Abstract Name: Toward Change Leadership in Teaching and Learning: Leveraging Mentored Undergraduate Research into Rigorous Spiral Curriculum Designs

Today, all academic disciplines and professional schools are responding to the continuing demands to augment and amplify high-quality teaching and learning. Recommended approaches for faculty include mentored integrated high-impact practices, interdisciplinary collaborations in communities of practice, proficiencies in the use of adaptive technologies, and inventive program design. Correspondingly, undergraduate students are reaching beyond accustomed patterns of learning and life experiences, toward new academic; professional goals; they strive to cultivate the minds of the future (Gardner 2006), to manage the complexity and uncertainty of the global/local environments. It is apparent that only continuing innovative, and transformative program/systems design can effectively enable these parallel yet interrelated emerging aspirations. Further, the research literature suggests that transforming our accustomed approach to research, inquiry, and creative activities from just traditional individual/group activities to a rigorous spiral curriculum can open strategic pathways to faculty and students' collective achievements. This presentation aims to (a) share a proposed cross-year spiral curriculum design that elevates mentored undergraduate research approaches to a dynamic intersection of content, changing context, and process; (b) engage participants in a discussion of the possibilities and challenges associated with cross-level spiral curriculum design in disciplinary and professional schools, and (c) seed interest in this line of inquiry. As such, this presentation emphasizes the potential of collaboration in communities of practice with multiple implications: it builds on the successes of prior researchers and advocates strongly for faculty engagement in program design for continuous research thinking; and it prioritizes leadership in teaching and learning while elevating strategic thinking and its subset, foresight/futures thinking.

Abstract Name: **Star Power: Views on Celebrity Activism**

This study examines public perception of celebrity activism. Celebrity activism is defined by the usage of a high platform, predominantly on social media, to promote social justice and/or advocacy. The study was two-fold.The study consisted of a preliminary survey to determine participants' familiarity with celebrities and social activism topics. Then, it followed with focus groups, each session with different members, that focused on a celebrity - either a musician or an actress - and the activism they partook in. The students were shown a piece of media that depicted the activism the celebrity engaged in.The study aims to find whether students of Georgia State University viewed a celebrity using their platform to support a cause as an effective use of their social standing. Questions such as 'should celebrities engage in celebrity activism?' and 'how effective was their campaign?' were asked of the students to gauge their opinions. This study wants to examine whether celebrity activism is an effective strategy to promoting social change. Topics such as Black Lives Matter and LGBTQ+ rights were discussed in the sesssions. Musicians such as Rihanna, Beyonce, and Lady Gaga were discussed. Also, actresses such as Angelina Jolie, Yara Shahidi, and Emma Watson were conversed about, as well.

Abstract Name: **Evaluating the ability of native plant species to tolerate acid mine drainage and implications for phytoremediation efforts**

Acid mine drainage (AMD) naturally occurs in iron-sulfide aggregated rocks and becomes a greater issue in regions where coalmining occurs, where it's commonly known as acid mine drainage. Produced when sulfide-bearing material is exposed to oxygen and water and characterized by its low pH and high concentrations of heavy metals and other toxic elements, AMD causes severe environmental degradation, posing risks to human health, and contaminates surface, groundwater, and soils. The purpose of this study is to evaluate the extent to which native plant species tolerate acid mine drainage and implications for phytorestoration efforts. Phytorestoration emphasizes the demand for native and diverse plant species used to restore ecosystems and promote biodiversity and improve soil fertility of non-agricultural impacted sites. In this study, five species of native plants were watered daily, separated into three groups of either pre-AMD treatment water, post-AMD treatment water, or tap water from the greenhouse as the control. There are 40 plants of each species, separated into 3 groups of 12, totaling 400 plants. Growth rates and seed germination times are recorded weekly. It is hypothesized that species that are least affected by AMD will show similar growth when exposed to pre- and post-treatment AMD water. The results of this study could potentially aid in funding for future phytoremediation projects, as well as determining which species are most suitable for these conditions.

Abstract Name: Biological Investigation of Phenylboronic Acid Nitrogen Mustards induced apoptosis (Cell Death in Triple Negative Breast Cancer)

Triple Negative Breast Cancer (TNBC) tests negative for the presence of hormonal receptors such as progesterone and estrogen receptors and excess human epidermal growth factor (HER2 protein). TNBC is unaffected by hormonal treatments that target these three growth factors. After diagnosis, there is less time than other cancers to treat TNBC. These characteristics of TNBC result in having poorer prognosis among all types of breast cancer. Therefore, there is dire need for a better understanding of the cancer and of potential drugs. Based on previous research, we have concluded that two Phenylboronic acid nitrogen mustard prodrugs, CWB-20I45 and FAN-NM-CH3 are effective in reducing tumor sizes due to prodrugs' enhanced activity in the presence of hydrogen peroxide (H2O2). Prodrugs are initially inactive that are then turned into active compounds upon metabolism. Inside cells, these prodrugs cause DNA cross-linking that ceases DNA replication and leads to cell death, making them superior to common chemotherapy drugs. Cancer cells have higher levels of reactive oxygen species (ROS) such as H2O2. The prodrugs are thus more selective to cancer cells and less toxic to normal cells. A series of in-vivo experiments determined that the prodrugs are safe in mice. To understand the drug's mechanism inside cells, we are investigating biological pathways by looking at protein expression levels, which vary in drug-treated cells. These proteins include tumor suppressor p53. This was done using RT-qPCR technique to amplify RNA upon extracting mRNA between cancerous cells that are untreated versus drug-treated.

Abstract Name: Musculoskeletal Disorders of the Hands and Arms: Preventative Ergonomic Measures and Optimal Scaler Design for Dental Practitioners in the United States

Currently, there is a rise in work-related musculoskeletal disorders among dental practitioners in the dental field. The root causes that have contributed to musculoskeletal disorders (MSDs) in dentistry have included irregular working postures, repetitive movements, extended muscular contractions, and inept dental instruments and equipment. With these implications, there has been an increase in poor dental ergonomics leading to high unemployment rates, increased medical attention, and job dissatisfaction within the field. Among dentists and dental hygienists, the most common MSDs occur within the hand, wrist, and arm during procedures like scaling and root planing. Common disorders of these include Carpal Tunnel, Tendonitis, DeQuervain's, etc., which have been primarily caused due to repetitive wrist movements, forceful gripping and twisting of the hands, sustained hyperextension of the arms, and an extended load on the shoulders. The purpose of this meta-analysis is to provide recommendations for the classic hand-held scaler by developing a new, ergonomically efficient instrument for practitioners. Based on previous findings of studies, the most optimal instrument should have aspects such as light weight (around less than 20 g) with larger diameters (11-12 mm), cordless and ultrasonic features, tapered handles, and round shapes to be implemented into this novel scaler. Administering ergonomically efficient equipment and instruments within clinics for dental practitioners may help enhance the overall health and wellbeing of dentists, while ensuring successful oral care, accurate diagnosis, and effective treatments for their patients as well.

Abstract Name: **How Non-Profits Can Help Residents Heal From "Tree Trauma" in Order to Implement Sustainable Initiatives in Low-Income Neighborhoods**

Low income neighborhoods in cities across the United States face moresevere environmental issues compared to their upper class counterparts, with air pollution being one of the urgent issues of our generation. In Stockton, California, the southern part of the city has someof the worst air quality as a result of redlining laws in the past, leading to aftereffects such as increasing asthma rates among children. Attempts to improve air quality in South Stockton by planting trees in neighborhoods have failed in the past, as non-profits and government officials would neglectthe trees unattended after planting them, resulting in incidents such as property damage. As a participant in California's College Corps Pilot Program, I work with a localnon-profit called Little Manilla Rising in their mission to rebuild trust within the community in order to improve the city's air quality by planting trees and properly care for them. Within our reasearch, we canvass South Stockton neighborhoods on a weekly basis and survey residents, asking if they would like a tree planted in their backyard, a tree care kit, and tree maintence by our organization for 2 years, all at no cost. We will use the data to upgrade supplies that are in demand for tree kits, determine how to gain the community's trust, keep track of all trees planted, and eventually garner enough support to advocate for environmental regulations in our city's laws. By April, I anticipate that the results will lead to an increasing rate of trust in non-profits by community members, at least a 10% increase in trees planted in our city since 2021, and increasing awareness of environmental problems in residents and how they can utilize their power to bring about change.

Abstract Name: **Effect of Nitrogen Addition in Argon DBD Plasma on Rotational and Vibrational Temperatures**

Dielectric Barrier Discharge (DBD) plasma is a non-thermal, non-equilibrium plasma that is used in the medical field for wound healing and sterilization. Reactive Oxygen/Nitrogen Species (RONS) in plasma interact with water in the blood to produce hydrogen peroxide, and thus, accelerate the wound healing and sterilization process through the production of growth factors. To optimize the concentration of RONS, this study uses small percentages of Nitrogen (up to 5%) in Argon plasma, to see the impact on radical concentrations. The Argon Plasma was generated in a multi-electrode plasma torch, with Argon flow up to 15 slpm, and an AC voltage between 5 and 10 kV (20-40 kHz). The concept of the multi-electrode plasma torch was designed at San Jose State University. This design provides us control over plasma characteristics (i.e., gas, rotational, vibrational, and excitational temperatures, and radical concentrations) without changing the operating conditions. In the current work, the impact of Nitrogen addition was investigated by conducting emission spectroscopy on the plasma. An OceanOptics UV-IR Spectrometer was used to capture the emission spectrum, and SpecAir was used to extract information on the rotational/vibrational/excitational temperatures. Experiments show that the rotational and vibrational temperatures, along with intensity the emission lines present, are impacted by Nitrogen addition. Up to 30% variation in the vibrational and rotational temperatures was observed as the Nitrogen was added into the plasma. Excitational temperatures faced minimal change, as Nitrogen was added. Addition of Nitrogen changed the relative intensities of emission lines, particularly in the NO Band (225-275 nm), Nitrogen Second Positive System (N2 SPS) (330-380 nm), and the N2 II Molecular Line (391.05 and 427.38 nm). This presentation will quantify these relative changes to plasma temperatures as a function of added Nitrogen.

Abstract Name: **Analysis of Long Term Egg Viability in Tadpole Shrimp**

Ephemeral wetlands are temporary waterbodies with highly connective, dynamic ecosystems that offer invaluable ecological processes. These habitats operate fundamentally different from permanent waterbodies due to their natural, reoccurring cycles of desiccation. Found globally, these vulnerable ecosystems support a high diversity of species, each with distinct adaptations to the harsh, frequently changing aspects of this habitat--such as the understudied species: Triops longicaudatus. Triops have eggs thatrequire the cycling desiccation of an ephemeral habitat, and can endure an extended period of diapause, protecting themfrom a variety of adverse environmental circumstances. From this quality,Triopshave maintained a consistent exterior shape for eons and are top predators that succeed early on within the system, persisting through various significant habitat changes and metacommunity collapse during thehydroperiod. This ability has allowed for their survival in areas of extreme temperatures and drought, indicating a potential resistance to climate change impacts. However, more research onTriopsegg hatching and degradation rates is necessary, as there is currently limited understanding on how long the suspended diapause can last.This study recognizes this and consists of an observational experiment for the hatching rates of dormantTriopseggs over a 20-year span. The primaryobjective of this long-term researchis to initiate a layout for future observational sessions using eggs from the educational science kit, TOYOPS Triassic Triops.With a microscope and tweezers, 20 eggs are separated from sand packages and placed into vials labeled by hatch year, starting in 2022 and going until 2044. Vials are then placed in long-term storage until hatching analysis on thedesignated year. Establishing atimeframe for egg diapause is critical to better evaluate the vulnerability ofTriops longicaudatus,especially considering the ecological impacts and potential preadaptations the species may have to mitigate consequences of climate change on ephemeral ecosystems.

Abstract Name: **Evaluating Motivating Operations and Patterns of Preference Displacement**

Stimulus preference assessments have been used to predict likely reinforcers, which often include edible and leisure items. Past research has shown that preference for a particular class of stimuli (e.g., edible items) can displace (show a disproportionate preference) another class (e.g., leisure items). Previous studies have investigated preference displacement of different classes by first conducting single-class preference assessments and then combining the most preferred items from each single-class assessment into a combined-class preference assessment (e.g., leisure vs. edible). The results of these studies have contradicted each other in that at times edible items displace leisure items or vice versa. Therefore, the purpose of this study is to further investigate motivating operations(motivation) and the extent that it influences preference displacement.

Abstract Name: **General Microbiology Students Searching for Antibiotics in Minnesota's Wetlands**

As antibiotic resistant pathogens continue to emerge, there is a dire need for the discovery and development of new antimicrobial agents. In Fall 2021,University of Minnesota Crookston General Microbiology students collected soil samples from wetlands of Northern Minnesota. They isolated and characterized the microbes to see if they have antimicrobial activity. Nineteen students were able isolate cultures that showed antimicrobial activity against the safe relatives of the ESKAPE pathogens. The current aim of the research is to conduct a longitudinal study to isolate and identify antibiotic-producing bacteria from bogs and fens collected from the previous student work. We hypothesized that some of the pure culture isolates would produce antimicrobial substances and show inhibition against the ESKAPE safe relative pathogens. Procedures followed the general protocols of the Tiny Earth-Studentsourcing Antibiotic Discovery Initiative. Soil samples were further analyzed using standardized techniques to identify the presence of potential antibiotic-producing microorganisms. Bacteria from these samples were transferred to isolates and tested against ESKAPE pathogens to show signs of antibacterial activity. Streak plates were created for all isolates showing antibacterial activity and incubated at room temperature to further separate the microorganisms to purity. This process was repeated until cultures reached purity. Pure isolates were then tested against ESKAPE pathogens to demonstrate inhibition. Pure isolates that showed inhibition underwent chemical fixation using acetone. Further testing is needed to isolate and extract the antimicrobacterial component. Further characterization of the twelve pure isolates that have antimicrobial activity will be reported. Findings from this research could aid in the development of antibiotics with new antimicrobial properties that can fight off pathogens resistant to current medications.

Abstract Name: **Designing an Inducible Telomerase RNA**

Telomeres are the protective DNA caps located at the end of eukaryotic chromosomes and are made of thousands of TTAGGG repeats. Telomeres are essential for suppressing the DNA damage response and the ends of linear chromosomes and protecting critical gene information from being lost when genomes replicate. Telomerase is the enzyme responsible for maintaining telomeres and is dependent on the expression of two genes: TERT which encodes the catalytic reverse transcriptase portion synthesizes de novo telomeres and TERC, which encodes the telomerase RNA template (TR). A mutant version of TR, termed AU5, changes the template sequence to ATATAT instead of the canonical TTAGGG and is toxic when expressed in cells. In order to generate a conditional system that would enable the generation of stable cell lines that express toxic non-coding RNAs, we used structure-guided design and placement of loxP sites within the TR sequence. LoxP sequences are recognized by Cre recombinase which catalyzes the recombination of two loxP sites, and can be used for inversion, deletion, or relocation of the DNA between the two sites. Four loxP locations were tested in AU5 TR to determine which site tolerated the loxP sequence without disrupting TR function. We performed functional assays using flow cytometry and competitive proliferation assays to determine which loxP placement was tolerated. Design of our conditional construct will be discussed and we anticipate that this system will be useful for the generation of cell lines or animals that conditionally express toxic non-coding RNAs.

Abstract Name: A comparison of concussion knowledge and attitude between college students in United States and Japan

Every state in the US has a concussion law that mandates concussion education among youth athletes, which is presumed to increase their knowledge and attitude.1 However, many countries have not implemented legal regulation on proper concussion management, despite the fatal risks of improperly managed concussions were proven. More severe forms of brain trauma has been reported in novice Japanese Judo athletes due to lack of knowledge on proper management.2 Therefore, the purpose of this study is to compare the concussion knowledge and attitude level between collegiate students in the US and Japan, where no concussion legal regulation exists. Methods: An English and Japanese-translated survey called modified Rosenbaum Concussion Knowledge and Attitudes Survey-Student Version (RoCKAS-ST) were used. Concussion Knowledge Index (CKI) and Concussion Attitude Index (CAI) were calculated from the survey responses for comparisons. An independent t-test was used for statistical analysis. Results: A total of 510 (US n=204, Japanese n=306) participants completed the survey. Of US participants, 116 identified as female (56.86%), 87 as male (42.65%), 1 as other (0.49%). Of Japanese participants, 43 identified as female (14.05%), 262 as male (85.62%), 1 as other (0.33%). The CKI of US participants was significantly higher than that of Japanese participants (US mean= 40.09, SD= 6.08; Japanese mean= 25.29, SD=8.15; t=22.16, df=508, p< .001). The CAI of US participants was also significantly higher than that of Japanese participants (US mean= 5.77, SD=2.41; Japanese mean= 3.56, SD=1.79; t=11.84, df=508, p< .001). Conclusion: The legal regulation in the US may have been a significant factor that contributed to higher concussion knowledge and attitude of US participants compared to Japanese participants.

Abstract Name: Marginal distribution method to check a generalized additive model assumption

One important step in the regression analysis is to check whether the data fits the regression model in the null hypothesis. Most existing methods to check the model assumptions make use of the residuals. In certain situations, the existing methods are invalid and they are often unlikely to reject the wrong model assumption. To overcome this disadvantage, we proposed a new model checking plotting method and new test to check a generalized additive model (GAM) assumption. The new method is based on the weighted average of the difference between the estimators of the marginal distribution of the response variable. A large weighted average of the difference indicates that the GAM assumption may not be satisfied. The new method is always valid and works well especially in the situations when the existing methods fail.

Abstract Name: **An optogenetic model of hemispatial neglect permits real-time induction of rightward spatial bias**

Hemispatial neglect is a disorder of spatial processing characterized by inability to attend to stimuli situated contralateral to lesions affecting the parietal cortex. Hemispatial neglect is a poor prognostic indicatior following stroke. Critically, while neglect is often marked by loss of attention to visual or somatosensory stimuli, clincial tests in which patients replicate simple figures or draw from memory reveal that neglect is a disorder not of information storage or attainment, but of spatial processing. Specifically, while spatial information may be stored or represented on an allocentric coordinate system, it must be mapped onto egocentric coordinates in a process which depends on the posterior parietal cortex. Indeed, lesion studies in humans as well as in rodents have revealed the importance of this region in the expression of neglect. However, more recent work has revealed that spatial processing requires a distributed network and a number of connected regions are also implicated in neglect. Lesion studies by their nature are limited by the static permanence of the lesions. We sought to create an inducible model of hemispatial neglect using stereotactic delivery of AAV-halorhodopsin to the posterior parietal cortex in mice, permitting the reversible optical silencing of this region by light. We show that in the presence of green light delivered via an optic fiber, mice devlop a rightward bias. We will next utilize this inducible model of neglect while recording from large numbers of neurons in the dorsal hyppocampus or prefrontal cortex to understand how the PPC influences spatial processing during goal-directed navigation.

Abstract Name: **Ridiculously Simple Idea**

The ridiculously simple idea that changed the landscape of Integrated marketing. This study analyzes Apple's "#ShotoniPhone" campaign from 2015 to present day on how they cultivated a ridiculously simple idea through Integrated marketing methodology and creative product launching. The campaign made its first appearance in 2015 on social media, billboards, and world art galleries to inspire consumers to engage in the latest iPhone 6 camera features. The campaign's success relied on Integrated marketing methodology and product launching expertise that was maintained solely based on consumer interaction. Implementing these strategies allowed Apple to better understand the likes of their target audience, how to effectively promote its product, and evaluate their business acumen. Companies worldwide have taken the ridiculously simple idea concept and made it their own, but nothing quite like Apple. Apple is a powerhouse in the technology field while offering simplicity, innovation and creativity.

Abstract Name: **Development of Empathy Scales and their Relation to Personality**

This study assesses the relation between empathy and personality. It is being conducted as a pilot for a larger twin study we are starting this year. In order to do a twin study, we need to have succinct measures that also correlate with each other. Building upon that, this current study has two main goals. First, we will assess all measures used for both empathy and personality, to see if strong composite variables can be created using a smaller subset of items. Second, we will assess the variables with one another to determine if empathy is correlated with different personality traits. Previous studies investigating the relation between the big five personality traits and empathy have had mixed findings. In a study of nurses, the personality traits were able to explain 37.5% of overall variation in empathy capability, with empathy being positively correlated with conscientiousness and agreeableness, and negatively correlated with neuroticism (Wan et al., 2019). In Wakabayashi and Kawashima (2015), however, nearly no relation was found between personality traits and empathy, with only 2-3% of variance being attributed to personality traits. In Nettle (2007), agreeableness and extraversion were positively correlated with empathy. These differences in variance, as well as which personality traits are found to be significant, suggest more research into the correlations between empathy and the big five personality traits is needed. To measure personality, we used questions from the Big Five Inventory (Benet-Martinez; John, 1998; John et al., 2008; John et al., 2011). To measure empathy, we used the Toronto Empathy Questionnaire (Spreng et al., 2009). Data collection is ongoing, but so far 136 participants have completed the survey. We hypothesize that empathy will be positively correlated with agreeableness, as this seems to be the most consistent finding.

