and inform land managers of areas that are susceptible to plant invasion.

Abstract Name: **Simulations in Non - Linear Optics for Quantum Applications**

Light and light-enabled technologies have been revolutionizing our world for the previous decades. A very particular type of light source is a laser, which excites atoms in a controlled manner emitting and amplifying lightin structures that confine light and enhance the light-matter interaction, called cavities. Lasers and photonicsare ubiquitous in telecommunications, cryptography, and sensing. Forty years ago, several groups around the world demonstrated experimentally a novel property in lightcalled: quantum entanglement. These experiments were awarded the 2022 Nobel Prize in Physics. The experimental generation, manipulation and detection of entangled light particles (photons)started a new wave of devices called the second quantum revolution. Quantum engineering companies already represent millions of dollars in many countries' economies such as the USA, France, UK, Japan, China and Germany, just to mention a few. In particular, the promises of secure communications and computing given by quantum entanglement are unparalleled. Most of those products are in free space or fibers and some explorations have been done on-chip. The ability to reliably fabricate and control on-chip entangled photon sources with desired characteristics are a key missing element to fully take advantage of quantum engineered technologies, as it will open the possibility of adding these quantum sources and detectors to technologies across the spectrum, even to cellphones. At present it is uncommon to use simulations to predict all characteristics of entangled photon sources. Conventionally, only dispersion engineering is done when designing photonic devices for this purpose and non-linear propagation is ignored. In this work, we present a full set of simulations using Frequency Domain Time Difference (FDTD) and Fourier Split-Step (FSS) methods to perform dispersion engineering and simulate the non-linear propagation of the optical field in a Photonic Integrated Circuit (PIC) in order to predict all the characteristics of an entangled photon source.

Abstract Name: **West Nile Virus Surveillance and Forecast in Oklahoma**

West Nile Virus (WNV) is a seasonal mosquito-borne disease characterized by a febrile illness and has the potential to result in a rare neuroinvasive disease. This disease propagates in an enzootic cycle between mosquitoes and birds. WNV is then transmitted to humans by an infected Culex mosquito. In Oklahoma, WNV is an epidemic disease characterized by three major outbreaks: 2003, 2007, and 2012. Environmental factors, such as bird migration,influence WNV, which can result in unpredictable aspects of the disease's transmission. Additionally, limited surveillance creates a need for an accurate, early-warning system that can inform public health practices and prevent disease outbreaks. In this study, we focused on validating the Arbovirus Monitoring and Prediction (ArboMAP). ArboMAP uses a generalized additive model that combines environmental data with mosquito WNV surveillance data to produce weekly, county-level forecasts of human WNV cases. ArboMAP uses a generalized additive model that combines environmental data with mosquito WNV surveillance data to produce weekly, county-level forecasts of human WNV cases. The outputs are relative and absolute risk maps, a yearly forecast, a case estimation of positive county weeks, and a multi-year forecast of 2002-2022. ArboMAP has a 91 percent forecast accuracy calculated using Area Under the Curve (AUC) calculations. Due to its accuracy, ArboMap has the potential to benefit local public health applications by providing information on when and where WNV outbreaks may occur.

Abstract Name: **Developing a streamlined bioassay to verify polyethylene breakdown to ethylene glycol by Galleria mellonella larvae**