Abstract Name: **The Persistence and Change of the Senpai/Kohai Relationship of Native Japanese Speakers in the United States**

With the increase in globalization the need for understanding different cultures is on the rise. -The focus of this research ishow thesenpai-kohaihierarchical relationship that is essential for Japanese society translates into other cultures. Five 30-minute interviews concerningsenpai-kohaiwere conducted with young native Japanese people living in the United States. All the interviewees were graduate students who are Japanese language teaching assistants at a university in the Midwest. The questions each interviewee was asked were about their time living in Japan and the United States concerning thesenpai-kohairelationship. Through these interviews insight was gained about thesenpai-kohairelationship before and after the interviewees came to the United States. Based on detailed analysis of interview results, this study proposes that thesenpai-kohairelationship remains the same in practice among young Japanese people after they move to the United States. However, it fades away when native talk to non-native Japanese speakers. Furthermore, there seemingly is a significant change in terms of their attitude toward thesenpai-kohairelationship; that is, instead of relying on discerment politeness, the research found that after living in the United States, Japanese youth instead use volitional politeness to theirsenpai.In other words, they make personal decisions to choose when and who to be polite to, instead of using polite-forms as expected or as an obligation just because the person is older or more experienced. This research implies that when a person lives in a different culture, even if changes to their original culture cannot be seen outwardly, there may be internal changes taking place as the person adjusts to the new culture.

Abstract Name: **Food For Change: The Political Economy of Wheat Production and Migration in 19th Century Spain**

Spanish economic and agricultural history has, until recently, been defined by the “backward” state of Spanish industry in the 19th century. Recent literature has explored the roots of this narrative and increased focus on the dynamic nature of Spanish economic activity. Contributing to this trend in Spanish history, this project explores the relationship between wheat production and migration to explore economic growth in 19th Century Spain. Using Spanish and English language primary sources such as newspaper articles, census data, and agricultural records in combination with emerging economic and historical literature, this study finds that the growth of Spanish agriculture and industry was dynamically shaped by agricultural producers reacting rationally to increasingly globalized market and political conditions. This study further finds that Spanish economic growth was contingent on the seasonal migration of farmers within Spain and to former Spanish colonies. This analysis of wheat production reveals how historical narratives of economic growth can be better understood through a broader understanding of the decisions made by individual producers within society.

Corinne McDaniels-Davidson

Abstract Name: **Contrasting the Social Needs and Circumstances of Hispanic/Latino and Non Hispanic White Patients in Southern California**

Societal inequities exacerbate the cancer health disparities between Hispanic/Latinos (H/Ls) and non-Hispanic whites (NHWs) in the United States. Thus, we compared the social and systemic life circumstances of H/L and NHW patients undergoing treatment at an NCI-designated cancer center in the southwest US. Via email we invited 5,901 cancer patients seen between 2018-2019 to complete a health survey. Social needs were compared between H/L and NHW patient respondents with Pearson Chi-Square tests using data weighted to the cancer center population.
A greater proportion of H/L patients (48.7%) reported household income <$50,000 than NHW patients (23%; $p<0.05$). A lower proportion (35.8%) of H/L patients reported living comfortably on present income compared to NHW patients (64.2%; $p<0.05$). Food insecurity indicators confirmed income disparities; 37% of H/L, compared to 7.6% of NHW, patients reported often or sometimes being worried their food would run out before they got money to buy more in the last 30 days ($p<0.05$). Likewise, in the last 30 days, 29.1% of H/L compared to 6.1% of NHW patients reported often or sometimes the food they bought just didn’t last, and they didn’t have the money to get more ($p<0.05$). Self-reported physical and mental health was lower among H/L patients compared to NHW patients. On a five-point Likert scale, 34.3% H/L patients rated their physical health to be very good or excellent compared to 50.8% of NHW patients ($p<0.05$). Similarly, 59.3% H/L patients rated their mental health to be very good or excellent compared to 66.6% of NHW patients ($p<0.05$). It's imperative that cancer centers address the systemic and social needs of H/L patients.

Abstract Name: **Factors that Influence College Students' Mathematical Identity and Perceived Proficiency**

The nature of mathematical knowledge is loosely defined by Kean (2017) as an individual's belief of how mathematical knowledge is organized and the source, justification, and content of this knowledge. Students' beliefs about the nature of mathematics can impact many aspects of their academic and overall life pursuits, and can be influenced by a myriad of experiences. In this study, we specifically examine the beliefs and experiences of college students enrolled in College Algebra courses, as we know the course is a gatekeeper that often predicts students' graduation (Bailey, et al., 2010). We use the figured worlds conceptual framework in the learning of mathematical experiences, to understand the multi-layered components of identity in varying contexts (Holland, et al., 1998). To examine undergraduate college students' past mathematics education experiences, beliefs about the nature of mathematics, and experiences in a College Algebra course, pre- and post-surveys were administered in spring 2022. We had 50 participants complete both the pre- and post-surveys. The Likert-items ranging from strongly agree to strongly disagree include scales intended to measure perceptions of mathematics proficiency and sense of belonging in mathematics. The open-ended questions aimed to understand participants' past mathematics experiences, experiences in College Algebra, and beliefs about the nature of mathematics. Preliminary results of open-ended responses indicated themes such as affective factors (e.g., stress, confusion), achievement (e.g., success or failure), acknowledgement (e.g., feeling seen, participation) and application (e.g., careers, daily life) of mathematics. Pre- to post-survey comparisons demonstrate gender differences with female participants showing a positive increase in their self-perceived proficiency in mathematics with pre-data starting lower than male participants and post-data higher than males. This change suggests that perceived gains in proficiency are related to female students experiencing a more positive mathematics college environment, which could influence their mathematics identity.

Parrinello, Vianney

Vianney Parrinello

Abstract Name: **Potential Picasso Project**

Since Summer of 2019, when an alumnus presented the University of Tampa with a “thriftshop” painting signed“Picasso 1905,” Museum Studies and Chemistry students have collaborated on the“Potential Picasso Project” to conduct stylistic, chemical, and comparative historical analyses. This project conducts visual(physical)analysis of the object and, with the aid of past chemical research, establishes its creative process and material composition in order to determine whether it may be attributed to Picasso between 1900-1910.A close physical inspection of the artwork resulted in an estimated timeline of techniques and materials used to create the overlapping layers of pigment and paint. The materials consist of at least four to five layers made up of multiple types of pigments(oil,airbrush, and spray paint) with several differing brush sizes combined with a noticeably large use of pallet knife work. The estimated production process was at least several days to weeks due to the need for the oil paint to dry in between sections. This research is supported by data previously generated by the chemistry collaborators, who used a process called“InductivelyCoupled Plasma Optical Emission Spectroscopy”(ICP-AES/OES)to determine what kinds and how much of particular elements were used within a paint sample taken from the given object. These tests showed consistent uses of titanium dioxide(TiO2),which is notable due to the fact that titanium paints were not commercially available within the time that the piece is allotted as“1905”.The next steps will focus on Picasso's known processes and materials based on stylistically similar works from 1900-1910 (hisBlue and Rose Periods and early Cubism). From there, a comparative analysis against the subject work will be possible to determine whether or not it correlates to actual historical processes and materials used by Picasso in the early 1900s.

Abstract Name: **Screening Click Chemistry Compounds for Antimicrobial Properties**

Microbes are becoming a major health risk as antibiotic resistance and multidrug resistant bacteria increase. Over prescribing of antibiotics has aided in this public health threat of antibiotic resistance genes in clinically relevant bacteria. Without action antibiotic resistance genes can lead to millions of deaths annually. One way that the challenge of antibiotic resistance can be handled is through the development of novel antibiotics. In a pharmaceutical lab, fully functionalized small molecule probes (FFSMPs) were synthesized, using click chemistry, in order to be pharmacologically evaluated. The purpose of these FFSMPs is that they can rapidly identify new chemical probes and drug targets for the treatment of infectious disease, as target identification is a rate limiting step in antibiotic discovery. The pipeline of synthesis can allow for further testing including phenotypic screening, and target identification to create a library of possible novel antibiotics. The objective of this study is to create a pipeline for the development of FFSMPs to then be subsequently tested for antimicrobial properties. The current primary focus is the synthesis of novel compounds and phenotypic screening of compounds. Currently, 54 total FFSMPs are being tested using disk assay for sensitivity and minimal inhibitory concentration assays. These compounds are screened using both Escherichia coli and Bacillus subtilis to test their effects on both gram-positive and gram-negative microbes. The 54 FFSMPs have all been tested using the disk sensitivity assay and are all moving to phase two of testing, the minimal inhibitory assay. After these compounds are all tested the compounds will be further screened using clinically relevant bacteria.

Abstract Name: **Development of Squeaky DC, a modular and affordable 3D-printed educational quadruped**

Squeaky DC is an updated and more powerful version of TREC Lab's Servo Squeaky, a modular and affordable 3D-printed quadruped robot. Quadrupeds have diverse applications as research and educational tools, but the higher cost of similar quadrupeds prohibits their widespread use. Squeaky DC has been manufactured using 3D printing technology and materialsto reduce the overall cost as well as manufacturing time. Due to theuse of 3D printing, Squeaky DC provides design flexibility and can be easily modified without restructuring the whole design. The objective for constructing Squeaky DC is to enhance the usefulness of the earlier version for research and education by implementing the ability to perform more complex tasks such as running and jumping. In this work, the existing servo motors in Servo Squeakyare replaced with more powerful brushless DC motors in Squeaky DC, and Siemens NX CAD software isused to redesign the parts for overall improvement in the design of the quadruped. The new limb design isinfluenced by the anatomical structures of canine and primate limbs. This bioinspired design results in a greater range of motion and improved aesthetics. Several design iterations have been investigated to finalize the overall geometry and dynamics of the design of Squeaky DC. To ensure the reliability and functionality of the design, the final design of the prototype is subsequently manufactured through 3D printing with PLA+ material. Further, this quadruped robot will be programmed and extensively tested to prepare it for release as an open-source educational tool. In the future, Squeaky DC has great potential to beuseful for the exploration of fields such associal robotics and swarm/collaborative robotics.

Abstract Name: MATLAB Image Processing for 2D Traversing Plasma Device designed for Wound Healing and Sterilization

Non-thermal Dielectric Barrier Discharge plasma jets find applications in plasma medicine. In practice, these incident plasma jets are exposed to skin wounds; therefore, an effective scanning of the wound surface is required. In the current research, a plasma scanning system was developed and tested. Various wound images were provided for the system to scan with a plasma jet. For this purpose, a Logitech camera connected to a Raspberry Pi was used to capture the required artificial wound (printed on a piece of paper) image area. This information was relayed to a 2D scanning device that held the plasma jet to scan the targeted area. A MATLAB based algorithm was used to identify the wound area by isolating red color pixels by using a specified threshold value. Inbuilt MATLAB functions were used to identify the minimum and maximum x- and y-values of the wound pixels to generate a bounding box. The developed program rotates the image and regenerates this bounding box at 1- degree intervals, and minimizes the area. The developed software was tested to identify a leg wound image (1.4in x7.3in). The pixel color contrasts were used to mark the boundary around the wound that ended up as a rectangle (1.3in x 7.4in). This was within an accuracy of 94% of the targeted area. To identify the limitations of the imaging software, different wound images (oblong, square, irregular, circular) were tested. Low color contrast between the skin and the wound surface appeared as the main limitation for the software. This presentation will include discussion on the scanning software development, the DBD plasma jet generation, and the functioning of the 2D traversing device which was employed to scan wound surfaces.

Abstract Name: The Function of Tfap2 in the Development of the Ocular Anterior Segment.

The vertebrate eye has two main components the anterior segment (AS) and the posterior segment, including the retina, with both being essential to proper vision. The AS includes the cornea, lens, iris, ciliary body, and iridocorneal angle. It functions to properly collect and project light onto the retina. Anterior Segment Dysgenesis (ASD), a potentially blinding disorder, occurs when there is an abnormality in AS formation. The gene family tfap2 is essential for the development of the vertebrae eye. The tfap2 gene family encodes the protein Transcription Factor AP-2. Expression of this protein occurs in Neural Crest Cells (NCC). NCCs are vital for the formation of the Periocular Mesenchyme (POM) cells. AS targeted POM are necessary to form numerous AS structures. In zebrafish there are 5 orthologs of tfap2, tfap2a-e. Tfap2a is required for proper AS development in mammals. Our aim in this study is to determine the function of tfap2 orthologs during zebrafish AS formation. Temporal and spatial expression of tfap2a-e was conducted using wholemount in situ hybridization (WISH) during AS development in 2-5 days post-fertilization embryos. Using cryosectioning we distinguished the spatial expression of tfap2 in the AS. Expression analysis was conducted at time points 2, 3, 4, 5 dpf. The results for 3dpf show that tfap2a, b, e are expressed within the AS. At 2dpf tfap2a, b, e AS expression is reduced. By 4, 5 dpf tfap2a-e AS expression has turned off. Cryosectioning of the 2-5 dpf embryos distinctly separates the expression of each tfap2 gene observed using WISH. With CRISPR established mutant zebrafish lines, tfap2b-e function is being observed at 5, 7 dpf through analysis of AS physiology using Toluidine blue staining (TBS). Overall, we plan to examine the resulting AS physiology, POM cell migratory effects, and NCC/POM gene expression in the absence of tfap2 function.

Abstract Name: Scaling GPA* for complex protein folding pathway simulations

Finding improved protein folding pathway modeling tools is crucial to develop more potent treatments for disorders caused by protein misfolding. The fast-folding streptococcal protein G (1GB1), which has alpha-helices and several beta-sheets, can be used to test models of protein folding. Pathway prediction is often computationally expensive and time-consuming, so current research focuses on accelerating Molecular Dynamics (MD) simulations. One of the common issues in protein folding simulations is the protein getting trapped in local minima of energy surface states until kinetic energy can drive it out. To fix this, past methods have imposed an unnatural bias on the potential and kinetic energies of the simulation environments. Finding unbiased methods for such simulations was an open problem and was addressed by (Syzonenko; Phillips, 2020), introducing a combination of the A* algorithm and MD simulations. This approach encourages progress that would otherwise be stifled due to the stochastic nature of MD simulations and is expected to lower the computing time required to acquire the folded conformation without adding artificial energy bias. The current implementation has storage issues due to system constraints preventing large-scale implementation. This was because therewas an abundant amount offiles produced.It is necessary to figure out methods to make the whole process scalable. A viable alternative could be the replacement of auxiliary file storage on disk with a key-value data structure for storage. This would prove less burdensome on the file systems. Instead of relying on GROMACS commands using OS system calls, the MDAnalysis library, which is based on GROMACS may be used for simulation commands and storing coordinates. Once validated on the complex and fast-folding 1GB1 protein, the approach may be applied to even larger α-β proteins.

Abstract Name: Developing Rho1 into a Reporter to Determine Yeast GGTase-I Specificity

Protein prenylation is a post-translational modification (PTM) of “CaaX proteins” which regulates their localization and function. Prenylation occurs to proteins having a C-terminal sequence that consists of a Cysteine (C), two aliphatic amino acids (a), and one of several amino acids (X). CaaX proteins typically undergo a coupled 3-step PTM pathway involving initial lipidation with a C15 or C20 isoprenyl group on the Cysteine, followed by endoproteolytic removal of the ‘aaX’ sequence, and finally methylation of the isoprenyl-cysteine carboxyl group. The 3-step PTM is documented for many CaaX proteins although emerging evidence indicates that some CaaX proteins are only subject to the first isoprenylation step. Ydj1 is an example of a CaaX protein that only undergoes isoprenylation, and it has been adapted as a genetic reporter to assess the prenylation potential of all 8000 possible CXXX sequences. Published results indicate that Ydj1 prenylation mediated by farnesyl transferase (FTase), which adds a C15 farnesyl lipid, extends beyond the traditional CaaX motif.Likewise,preliminary evidence indicates that Ydj1 prenylation mediated by geranylgeranyl transferase-I (GGTase-I), which adds a C20 geranylgeranyl lipid, extends beyond the traditional CaaL/F motif.These results suggest that the prenyltransferases, FTase and GGTase-I, have broader specificity than previously considered. Reliance on the naturally farnesylated Ydj1 reporter limits interpretation of these results for GGTase-I. This study reports on a method for assessing GGTase-I specificity through the naturally geranylgeranylated Rho1 GTPase that is a more appropriate reporter for GGTase-I activity. The method uses the essential nature of Rho1 and genetic recombination to create and assess the function of a plasmid library of Rho1-Cxxx sequences for insight into GGTase-I specificity. This study will refine the breadth of potential targets of the CaaX PTM pathway and provide insight into the implications of using GGTase-I inhibitors as human therapeutics in a variety of disease states.

Abstract Name: SARS-CoV-2 Infection of the Human Brain

SARS-CoV-2 is a respiratory disease, however, it is known to affect multiple organ systems, including the nervous system. Neurological symptoms have been previously reported to occur with SARS-CoV-2 infection, however the mechanisms through which the virus is associated with these symptoms is unknown. Previous studies have indicated some evidence of neural invasion of SARS-CoV-2 among postmortem COVID-19 patient brains [1]. Here, we examine fifty-five human brain tissue samples from twelve different postmortem COVID-19 patient brains using immunohistochemistry to identify the presence of SARS-CoV-2 spike protein among the tissue samples. The samples included tissue from the hippocampus, midbrain, pons, medulla, and olfactory tracts. Chromogen staining was utilized to stain the tissue. Through microscopic analysis, the presence of SARS-CoV-2 spike protein was identified in over a third of the tissue samples among multiple brain regions. The findings of this study will be furthered to identify the specific cell types infected by SARS-CoV-2 in the human brain.

Abstract Name: The Forest or the Trees: A Holistic Approach to Platonic Ethics

A flawed ethic harms the whole of society, both the individual and the community. Philosopher Melissa Lane, in her recent work Eco-Republic: What the ancients can teach us about ethics, virtue, and sustainable living, demonstrates that as understanding of the whole society emerges, individual people can no longer see themselves as ineffectual and unimportant parts of a system beyond their control; instead, through her work we come to see that no good society can afford individual indifference. This connection between the personal and social in regards to ethics is especially significant when applied to areas where we see our current ethic fall short: environmental justice, and gender theory. Previous efforts at ethical reform have failed to significantly change the status quo because they have not ventured deep enough into nature, our treatment of which is rooted in our ways of treating humanity. While building on Lane's work to shape how we treat the environment, this project will demonstrate this connection between the personal and social by critiquing popular understandings of gender theory. I take up Lane's project of holistic ethics by responding to our common human responsibilities as re-imagined in Lane's work. Just as Socrates in Plato's Republic uses the city to talk about the soul, this project will look at Melissa Lane's analysis of a Platonic environmental ethic to talk about inherited ideas of gender. Throughout this process, we will learn that just as environmental ethics is rooted in 'the Good', so too is gender theory. Because of this interconnectedness, a truly holistic application of virtue ethics requires that we keep the entire landscape in view in every aspect of our lives.

Abstract Name: **Parental status, beliefs about verbal ability, and support for behaviorist ideas on language development**

Parents and non-parents may differ in their support for the behaviorist approach to language acquisition. Behaviorist theory posits that preschool children learn language as a result of caregivers' modeling, shaping, and rewarding of correct verbal behaviors. In a previous study conducted in our lab, parents unlike non-parents, on average, did not endorse the behaviorist approach. It is not clear why this difference emerged, but an earlier study showed similar trends in beliefs about child development whereparents were less likely to attribute children's behavioral tendencies to "nurture" and more likely to associate these with their inherent nature. Further, the behaviorist theory is comparable to a controlling, pedantic style of parenting as opposed to an autonomy-supportive style. This is an important comparison as previous research has demonstrated that individuals who adopted a controlling style of parenting also believed that the verbal ability of their children was highly fixed, that is less malleable. We examined our survey data of 451 participants (226 parents and 225 non-parents) to determine if parental/non-parental status and beliefs about fixedness of verbal ability (via a pre-validated scale) predicted the overall endorsement of behaviorist statements on language development. We also included income and educational status as predictor variables. In addition to parental status, beliefs about fixedness of verbal ability emerged as a significant predictor but not income or education. Parents were less supportive of behaviorist statements than non-parents. The stronger the fixedness beliefs of individuals (regardless of parental status) the stronger the support for behaviorist statements on language development. We discuss these findings from a multidisciplinary perspective.

Abstract Name: **Novel Mechanism of Methane Synthesis**

Aerobic methane synthesis has now been demonstrated in multiple situations, essentially upending the paradigm that biological methanogenesis is limited to anaerobic methanogens. In one case, the McDermott and Bothner labs at Montana State University isolated a bacterial strain of Acidovorax from Yellowstone Lake that was shown to produce methane in aerobic conditions. Transposon mutagenesis revealed a 5' pyridoxal phosphate-dependent aminotransferase (AAT) was required for growth on methylamine and production of methane. Even more recently, a publication demonstrated that interactions between reactive oxygen species (ROS) and free iron may result in the formation of methane in all living organisms. This methane production has been shown to be increased by cellular oxidative stress. The formation of methane through the involvement of ROS is hypothesized to involve the Fenton reaction. I have demonstrated that methane can be produced through this mechanism in an in vitro system containing Fe(II), a methyl donor, and cellular extract. The mechanism(s) behind methane production in both of these cases remains unclear. Thus far, it is known that both processes are aerobic and require cellular components. However, the substrates employed and the mechanisms responsible for these reactions are unknown. My research is focused on elucidating the substrates and biomolecules responsible for aerobic methane production. It is unknown how methylamine is converted to methane, so I have focused on solving this issue, attempting to determine the first step of methane production by an AAT. Furthermore, I have conducted a metals screen to determine if other metals can employ Fenton-like chemistry to produce methane.

Abstract Name: The Effects of Voluntary Exercise on Memory and Anxiety in Young Adult Female C57BL/6 Mice

Exercise increases spatial memory and decreases anxiety. Physiological mechanisms are unknown, but a larger hippocampus can be associated with both of these outcomes. Nonspatial memory is not necessarily associated with the hippocampus, and thus may not similarly be increased by exercise. This study investigated the effect of three weeks of exercise on nonspatial memory and anxiety levels in young adult female C57BL/6 mice using the open field test (anxiety) and object recognition test (nonspatial memory). We hypothesized that mice in the exercise group would exhibit less anxiety-like behavior and would perform better on the nonspatial memory task compared to the sedentary group. Results showed that exercise did not change nonspatial memory and may have increased anxiety, contrary to the hypothesis. These findings may have been due to the tests used, so future studies could investigate other nonspatial memory and anxiety tests.

Abstract Name: Undergraduate Nursing Students' Knowledge and Attitudes Toward LGBTQ+ Patients: An Assessment Related to an LGBTQ+ Cultural Competency Module

Background: Nursing research has demonstrated knowledge deficits specific to care of the patient who identifies as lesbian, gay, bisexual, transgender, queer, + (LGBTQ+). Lack of knowledge specific to the care of people in LGBTQ+ communities continues in spite of this populations' increased health disparities. In an effort to address this lack of knowledge, both the Institute of Medicine and the US Department of Health and Human Services have called for prioritization in addressing these disparities. In fact, in their position statement on LGBTQ+ populations, the American Nurses Association (ANA) recognizes that nurses need to deliver care that is culturally congruent for LGBTQ+ populations. The ANA has therefore put forth recommendations that nursing education help to fill the void in the existing knowledge by incorporating content specific to the issues faced by LGBTQ+ populations. Toward that goal, this study sought to include a learning module covering healthcare considerations for the patient who identifies as LGBTQ+ within a required undergraduate nursing cultural competency course.Method:Student (N=124) knowledge related to care of the patient who identifies as LGBTQ+ was assessed before and after participating in a module entitled Cultural Consideration in Clinical Care: Working with LGBTQ+ Patients. Attitudes toward sexual orientation and gender identity were assessed before and after participation using the Modern Homonegativity Scale and Transphobia Scale respectively. A Wilcoxon signed rank test was conducted to evaluate whether students showed improved knowledgeand attitudes. Findings:Student knowledge scores related to care of the LGBTQ+ patient improved significantly after participating in the module. In addition, attitudes toward sexual orientation and gender identity improved significantly. Discussion: Incorporating content specific to issues faced by LGBTQ+ populations within undergraduate nursing education has the potential to improve clinical knowledge necessary for culturally competent care of LGBTQ+ population, as well as to improve attitudes toward these populations.

Abstract Name: **Thrust Measurements of a Coaxial Rotor Helicopter along with Flow Visualization Between Rotating Blades**

A robust thrust stand was developed for thrust measurements of a coaxial rotor helicopter. Thrust measurements were used to gauge the effectiveness of the mounted rotor blades. The thrust stand consisted of a load cell and a sensor for rotational speed measurements. A Degraw (HX711-5kg) load cell with strain gauges and a preamplifier was employed. The strain gauge response was recorded by an Arduino based system to get real time thrust measurements. Before using it for the thrust measurements, the system was calibrated with known weights and a calibration curve was established for accurate thrust measurements. A coaxial rotor helicopter (SKY/Rover King) was mounted on the thrust stand where thrust was measured as a function of rotor rpm. In order to optimize the thrust, the design of the commercial helicopter was altered to vary the distance between the opposite rotating rotor blades. Experiments indicate that the thrust peaked around 3000 rpm to about 25 N as the rotor speed was varied from 0 to 4000 rpm. Similarly, the separation between the two rotors was altered and an optimized separation between the blades was found. In order to understand the flow structures between the two opposite rotating rotors, flow visualization was conducted. This was achieved by incorporating a smoke generator along with a helium neon laser sheet that was set at various angles between the rotating blades. A camera was used to capture the motion of the smoke particles within the rotating blades. Images reveal the existence of wake and flow instabilities that are currently under review. Final presentation will describe the thrust stand design along with the thrust measurements at various operating conditions. The discussion on the flow visualization and its impact on the thrust measurements as a function of the separation between the two rotors will be included.

Abstract Name: **The Future of Plastic Waste: A Multi-Disciplinary Approach**

Approximately 300 million tons of plastic waste is produced every year worldwide; only ~7-9% is recycled.The result is harmful plastic waste accumulation that negatively impacts ecosystems and communities around the world. Polyethylene terephthalate(PET) is one of the most abundant plastics due to its transparency and chemical strength. While naturally occurring PET-degrading bacterial enzymes have been identified (i.e., PETase and MHETase), their physiological requirements make them ill-suited for industrial use. We attempted to address this problem by bioengineering a chimeric PETase::MHETase protein for enhanced PET degradation. Review of recent literature revealed a collection of PETase and MHETase-optimizing mutations shown to enhance temperature and pH tolerance. Building from this work, our approach was to combine these nucleic acid changes into a single modified open reading frame (ORF) to support even greater PET degradation capabilities. The synthetic plasmid DNA construct was transformed intoE. coliand expressed to produce a novel chimeric protein. The biomanufactured product was purified by nickel column chromatography and quality-tested using standard assays. Finally, functional assays allowed us to measure PET plastic degradation. Recognizing that typical practices in life science laboratories are part of the plastic waste problem, our team explored and implemented ways to make our laboratory—and others like it—more sustainable. Additional methodologies from the field of STS (Science, Technology and Society) were used to consider, imagine, and develop greater understanding of the implications of plastic waste and how a bioremediation-based solution might be implemented in the future.

Pearce, Mackenzie

Abstract Name: **The Women of the Magnolia State: Understanding the Status of Contemporary Southern Women's Movement**

Little research has been done to fully understand the Women's Movement in Southern states; however, this research seeks to correct that. The initial questions that spurred this research are as follows: Why do women organize in a state that has, in a sense, already predetermined their political destinies? In other words, why do conservative women organize in a state that is satiated with support? Are they even members of women's organizations at all, or are they instead members of other organizations like the Rotary or the Chamber of Commerce? On the other hand, why do progressive women organize in a state that has a conservative super majority stacked against them? Is it for solidarity, a sense of belonging, or the hope for change, even if it is unlikely to happen in the near future? This research is largely built upon Verta Taylor's 1989 article on abeyance (a period of time in which movement organizations are sustained in periods of low mobilization), where she delineates several abeyance structures and processes. Combining other social movement literature and social network analysis theories, the purpose of this research is to understand the status of the Women's Movement in Mississippi. Using a survey to map the network of both conservative and progressive organizations that identify themselves within the movement will allow the researcher to answer key questions surrounding the status of the movement. The ultimate goal of this research is to provide a mapped network of the organizations of women who self-identify as members of the Women's Movement, as well as report on the status of the Women's Movement in a state previously left out of the national narrative.

Moriah Pearce

Abstract Name: **A Perceptual Study: The Effect of "Intent" and "Loud" Instructions on Individuals with Parkinson's disease**

The present study is based on a research question, "how do people speak differently with a given instruction." The goal of this study is to examine how people perceive speech produced by individuals with Parkinson's disease (PD) under three different conditions. PD is the second most common neurodegenerative disease. PD is a movement disorder due to the loss of Dopamine-producing cells in the brain. Because speech production is a motoric behavior, many individuals with PD develop hypokinetic dysarthria, a communication disorder. Little is known about how speech by individuals with PD is perceived. It is essential to gain knowledge on the perception of speech/voice of individuals with PD from an untrained person. The present study will focus on how individuals with PD can change their speech/voice under different instructions and the effects of these instructions on the listener's perception of their speech/voice. The goal of this study is to examine how people perceive speech produced by individuals with PD under three different conditions:"natural voice," "speakloud(ly)," and "speak with intent."Forty college students participated in this study as listeners. They rated the recorded speech of individuals with PD in terms of (1) intelligibility, (2) loudness, (3) pitch, and (4) similarity to normal speech. The acoustic analyses of the stimuli revealed that both "Loud" and "Intent" instructions facilitate the communication of people with PD differently. The author expects that both "Loud" and "Intent" instructions facilitate greater intelligibility with increased articulator movements and voice projection. The "Loud" instruction may effectively make one's voice louder with single-target guidance. The "Intent" instruction may facilitate prosody. Either instruction may not approximate speech to the normal level due to the decreased amplitude of breathing efforts with PD.

Abstract Name: **Associations Between Early Life Stress and Problematic Alcohol Use: The Mediating Effects of Executive Function Components**

The Addictions Neuroclinical Assessment (ANA) is a clinical framework that seeks to understand the etiology and heterogeneity of addiction. It is composed of three neurofunctional domains derived from the neurocircuitry of addiction (incentive salience, executive function, and negative emotionality). Executive function (EF) encompasses processes related to the organization of behavior for the achievement of future goals. Early life stress (ELS) refers to extreme or prolonged stress experienced during early life. High levels of ELS have been shown to negatively impact executive functioning and is associated with problematic alcohol use. The goal of the present study is to understand how changes in EF mediate the relationship between ELS and problematic alcohol use. Individuals (N=300; 40.0% female, 49.7% non-white, 60.9% with current AUD) enrolled in the NIAAA Screening and Natural History Protocol completed the ANA battery. EF was assessed using measures of response inhibition, attention, inference, mental rotation, working memory, interoceptive awareness, metacognition, and impulsivity. Early life stress was measured using the Early Life Stress Questionnaire (ELSQ). Alcohol outcomes include the Alcohol Use Disorder Identification Test (AUDIT) and lifetime AUD diagnosis. Structural equation modeling was used to derive components of EF to determine the associations between ELS factors, EF components, problematic alcohol use, and. We expect to identify subcomponents of EF, and that these subcomponents are associated with problematic alcohol use and ELS. We also expect EF to mediate the relationship between ELS and problematic alcohol use. Findings from these analyses will provide novel insights into the etiology of AUD.

Abstract Name: **Environmental Justice from the Ground(water) Up: Coping with Contamination in Tallevast, Florida**

This research explores the history of groundwater contamination in Tallevast, Florida and how community residents have responded with coping strategies and environmental justice organizing. Tallevast is an historically segregated African American community in central Florida where residents discovered groundwater contamination from a local manufacturing plant. Since then, studies have documented high rates of cancer and other diseases. Using oral history interviews, we document the social, political, and economic strategies community residents developed in response to the contamination and health outcomes. These strategies focus on environmental justice activism that emphasizes community organizing, local citizen science efforts, and university-community partnerships.

Abstract Name: **Memory tests and microglia in a mouse model of Alzheimer's Disease**

Alzheimer's Disease (AD) is characterized by amyloid plaque development and tauopathy, leading to crippling deficits in learning and memory. Most research has focused on how these amyloid plaques and tauopathy impact neurons in the hippocampus and cortical regions. The extent to which this pathology extends to other nervous system cells remains to be fully investigated. Microglia are a potential cell type contributing to AD pathology due to their accumulation around amyloid plaques. To investigate the changes that occur in microglia during AD progression, we compared wild type mice (JAX stock #101045) to 3xTg-AD transgenic mice (MMRRC stock #34830). This mouse line develops plaques and tauopathy beginning around 3-4 months. Mice were tested on an object location task and an object recognition task at early (7 weeks) or late (47 weeks) in development of the pathology. Briefly, mice were tested on behavior over three days, with one day for habituation to the apparatus, and then one day each for the object location and the object recognition tasks. Following behavioral tests, brains were removed and immunohistochemistry was performed to examine microglia (TMEM119 antibody) within the hippocampus and surrounding regions. Micrographs will be analyzed for the number and shape of microglia. Comparisons between wild type and 3xTg-AD mice and between the behavioral time points will be examined using T-tests and ANOVAs. This examination provides additional details on the development of the AD pathology in the 3xTg-AD mice and its contribution to learning and memory processes.

Abstract Name: **Using Community-Based Participatory Action Research Frameworks to Enhance Undergraduate Research and Connect Students to Historically Excluded and Exploited Communities**

Community-based participatory action research models (CbPAR) are unique research frameworks that involve the community of interest (CoI) in the research process. The aim is to address concerns of interest and value to the CoI, which increases investment in the research by the CoI. CbPAR should always be founded in the needs of the CoI, informed by community knowledge, and aimed to lead to community and social changes. Unlike traditional research models, CbPAR focuses on empowering the CoI, amplifying their voices, and sharing their unique stories. These aims are especially important for historically excluded and exploited communities (e.g., the LGBTQIA+ community and Veterans) in research. Within these communities, there is a high degree of distrust and disenfranchisement towards the scientific community due to historical and current exploitation. CbPAR methods are a first step towards mending relationships with these communities. It also connects undergraduate students to these communities in a meaningful way. Students learn to empathetically listen and connect to the stories of the community, becoming more than consumers of knowledge, but rather stewards of that knowledge to promote mutually beneficial change in their communities. Additionally, these qualitative, CbPAR research frameworks provide students with hands-on learning opportunities with interview techniques, transcription, and analyses. CbPAR allows students the unique experience of working directly with the CoI through the phases of the research. Too often, traditional service-learning opportunities in the classroom benefits the insular culture of academia more than the community itself. Through CbPAR, students learn how to connect with the community from a scholar-activist perspective, which emboldens them to to affect social and political change in their communities. We argue that CbPAR methods are mutually beneficial to faculty, students, and the community and should be used more often to allow for research to be less exploitative in our drive to advance science.

Abstract Name: Bioreactor for Corneal Tissue Engineering

Millions worldwide are negatively affected by a shortage in transplants used to treat patients with visual impairment caused by corneal damage[1]. Developments in tissue engineering of human corneas can increase the supply of corneal transplants to resolve the donor shortage. A bioreactor and a pressure control system to impart mechanical strain to growing tissue was developed and optimized to mimic the in-vivo corneal environment. Understanding how mechanical signals affect the protein expression of growing corneal cells can lead to more effective methods of engineering accurate corneal transplants. Previous studies have shown that corneal fibroblasts grown under physiological levels of mechanical strain differentiated into quiescent keratocytes, which have lower α-SMA protein levels compared to myofibroblasts, and are more representative of normal corneal tissue [2]. Corneal fibroblasts were isolated from the stromal layer of harvested New Zealand white rabbit eyes, and successfully seeded in our bioreactor system. Our bioreactor system allows us to study the effects of different levels of mechanical strain as well as electromagnetic stimuli on α-SMA protein levels in growing corneal tissue. These studies will help to produce more efficient methods of engineering new corneal tissue for transplants.

Abstract Name: Competition Demands of NCAA Division III Women?s Collegiate Lacrosse

In an effort to assess the demands of NCAA DIVISION III woman's collegiate lacrosse, Global Positioning Systems (GPS) were used to quantify positional demands during the 2022 College Conference of Illinois and Wisconsin season (NCAA Division III) for the Carthage College Women's Lacrosse team. GPS data was collected from twelve female athletes using a sampling rate of 10 Hz (Titan 2, Integrated Bionics Inc. Austin, Texas). When comparing total distance by position, a statistically significant difference was found between the midfielders and attackers (0.01; ES = 1.75, large) and between the midfielders and defenders (0.01; ES = 1.95, large). No differences were observed between attackers and defenders (p = 0.15; d = 0.34, small). The main finding was that midfielders covered significantly more total distance than both attackers and defenders. Calder et al. (2021) observed similar distances among female defenders (7517 ± 786 m), midfielders (6972 ± 770 m), and attackers (6806 ± 586 m) at the NCAA Division I level. Calder's findings were that defenders covered the most distance during competition; conversely, the midfielders covered the most distance in this study. These differences are likely due to the teams' style of play and talent level. Furthermore, all positions experienced a decline in total distance covered as the game progressed, consistent with other studies (Calder et al., 2021; Varley et al., 2014). These effects are likely due to fatigue, and by developing positional profiles of volumes throughout match-play, coaches can ensure their athletes are prepared for competition demands. It is suggested that coaches and practitioners ensure lacrosse players can handle distances of 6130-8110 m during match play; it is best achieved if players are trained by positional needs. This specific training may help reduce the progressive loss in total distance covered with each quarter played.

Abstract Name: Determining the Dose of Exercise Necessary to Attenuate Methamphetamine Neurotoxicity

Methamphetamine (METH) use continues to be a major public health concern. Upwards of 14.7 million people in the U.S report having tried METH. The use of METH is troublesome, not only due to the acute effects of the drug which can include psychosis and aggressive behavior, but also due to the long-term consequences including neurotoxicity, cognitive deficits, and addiction. In fact, individuals who use and abuse METH are more likely to develop Parkinson's disease, suggesting a possibly progressive dopamine loss due to METH use. Exercise is well known for its beneficial physiological effects and cognition-enhancing properties and has long been investigated in the context of Parkinson's disease and other neurodegenerative diseases. Only recently has exercise been studied as a potential therapeutic treatment of substance use disorder. Previously, we have shown that 3 weeks of voluntary running after a METH binge regemine protects against METH-induced dopaminergic neurotoxicity. The aim of this project is to discover whether or not the amount of exercise done has an effect on neurotoxicity attenuation. Male Sprague Dawley rats were dosed with a neurotoxic regimen of (+)-METH-HCl (4 x 4 mg/kg, s.c. at 2-hr intervals) or saline (4 x 1 ml/kg, s.c. at 2-hr intervals). Beginning 1, 7, or 30 days after injections, animals were then subdivided into one of two exercise conditions, voluntary exercise or sedentary control. Afterwards, animals were split into low or high exercise groups by average amount ran in order to compare amounts of neurotoxicity attenuation in animals that exercised at different rates. Results will be analyzed to understand whether a threshold of exercise needs to be met in order to attenuate neurotoxicity after METH use.

Abstract Name: Continuous Mobile Authentication with Multi Finger Touch Dynamics

Mobile Devices are growing in use day by day causing a need for better mobile security. Mobile devices have some security features built into them already, but if the intruder has already unlocked the device those features will not work. Identifying where this security can be improved is a difficult task, however improvements in Touch Dynamics Authentication show that it could be used as a form of continuous authentication once the device has been unlocked. Oftentimes users on a device will have very repetitive movements that humans can not detect, but a program can be trained to understand these patterns. In this research we will be looking into specifically Multi-Finger Touch Dynamics and attempting to work out three models that are able to detect an authentic user from an imposter. We will be extracting several features in order to train these programs and some include velocity, acceleration, and how many pixels each finger covers

Abstract Name: **A Mathematical Model for Analysis of Traffic Flow in State Road 826 using Incremental Trajectory Clustering and Reinforced Neural Network**

Proper modeling of highway environments is essential when attempting to address traffic flow in it. Redesigning infrastructure, planification and the subsequent execution often seem like the appropriate solution, yet its effectiveness is identifiable in the long term. Having the State Road 826 located in Miami-Dade County, considered as the second most dangerous highway in Miami, as the scenario, this research aims at identifying (1) the most common situations in which the traffic is very slow or stationary; and (2) small areas where traffic congestions habitually occur. The use of data analysis and machine learning to evaluate the traffic flow within a delimited area can provide insight into the traffic conditions, especially by performing abnormality detection and classification. If conditions of traffic in highways are studied in a nonparametric way, short-term solutions as application of new transit rules seem to be suitably achievable. We proposed an unsupervised and nonparametric method to analyze rush-hours traffic conditions in $\Theta(d)$ time, where d represents the number of trajectory clusters. In the intended method, temporal association of the vehicles and the infrastructure of the studied highway is taken into consideration using Temporally Incremental Gravity Model-Dynamic Trajectory Model (TIGM-DTM). Further, the distance-based scene learning is realistically intuitive in predicting the parameters of the model. The collection of these parameters plays a crucial role in the interpretation of the data and enables us to create statistical simulations and outputs using a reinforced neural network. For this study, we use data provided by the Leading Transportation Analytics Solutions, INRIX.