As plastic use increases on Earth, disposal of plastic waste is an immediate and growing environmental challenge. Likewise, this challenge extends to long-term space travel and remains a concern with our expanding presence in space. A potential plastic waste management solution is the larvae of Galleria mellonella (waxworms), a common beehive pest. These organisms have a unique intestinal microbiome capable of biodegrading low-density polyethylene (LDPE) film (e.g. sandwich or grocery store bags) into a reusable product, ethylene glycol (EG). The natural food source of the waxworm, the waxcomb of beehives, is hypothesized to facilitate the breakdown of long hydrocarbon chains found in polyethylene plastics. In this project, 32 waxworm larvae were sent to the International Space Station (ISS) for 33 days in July of 2022 with support from the NASA SPOCS (Student Payload Opportunity with Citizen Science) Program. To verify these waxworm larvae biodegraded plastic in microgravity, a robust assay is needed to detect the presence of the endpoint LDPE breakdown product, ethylene glycol, contained within their excreta (frass). To confirm the chemical breakdown of LDPE in earth control and ISS-treated larvae, a previously developed enzymatic bioassay for detecting EG in animal serum was modified to detect the compound in frass. To validate the accuracy of this modified enzyme-based assay, collaborators at Virginia Tech University (VT) have developed a GC-MS detection method, a technique frequently used in the literature to identify chemical intermediates and breakdown products from LDPE biodegradation. Results across the two methods will reveal how the microgravity environment impacts the G. mellonella larval ability to biodegrade LDPE. Development and validation of this enzyme-based EG assay will provide a new high throughput (HTP), more facile method for detecting EG in more complex, non-serum samples.

Abstract Name: **Peptone Variation in Plant-Based Media Formulations for Increased Protein Production in Escherichia coli**

The basis of this project focuses on ideology of producing a sustainable “food source” to supply the cells that make the medicine. Microorganisms, such asEscherichia coli, often have a negative connotation for causing disease, yet the majority of microorganisms are the main producers of pharmaceuticals. Understanding the metabolism and energetic use of microorganisms can guide the supply of nutrients in the culture media that are essential to a cell. Traditionally, cell culture media is made with animal-based products producing a large carbon emission. A more sustainable option to decrease the carbon footprint is plant-based media formulations, specifically pea and soy peptones.To evaluate the plant-based peptones success on bacteria growth and production of a protein, this study will measure the production of Green Fluorescent Proteins (GFP) expressed in the bacterial strainE. coli. Variations of pea and soy peptones will be used in the culture media to test the cell growth and protein production. The specific media contents will be analyzed before and after each trial for comparison. This will show which nutrients were unused and which were under supplied. If the cells are provided with an ample amount of its necessary nutrients, this should produce a higher yield of protein. Optimizing the sustainable media options to compete with the animal-based media would help reduce the environmental impact of research and pharmaceutical industries using animal-based medias, while still generating the desired product. This is important as E. coli is used to produce a variety of medicines. Insulin is an example of important product ofE. colias it supplies millions of people a year who suffer from diabetes.Providing a media that has specific nutrients for E. coli will be useful for producing these medicines.

Abstract Name: **An EEG Investigation of the Discrepancy Between Auditory and Visual Memory**

Previous research has indicated that visual recognition memory has a much larger capacity than auditory recognition memory. The purpose of this study was to investigate the disparity between the two memory systems by examining the neural circuitry involved in accurate recognition of visual and auditory stimuli, to examine the size of the discrepancy between auditory and visual memory across the lifespan, and to measure the relationship between working memory ability and recognition memory. In Experiment 1, participants completed a recognition memory task while neural responses were recorded with a 32-channel Brain Vision EEG system. Participants received a study phase with pictures/sounds, followed by an immediate recognition memory test. During the memory test, participants were presented with pictures/sounds that were old (presented during study), new (not presented during study), or exemplars that were variants of objects presented during the study phase. Participants were instructed to classify each picture/sound as “old” or “new” by pressing a corresponding key. In Experiment 2, participants ranging from 18 to 65 years of age completed a working memory assessment, followed by the recognition memory task from Experiment 1. The data analyses have the potential to indicate whether the discrepancy between visual and auditory memory is related to changes in gray matter density of the prefrontal cortex as we age. The results of this study will also improve our understanding of the connections between auditory memory, visual memory, and general cognitive ability and will allow a better understanding of the relationship between memory and general cognitive decline.