Abstract Name: **Dietary Intake Patterns in Adults with Migraine**

According to the World Health Organization, migraine disease is one of the top 10 most disabling medical conditions. Previously, migraine research focused primarily on pharmacological interventions that could “treat” or “prevent” a migraine. Migraine research now also focuses on the prevention of migraines through diet or supplements, such as magnesium, and other behavioral interventions. However, there has been a lack of high – quality data used to determine dietary patterns of individuals with migraine. Most often in prior studies of migraine, dietary data was collected through nutrition surveys at a single point in time. Although nutritional surveys are easily accessible for participants, they provide limited results regarding the participants’ dietary intake. This study is using the Nutrition Data System for Researchers (NDSR) software, following the Multiple Pass dietary interview method, to get a broader and more accurate assessment of usual dietary intake of people with migraines. We aim to collect dietary data across 8 dietary interviews in 20 people with migraine to demonstrate the feasibility of using this method in this population. The NDSR software will provide data on the nutrient and food intake, which will be analyzed to observe dietary patterns that emerge among the migraine population. These results will advance the methodology dietary intake data collection in the migraine population.

Abstract Name: **Foreign Funding of Al-Qaeda in the Arabian Peninsula: Soft Power Implementation in Yemen**

Since the outbreak of the Yemeni Civil War in 2014, foreign nations continually invest in social welfare programs with the goal of aiding Yemenis; however, involvement in Al-Qaeda in the Arabian Peninsula (AQAP) increases. Analyzing the relationship between the two illustrates the effectivity of soft power implementation in addressing socioeconomic issues within each governorate. Scholars ponder how the role of social welfare programs affects extremism participation in the Middle East. Further, scholars call for more social welfare programs in the Middle East and for more research about the relationship between social welfare programs and extremism. The project will utilize data from the World Bank about foreign-invested social welfare programs in Yemen to illustrate efficiency and potential impacts. In addition, this project will utilize government records on known AQAP extremists to analyze recruitment factors and socioeconomic conditions. The mixture of descriptive and explanatory analysis may reveal the influence of foreign-invested social welfare programs on increasing AQAP extremist involvement since 2014. Considering the implications of this project and the potential to aid future counter-extremism measures by utilizing socio-cultural understanding will help keep governments from repeating costly and relation-straining mistakes.

Abstract Name: **Impact of Caffeine Combined with Resistance Training on Post-Exercise Arterial Stiffness in Habitual Caffeine Consumers**

Background/Purpose: Increased arterial stiffness has been shown as a marker of cardiovascular-related events. Previous research has revealed resistance training and caffeine consumption leads to increases in arterial stiffness independently. Therefore, the purpose of this study was to determine the residual effect of combining resistance training and caffeine on arterial stiffness in resistance trained females. Methods: This experimental study was conducted on 18participants between the age of 18and 23yrs who were resistance trained in accordance to ACSM resistance training guidelines. All participants were habitual caffeine drinkers as defined by consumption of at least 200 mg/day, 5 days/wk. Pre-trial evaluation of 10-rep max was performed to determine individual training load for each exercise session. Subjects completed both caffeine and placebo conditions in a counterbalance fashion to avoid an order effect. Caffeine was administered during each trial a dose equal to 3 mg/kg body weight. Each condition was followed by an exercise intervention consisting of a full-body superset resistance training protocol. Measurements of arterial stiffness (pulse wave velocity, pulse wave analysis, and pulse pressure) were obtained using the SphygmoCor® system at 4 different time points (baseline, post-exercis, 10min post-, 20min post-, and 40min post-exercise). Results: A two-way repeated measure analysis of variance (within-subjects) did not indicate a significant difference in measurements of arterial stiffness between placebo and caffeine trials, but a time effect was revealed to be significant within both trials ($p = 0.008$). Conclusion: The results did not indicate a summative increase in measurements of arterial stiffness due to the combination of resistance training and caffeine consumption.

Abstract Name: **Impact of Biodegrading Plastic in Microgravity on Long Term Space Sustainability**

The use of low density plastics is a prevalent part of our everyday life, and space travel. From bottling devices to radiation shielding there are many convenient uses for these polymers. This proves detrimental to our environment, however, as it takes hundreds of years for these plastics to degrade naturally, leading tooverpopulation of landfills and stray debris in our oceans. As we travel further into the expanse of our solar system, inevitably, the use of these plastics will follow, as well as the accumulation of waste. Galleria mellonella, or the “waxworm”, is capable of biodegrading low density polyethylene (LDPE, plastic) into ethylene glycol, the major component of antifreeze. In an effort to test this novel plastic management strategy for space, our team was chosen to send an experimental payload to the International Space Station and address two key questions: if waxworms could survive space travel and if they were capable of biodegrading plastic under microgravity conditions. Preliminary results included time- lapse imaging that confirmed waxworm survival on the ISS for the 30-day testing period. In addition, waxworm larvae consumed similar amounts of plastic to earth gravity controls. This study provides unique insight into how this organism may provide a means of repurposing the large volumes of plastic used in space travel for a more sustainable future in our solar system.

Abstract Name: **Charles Coughlin, Antisemitism, Right Wing Populism, and influecne of Radio Propaganda**

The study of right-wing populism has seen a resurgence since the aftermath of the 2016 election. More attention has been paid to right-wing populists of the past to understand the present political climate. Father Charles E. Coughlin was a major right-wing populist who emerged from the social upheaval caused by the great depression. What is unique about Charles Coughlin is that he utilized the medium of radio more effectively than his contemporaries. Originally, he used the radio to broadcast his sermons, but quickly inserted his own politics into his broadcasts. His fiery rhetoric and natural charisma naturally led to a massive audience. At his peak, he garnered nearly thirty million listeners. Originally, Coughlin was a fervent supporter of Franklin Delano Roosevelt’s New Deal but withdrew his support after his attempts to get FDR to implement his own policy proposals failed. Coughlin mounted a third-party campaign in 1936 with the remnants of the ‘Share Our Wealth” Movement and the Townsend movement, but it failed because there was little, if any, organizing on the ground. Following this defeat, Coughlin saw no more inroads into electoral politics and began to focus his efforts on his radio show as a means to influence politics. More than anyone else in America, Coughlin showed how powerful the new medium of radio could be in spreading hateful propaganda and rhetoric. For Coughlin, this manifested in his antisemitic and fascist tendencies. At the same time, Coughlin’s popularity did not translate into a real movement like Huey Long’s. While Coughlin was a popular figure who had a massive influence on public opinion, this only created the illusion of a mass movement. The radio was his greatest asset, but also his greatest liability, as the nature of the medium fostered the illusion of movement.

Abstract Name: **The role of COVID-19 in anti-Asian prejudice**

Terror management theory (TMT; Greenberg, Pyszczynski,; Solomon, 1986) states that reminders of death create the potential for anxiety, but a way to keep this anxiety managed is through cultural worldviews, self-esteem, and relationships. Cultural worldviews, like religion or political beliefs, involve having shared beliefs about reality that can provide a basis for self-esteem and a sense of immortality. TMT research demonstrates that reminders of death increase support for one's own worldview and hostility toward those with differing worldviews. For example, Germans reminded of death strongly preferred German products over foreign ones (Jonas et al., 2005). Reminders of death increase ingroup preference which increases one's sense of personal and group value. Recently the COVID-19 virus has caused both an increase in death reminders and prejudice, specifically anti-Asian prejudice due to stereotyped connections made between the virus and its origin in China. Comments tweeted by former President Trump calling COVID-19 the 'Chinese Virus' provide fuel for this prejudice. The present study investigates whether statements regarding the Chinese origination of COVID-19 heighten anti-Asian prejudice following reminders of death. To do this, half of the participants are reminded of their own death, while the other half are reminded of a control topic. Participants also read about the Chinese origin of COVID-19 or an article about COVID-19 that doesn't mention the origin of the virus. For the dependent variable, participants complete a measure of anti-Asian prejudice. The hypothesis for this study is that reminders of death will heighten anti-Asian prejudice for those participants who read the article mentioning the Chinese origin of COVID-19 compared to those not reminded of death or the Chinese origin of COVID-19. The results of this study will help us to better understand the causes and consequences of prejudice.

Abstract Name: **Free Radical Polymerization by a Direct Current Pin to Water Discharge Plasma**

This study is being done out of inspiration from previous studies that have used a myriad of free radical generating sources such as a radio frequency (RF) driven plasma or catalyst systems to produce industry useful polymers. This study will utilize a direct current (DC) pin to water glow discharge cold atmospheric pressure plasma (CAP) in its ability to generate silver polyacrylamide composites and copolymers of acrylamide and acrylic acid. These resulting polymers find applications in many fields such as waste water treatment and other vocations dealing with the production of artificial muscles, switches, memory devices, and etc. A set of spectrophotometry, such as proton nuclear magnetic resonance (HNMR) and fourier-transform infrared spectroscopy (FTIR), were conducted to confirm polymerization, copolymerization, and linkages between metallic cations; the results of such analysis is that polymer occurred to form the desired metal composites and polymers. Analysis of differing treatment times provided insight into the optimization of this system and inhibition zone tests confirmed the antimicrobial properties of silver polymer composites produced in this system. In conclusion, this system has shown to be capable in the production of metal polymer composites and polymers. It is recommended that further optimization to the system be performed to achieve higher yields.

Abstract Name: Development of a Pin-on-Disk Tribometer to Evaluate Advanced Materials and Lubricants at Elevated Temperatures

A tribometer is an instrument that measures tribological quantities, such as coefficient of friction, friction force, and wear volume, between two surfaces in contact. The first wear testers relied on Archard's law, where the wear rate only depends on load and sliding distance. A tribotester is the general name given to a machine or device used to perform tests and simulations of wear, friction, and lubrication which are the subject of the study of tribology. The current research project realizes three objectives: (1) to design and develop a new wear testing device capable of reproducing unidirectional reciprocating motion at high frequencies (5 to 10 Hz) and high temperature, (2) to validate the functionality of the new wear testing device by evaluating the influence of the unidirectional reciprocating motion at high frequencies and high temperature on the wear rate of advanced metal matrix composite (MMC) coatings and biomaterials intended for human joint replacements, and (3) gather experience in the design and manufacturing of different complex mechanisms. The proposed pin-on-disk wear testing device is modeled on the original design concepts of a basic pin-on-disk wear testing platform. The design incorporates an upper-bearing material (ball or pin) attached to a pin holder and a lower-bearing material or disk attached to a disk holder. The primary advantage of this classic arrangement is that any combination of candidate-bearing materials can be evaluated on this testing setup. In order to operate, the proposed device includes different components such as specimen holders for pin and disk, a motion system, a load system, and a heating chamber.The proposed instrument could be implemented as a universal testing device to perform tribological tests following the specifications included in different standards, such as ASTM G133 and ASTM F732.

Abstract Name: Evaluating the antioxidant properties of berberine metabolites using computational chemistry methods.

Free radicals are molecules that contain one or more unpaired electrons and can cause damage on the microscopic level in the human body. They can cause damage to DNA, cancer, and inflammations. These harmful free radicals can be naturally metabolized using the body's defense mechanisms to minimize their harmful effects. However, in today's world there are many external factors that can lead to an excess production of free radicals in the body. One way to combat this is to consume food containing natural antioxidants. Our research is focused on evaluating the antioxidant properties of the metabolites of berberine. Berberine is an herbal supplement that can be extracted from the plant, Berberis vulgaris, the common barberry. It has historically been used for treating gastrointestinal infections and can act as an anti-inflammatory compound in patients with diabetes. When berberine is ingested, it is metabolized into six different forms called metabolites. Density functional theory (DFT) level of calculations were used to evaluate the antioxidant properties of the six metabolites using Gaussian 09 software. The DFT geometry optimization and thermodynamic property calculations of the berberine metabolites were carried out using the B3LYP method and 6-311G (d,p) basis set in both gas and solvent phases. Gas phase bond dissociation energies reveal that the hydrogen energy transfer mechanism is dominant in two metabolites that contain one hydroxyl and one methoxy group in their structures. The single electron transfer, followed by proton transfer (SET-PT) and the sequential proton loss electron transfer (SPLET) mechanisms will be investigated, and the antioxidant properties will be compared among standard antioxidant molecules including vitamin C, quercetin, and gallic acid.

Abstract Name: **Finding the Right Words: Community Building Through Language**

When coming to college as a freshman, many people are leaving their homes and communities for the first time. For queer students, this can involve exploring aspects of their identity freely for in ways they might not have been able to before. But where do students find the space to do that? On this midsized public university in the Midwest, students carved out a space for themselves to co-create a queer community in a student led queer organization.This study examines how marginalized students form connections and social bonds through language and shared culture in this on-campus queer organization. All of these students identify as queer in someway and came to the organization for varying reasons, but many of them center around finding a place of community, and togetherness. This study draws on ethnographic tools such as observations, audio and visual recordings, and interviews to collect narratives and interactions the students have with each other.I am analyzing and explaining these interactions with queer theory by looking at everything as a text, including a meeting room and the meeting itself. Queer theory as a field of critical theory analyzes texts outside the heteronormative interpretation. I use queer theory to explain the students creating their own queer power dynamics while also using existing power dynamics to negotiate in-group and out-group in their hierarchy/democracy.These power dynamics and inclusion can be used to understand the power relationship in a peer-peer setting, and further research done on queer social relationship creation and maintenance.

Abstract Name: **Implementation of Raman Spectroscopy on Lithium-Ion Pouch Cells**

With electric vehicles becoming more mainstream and power companies moving to renewable energy, the need for efficient energy storage has exponentially grown over recent years. Lithium-ion batteries are currently the most efficient form of energy storage, and new battery technology must be developed to meet today's increased demand. One of the major challenges preventing battery development is a lack of research into how cells chemically evolve over time and under various conditions. In collaboration with battery research and development company, Electric Goddess, the proposed project seeks to learn about the internals of different cells through the implementation of Raman spectroscopy technique. This data will be valuable for battery research companies as well as corporations looking to the future of more sustainable and safe Li-ion batteries. The proposed outcome of this project is to gain a better understanding of the damage, state of charge, and chemical makeup of each cell.

Abstract Name: **Graphic Novelization: An Underused Form of Visual Communication**

Graphic Novels tend to be one of the most underused and underutilized forms of visual communication. This essay seeks to understand and take a look at graphic novels to show how Graphic novels have the ability to convey cultural and historical phenomena in graphic design both domestically and internationally through their storytelling characteristics. Graphic novels began in versions of visual communication known as cave paintings, petroglyphs, hieroglyphs, and more.These things were the first forms of storytelling as well and thus set the stage for graphic novels. Storytelling has always beena significant component of graphic novels as well as past forms of visual communication. This essay also reflects on the idea of incorporating storytelling in order to tell of the past.From there we can seek to understand how the impact of the first graphics contributed to the start of graphic publications, such as comic books, comic strips, graphic novels, etc. Graphic novels differ from their illustrative counterparts, but recognizing the differences is important as graphic novels can incorporate more detailed and more sources to convey the message of the creator. This essay is meant to educate and explore the research on the history of graphic novels and how they are relevant to the history of graphic design.

Abstract Name: **Discrepancies Between Cleaning Procedures in Medical Settings Regarding Clostridioides difficile Prevention**

Clostridioides difficile (C.diff), a common healthcare-associated infection (HAI), is a gram positive bacteria that causes life-threatening diarrhea (12,800 deaths in the US in 2017) especially in immunocompromised individuals. Patients who receive extensive broad-spectrum antibiotic treatment develop this infection and it is highly contagious in clinical environments. Despite it being primarily spread through exposure in medical settings, there are no standardized procedures between facilites on sanitizing surfaces after coming into contact with a patient who is positive for C.diff. The goal of this research is to compare cleaning procedures and determine which is most effective at killing C.diff on surfaces as it survives common disinfection due to sporulation. Surveys will be sent to various medical facilities nationwide inquiring about patient history, cleaning techniques, and follow up testing to see if the C.diff spores were eradicated. Following their responses, each procedure will be evaluated on its efficacy to eliminate spores based on CDC guidelines. After the research is performed, it will be evident by the variation of C.diff isolates between regimens that some policies are superior to others and there should be standardization between healthcare facilitesto better prevent the spread of severe HAIs.

Abstract Name: **Examining the Relationship between Air Quality Trends and Glycemic Outcomes Among Patients With Type 2 Diabetes Mellitus.**

Type 2 diabetes mellitus (T2DM) is a chronic condition caused by insulin resistance and metabolic dysfunction. T2DM is associated with many diabetes related complications, including heart disease, vision loss, and kidney disease. Long term exposure to ultrafine components of particulate matter with an aerodynamic diameter ≤ 2.5 μm (PM2.5) can cross the pulmonary alveolar membrane and direct inflammatory effects on target organs, leading to oxidative stress and increased insulin resistance. While several studies have identified a relationship between PM2.5 concentrations and onset of T2DM, few studies have examined the role of air pollution on glycemic outcomes after T2DM diagnosis. Continued exposure to PM2.5 may worsen glycemic control and metabolic dysfunction, contributing to poor glycemic outcomes and increased morbidity/mortality in individuals with T2DM. Therefore, the objective of this research was to evaluate the relationship between temporal trends in PM2.5 concentrations and glycemic outcomes among patients with T2DM in Davis, Utah, and Salt Lake Counties in Utah. Electronic medical record data for 143,434 individuals with an eligible ICD-10 diagnosis code for T2DM from 2010-2022 were selected for analysis. PM2.5 concentrations were extracted from the Environmental Protection Agency's (EPA) Air Quality System in Davis, Utah, and Salt Lake counties in Utah. The date of a patient's initial diagnosis was found and used to create exposure profiles for one year following diagnosis. Preliminary analysis was performed using a kShape time-series clustering with 12 clusters. This created a visual representation of individual exposure for one year following diagnosis, making patterns in air pollution exposure more apparent. Analysis is ongoing and it is hopeful that the results of this study will elucidate the role of PM2.5 concentrations on glycemic outcomes in patients with T2DM and may inform public health interventions to minimize air pollution and encourage better outcomes for individuals with T2DM.

Abstract Name: **Optimization of casein micelle nanoparticle formation using high-pressure homogenization**

Casein proteins are the most abundant proteins in milk. They orient themselves into micellar structures to create hydrophobic (water repelling) cores. When this protein structure is disrupted and then reaggregated the proteins can form nanoparticles. Different substances can be encapsulated inside these nanoparticles, which improves their stability and bioavailability. One technique known to induce nanoparticles to form is high pressure homogenization (HPH). In this research we used HPH with ethanol (EtOH) as a solvent at different concentrations and temperatures to find the optimal nanoparticle formation. We used absorbance to measure casein micelle dissociation. The control sample, with no HPH, at 65ºC had an average absorbance of 0.156±0.01 with 0% ethanol and 0.052±0.03 with 60% ethanol. This reflects the dissociation of casein micelles with a high ethanol concentration at elevated temperatures. At a HPH of 300 MPa and a temperature of 65ºC, the average absorbance with 0% ethanol was 0.126±0.019 and with 60% ethanol was 0.036±0.032. At 5ºC with or without HPH, the ethanol did not dissociate the casein proteins and showed possible aggregation, the opposite of what we were trying to achieve. The results of our experiments tell us that we achieved dissociation with HPH and ethanol, especially at higher temperatures and a higher ethanol concentration.

Abstract Name: **Topical Bacteriophage Treatment Against Common Epidermal Infections**

Bacteriophages have shown promise in killing resistant organisms and in controlling infections to antibiotic resistant organisms. Both S. aureus, specifically MRSA, and S. pyogenes are common in epidermal infections and their respective bacteriophages have proven effective in resolving epidermal infections. While broad spectrum bacteriophages targeting these bacteria have been assessed in topical administration, little research has been published on bivalent phage therapies. The aim of this study is to assess the efficacy of a mixture of S. aureus and S. pyogenes bacteriophages in treating common skin infections that may be resistant to topical antibiotic creams. Laboratory strains of S. aureus and S. pyogenes will be used in an in vitro model of skin infection, using epithelial cell monolayers, and will be treated with a combination of their phages. Effective phage dosing against combinations and concentrations of organisms will be determined through calibration curves. Calculations from these calibration curves will provide information about the optimal doses of the bivalent phage treatment and used to assess the ability of the phages to clear infection in the in-vitro skin model. The epithelial monolayers will have different groups assigned to them, namely: controls for both bacteria and bacteriophages, individual bacteriophages in a mixture of MRSA and S. pyogenes, and finally a mixture of both genera of bacteria and both groups of bacteriophages. Following treatment, supernatant and cell layers will be tested using a standard IL-36 ELISA and confocal microscopy to assess overall pathology and success of the phage treatment compared to that of the control epithelial monolayers. If successful, the bivalent phage therapy will show reduction of bacterial growth and tissue damage. This would provide insight into how bivalent phage therapies treat wound infections and how it may reduce future reliance on antibiotics.

Abstract Name: **Undergraduate Pedagogy in Augmentative and Assistive Communication: The Influence of Hands-On Experience**

Research question: This research investigated instructional practices in undergraduate courses to determine how hands-on experience influences undergraduate students' knowledge and skill in an augmentative and assistive communication (AAC) course.Contextualize: According to the American Speech-Language-Hearing Association (ASHA) 2020 Schools Survey of SLP Caseloads and Statistics, the percentage of SLPs who regularly serve nonverbal, AAC cases was 63.1%. There is a gap in the research that investigates teaching practices at the university level training students that contribute to knowledge and skills in AAC. Rosenshine (2015) says that experiential, hands-on activities should be offered after basic material is learned. Therefore, the aim of this study is to investigate the impact of high-quality instruction that embeds hands-on experiences with AAC tools and devices on the knowledge and skills of undergraduate students compared to a non-hands-on experience in an AAC course.Methods: Data was collected through a pre-survey, a post-survey, and at three checkpoints throughout the semester. All students received high-quality direct instruction for approximately one hour of the class. For approximately 50 minutes after instruction, half of the students in the class workedin a hands-on condition and half ina hands-off condition each in a separate classroom. Students who consented to participate in the study submitted their coursework anonymously with no presence by a co-primary investigator. Qualtrics surveys were completed after project work across the four data collection points. Conclusions: The researchers will present qualitative and quantitative data regarding the impact a hands-on experience has on undergraduate students' knowledge, skill, and perception of AAC tools and devices. It is anticipated that the results of this survey will connect teaching practices at the university level withthe knowledge and skills undergraduate students gain in an AAC course.The implications of this study may inform the benefit of hands-on experiences in undergraduate coursework.

Abstract Name: **Biological Investigation of Phenylboronic Acid Nitrogen Mustards induced apoptosis (Cell Death in Triple Negative Breast Cancer)**

Triple Negative Breast Cancer (TNBC) tests negative for the presence of hormonal receptors such as progesterone and estrogen receptors and excess human epidermal growth factor (HER2 protein). TNBC is unaffected by hormonal treatments that target these three growth factors. After diagnosis, there is less time than other cancers to treat TNBC. These characteristics of TNBC result in having poorer prognosis among all types of breast cancer. Therefore, there is dire need for a better understanding of the cancer and of potential drugs. Based on previous research, we have concluded that two Phenylboronic acid nitrogen mustard prodrugs, CWB-20I45 and FAN-NM-CH3 are effective in reducing tumor sizes due to prodrugs' enhanced activity in the presence of hydrogen peroxide (H2O2). Prodrugs are initially inactive that are then turned into active compounds upon metabolism. Inside cells, these prodrugs cause DNA cross-linking that ceases DNA replication and leads to cell death, making them superior to common chemotherapy drugs. Cancer cells have higher levels of reactive oxygen species (ROS) such as H2O2. The prodrugs are thus more selective to cancer cells and less toxic to normal cells. A series of in-vivo experiments determined that the prodrugs are safe in mice. To understand the drug's mechanism inside cells, we are investigating biological pathways by looking at protein expression levels, which vary in drug-treated cells. These proteins include tumor suppressor p53. This was done using RT-qPCR technique to amplify RNA upon extracting mRNA between cancerous cells that are untreated versus drug-treated.

Abstract Name: **Representation Matters: Communication Disorders in Children's Literature**

We are conducting qualitative research looking at the representation of communication disorders in children's story books. To begin the process of data collection, we searched for books using a variety of sources including: the Children's Core Collection Database using a list of communication disorders as search terms and limiting the search results by publication date, from 1998 to 2022.Upon evaluation of the database results books known to us were missing. We added to the database result books from booklists made by speech-language pathologists (SLP) found by internet searches, and individual articles listing children's books for children with communication disorders from the ASHA Leader and HuffPost. We gathered all the books together and eliminated any books that were not related to Communication Disorders or that were more than fifty pages long, leaving 175 books that can serve as useful resources for children with communication disorders and those who care for them. Of the 175 books 77 were about hearing disorders, 33 were about autism, 21 regarded language and cognition disorders, the remaining come from other speech and language disorders including, but not limited to, articulation and phonological disorders, stuttering, cleft palate, cerebral palsy and Down Syndrome. Our analysis is ongoing, during which we will examine the books and will describe the authors' features (e.g., person with communication disorder, parent, clinician); character representation (e.g., species, race, gender, disability etc); and major themes of the books (e.g., familiarization to therapy, building self-efficacy etc).

Abstract Name: **The effect of adolescent isotretinoin exposure on the hippocampus, stress coping behavior, and recognition memory**

13-cis-retinoic acid (Isotretinoin) is a commonly prescribed medication for the treatment of persistent cystic acne but has also been shown to cause depressive behaviors and suicidal thoughts in patients. The hippocampus is a brain area involved in regulation of the stress response as well as cognitive functions such as novel memory formation, and alterations to this area may be important to the development of symptoms following adolescent isotretinoin exposure. In the present study, we assessed the effects of adolescent isotretinoin exposure on stress-coping behavior and novel object recognition, followed by measurement of hippocampal dopamine D2 receptor expression and dendritic spine density. From approximately postnatal day (P)35 through P49, C57BL/6J mice were injected with 1 mg/kg of isotretinoin intraperitoneally for 10 total injection days. From approximately P50 through P52, mice underwent novel object recognition testing, followed by a 6-minute forced swim test on approximately P53. Brains were extracted for western blotting of dopamine D2 receptor density in the hippocampus and striatum, and Golgi-Cox tissue staining for analysis of dendritic spine density. To date, our results indicate an increase in immobility in the forced swim test, but no effect on novel object recognition, in isotretinoin exposed mice compared to controls. These results suggest that adolescent isotretinoin exposure is associated with depressive-like behavior in mice but does not influence hippocampal dependent memory formation. Ongoing research aims to correlate hippocampal dopamine D2 receptor expression and dendritic spine density with our behavioral results.

Abstract Name: **Luis Miguel and Mexicanidad in Boleros and Mariachi Music**

In Mexico, Mexicanidad is the essence of embodying Mexican culture through nostalgia, love, masculinity, and a strong display of emotions in how one lives. The music of bolero, a traditional love song in Mexico, and mariachi, Mexico's musical symbol of nationalism, are the artistic representations of Mexicanidad that reigned on radio stations and in concerts in the country. A contemporary singer that has made these two genres appealing to recent generations is Luis Miguel. While Luis Miguel began his career singing pop music, a genre that is far removed from the traditional culture of Mexico, his multiple bolero and mariachi albums are perhaps among the most successful in his career. In this presentation, I will analyze the ways in which Luis Miguel embodies Mexicanidad through bolero and mariachi songs. I will specifically compare Luis Miguel with two of the greatest bolero artists and mariachi singers of Mexico, Agustín Lara and Pedro Infante, respectively, emphasizing the different ways in which Luis Miguel embodies Mexicanidad in his videos and performances. I argue that despite Luis Miguel's early success with pop music, he was able to embody Mexicanidad through the emotional lyrics of his bolero music and his stage presence during mariachi concerts.For my analysis, I will concentrate on the similarities of Luis Miguel's song "No se tú" and "Solamente una vez" by Agustín Lara, underscoring elements of Mexicanidad within bolero. Regarding mariachi music, I compare Luis Miguel's version of "El viajero" with "Esta noche" by Pedro Infante.

Abstract Name: **The Performativity of Gender in the Concerts of Juan Gabriel and Harry Styles**

Mexican icon Juan Gabriel and British singer Harry Styles are both musical artists well-known for their remarkable careers in entertainment. They excel in their musical performances and have been publicized for their fluid movements, eccentric wardrobes, and playful audience interactions in concerts around the globe. Even though they are from different countries and a couple of generations apart, Juan Gabriel and Harry Styles have, over the courses of their careers, adapted their conforming, masculine displays of gender to disregard the norms of masculinity in favor of a more feminized performativity of gender. Each have adapted their gender performances, whether that be through the use of sequins or a simple hand on the hip, to accordingly reflect something more often associated with feminine standards. Using Judith Butler's notions of gender construction, I explore how Juan Gabriel and Harry Styles have performed femininity during their live concert performances. I analyze how their vivacious dances on-stage, colorful concert attire, and mirthful interactions with their respective audiences contribute to this feminized display of gender. By analyzing the mannerisms of these two pop stars, in this presentation, I will call into light the ways in which gender is something that is performed. Through glancing into the specificities of these two men's concerts videos, I show that Juan Gabriel and Harry Styles challenge social conventions and that gender can, indeed, be an act.

Abstract Name: **Smartphone Use on Well Being**

How has Smartphone use impacted the general well-being of people today? The Smartphone usage has certainly increased over the past generation. The use is so prevalent that nearly everyone from 9-99 has one. Questions regarding how this intense Smartphone use is impacting the overall health and well-being of society has been discussed across many different aspects of research. This research intends to study how Smartphone use impacts the physical, psychological, cognitive, and social well-being of individuals across the generations. Previous research tendedto focus on one aspect or another of well-being, for example sleep or academic performance (cognitive functioning) or anxiety (psychological functioning). The research is lacking when looking at the global health of an individual and its association with Smartphone use. Thisstudy will also examine the specific ways individuals are using the Smartphones as well as how much of their daily life is consumed by the use. A correlational analysis will be completed in the spring semester of 2023 to determine what factors are impacted by Smartphone use.

Abstract Name: **Growth curves of International Space Station- isolated organisms**

Biofilms are groups of microorganisms which cover surfaces by attaching to each other and the surface. These are advantageous to microorganisms as biofilms stimulate increased growth and survival of cells. Biofilms are concerning because they can cause obstruction and corrosion, especially in moist and submerged environments such as wastewater systems on spacecraft. NASA is interested in studying biofilms in space as obstruction of water systems can force a pause in operation of the International Space Station(ISS) water recycle system. Additionally, the microgravity environment aboard the ISS stimulates the growth of biofilms as well as antibiotic resistance of organisms. The nature of the biofilms aboard the ISS may pose health concerns to the astronauts working there. Research presented will include growth curves for organ-isms isolated from the ISS wastewater system. Four of the species are bacteria, Burkholderia contaminans, Cupriavidus metallidurans, Methylobacterium organophilum, and Ralstonia insidiosa and one of the species is a fungus, Lecythophora mutabilis. Growth curves presented will include these five organisms, both alone and in combination. Experiments feature a medium called ersatz, a culturing medium which was designed to represent the ISS wastewater system nutrient availability and chemical composition. Results of this project are important as they provide significant information regarding the organisms and how they interact. This information is useful to an ongoing Montana NASA EPSCoR project as it can explain how the interactions of the five species may affect the growth of the others. An example would be if multiple bacterial species grow more rapidly when in culture with the fungus, then targeting the fungus may help in mitigating biofilm growth. Additionally these results will allow for the organismal growth in future Montana EPSCoR experiments to be compared to a normal growth rate.

Abstract Name: **Exposing Sperm to Thalidomide Prior to Fertilization Results in Abnormal Embryogenesis in Sea Urchins**

Thalidomide, originally introduced in the 1950s for off-label treatment of hyperemis gravidarum, resulted in birth defects in approximately 10,000 children exposed in utero (1957-1962). Due to its anti-inflammatory properties and non-addictive nature, the U.S. FDA approved thalidomide in 1998 for treatment for leprosy and other diseases with inflammatory components. Clinical pharmacokinetic research indicated that thalidomide can be found in semen. Whilst the FDA classified thalidomide as unsafe for use by pregnant females, little work focused on the effects on embryos exposed to thalidomide through either sperm or semen. The FDA Thalidomide REMS program recommends males using protection for pregnancy prevention while taking the drug and for 4 weeks after stopping treatment. Sea urchin embryos serve as good model organisms for studying early embryogenesis. They are also sensitive to thalidomide. Previous research in this lab noted that sea urchin embryos fertilized with thalidomide pretreated sperm exhibit five times more abnormalities than controls. To examine this in more detail, we will generate a dose response curve for sperm pretreatment and observe embryos at 24-hours (gastrula), 48 hours (blastula), and 72 hours (pluteus) for malformations and other abnormalities. To evaluate teratogenesis compared to toxicity, we will evaluate cell viability and apoptosis comparing treated embryos to controls. We expect to find that higher concentrations of thalidomide sperm exposure will yield a higher percentage of malformations in embryos compared to controls. In addition, immunofluorescent cell dyes will be used to evaluate cell viability and apoptosis. We anticipate that embryos resulting from thalidomide pretreated sperm will exhibit differences in cell viability and apoptosis induced cell death compared to controls. This research addresses broader implications about the potential paternal contributions to teratogenesis.

Abstract Name: Racial-Ethnic Identity and Academic Success B

There is immense discussion on what helps orhinders academic success. A person knowing who they are, no matter who, tends to know what they want and how to get it. This is not different in the academic setting. There are many different levels of understanding who we are within the culture from which we come. This study aims to connect several components of identity development with the resulting success in college. The aim is to see how the level of connection with one's racial-ethnic group, awareness of the perceptions by others and how one's racial-ethnic group is seen through the lens of academic achievement will impact the overall success in college. Other areas of interest in this study include college experience and how it impacts the motivation to attend classes and involvement in on campus activities connecting the student to the college leading to academic success. The final area that will be considered in this research is the level of college preparedness of the student and how the family or culture contributed to that preparedness. Correlational analysis will be completed through data collection in the spring semester of 2023.

Abstract Name: Heavy Metal Accumulation onto Sediments in Northeast Iowa

Metal supplements are commonly added to hog feed to prevent post-weaning diarrhea and promote growth in piglets. The manure that is produced by the hogs is then injected into nearby fields, where leaching or erosion could cause metal loss to the watersheds. Metal cations transported in runoff could adsorb to surfaces of sediment particles, resulting in a change to the overall sediment composition and microbial communities. To determine if metal cations are adsorbing to sediment particles due to agricultural runoff, we quantified the metal composition of sediment samples from sites downstream of fields where hog manure is injected as well as controls in northeast Iowa. Measurements of acid-digested samples were done with ICP-OES and results were used to identify differences among sampling locations. These results can be used to understand the extent to which the addition of metals to animal feed has an effect on local environments.

Abbey Joyner

Abstract Name: **The Associations between Belongingness, Trust, and the Willingness to Donate to One?s Alma Mater**

Donations are a vital part of keeping universities up and running across the globe. Thus, it makes sense that universities have a vested interest in fostering relationships with students that will generate future donations. This study examines the degree to which feelings of belongingness, trust, and engagement in campus activities affect an individual's willingness to donate to their alma mater. The 72 participants in this study represent a diverse group of students at the University of Wisconsin-Eau Claire. The findings indicate that feelings of belongingness with the university and the belief that one can trust the university are more strongly associated with a willingness to donate. Engagement in campus activities was not significantly associated with a willingness to donate. Thus, we learned that while it is important for a university to provide opportunities for students to engage in campus life, the university should spend equal time fostering a sense of belongingness and trust with their students.

Abstract Name: **Business Model for a Food and Beverage Truck on Campus**

This presentation articulates about the different aspects of designing and launching a business model for a beverage and food truck at a college campus. It covers the specifics of the bureaucracy, regulations, and legal implications; the cost and benefit analysis, including start-up and operating costs; and the marketing study, considering students' interests and habits, and cafeteria operation hours. The business model provides an extended menu along with additional hours of operation past what the cafeteria offers. The business works alongside the campus cafeteria, not competing with it though. The business model also provides experience and skills for the members of our community. It plans on partnering with local non-profit organizations to get the labor needed to operate the food and beverage cart on the day-to-day basis, creating in this way job or internship opportunities for students and people who otherwise would have a harder time obtaining a first managerial, cooking, marketing, or in general, professional experience.In addition to describing how to operate a food and beverage truck, the presentation will also show how beneficial it will be in the long run for the students at a community college and the local community at large. We have funds to actually launch the project and we expect our presentation to be detailed enough as to help other campuses actually launch their own beverage and food truck staying within an initial budget of $20,000. The operational costs and the numbers needed to make it sustainable and profitable in the long run are also included.

Paji Yang

Abstract Name: **Remaking Culture: Hmong American Queer and Refugee Identities**

This current research project asks: What are the experiences of queer Hmong American young adults as they reimagine the concept “Hmong culture”? How do queer Hmong American young adults navigate themes such as identity, religion and spirituality, language, and marriage in ways that are empowering? This study utilized a methodology of targeted contact to recruit research participants. We reached out to personal contacts within our social networks using social media and email as methods to promote our research project. Drawing from qualitative interviews with six participants who self-identity as Hmong and LGBTQ within the Eau Claire and Minneapolis-St.Paul region, this study seeks to understand transforming notions of Hmong American culture and belonging in the United States. Qualitative analysis and close reading of interview transcripts allowed the researchers to establish prevailing themes, including religion/spirituality, sexuality, language, empowerment and resistance, and marriage, and their subsequent implications on Hmong culture and identities in the U.S. This study reveals that Hmong LGBTQ individuals experience constant erasure within their ethnic communities due to the historical nonexistence of terminology to name identities, and queer and sexual identities in particular. However, Hmong LGBTQ individuals have found ways to remake themselves in the diaspora by drawing upon their unique indigenous cultures and religion to maintain some sense of Hmong spirituality and language in their lives. Contrary to dominant narratives that communities of color may not be as “accepting” of gender and sexual difference, Hmong LGBTQ individuals reveal that they are actively seeking forms of belonging in their own communities in ways that are empowering. This study contributes to deeper understandings of changing Hmong communities in the U.S. by examining gender and sexual identities as they intersect with Hmong refugee identities.

Abstract Name: **Titan Providence: Autonomous Drone System utilizing AI and GPS for Navigation**

Data and analysis of information have become a crucial aspect of society’s current development, allowing accurate awareness of our environments, and benefitting maintenance, safety, and overall innovation. At the same time, the big data trend has grown in popularity, and the use of drones has also taken off to be considered valuable data collection devices. However, the control of the drone always lies with the pilot who uses visual tracking to determine its position and orientation. To overcome these issues, we propose an advanced technology that allows a drone to autonomously fly with little to no input from a human pilot. Differing from common Unmanned Aerial Vehicle (UAV) systems, Titan Providence implements AI vision with a GPS system, allowing for fully autonomous completion of a given “mission”. Our objectives for this project include the construction and design of the drone framework, adaptive pathfinding, and awareness, in addition to task assignments.To achieve our goals, we integrated a Raspberry Pi with a compatible flight control module with additional telemetry and peripherals docked on a custom quadcopter chassis that allows modularity and expansions in accordance with a task’s outline and requirements. By using these two systems in conjunction, we passively maintain the stability of the system through its inertial measurement unit (IMU) and individual multirotor electronic speed controllers (ESC), allowing further independence of the system’s microcomputer. Regarding autonomy, the Raspberry Pi hosts the machine learning platform known as Tensorflow lite which would allow the drone to recognize obstacles and relay this information to the flight computer to avoid them. We also plan to utilize OSMNx which would allow the drone to create routes through urban environments where extra care and consideration for the law, powerlines, and private property is needed.

Abstract Name: The Determinants of Business Cycles: An Empirical Examination of Competing Theories

The 2008 Financial Crisis came as a shock to many in the economics discipline, as well as to those in the general public. Despite being the deepest and longest economic slump since the Great Depression, most mainstream economists found themselves unable to offer a consistent explanation of its cause rather than " something bizarre happened". In contrast, some non-mainstream schools of thought have argued that they saw it coming and that they can offer insightful explanations of the Great Recession. Two of those were the Austrian and Post Keynesian. This paper lays out the basic Austrian and Post-Keynesian explanations of the business cycle and then shows how they employed these to predict/ explain the Financial Crisis. I then conduct an empirical test of each in an attempt to determine which appears to have the most support from the data.