Abstract Name: **The Use of Essential Oils in Increasing Potency of Insecticides on Mosquitoes**

Mosquito-borne illness is a worldwide problem, with over one million people dying from them every year. The current tools for controlling mosquito-borne diseases are insecticides. Unfortunately, the overuse of insecticides has caused increased insecticide resistance. Our research focuses on finding a chemical tool for better penetration of the insecticides into the mosquitoes and therefore allowing a decrease in insecticide use. The tool being used is essential oils, research in the literature shows that there is a correlation between essential oils being added to insecticide mixtures and their increased potency in mosquitoes. One potential mechanism for this improvement is that the essential oils assist the insecticide in diffusing through the exoskeleton of the mosquito. We have chosen to explore this mechanism by studying the changes in insecticide transport into a simulated mosquito exoskeleton (wax) as a function of various solvents using an infrared spectroscopic imaging system. Using this instrument, we measured infrared spectra as a function of the time of the wax before, during, and after adding a component from the essential oil with or without an insecticide (solution) to the edge of the wax. IR spectra of the solutions and their diffusion curves were collected to show the correlation between insecticides and essential oils. While new, this research has the potential to make current insecticides more potent and protect the ecosystem from over usage of insecticides.

Abstract Name: **End-of-Life Patient Communication: Exploring Comfort, Communication and Education of Healthcare Professionals for End-of-Life Care**

Historically, the medical field has viewed death and dying as incurable 'medical failures,' and as a result, many healthcare professionals have difficulties when facing a patient who is dying or at the end of their life (DeSpelder, 1983). These individuals will use avoidant behavior to avoid end-of-life (EOL) patients or can have difficulty providing essential aspects of care including communication, which contribute to building a strong relationship between the healthcare provider and patient. For the healthcare professional (HCP), this can stem from anxiety related to thoughts of death and a lack of educational support or experience. The researcher in the current study interviewed healthcare professionals within EOL care specialties such as hospice and palliative care as well as other specialties focusing on questions related to experiences, education, and comfort around EOL interactions. Participants include professionals in grief counseling, oncology, and palliative care. Phenomenological qualitative thematic analysis has been used to derive common themes from the interviews, integrated with available published research to identify why HCPs in general healthcare settings may feel under-prepared to have EOL discussions with dying patients compared to those in EOL care specialties. These themes include what experiences or educational supplementation has aided in the comfort and success in EOL communication and how US cultural perceptions of death affect healthcare perceptions of death. This research will provide a foundation of data for future research paths regarding the development of education and support for HCPs interacting with EOL patients.

Abstract Name: **The effects of Time Poverty on Stress and Life Satisfaction in university students and workforce participants**

In an increasingly connected world, where work and school are just a click away, work-life has integrated more and more into personal-life taking more of one's personal time. Advancements in telecommunication, telecommuting to work, has contributed to an 'always on' culture that values productivity and always being available. In light of this, there is limited research on perceived time poverty. This study examines perceived time poverty in conjunction with environmental demands and their effects on stress and life satisfaction in the context of university students and workforce participants. A survey using scales on time poverty, irritation, and environmental demands were used in a quantitative analysis to measure their effects on stress and life satisfaction.

Abstract Name: **Rolling a Nat 20 in Identity: How Dungeons and Dragons is Used for Exploration and Representation by Queer Individuals**

Imagine you are a queer person in a society where you are told you are wrong, disgusting, and monstrous. You don't get to see people like you up on the big screens or in mainstream media. This can have disastrous consequences.Now imagine that as a queer person you find a community where you can be yourself without fear of the repercussions. For many people, that safe and welcoming environment has been found through Dungeons and Dragons (D&D).Since its debut in 1974, Dungeons and Dragons has quickly become the most popular role-playing game in the world. In total, a reported 50 million individuals played Dungeons and Dragons regularly.Dungeons and Dragons also is no longer a game meant for cishet men; with around 49% of players self-identified as queer. Creating characters and extensions of the individuals themselves outside of the societal norms of sex and gender, Dungeons and Dragons have opened itself up to those who's lives already fall outside of those boundaries in a day to day setting.Exploring one's identity is a vital part of growing up queer. With such nuances between gender roles, gender identities and sexualities, there's a lot to consider and account for when trying to find who you are. Having a place where the individual can freely and safely explore those complex thoughts and emotions can lead to that individual being more confident in their identity.Through IRB certified surveys and analysis of Dungeon and Dragon live plays, I have explored just how vital something such as a game is when it comes to the queer experience. When proper exploration and representation is given, queer people excel in their identities. It is often said that fantasy effects reality in profound ways and I believe that is true especially within the queer community.