Abstract Name: Estimating Settlement of Strip Footings on Soft Clay Stabilized with a Granular Trench

Research on foundation systems has brought increasing opportunity in the building construction sector for greater efficiency and accuracy in design. Available research development shows exploratory opportunity with a focus on quantifying the improvement offered by ground reinforcement through granular trench support in clay soils. Settlement analyses will be performed for a continuous strip footing placed on soft clay soil stabilized with a granular trench. The analysis software PLAXIS and LimitState:Geo will be used to develop models for evaluation and provide ultimate bearing capacity the along with settlement for considered configurations. Results from the theoretically developed model will be compared with published research for physical modeling and numerical method results in literature. The results will help the engineer to estimate the settlement when considering the inclusion of a granular trench beneath the strip footing. Design parameters such as trench depth, trench width, footing width, and friction angle of the granular material in the trench will be varied in this study to investigate their influence on the foundation settlement. Phase 1 of this research, which focused on quantifying the ultimate bearing capacity, was completed and concluded that these design parameters influence the design significantly. The current research (Phase 2) continues the investigation efforts of the various design loading parameters based on a set settlement. The models being used in the settlementevaluated used ratios of trench width to foundation width and then increasing the trench depth to width until the loading needed shows a plateau. With the addition of settlement, the engineer will be able to create a comprehensive foundation design for the problems in hand byaddressing the maindesign constraints: strength and settlement. As an availableresource, the results will provide progression in ability to accurately design reinforced foundation supports in building projects.

Abstract Name: **DOES PREFRONTAL CORTEX DAMAGE INCREASES PSEUDOSCIENTIFIC, CONSPIRACY THEORY, AND PARANORMAL BELIEFS?**

Many people hold beliefs that conflict with current evidence and general human knowledge. Epistemically suspect beliefs (ESB) can include propositions from pseudoscientific, conspiracy theory, and paranormal domains. Understanding the neural and psychological mechanics of why individuals endorse ESBs, such as the false idea that MMR (measles, mumps, and rubella) vaccines cause autism; may help mitigate the personal cost and negative economic impact that the general acceptance of empirically unsubstantiated claims produces, such as the billions lost to fraud. The False Tagging Theory (FTT) posits that the ventromedial prefrontal cortex (vmPFC) is critical for skepticism and doubt. Doubt of a proposition causes critical thought that leads to falsification of the proposition. Without doubt, the proposition goes unchecked and is accepted with little to no thought. When the vmPFC is damaged from stroke or tumor resections, individuals should have a general increased credulity toward propositions. Healthy individuals often have skepticism toward ESBs; doubt is often utilized upon mental representation of the idea and then is falsified later. The FTT predicts that damage to the vmPFC will reduce doubt toward ESB propositions resulting in an increased endorsement rate. To test our hypothesis, we used patients from the Patient Registry, Neurology Department, University of Iowa; we gave 9 patients with vmPFC damage, 11 brain damage comparisons or “other brain damage” (BDC), and 15 healthy comparison (HC) ESB propositions and had them agree or disagree on a 1-9 Likert scale. Results indicated that patients with damage to the vmPFC had increased ESBs relative to BDC and HC. These findings support the FTT and argue that the neural integrity of the ventromedial prefrontal cortex is necessary for skepticism toward claims that are unsubstantiated by current evidence and general human knowledge.

Abstract Name: **Deep learning Approach for Detection of Inferior Vena Cava Filters from CT Scans**

IVC filters (IVCF) perform the important function of breaking down blood clots. However, most IVCF are temporary, and delays in their removal can cause complications. Current tracking of temporary IVCF is performed manually,which can delay treatmentif the patient transfers healthcare providers.This study proposes apipeline to automate detection of IVCF.A patch-based 3D Convolutional Neural Network (CNN) is created using a database ofpatient’sabdominal CT scans. The data is preprocessed using normalization techniques, along with a window/level to enhance the brightness of dense materials, which makes the metal IVC filter easier to detect. The database is split into training and testing, and patches are extracted from each. A postprocessing step is performed on the segmentation, where neighborhood connectivity is used to remove small objects. The scan is then classified as either IVC or non-IVC if the number of positive slices is greater than our selected threshold.The model’s DICE score reached 0.93 for training and 0.81 for validation. The prediction pipeline was able to accurately detect scans with IVC filters 100% of the time. The false positive rate on scans from normal patients was also 0.The proposed IVCFfilter prediction pipeline requires lesscomputing power while providing high accuracy, therebyreducing the time needed to track IVCFin health records.

Abstract Name: Monitoring Particle Pollution Through Inexpensive Programmable Devices

Fine particulates in the atmosphere are a serious threat to human health and are typically emitted from a wide range of sources, including industrial activities. Breathing in fine particulate matter (PM) increases the risk for respiratory and cardiovascular diseases, resulting in millions of annual premature deaths around the world. Regulations and technologies for reducing the total mass of emitted particles less than 2.5 microns in diameter (PM2.5) have improved over the years, but spatial and temporal inconsistencies in monitoring techniques is a growing issue. This is especially true in low- and middle-income locations with little access to data that would support efforts to regulate local polluters. This study aims to assess the ability of inexpensive, open-source hardware and accompanying environmental sensors to provide accurate data for PM2.5 concentrations, particle counts in various size ranges, and meteorological conditions over time. Four low-cost Arduino microcontrollers were programmed to measure and store this data at desired intervals, and the results were compared to each other as well as to a research-grade device. The Arduino devices have provided nearly identical data at a single indoor location and are comparable to the reference device. Weather-proof setups were also constructed to contain each microcontroller with the objective of making PM2.5 measurements at an outdoor local source of PM, like a busy roadway. It is anticipated that the Arduinos will be able to characterize local PM2.5 sources at low cost and therefore demonstrate the potential for monitoring the environment more widely across communities for personal health purposes.

Abstract Name: Investigating the impacts of parasitism on herbivory & chemical communication in an insect herbivore.

Background and Purpose- Parasitoid insects are well known for their role as regulate herbivores though trophic cascades and in their ability to manipulate their hosts behavior. The presence of parasitoids has been found to influence communicative behaviors such as calling in crickets, however, little is known about how parasitism could directly affect communication within a species. In this study, we investigated how parasitism by Celatoria setosa [Diptera: Tachinidae] can affect the release of a pheromone - vittatalactone - and affect herbivory in Acalymma vittatum [Coleoptera: Chrysomelidae] adult beetles (SCB).Methods- Wild A. vittatum and parasitoid flies were collected from organically managed farms from June through August 2022 in the Finger Lakes region of upstate New York, USA. Male adults' beetles were directly parasitized in laboratory conditions. We then collected headspace volatiles from parasitized and non-parasitized beetles in groups of six for 72 hours three days post-parasitism. In addition, we measured leaf area removed in single parasitized and non-parasitized female adult A. vittatum every two days over ten days and analyzed the herbivory utilizing ImageJ software.Results- Parasitized male SCB produced less vittatalactone than non-parasitized beetles. We did however find that individual females parasitized consumed less leaf material than non-parasitized females two days post-parasitism and four days post-parasitism, and then consumed more leaf material than non-parasitized beetles six days post parasitism. Conclusions- The results highlight two dynamic changes in insect herbivore behavior in response to parasitism, suggesting that parasitoids may be able to disrupt communication signals in their hosts, thus disrupting sexual reproduction and aggregation behavior. This is the first study to explore the predator-prey like interaction between A. vittatum and C. setosa on behavior, which may play a role in integrative pest management of SCBs in the field. Key Words: Parasitoids, Parasitism, Insect Behavior, Chemical Communication, Herbivory

Abstract Name: The Joys and Challenges of Collaborative Research in the Arts: A Discussion Session for Faculty in the Fine and Performing Arts

Join faculty from the fine and performing arts for a conversation about the joys and challenges of conducting collaborative research/creative inquiry with undergraduates. You'll have a chance to talk with colleagues from different departments and institutions across the country about the unique perspectives that undergraduates bring to different arts disciplines, ways that collaborative research projects enrich our work as faculty, and the unique challenges we face in the arts when we involve undergraduates in research. Session leaders – Jennifer Chapman (UW-Eau Claire theatre) and Nick Phillips (UW-Eau Claire music) – will facilitate a structured discussion with the group. There will also be time for participants to bring specific questions for the group (such as feedback on a current project, or advice on a current challenge) and for participants to ask for/share ideas about future projects.

Abstract Name: Ground Penetrating Radar Analysis of Holocaust Mass Grave Site in Alytus, Lithuania

As many as 70,000 Jewish people were killed in the Vidzgiris forest located southeast of the city of Alytus in Nazi German occupied Lithuania from 1941 to 1944. Currently, several monuments stand in the forest memorializing those who lost their lives including one such monument constructed by the Soviet Union. Eyewitness reports suggest there could be mass graves located near the Soviet monument. This project uses ground penetrating radar (GPR) to investigate a site southeast of the monument. GPR is a tool that uses electromagnetic waves to create a view of the subsurface. GPR is an excellent tool for non-invasive geoarchaeology as it does not disturb the subsurface. A grid measuring 8m x 15.25m was cleared east of the monument in a vegetated opening in the forest. The gride was split into 32 lines with a 0.25m spacing and data were collected along those lines using a pulseEKKO Pro GPR system with an antennae frequency of 500 MHz and a 0.02m step size as measured by the on-board odometer. Topography of the grid was collected at 1m intervals using a Topcon RL-H5A self-leveling laser, LS-80L receiver, and measuring rod. The data is currently being processed and visualized using EKKO_Project V5 software. Based on analysis of the raw data in the field, there is an unnatural feature present in the southwest corner of the grid. Upon completion of data processing, it is anticipated that the unnatural feature will be interpreted as a burial trench. However, exposed wiring located about 10m northeast of the grid suggests more recent digging in the area, which could be the cause of the unnatural feature. GPR is and will continue to be a crucial tool in Holocaust research and will help to memorialize those who lost their lives to the atrocities of the Nazi genocide.

Abstract Name: **The Lesion Network Mapping Approach to Cognitive Neuroscience Research: Case Study of Discounting**

This study incorporates an emerging method of lesion analysis known as “lesion network mapping” (LNM) to explore functional neurological networks that are potentially implicated in temporal and probability discounting. LNM combines both anatomical lesion maps and functional connectivity data. Rather than performing analysis at the level of individual lesions as existing methods do, LNM considers each lesion as part of a functional network, which becomes the new unit of analysis. First, binarized focal lesion masks are used as seed regions in a normative functional connectome (FC) to produce correlations between the average BOLD signal in the affected area with each voxel in the functional scan. This is repeated for every image in the FC, with the results being combined to produce a lesion network for each subject in the lesion dataset. This data becomes the input to voxel-wise general linear models with discounting score as the response variable. Permutation testing is used to determine significance of results, which is accomplished using PALM (Permutation Analysis of Linear Models), an open-source software package. This approach overcomes some of the limitations of existing lesion-based research methods: it allows information to be obtained for areas in which there is no lesion overlap in the dataset, and conclusions can be more readily drawn about networks rather than individual regions. This project uses over 120 subjects from the Iowa Lesion Patient Registry in the Carver College of Medicine who have a mapped, chronic, focal brain lesion and have completed at least one neuropsychological task that assesses temporal or probability discounting. Functional connectome data is sourced from the GSP1000 Preprocessed Connectome, a publicly available subset of the Brain Genomics Superstruct Project, which contains resting-state functional MRI data for 1000 subjects. We discuss the process of data analysis for this project.

Abstract Name: **Heavy Metal Accumulation onto Sediments in Northeast Iowa**

Metal supplements are commonly added to hog feed to prevent post-weaning diarrhea and promote growth in piglets. The manure that is produced by the hogs is then injected into nearby fields, where leaching or erosion could cause metal loss to the watersheds. Metal cations transported in runoff could adsorb to surfaces of sediment particles, resulting in a change to the overall sediment composition and microbial communities. To determine if metal cations are adsorbing to sediment particles due to agricultural runoff, we quantified the metal composition of sediment samples from sites downstream of fields where hog manure is injected as well as controls in northeast Iowa. Measurements of acid-digested samples were done with ICP-OES and results were used to identify differences among sampling locations. These results can be used to understand the extent to which the addition of metals to animal feed has an effect on local environments.

Abstract Name: **Effects of seasonality on the infection intensity of the amphibian skin pathogen Batrachochytrium dendrobatidis on crayfish**

Batrachochytriumdendrobatidis(Bd) continues to be a major contributor to global amphibian declines and lowers the quality of life of manyother creatures. Bd is a chytrid fungus that causes mortality of many amphibians and is known to damage the gills of crayfish. As potential carriers of Bd, crayfish are likely a major source of moving Bd from one aquatic habitat to another. Such aquatic environments are essential for amphibian life history patterns. One way to test the overall health ofan aquatic environment regarding Bd is to measure Bd levels in potential carriers. Since the crayfish carapace is constantly interactingwith the external environment, it is a convenient location to take these measurements. However, periodic molting can impactthese levels and skew the results. A more reliable indication of Bd prevalence and intensity in the crayfish population can befound by measuring the Bd levels in the GI tract, as it is known to embed here as well.This project investigates the seasonal Bd infection prevalence on a local crayfish populationby collecting DNA with swabs(carapace and GI tract)and by confirming infection intensity with pathogen specific real-time PCR (qPCR).

Abstract Name: **mRNA expression analysis of a novel deregulated anthocyanin pigmentation mutant in the model legume plant Medicago truncatula**

Anthocyanins are flavonoid pigments that are produced by plants, which can be seen in leaves, stems, and petioles. Anthocyanins are responsible for the bright red color of strawberries, as well as blue, red, and purple pigments in flowers. Consumption of anthocyanins is linked to health benefits to humans, including prevention of neurological disorders, heart conditions, and some types of cancer. We are using a forward genetics approach to find genes that control anthocyanin pigmentation in plants. Previously, a novel deregulated anthocyanin pigmentation (dap) mutant was identified in the model legume plant Medicago truncatula. This plant is used for research as it grows quickly, and has a fully sequenced reference genome, allowing for better understanding of genetic information. In wild-type (WT) plants, anthocyanin pigmentation is visible as red spots on leaves. In the dap mutant, significantly increased red spots occur throughout top and bottom parts of leaves. messenger RNA (mRNA) expression analysis of biosynthetic and transcriptional regulator genes in dap mutant compared to the WT, using the reverse transcription quantitative real-time PCR (RT-qPCR) technique was performed. Total RNA was extracted from WT and dap mutant leaves and treated with deoxyribonuclease enzyme to remove any residual genomic DNA. Then, mRNA was converted into complementary DNA and used in RT-qPCR reactions. I will present data on the mRNA expression of several biosynthetic genes and transcriptional factor genes that regulate anthocyanin pigmentation. Results showed that several genes were significantly upregulated in dap mutant. Understanding molecular and genetic mechanisms of how anthocyanin pigmentation is regulated dap mutant will help us to develop agricultural crops with increased anthocyanin content through genetic manipulation for medicinal and nutritional benefits.

Abstract Name: Rehearsal Visualization Therapy: The Test of Following Directions Evaluation

Children with language and learning disorders often have co-occurring difficulties in remembering and following verbal directions. This is often due to the syntactic complexity of the directions along with the children's working memory limitations. Few research studies have examined the effects of therapy designed to assist children in improving their ability to follow directions. Due to the lack of research, speech-language pathologists struggle to find evidence-based practices for increasing children's direction-following skills. The current study examined the effects of a therapy called "rehearsal-visualization intervention" on children from 5.0-10.5 years of age. This intervention requires the child to repeat or rephrase the given instruction and to imagine the instruction as it was carried out and completed. Forty-five participants, who had been diagnosed with a language or learning disability, completed the intervention under the direction of speech-language pathology (SLP) graduate students in the public schools of Texas. Data collected by the SLPs was analyzed for changes in direction-following ability as measured by the Test of Following Oral Directions, an assessment to determine the difficulty of directions based on linguistic complexity. Pretest and posttest data from the participants indicated that 86.67% of the children demonstrated increases in the difficulty of the directions they were able to carry out. This suggests that rehearsal-visualization strategy training may offer an effective way to teach elementary-aged children to process and carry out difficult instructions.

Abstract Name: Optimizing Course Schedules with Linear Programming in Python

Scheduling classes is a challenging and time-consuming task. To make this process less time-consuming and ensure an optimal result, we are using Python and linear algebra. We are using the Cplex library to build a model consisting of an objective function and a system of constraints. The objective function represents instructor satisfaction with different courses and the constraints represent limitations such as the fact that one instructor cannot teach two courses at the same time. Our model can successfully use interval variables to optimize small example schedules. We will present results involving limits on the number of credits and preps a professor teaches, as well as the results of applying our code to scheduling math courses at UWEC.

Abstract Name: Just Another Pretty Face? How Physical Attractiveness Affects Memory of Same-race and Other-race Faces

Undoubtedly, we have seen somebody casually going by and instantaneously determining whether they are attractive or not. Intuitively, attractive faces draw attention; thus one would expect they are memorable. Past studies have shown that faces outside of one's race are more poorly remembered than faces within one's race, a phenomenon called the cross-race effect (CRE). However, if attractive faces have a memorable quality, perhaps highly attractive other-race faces are remembered just as well as same-race faces. Thirty-four White female students studied 48 faces that were White, Latino, Black, and Asian and were classified as High attractiveness, Average attractiveness, and Low attractiveness. Afterward, their memory of those faces was tested by intermixing the studied faces with 48 new faces. Each face was presented one at a time alongside survey questions where they responded via mouse click whether they remember seeing the face. Additionally, we used an eye-tracking device to determine whether attraction or race influenced how long they looked at a face while taking the memory test. The results were rather surprising in that we discovered that more participants tended to recall faces low in attractiveness more accurately than faces high in attractiveness. Unsurprisingly, White faces were more accurately recalled than all other-race faces. Moreover, there was an interaction effect between race and attractiveness in that the CRE occurred among faces low in attractiveness, but not faces average or high in attractiveness. While this result was predicted, it was expected to be due to improved memory for other-race faces. However, it was largely due to poorer memory for same-race faces. As for the eye tracking data, participants visually fixated more often on high-attractiveness than low-attractiveness faces during the test phase. This behavior is either a sign of highly attractive faces' alluring quality or participants' uncertainty about their memory.

Abstract Name: Development of a Wound Infection Detection Device

An infection within a wound is a devastating circumstance that can potentially turn a simple graze to a multi year long healing process. The latest methods for wound infection detection are cumbersome and time consuming. These practices often need to undress the wound and leave it exposed for a few seconds or up to an hour. Undressing a wound is counterproductive to the healing process and this small window of exposure can possibly result in an infection in itself. There is a need for a tool that allows for active infection detection that causes very little to no compromise to a wounds healing environment. The device we propose is placed amongst the gauze whenever a wound is initially dressed and implements an array of sensors to collect a wide range of data. The type of data we plan to collect is pH, pressure, moisture, and temperature. We also want to have an integrated RFID or WIFI module so that this data can be wirelessly collected from the device. The specific methods involved for this developmental project start with designing and testing the responses of multiple sensors in an infected wound environment compared to a healthy environment. This is done so that a reference point can be made when a healthy wound transitions to an infected wound. Currently, progress is being made towards gathering preliminary data and calibration of our sensors for our design. Although the project is still in its early stages, It will be beneficial to observe the outcomes from the system in simulated wound environments to provide a baseline for further research and applications.

Abstract Name: **Student Perspectives on Sustainability at Iowa State University**

Today's university students will face unprecedented environmental, economic, and societal sustainability challenges upon graduation. The Sustainability in Curriculum Change Project (SiC-CHANGE) employed focus groups and a student body survey to understand Iowa State University (ISU) students' perspectives on how well the curriculum and extracurricular activities are preparing them to address the various sustainability challenges that society faces. Although ISU has incorporated sustainability language into its strategic plans and actions over the years, we are not aware of any systematic efforts to assess the adequacy of the university's efforts to increase student knowledge and skills related to sustainability. This research project is a rigorous effort to learn from students about their interest in and their experiences with sustainability at ISU. Twenty-one students from select colleges participated in focus group discussions between October 2021 and December 2021, and 1,206 students responded to a web-based survey of juniors and seniors conducted between April 18 and May 16, 2022. Our sample represents all colleges offering undergraduate degree programs at Iowa State University. Most respondents placed high importance on addressing environmental, economic, and social sustainability outcomes articulated in the UN sustainable development goals. Students at Iowa State feel empowered to solve climate change issues in the future, but they want more courses that integrate sustainability into their curriculum. Additionally, students believe that public universities should be leaders in sustainability. Our results show that most students don't think Iowa State prioritizes sustainability in education or that they are leaders in sustainability. Survey and focus group participants suggested many ways that ISU could incorporate this topic into the ISU experience to better prepare students with the knowledge and skills needed to face present and future sustainability challenges.

Abstract Name: **Comparison of Calcium Phosphate and Liposome-based Transfection Efficacy in CHO-K1 Cells**

Chinese hamster ovary (CHO) cells are epithelial cells used in biological research and industrial production of recombinant proteins. Their popularity is due in part to high tolerance to changes in environmental parameters such as oxygen levels, pH, temperature, and cell density. Recombinant protein expression is a primary use for CHO cells, leading to the development of many protocols and reagents intended for DNA transfection. The combination of CHO cells' high tolerances to environmental parameters and commonly used transfection protocols provides a research opportunity to explore the mechanisms by which DNA can be transferred into these cells.This project explores the efficacy of transient transfections into a CHO-K1 cell line utilizing calcium phosphate and liposome-based protocols. The quantitation of the efficiency of each transfection method is determined by utilizing gWIZ-GFP expression plasmid. The growth rates of parental and transfected cells are first determined to time a desirable window for transfection. Fluorescence microscopy is used to illustrate transfection efficiencies. Data analysis of these two methods will provide insight into the best mode of transfection for future research as well as the possible development of a classroom laboratory experience.