Abstract Name: **Photorealistic Environment Generation**

There have been recent efforts to advance the overall understanding of Mars. Information remains as important as it was when the rover named Pathfinder left the Earth. As it is difficult to achieve efficient human travel to Mars, the National Aeronautics and Space Administration (NASA) has continued to send these rovers to collect information about the red planet. Bringing data and results allows NASA to test hypotheses and develop scientific theories about Mars. Our goal is to generate a reliable synthetic environment similar to the Martian surface, using the Unity engine. Robots can be simulated in this environment with the Robot Operating System (ROS) and Unity bridge to resemble the process of recording and relaying information. Simulation in robotics is an integral part of the design process, most notably in space robotics where you often only get one chance for everything to work properly. Synthesizing the environment can help provide the quantitative data used to train machine learning models. This gives artificial intelligence the ability to complete tasks like object detection and vision-based navigation. The Unity engine allows for the seamless usage of realistic 3D objects from a wide variety of libraries and resources. This simulation will be able to generate geographic features like those found on Mars; the environment includes sand-like meshes, photorealistic rock walls, and rock patches. The collaboration between our team and other teams within the research program is feeding into a larger project. We're working forward to establishing a business that finds and authenticates data using trained AI robotics.

Abstract Name: **The Elephants of Guinea-Conakry: Nuclear and Mitochondrial Genetic Patterns**

Elephant populations in Africa are threatened by poaching and habitat destruction. The disappearing elephant range has caused small elephant populations to be isolated from others which may lead to a loss in genetic diversity due to inbreeding. Non-invasively collected fecal samples were obtained from elephants in Guinea-Conakry. DNA was isolated from these samples, and a portion of the mitochondrial DNA control region and three nuclear genes (PLP1, PHKA2, and BGN) were amplified by PCR and sequenced. Sequences were analyzed to determine mitochondrial haplotype diversity and species-diagnostic single nucleotide polymorphisms (SNPs). Data from this work will aid in conservation and anti-poaching efforts by contributing to a growing genetic database of African elephants.

Abstract Name: **Designing a Space to Support Sensory Regulation Within the Eau Claire Children's Museum**

With the recent rebuild and renovation of the Eau Claire Children's Museum, the museum's executive team elicited the support of students and faculty within the Special Education and Inclusive Practices Department at the University of Wisconsin – Eau Claire to create a sensory room within the museum. The research team was comprised of student volunteers who previously took a class with Dr. Kirstin Rossi about play and sensory pedagogy, as part of the Unified Special Education program. The team began the development process by meeting with executives from the museum and touring the designated space. During the initial visit, the executive team discussed the goals of the museum. The main goal was to create a designated space for children to regulate themselves and re-enter the museum when ready. Previously, children who were dysregulated usually left the museum and ended their visit early. With these objectives in mind, student researchers used their learning from the aforementioned class and gathered further information on sensory integration to develop and design specific spaces in the sensory room. Within the design,all eight senses were supported through equipment, spacing, and materials. Additionally, a space was created toprovide a specific area for children to calm their bodies. The last project component was to identify materials and tools that would help children successfully reengage into the larger museumonce re-regulated. The sensory room was designed to be open to a variety of children while also providing tools and information for families to better understand their child's sensory needs, regardless of age or ability. Beyond the sensory room itself, informational materials were also created to share that increase community understanding of sensory needs and integration. This poster presentation will outline the research process and project development, including the final design and use of the space.

Abstract Name: **Variations in Anticipated Stigma Reported by Men and Women Participating in a Mixed-Sex Threesome**

Sexual script theorists posit that people are socialized to believe that mixed-sex sexual behavior occurring between two (and only two) adults is the norm. In addition, women are expected to follow passive norms regarding their sexuality, particularly submitting to the more culturally accepted male sexual behaviors. Violation of these sexual norms often results in social sanction, or stigma. Thus, this study explored men's and women's anticipated stigma from friends, acquaintances, and society for their engagement in mixed-sex threesomes (MSTs; sexual activity involving three people at the same time in which persons of more than one sex are present). The results obtained from 364 adults who were asked to reflect on their most recent MST revealed that 50.0% of men and 36.9% of women engaged in a MST-O, whereas 50.0% of men and 63.1% of women engaged in a MST-S. Women and those engaging in an MST-S expected to be judged more harshly from all sources than did men and that those engaging in a MST-O. However, the effect of gender was not consistent across MST type, such that women only expected to be judged more harshly than men when engaging in a MST-O. Our results support research documenting the continued presence of a sexual double standard in western society, such that women anticipate being stigmatized to a greater extent than men. However, the gender discrepancy in anticipated stigma was only true for MST-Os, whereby participation in same-sex sexual behavior was believed to produce the most stigma regardless of one's gender.

Abstract Name: **Passive Acoustic Monitoring of Cao-Vit Gibbons (Nomascus nasutus) Utilizing Multilaterations of Vocalizations**

Since their rediscovery in 2002, the cao-vit gibbon population has remained critically endangered and thus, a limited amount of information regarding their vocalization and general behaviors has been discovered. The use of Passive Acoustic Monitoring has been utilized as a non-invasive method to monitor individuals and wildlife populations alike. In this study, twenty GPS-synced audio recording units were deployed in a limestone karst rainforest in Northern Vietnam. The goal of the deployment was to determine the feasibility of finding precise locations of these individuals. Approximately 3,000 hours of audio data was collected and manually marked to locate times in which male or female calls were received at the units. The results of the multilateration analysis successfully generated a map showing the locations that different groups of cao-vit gibbons were calling. Future goals that have arisen from this research include gathering data for long-term research on gibbon communication, intraspecific behavioral interactions, as well as the potential development of technologically based solutions for applied conservation.

Abstract Name: **When Stigma is Worse than Hunger: How Social Stigma Influences BHSU-RC Students - Use of the BHSU-RC Food Pantry**

Not only is food insecurity rampant among college students,but it contributes to an increased risk of suffering from adverse health impacts and barriers to accessing food and services even when food pantries exist on campuses. We are interested not only in checking out the demographics of who uses the food pantry but also reasons why they do/do not, especially when it comes to social stigma and the actual, physical, or emotional experience of the pantry. We apply a combination of sociological, statistical analysis, and social-psychological exploration of pantry users. Collectively utilize surveys to determine demographics, how many respondents do/do not use the pantry, and why, including how many college students experience social stigma or perceived stigma. Student researchers conduct interviews to flesh out these experiences of using the pantry, including why they choose to use it or not use it, how they experience actual or perceived stigma, and how we could arrange the physical situation of the pantry to minimize negative experiences. Influenced by Goffman's concepts of stigma and spatial sociology. Limited financial resources, the reduced purchasing power of federal aid, rising costs of tuition, food, and housing, and diminished social support resulting from prolonged emotional and physical separation from family and friends are some of the significant factors that have contributed to the issue of food insecurity among college students. These effects have generally jeopardized their regular eating patterns, thereby leading to food insecurities. The research question that this study aims to explore is: Is there a risk that food insecurity may negatively impact college students' health and well-being? What are the causes that have contributed to food insecurities among college students?

Abstract Name: **Achike Ri Kayewal? Evaluating the United States Healthcare System's Responsiveness to COVID-19 in Guatemalan Mayan Immigrants**