Abstract Name: The Importance of African American Vernacular English

Higher education that studies American literature and American writers tends to exclude African American individuals from the praise, acknowledgment, and conversations surrounding important and transformative American literature– this is especially true for people using African American Vernacular English "AAVE". African Americans and their speech are often purposely excluded and viewed as invalid and unimportant on a large scale, particularly in the conversations surrounding notable and crucial American literature that is continuously taught and celebrated as groundbreaking and transformative. This paper, while anchored in the work of Danez Smith, will explore how African Americans counter this exclusion by purposely using aspects of their culture and AAVE proudly in their work. This self-appreciative work of African Americans isn't new, writers and poets such as Langston Hughes during the Harlem renaissance encouraged African Americans to be proud of their culture and speech, discouraging them to assimilate into social expectations. While examining writers from the past to now, I will look at how there is an understood goal and bridge between many African American writers regardless of time or location. The goal to be unapologetically and proudly African American. And to be specifically African American, an ethnicity and culture that is often diminished and invalidated in the larger conversations surrounding identity. AAVE is traced through their work, purposely being unexplained to those who do not understand. This reinforces their desired audience while simultaneously validating and acknowledging their own culture and speech. By exploring the importance of African American Vernacular English one is able to see the individuality, creativity, and intelligence in writing that otherwise would be overlooked because of the way someone writes or communicates.

Abstract Name: Improvement of Trauma-Informed Care for Women with MRKH Syndrome

Mayer-Rokitansky-Küster-Hauser Syndrome (MRKH) is a congenital disorder among biological females that is characterized by the absence or underdevelopment of the uterus, vagina, and cervix (Laggari et al., 2009). For most women, diagnosis does not occur until adolescence, most commonly in response to concern for not beginning to menstruate. This diagnosis can be disheartening for many women who have anticipated bearing children at some point in their life, because that is nearly unattainable with MRKH. Though this syndrome affects approximately one in 4,500 women, the research is scarce, and most have never heard of it before, including medical professionals (Morcel et al., 2007). It is not an uncommon experience within the MRKH community to be forced to explain what MRKH is when meeting with a medical professional. This and related experiences in the healthcare setting can be retraumatizing and can lead to healthcare avoidance. The current study investigates the relationship between negative experiences within healthcare settings and subsequent healthcare avoidance. I tested three hypotheses, (1) people with MRKH experience retraumatization at healthcare appointments, (2) this retraumatization is a universal experience, not limited to the United States' healthcare system, and (3) people with MRKH experience more healthcare avoidance than the general population. A sample of 163 participants responded to an online survey. Within this survey, participants named the psychological triggers associated with their diagnosis, rated the emotional impact of given scenarios related to the healthcare system, and reported their levels of doctor avoidance. Results highlight the ongoing psychological impact of an MRKH diagnosis by demonstrating the relationship between interpersonal interactions during medical appointments and subsequent healthcare avoidance.

Abstract Name: **Listeria monocytogenes: Survival of the Fittest**

Listeria monocytogenesis a foodborne bacterial pathogen that grows well at refrigeration temperatures. To determine survival for risk assessment and inactivation approaches, non-pathogenicL. innocuaM1 is used as a surrogate.The objective of this study was to determine the survival ofL. monocytogenes4b andL. innocuaM1 under soiled conditions at two temperature and humidity conditions.Dust particles containing these bacteria were inoculated on stainless steel coupons (to mimic food industry surfaces) and stored at room temperature or at refrigeration over 0 to 10 days. Bacteria were recovered after serially diluting ten-fold and surface spread plating on Tryptic Soy Agar plates. Each experiment was plated in duplicate and replicated thrice.L. monocytogenesat room temperature and 52% relative humidity (RH) showed recovery of 7.06±0.38 log CFU/coupon at day 0 and 3.97±0.72 log CFU/coupon after 10 days(~3.09 log reduction), whileL. innoculashowed recovery of 6.37±0.45 log CFU/coupon at 0 days and 3.42±0.23 log CFU/coupon at 10 days (~2.95 log reduction).L. monocytogenesat refrigeration and higher 83% RH showed recovery of 7.13±0.29 log CFU/coupon at 0 days and 7.0±0.58 log CFU/coupon after 10 days (~0.13 log reduction), whileL. innocuarecovered was 6.69±0.79 log CFU/coupon at 0 days and 5.87±0.21 log CFU/coupon after 10 days (~0.82 log reduction).Overall, both bacteria showed higher ability to survive at low temperature and high humidity. Low temperature, high humidity and dust particulates that trap microorganisms play key roles in survival ofL. monocytogenesand ability to transfer to foods.

Abstract Name: **Machine Learning Guided Investigation of Polymers for CO2 Separation**

Membrane separation is significantly more environmentally friendly and energy-efficient than other carbon capture methods; however, it has been found empirically that polymer properties are often negatively correlated and limited by the Robeson upper bound. Our objective is to efficiently find new polymers with competing properties past this bound, which can be effectively implemented with a machine learning (ML) approach. Polymer properties are predicted via regression analysis on data from literature and are then fed into a genetic algorithm (GA) as a property prediction function (PPF). The GA cycles through the following: 1) fragmented polymer strings are converted to fingerprints and fed to the PPF, 2) fragments are scored based on a fitness function, and 3) the fragments are combined, crossed over, and mutated. The GA is functional, and promising polymers have been predicted past the upper bound with realistic predicted property values. The most common functional groups discovered among the best-fitted polymers are pyridine-3,5-diyl and the combinations of arenes and azaarenes. Our current work involves algorithm tweaking and data collection optimization, and in the future we hope to experimentally test and/or simulate the properties of the most promising predicted polymers.

Abstract Name: **Effects of Olfactory Stimulation on Short- and Long-Term Memory of Vocabulary**

Scent has long been used as a strategy to improve memory for tested material due to the state dependence of memory. The purpose of this experiment was to examine how peppermint and rosemary odors affect participants' ability to recall and recognize a list of words. It was hypothesized that memory performance would be better after a short delay than a long one, which was found to be significantly supported for recall and recognition. It was also hypothesized that odors would increase memory performance for both time frames compared to no odor, which was not supported for recall or recognition. It was also believed that peppermint odor would have a stronger effect on memory than rosemary odor, which was also not supported for recall or recognition. Participants studied a list of terms and were first tested on recall and then on recognition from a word bank while exposed to a scent-free environment and peppermint scent environment, or a scent-free environment and a rosemary scent environment. They were called back to repeat the vocabulary tests two days later to examine their long-term retention.Investigating the role that odors play in the different forms of memory can evaluate the use of scents as a study aid in educational settings. This was the first known study to compare the effectiveness of peppermint versus rosemary as stimulating odors.Keywords: recall, recognition, memory, olfactory stimulation, aromatherapy

Abstract Name: **Analysis of human decomposition odor using Gas Chromatography Mass Spectrometry**

After death, the human body almost immediately begins to decompose. As tissues begin to breakdown within the vessel, putrefaction commences. This is the buildup of various gases within the body, causing it to bloat. These gases are typically called volatile organic compounds or VOC's. Different parts of the body such as muscles and organs, release different chemical compounds during the decomposition process. They seep into the soil around the body and float into the air as particulates. In order to collect these compounds, an air pump is used with charcoal sorbent tubes. The pump is placed next to a body at Western Carolina University's FOREST (Forensic Osteology Research Station) facility, and the air surrounding the body is pulled in through the pump. The air pump is set to 4.00 L/minute for 30 minutes. Once collected, the charcoal tube is taken to the laboratory and extracted with 2 mL of diethyl ether. After extraction for around 12 hours, the remnants are filtered into a vial and analyzed using GCMS (Gas chromatography- mass spectrometry). In the interest of finding comparable results, a cadaver pseudo scent is also needed. The pseudo scent is broken and placed into a weigh boat and then into a flow cell where it is sealed. The same procedure using the air pump and charcoal tube is followed. It is then analyzed using GCMS where it produced quite similar results to the many chromatograms that were found from previous air samples. Some of the compounds found in both the pseudo scent chromatogram and air sample chromatograms were heptane, dodecane, hexane and many other long carbon chains.

Abstract Name: **Oxidative Reactivity of Biomimetic Nonheme Diiron(III)-Peroxide Compounds**

Diiron(II) compounds of the anion of the dinucleating ligand N-EtHPTB (N, N, N′, N′-tetrakis(2-benzimidazolylmethyl)-2-hydroxy-1,3-diaminopropane) and the bridging anion (O2X) of either HO2PPh2, HO2PMe2, or HO2AsMe2 were synthesized. Upon reaction with O2 in MeCN at -40° C, these compounds form metastable O2 adducts previously described as (mu-eta1:eta1-peroxo)diiron(III) complexes with 1,3-O2X bridges. When warmed to -30° C, the O2PPh2-bridged peroxo complex irreversibly converts to a peroxo complex with the O2PPh2 moiety in a terminal position on one iron. The same effect can be produced by adding OPPh3 to the O2PMe2-bridged complex. The oxidative capabilities of these different peroxo species are compared with each other by reaction with various substrates. The effects of bridging O2X versus non-bridging O2X ligands are discussed, as well as the effects of electronic differences in the O2X ligands and the effects of coordinated OPPh3.

Kye Ponce

Abstract Name: **How Slavery and Racism are embedded in the Carceral System**

This Comparative Analysis is a comprehensive and analytical research project reflecting on facets of everyday life in the Justice System and the inmates of the United States. This project will go in-depth as to how there is a great disparity in how the mediatization of imprisonment in documentaries shows one story and the reality of what the former inmates experienced in their written autobiographies and bibliographies. This shows us how racism affects the systemic treatment and resources that the inmates and former occupants receive and how that also profoundly affects the community around them for the lack of them. It is a deeply investigative outlook on the experience within structures of incarceration, including placement, treatment, and structural inequality, and questioning the development of the prison system across the United States. Given the meager local and national documentation of the most vulnerable in the U.S., through this project, the aims are to bring together approaches from critical media studies to advance media that portrays the histories embedded across America, thus promoting the vital need for equity and justice among confined communities. This work charts a community often ignored with neglect in the carceral system.

Abstract Name: **The Effect of Bisphenol A (BPA) Substitutes on CD4+ T Cell Immunity**

CD4+ helper T cells are an important immune system cell. One key factor in the mediation of the immune system in general, and T cells in particular, is the female sex hormone estrogen. Abnormal estrogen levels are associated with a variety of conditions, including autoimmune diseases, and several types of cancer, including breast cancer. BPA is a well known estrogen mimicking compound, used in the manufacturing of plastics, epoxy resins, and polystyrenes. As the negative effects of BPA are becoming known, many BPA substitutes have been developed. While the effect of estrogen on T cells is well known, the effect of estrogen mimics like BPA is less certain. The aim of this research is to determine if BPA substitutes affect the differentiation and function of CD4+ T cells, and if they behave like estrogen in the body, to assess the safety of commonly used BPA substitutes. Murine CD4+ T cells were stimulated to encourage differentiation into T cell subsets Th1, Th2, Th17, and Treg. T cells were cultured with BPA substitutes BPAF, BPS, TMBPF, BHPF, and DD-70, as well as BPA, estrogen, media, and DMSO, for comparison and control. Cell viability and proliferation were not affected by treatment with BPA substitutes. ELISAs were performed in order to assess cytokine secretion. In proinflammatory Th1 and Th17 cells, BPA, BPAF and BPS were found to suppress cytokine secretion in a similar manner to estrogen. TMBPF, BHPF, and DD-70 did not affect cytokine secretion. In anti-inflammatory Th2 and Treg cells, BPA, BPAF, and BPS were found to increase cytokine secretion on a similar level to estrogen. TMBPF, BHPF, and DD-70 were found to slightly reduce cytokine secretion. This suggests that while BPAF and BPS are poor choices as substitutes for BPA, TMBPF, BHPF, or DD-70 may be safer, though certainly not perfect, substitutes.

Abstract Name: **The Case for Gross Art**

Mainstream art has, for centuries, been described as beautiful. These pieces are designed to make you feel good, however, art that is beautiful does not capture the breadth of human experiences and work that does not conform to the cultural “good” is often thrown to the side. There should be space on the mainstream stage of art that reflects the darker side of humanity. I argue that gross and disgusting art has value as it allows artists to show a side of the human experience that most try to hide. Reconciling with the harsher parts of the human experience can give us a more well-rounded view of life. Showing disgusting aspects of life can even be validating for people, especially those who must deal with that aspect on a daily basis. If enough gross art is produced it can destigmatize things like addiction, animal testing, and mental health problems making these things much more normal.

I propose an art piece consisting of a sculpture of a pig’s heart with quotes from Edgar Allen Poe’s “The Tell-Tale Heart” written on it displayed within a gallery. A sculpture of a pig’s heart is chosen for its anatomical similarity to a human heart. Additionally, a pig’s heart is chosen for David Bennett, the late recipient of a genetically modified pig heart in January of 2022, who survived for two only months after the transplant. “The Tell-Tale Heart” is chosen to harken back to more traditional art, although it will be carved into the heart and accentuated with paint simulating blood. The piece will be presented in a glass enclosure on top of a small pedestal.

Abstract Name: **"What Children Eat": Children's Dietary Recall Accuracy by Quantification Type**

Background: 18% of children in the state of Georgia are classified as obese. Assessing children's diets could share information on childhood obesity prevention and treatment. Obtaining the 24-hour dietary analysis from a child is particularly difficult due to children not displaying proper developmental and cognitive maturity levels. While information could be gathered by proxy from parents and guardians, only a limited amount of data can be collected as parents cannot account for what their child eats outside the home. Purpose: This study aims to understand if a child's meal recall accuracy, overall and by meal component, differs between those interviewed via quantified vs. non-quantified methodology. Methods Students at a summer camp serving the whole state of Georgia were selected to participate based on what BMI category they fall in (Normal or High). We observed them at meal time and, after 24 hours, interviewed them using a quantified or non-quantified method to recall what they ate at the last meal time to the best of their ability. Conclusion: The results noted participants interviewed via the Non-Quantified method have an Overall higher percentage of foods reported as Omissions and Intrusions. Among food groups, quantified interviewees had a more significant rate of intrusions from the dessert food group and a high number of omissions from the vegetable food group. Non-quantified interviewees reported a larger percentage of Beverages as intrusions and Desserts as omissions. This study concludes that delivering interviews using a quantified methodology provides better insight into what children eat.

Abstract Name: **Feasibility Checking for Intersection-tree Construction: Design, Implementation, and Evaluation**

The Intersection-tree makes it possible for highly efficient processing of rank-aware queries such as top k, rank, and kNN queries. The tree, unfortunately, is computation-intensive to build. A major computation cost is feasibility checking, i.e., given a domain space S and a pair of functions fi(X) and fj(X), checking if the intersection of the function pair fi(X) = fj(X) partitions S into two parts. The current solution applies the standard Simplex algorithm to compute the maximum and minimum values of F(X) in S. If the maximum is positive and the minimum is negative, the intersection indeed partitions S; otherwise, it does not. In this work, we argue that this is not necessary. For feasibility checking, all we need is to find out if there exist two inputs, X and X', in S such that fi(X) > fj(X) and fi(X') < fj(X'). Accordingly, we develop a new algorithm, referred to as Sign-changing Simplex, that searches toward the respective extremum and terminates the search as soon as the sign changes. We implement the algorithm and evaluate the performance with experimental settings. Our expensive evaluation shows that the new approach incurs significantly less computation overhead than the original one.

Abstract Name: **Trilingual families in the U.S. voice their experiences: Examining literacy practices and reviewing cognitive benefits**

Trilingual literacy practices in the United States have not been widely researched. It is hypothesized that there is a growing crisis in the field of humanities due to the failing efforts to promote language maintenance, diversity, and language rights. Families still live in the multilingual world of vanishing languages as many languages are dying, while many others are being marginalized (Skutnabb- Kangas et al., 2009). Additionally, when evaluating the benefits of trilingualism, most of the ongoing conversation has largely concentrated on theories of subtractive and additive bilingualism, which have recently been identified as inadequate to explain the complexity of a three-language development.The proposed research has two main foci: (a) to qualitatively examine empirical interview data of trilingual families in the U.S. to uncover complex language practices, and (b) to conduct a literature review to report the evidence of the effects on executive functions (EF) in trilingual children. Using a case study methodology, a group of themes will be identified from a pool of three virtual interviews conducted in 2022 in which parents voice their experiences of raising their children in a trilingual household while in the United States. Additionally, several databases will be accessed such as PubMed, Web of Science, and PsychINFO. Keyword generation will include executive functions, cognition, trilingualism, neuroplasticity, and protective factor.Preliminary findings suggest that children tend to lack a cultural context to both heritage languages when learning them in a monolingual society, which places many challenges when developing a clear self-image and identity. This research aims to uncover complex language practices that different trilingual groups in the United States experience as they are adversely affected by language marginalization and social injustice related to language differences. The goal is to help craft empowering linguistic identities that can help them develop trilingual competence in the US.

Abstract Name: **Investigation of the Effect of Nozzle Temperature on Tensile Strength of Reinforced and Nonreinforced Polypropylene in Fused Filament Fabrication Process**

Fused filament fabrication (FFF), a popular 3D printing method, is increasingly being used to create parts for service rather than simply for form prototypes. A primary advantage of FFF is the short lead time from design to realization of a part; this allows third-party users to quickly make parts for repairs. Commercially available filaments are made of a range of materials, including unreinforced or “neat” polypropylene, bead-reinforced polypropylene, and fiber-reinforced polypropylene. While manufacturers of filament rolls typically provide preferred printer settings (including nozzle temperature) it is valuable to understand the effect of nozzle temperature variation on part strength as well as the tradeoffs incurred with the usage of different polypropylene variants. Furthermore, the most readily available strength data refers to material that has not undergone the FFF process. Having specific information on the tensile strength of polypropylene variants subject to a range of manufacturing conditions will provide valuable design information for those who intend to create service parts from polypropylene via the FFF process.

Abstract Name: **Examining the Role of Excess Vitamin D and the Dopaminergic System in the Manifestation of ADHD-like Behaviors in Rats**

Vitamin D is an essential nutrient for many biological processes. Some neurodevelopmental disorders are associated with Vitamin D deficiencies, such as attention-deficit/hyperactivity disorder (ADHD) and autism spectrum disorder (ASD). There is an overall lack of knowledge in how total systemic Vitamin D levels affect behavior. The current study investigated the role that excess Vitamin D has in the manifestation of ADHD-like behaviors when the dopaminergic system is disrupted pharmacologically. Rats with elevated levels of Vitamin D will exhibit more hyperactive, ADHD-like behaviors in the open field and nest building tasks than rats with normal Vitamin D levels after receiving the DAT inhibitor, GBR 12909. Twenty-two rats (equal number males and females; 5-7 weeks old) received an oral treatment of either acute high doses of Vitamin D (2 mg/kg) or corn oil and either an intraperitoneal (IP) injection of saline or GBR12909, yielding four treatment groups. Each rat underwent testing in an open field, social preference, marble burying, and nest building tasks, with open field and nest building task data evaluated for ADHD-like behaviors. In the open field activity task, rats that received Vitamin D trended towards increased activity, indicated by greater distance travelled compared to control rats, but this was not statistically significant with the current power. In the nest building task, quality of nest (score of 0-3) showed no differences among treatment groups. There was a significant interaction between treatment groups and food consumed overnight during the nest building task with the Vitamin D group eating less than the control group. The overall behavioral results are trending towards significance in the predicted direction and further testing with additional rats should be considered. Additional molecular techniques will be used to measure the total vitamin D and dopamine levels in the brains of these rats.