In recent decades, there has been a rapidly growing number of Guatemalan Mayan immigrant communities in the United States. This research project attempts to examine how prepared the US healthcare system is to provide quality care for COVID-19 outbreaks in Guatemalan Mayan immigrant communities. Previous literature has studied how immigration to the United States leads to health disparities for Indigenous immigrants from Latin America; however, most of this literature focuses on Yucatec Maya from Southern Mexico. Additionally, while scholars have studied some health disparities for Guatemalan Maya in the United States and within Guatemala, little research exists about the US healthcare system's preparation to provide quality COVID-19 care to these communities. This research will use a questionnaire to collect data from US healthcare workers regarding their perception of preparedness to treat COVID-19 in Guatemalan Mayan immigrant communities. This research will also analyze COVID-19 resources to evaluate whether the resources sufficiently target Mayan immigrants. I predict both methods of analyses will reveal a lack of adequate preparation in the US healthcare system for being able to treat COVID-19 in Guatemalan Mayan communities. This research will foster some visibility and discussions about adequate healthcare for a marginalized immigrant group often misidentified as Latino.

Abstract Name: **Examining Resiliency and Mindfulness as Moderators of Stress in College Students**

Stress is a common experience for many individuals. From the recent COVID-19 pandemic to managing daily demands, situations that induce stress are common. Etherton et al. (2022) noted that college students, in particular, undergo an abundance of stressful experiences, such as rising tuition rates, high academic standards, money management, and concern for grades. According to Hudd et al. (2000), stress negatively impacts students, such that students under greater stress exhibited lower self-esteem, increased drinking, difficulty sleeping, lack of energy, and reductions in overall health. This can impact college students' ability to perform academically and meet various demands. As the number and intensity of stressors in college continue to increase, we chose to research the impact of stress on academic performance and well-being. Additionally, we explore how aspects of positive psychology (resilience, empathy, self-efficacy, mindfulness) may moderate stress in college students. According to Allan et al. (2014), resilience predicts academic performance, such that increased resilience is correlated with higher grades. Therefore, this study aims to investigate how resilience relates to perceived levels of stress in college students via a survey measuring behaviors related to their academic and everyday lives. We created a survey which was distributed electronically to college students, with a goal of obtaining at least 100 responses across different school levels and other demographic characteristics. We began data collection in fall semester 2022 (current N = 50) and will continue collecting data throughout winter and spring of 2023. We hypothesize that the college students who have higher levels of resilience, mindfulness, and empathy will also report lower stress and higher achievement in academics.The analysis will aid us in understanding the relationship between stress and resilience in current students at our university.

Abstract Name: **Correlation between college tuition and military recruitment**

The cost of college tuition in this country is rising at a rate that will, in the near future, become unattainable. On average college tuition is about forty-eight thousand dollars for a four-year degree which is impossible for most families. College tuition started becoming harder to afford beginning in 1981, as the cost was rising much higher than previous years. At the same time what is also seen as a growth in military recruitment after a decline in recruitment, post-Vietnam. That decline was heavily motivated with a general distaste in military service as many Americans saw the Vietnam conflict as unnecessary. To build onto that, minimum wage starting in 1981 was not rising with inflation and wouldn't see a rise again until the 90's. Why this is all important is because it seems that this financial hardship is forcing many college and high school age individuals into the military. That ability to pay for it is being done using the GI bill which requires said person to serve four to six years. This is backed up with the use of the statistical data showing a growth in college tuition and the military recruitment numbers since the 1950's. Along with that, government policies such as No Child Left Behind that have policies that benefit military recruitment in schools and other educational institutions. With this all-in mind, it shows a trend that using costs of tuition to force people into the military. This trend seems to only be growing and will for the foreseeable future.

Abstract Name: **Signal Recovery from Temporal Noise**

The Shannon-Whittaker Sampling Theorem guarantees that any band-limited signal with frequency band [−B, B] can be reconstructed using only its sampled values at times from an evenly spaced lattice. That is, the signal f is completely determined by its sampled values on the lattice, giving us a discrete (digital) representation of an analog signal. Human hearing is limited to frequencies within B = 20,000 Hz; therefore, band-limited signals are ubiquitous in signal processing. Temporal noise occurs when we sample at time values that differ from the intended lattice. We recently developed an algorithm that utilizes finite matrix computations to reconstruct a signal from temporal noise. In this talk, we will discuss this reconstruction and demonstrate several numerical applications. Moreover, we will present bounds to prove that the reconstruction procedure is stable under very mild assumptions.