Abstract Name: **Development of a Coffee-Based Toothpaste to Inhibit the Growth of Cavity-Promoting Strep mutans on Model Tooth Structures**

A previous study has shown that the antibacterial activity in Coffee canephora (C. canephora) extract is effective in reducing Strepmutans (S. mutans), the main bacteria to cause dental caries. This study showed that bactericidal effects on S. mutans were greatest with light roast C. canephora extract at 16% and 20% concentrations. The study showed a 4-log reduction of S. mutans compared to the control group in 3 hours, demonstrating that C. canephora is effective against S. mutans. However, this study reported that the plaque-fighting benefits of C. canephora are only available in black coffee, without the added cream and sugar that many coffee lovers enjoy. Toothpaste is used by people every day and provides an alternative method for C. canephora to interact with S. mutans. In order to help consumers reap the potential dental benefits of coffee in an alternative manner, would it be possible to include a C. canephora extract in toothpaste?My project focuses on growingS. mutansbiofilm in a lab setting and applying light roast coffee (at three different concentrations), green coffee, and chlorhexidinetreatments to the biofilm. After observing the preliminary effects of each of the treatments onS. mutans, the application of treatments will be repeated, but this time onS. mutans-coated hydroxyapatite tablets. Teeth are composed of hydroxyapatite, so these tablets will act as simulated teeth. The light roast treatment and concentration that is most effective at inhibitingS. mutanswill be put into a base toothpaste. This toothpaste will be applied to model teeth and compared to commercial fluoride and fluoride-free toothpaste to see if it is effective as another natural, plaque-preventing toothpaste.It is commonlymisconceivedthat coffee causes tooth decay, and the results of this study could assist in disproving this misconception.

Mike Sloane

Abstract Name: When is race a useful variable in research?

The use of race or ethnicity as a variable in social science and biomedical science research has had a long and tortured history. The history of social science research is replete with studies examining race as a variable. The issue of race and IQ is a notorious example where research has been coopted to support racial stereotypes, structural racism, and policies driven by majority groups. Genetic and biomedical research have not been immune from similar abuses and misuses. Given more advanced understanding of the complexity of social issues that include disparities and injustices as well as advances in personalized genomic medicine it is useful to pause to examine under what circumstances should race or ethnicity be included as a variable in modern scientific research. Given the preponderance of biased media, increased levels of intolerance and racial bigotry, and the polarization of attitudes on most issues related to inequalities and disparities, one has to ask what are the responsibilities of researchers to incorporate race or ethnicity as a variable and what additional constraints might they consider in how such information is reported? The implications for using race or ethnicity in the social and behavioral sciences will be compared to the implications for its use in biomedical sciences and health-related research.

Abstract Name: The (In) Expressibility of Pain

Since its publication, scholars have examined what appears to be every angle of pain in Virginia Woolf's novel Mrs. Dalloway - except for what would appear to be the obvious: the invisible pain that Woolf's characters such as Clarissa and Septimus suffer from. In her novel The Body in Pain, Elaine Scarry claims that pain is inexpressible, and to some extent that appears to be true in Woolf's writing, as the characters never express their pain directly, and yet I argue that Woolf also appears to have found a loophole to Scarry's argument, as her characters express their invisible pain through their actions, through objects, and through usage of the setting around them. This essay examines both Scarry's and Woolf's views on the expression of pain, how pain is expressed - or not expressed - in Mrs. Dalloway, using scholars such as Christine Froula, who looks at the novel as an elegy; and Karen DeMeester, who shares the true impact of trauma. Using these scholars and many more, we come to the conclusion that pain is not inexpressible, it is just hard to communicate and the person you are trying to express it to must be willing to see your pain, something that matters even today as people deal with invisible pain such as anxiety, depression, grief, and pain and mental illnesses much worse.

Abstract Name: **A Revised Typology of the Greek Middle Voice: A Case Study in the Septuagint of Esther**

While most native English speakers understand the active voice ("the chef cooked pasta") and the passive voice ("the pasta was cooked by the chef"), most are unfamiliar with the middle voice. The middle voice ("the pasta cooks") describes a sentence where the subject is neither fully the agent nor the patient. This voice, though rare in English, is common amongst world languages. Of a sample containing over 400 languages (Mattiola 2020), Inglese (2022) found that 105 contain middle markers. One of these, Ancient Greek, prominently features the middle voice. Yet Greek grammarians have only recently turned to linguistics to determine the functions of these verbs. Since Allen's (2003) work on the middle voice, most Greek scholars have utilized Kemmer's (1993) typological framework because it stands as the most comprehensive study of the middle voice cross-linguistically. Despite her contributions, her typology contains too many categoriesand over-emphasizes semantic domains thereby failing to provide criteria for identifying middle markers cross-linguistically. This has led Inglese (2022) to propose a middle voice typology that divides into two major categories: oppositional and non-oppositional middles, with specific subcategories. This paper will fuse Inglese's middle voice typology with Aubrey's (2016) work on middle voice morphology in Koine Greek, making this the first application of Inglese's typology in any language. This typology will be applied to the Septuagint of Esther by providing an analysis of its middle verbs and their functions. The book of Esther allows for a broader study of the Koine period than the New Testament affords. The Septuagint of Esther was written early in the Koine period, prior to the New Testament, and it contains six apocryphal additions. Two of these additions are stylized Greek compositions with a higher volume of middles (Domazakis 2021), making this case study a fruitful inquiry of the middle voice.

Abstract Name: **Analysis of the Parameter Space for a Discrete Analog of the Lotka-Volterra System Using the Framework of the Time Scale Calculus**

We are working on generalizing the Lotka-Volterra system of differential equations. This system of equations is commonly used to model predator-prey relationships. We are using the framework of the time scale calculus to discretize these differential equations and analyze solution behavior for a set of parameters. In our investigation, we are performing phase plane analysis and inspecting the lack of uniqueness in solution behavior. Our goal for this study is to find necessary and sufficient conditions on the parameters that yield various types of solution behavior. We also seek to determine long-term behavior for any initial condition.The time scale calculus is a framework that is used to extend and unify discrete and continuous analysis. It is often used to connect differential equations (where solutions have a domain in the real numbers—continuous) with difference equations (where solutions have a domain in the integers—discrete). The time scale calculus also allows for solving dynamic equations on other domains as well, which leads to results that do not have a direct analog in either differential or difference equations.

Abstract Name: **Measuring the Impact of a Dementia Simulation with Health Care Administration Students**

Problem: Worldwide, there are 50 million people living with dementia and with no treatment available as a cure for dementia, the impaired ability has been recognized as a priority for public health. Because caregivers spend so much time providing care, they may also receive detrimental effects on their psychosocial and physical health. This project focuses on identifying the effects on conducting a dementia simulation in pre-professional student training. Rationale Studies conducted on nursing students showed promising results of increased empathy and learning outcomes after completing a virtual simulation. Research on the effects of dementia simulation conducted on health care administration students has not been done. Results will determine the importance of implementing a hands-on learning experience in the training of health care administration students. Methodology: 34 students were brought into a PREP Room where they received instructions, simulation gear, and pre-simulation survey. Then students were led into a classroom in groups of 4 and completed a dementia live simulation. Once the simulation was completed, the researcher led students back to the PREP Room where students took off gear and filled out a post simulation survey. Responses from pre- and post-simulation questionnaires were collected and compiled into a single dataset to be analyzed . Results: The data collected is currently being analyzed by comparing results from pre- and post- simulation questionnaire results. Analysis of students' empathy and compassion for people with dementia will determine effectiveness of implementing virtual simulation into health care administration programs. Conclusion: If experiencing a virtual simulation of what it is like from the perspective of someone with dementia enhances learning outcomes for pre-professional students, there can be improved training provided for students who will eventually provide care for patients, thus, advancing towards better caregiving.

Abstract Name: **Perception vs. Reality: Understanding and Evaluating the Impact of Image Deepfakes over College Students**

Artificial Intelligence (AI)-powered Deepfakes are responsible for new challenges in consumers' visual experience, and pose a wide range of negative conse- quences (i.e., non-consensual intimate imagery, political dis/misinformation, financial fraud, and cybersecurity is- sues) for individuals, societies, and organizations. Research suggested legislation, corporate policies, anti-Deepfake tech- nology, education, and training to combat Deepfakes in-cluding the usage of synthetic media to raise awareness so that people can become more critical in detection when evaluating these contents in the future. To educate and raise awareness among the college-going students, this pilot survey study utilized both synthetic and real images over undergraduate students (N=19) to understand the human cognition and perception demonstrated by the literate pop- ulation in detecting Deepfake media with their bare eyes. The results showed that human cognition and perception are insufficient in detecting synthetic media with their inexperienced eyes and even the intelligent population is vulnerable to this technology. While Deepfakes are becoming sophisticated and imperceptible, it was observed that this kind of survey study can be beneficial in raising awareness among the population about the societal impact of the technology and may also improve their detection ability for future encounters.

Abstract Name: Does Monotropa uniflora Produce Grayanotoxin?

Finding new pain management therapies is important to mitigate the effect addictive opioids have on our society. One folk medicine that shows promise as a pain management tool is Monotropa uniflora. M. uniflora is a member of the Ericaceae family of plants, many of which produce a neurotoxin called grayanotoxin (GTX). The primary purpose of the experiment is to determine if the alcohol extract of M. uniflora effects MCF-7 cells in the same way as other Ericaceae family plants that produce GTX. Previous studies concerning M. uniflora were studying anti-microbial activity of the ethanol extract, among other solvents. The physiological effects of M. uniflora extract on human cell culture have largely been unexplored in western literature. By studying the dosage effect of the ethanol extract in human breast cancer (MCF-7) cells, the activity of M. uniflora extract can begin to be characterized via Raman spectroscopy. Preliminary findings suggest that the M. uniflora ethanol extract effects the MCF-7 cells independently of the ethanol solvent. Additional analysis is continuing to expand effects across time to determine if the cells are metabolizing the extract and solvent differently. Comparing Raman characterization between M. uniflora extract with characterization of GTX in MCF-7 cells will give further evidence to determine whether M. uniflora produces GTX and lend to future research determining if either are safe alternatives to opioid painkillers.

Abstract Name: Determining the Effects of Poly-A Tracts and Monovalent Cations on Nucleosome Unwrapping Equilibrium

Nucleosomes, composed of 147 base pairs of DNA wrapped around an octamer of histone proteins, play a role in gene regulation and cellular function by controlling access to the genetic information stored within DNA. The placement and movement of nucleosomes along strands of DNA is determined, in part, by the presence of homopolymeric stretches of deoxyadenosine nucleotides on one strand of double stranded DNA, commonly referred to as poly-A tracts, which are overabundant in eukaryotic genomes. The poly-A tracts exclude nucleosomes in a manner that depends upon the purity and length of the A-tract. We have previously shown that A-tracts adopt unique structures that are preferentially stabilized by specific monovalent cations. The exclusion of nucleosomes by these long A-tracts, greater than 15 base pairs, impacts the accessibility of nearby DNA. The equilibrium accessibility of DNA within the nucleosomes, determined by unwrapping and rewrapping rates, is also an important factor in regulating DNA dependent processes. The impact of short A-tracts, 6-8 base pairs, on nucleosome dynamics is poorly understood. Using competitive reconstitution and equilibrium FRET measurements in the presence of different monovalent cations, we have investigated how the length and placement of short A-tracts within the nucleosome affects the formation and equilibrium accessibility of the nucleosomes. We demonstrate that the same cations that stabilize the unique A-tract structure exacerbate the effects of A-tracts on nucleosome stability and equilibrium accessibility.

Abstract Name: **Musicianship Explored Through Mahler's Fifth Symphony**

Gustav Mahler's Symphony No. 5 represents one of the pinnacle orchestral works of the Romantic Era. In addition to its physically and emotionally demanding passages, it beautifully expresses the beauty, heartache, and pain Mahler experienced throughout his life. Therefore, when performing his music, musicians must be careful to understand the grief that was Mahler's muse and the solace he found in music. This thesis project aims to aid trumpet players in their understanding of the piece and its composer and assist in developing the technical and musical abilities necessary to perform this magnificent work. Description and Instrumentation: This thesis takes the form of a suite of solo trumpet and small trumpet ensemble pieces that are based on each movement of the fifth symphony. The first, second, and fourth require solo trumpet, the fifth is a duet, and the third is a trio.

Abstract Name: **Trauma and Transparency in True Crime Documentary Filmmaking**

In February 1981, 14-year-old Deanie Peters left her brother's wrestling match to use the bathroom and was never seen again. The cold case left the Michigan town of Grand Rapids shaken, and decades later residents still hope for justice. This story has been turned into ashort documentary film titled Not Without a Trace, which aims to capture how the Deanie Peterscase has affected the community. Throughout all aspects of production, relevant literature and true crime documentaries have been analyzedin order to avoid the ethical pitfalls that plague the growing genre. The research specifically examines how to navigate participant trauma and promote transparency in documentary filmmaking by pulling from sources across the fields of film studies, journalism, and ethical frameworks. This will result in an addendum to the Documentary Accountability Working Group framework for ethics that specifically caters to documentary students, along with a reflective paper that outlines how the ethical guide was used in the production of Not Without a Trace.

Abstract Name: **It's our Duty: Cortisol Level in Goldfish Feces and Mucus**

Stress can affect a fish's overall physiological health; environmental stressors can affect a fish's stress levels which may lead to complicated health and wellness. This is important especially for fish hatcheries. Cortisol is a hormone that regulates the body's stress response and can be studied to measure the amount of stress induced on a fish.The fish's first line of defense is the mucus coat. The mucus coat protects the fish against parasites and other invading organisms like bacteria and fungus. In this study, a comparison of stress caused by the different environment, water source, was studied on Carassius auratus, goldfish. The water source was the Rio Grande, tap water with AquaSafe, and a control using bottled Spring Water. Water quality was tested using the Vernier Labquest®2.0 (Beaverton, OR 97005 USA) to determine pH, temperature, and water turbidity. The 5 in 1 API Test Strips for fresh water was used to measure water hardness, nitrates, and nitrites. The average pH were 7.67, 8.125, and 8.2066 for the control, tap water, and Rio grande water, respectively. The control had a hardness of 30 ppm while tap water and Rio Grande hardness was at a consistent 180 ppm. Slime mucus and fecal matter of goldfish were collected to measure the Cortisol level throughout a 15 day period. Since the cortisol melting point is 220℃ and its boiling point is 566.4℃, the plan to use a gas chromatography to quantify the cortisol level in mucus and stool was not reasonable. Future analysis will be done using a Cortisol enzyme-linked immunoassay kit. Information from this research is beneficial in understanding the relationship between stress, cortisol level, and the environment a fish is maintained in.Key words: Stress coat, microbiome, cortisol, water quality, productivity, Rio Grande

Abstract Name: **Targeting the ATR pathway in Merkel Cell Carcinoma**

Merkel Cell Carcinoma (MCC) is a rare neuroendocrine skin tumor and the most deadly type of skin cancer currently identified. In the United States, 80% of the cases are caused by the integration of the Merkel cell polyomavirus (MCPyV) in the human genome. The MCPyV ST – EP400 – MYCL complex plays a critical role in this cancer by specifically activating gene expression. The MYC family oncoproteins including MYCL are general amplifiers of RNA production. The increased RNA production may overwhelm the splicing machinery and render MYC-driven cancer cells more dependent on the ATR-Chk1 pathway in order to mitigate RNA-DNA hybrid (R-loop) induced DNA damage and genomic instability. Furthermore, the EP400 histone acetylase complex is also involved in the regulation of DNA damage repair. Here, I use MCC cells that overexpress MYCL and EP400 complex components to investigate the sensitivity of cancer cells to ATR inhibition. I have found that an ATR inhibitor AZD6738 is effective at decreasing MCC cell proliferation. mTOR activation has also been suggested in MCC without extensive study. The PI3K-AKT-mTOR pathway is involved in cancer cell proliferation but is also essential for normal physiology, warranting the search for combinatorial approaches using mTOR inhibitors in cancer treatment. Given that both mTOR and MYC pathways are involved in nutrient sensing and cell proliferation, I tested whether MCC cells are sensitive to mTOR inhibitors in combination with AZD6738. However, the two inhibitors are antagonistic to each other. Further evaluation of the ATR and mTOR pathways in MCC would shed light on future therapies that can be developed for other neuroendocrine tumors or virally induced diseases.

Abstract Name: **Qualitative Study to Identify Factors Related to Job Satisfaction among Early Career K-12 Physical Educators**

It has been reported that 44% of K-12 teachers leave the profession in their first 5 years. Physical education (PE) is among those having difficulties retaining teachers. The purpose of this qualitative study was to explore emerging themes related to job satisfaction and dissatisfaction of early career PE teachers in the Midwest region. Using purposive and convenience sampling, eight early career PE teachers were interviewed over Zoom for 45-60 minutes on their perspectives on factors that would influence job satisfaction or dissatisfaction. Prior to the interviews, participants completed a survey on Qualtrics to obtain demographic information. The interviews were audio-recorded, and researchers transcribed the interview for qualitative analysis. Data were analyzed using categorical aggregation and direct interpretation. Researchers triangulated to ensure data trustworthiness. Five primary themes surrounding job satisfaction included: 1) relationships with administrators, supports, and school demographics, 2) co-worker relations and values, 3) PE teaching external factors (i.e., teacher salary, class sizes, class types, subs,; location of gym/office), 4) student relations and motivations; and 5) teacher attitudes and sense of autonomy.The five major themes resulted in the following suggestions for administrators to possibly increase retention of early career teachers: 1) provide intentional guidance and support; 2) hire PE teachers who are passionate; and 3) provide meaningful professional development opportunities. It is also suggested that PE teachers invest in developing professional relationships with coworkers and students. Future research should quantitatively examine the effectiveness of implementing interventions to improve PE teachers' job satisfaction and the decrease attrition rate.

Abstract Name: **Virtual Stories to Support Undergraduate Students in Developing Cultural Awareness**

The Human Library project is working to connect "human books" (people with unique experiences and backgrounds) to "readers" (people who want to learn and grow) to challenge what they know. Inspired by events held by The Human Library, this research aims to create an opportunity for undergraduate communication sciences and disorders students to grow and learn from those whose backgrounds differ from their own and apply it to their professional development. In this research project, stories will be created and presented online by graduate students, alumni, or other professionals who self-identifyexperiences related to diversity in the field of communication sciences and disorders. These stories will create a virtual library for the undergraduate students enrolled in a senior-level course on serving diverse populations. Undergraduate students will choose to review and analyze a story, generating a shareable presentation for the class and a personal reflection on the experience. To measure the effectiveness of this project on diversifying student cultural perspectives, a survey based on the American Speech-Language-Hearing Association (ASHA) Cultural Competence Check-In: Self-Reflection, will be given to the students before and after the story analysis project. After that, change scores will be calculated for statistical significance. Reflections will be analyzed for general themes to further explain student learning. The results of this study will reveal whether this is an effective pedagogical method for diversifying student perspectives on culture within the scope of communication sciences and disorders.

Abstract Name: **Titanocene(III) Catalyzed Radical Arylation of Diphenyl Amino Epoxides with Electronically Different Substituents**

The reaction being studied is a titanocene(III) catalyzed atom-economical radical arylation of amino epoxides to form indoline derivatives that are basic motifs of common antitumor agents. To maximize the potential of the arylation process, a thorough mechanistic study was carried out and it was determined that the catalyst is stabilized by a salt additive and the turnover-limiting step is the back electron transfer from the radical sigma complex to the pendant titanium metal. To further establish the synthetic scope of this reaction, the regioselectivity of radical addition to diphenyl amino moieties with electronically different substituents on the arene needs to be studied. However, there are no synthetic protocols for synthesizing these epoxides with electronically different substituents on the arene. In this study, diphenyl amino epoxides with electronically different substituents on the arene were synthesized using multiple steps and analyzed using FTIR, NMR, and GC-MS. Future studies will focus on running a titanocene(III) catalyzed arylation reaction with the newly synthesized epoxides, on a Schlenk-line under inert atmosphere, to investigate the regioselectively of radical addition.

Julia Prouty

Abstract Name: **Three Good Things: Families and The Power of Perception**

A national research study is being conducted to examine family happiness and the power of perception. The measure of happiness in families is predictive in a variety of health outcomes such as emotional and relational well-being, physical health, cognitive functioning, and life longevity. Happiness is seen as a protective factor, having an inverse relationship with depressive symptoms while promoting a better quality of life. Emerging as an adequate theoretical framework, the field of positive psychology has grown since its conception in 1998. Specifically, the field of positive psychology created and follows the 50-10-40 model of happiness, meaning that 50% of our happiness is derived from biological predeterminants (genes), 10% is from our circumstances (e.g., where you live, your job, etc.), and a whopping 40% from your actions or attitude (perceptions; things you can change). Over the last 25 years, the field of positive psychology has grown in general popularity with self-help books, articles, speakers, and workshops, but it is also supported by clinical data and academic rigor. This current study plans to leverage the 40% actions (perception) principle to test the positive psychology approved/created “Three Good Things” (TGT) exercise within a rural and urban American family sample. Other studies have revealed that using the TGT exercise has a positive outcome for alleviating depressive symptoms, enhancing college students’ well-being, and improving marital satisfaction. However, there are limited studies of this scope that strictly focus on the TGT exercise and American families. This mixed-method study intends to analyze the impact of the TGT exercise and find qualitative themes with a rural and urban American family sample through an online survey. The hope is findings from this study can be utilized to inform educators, clinicians, and policymakers as well as provide participants with a free evidence-based intervention.

Abstract Name: **Redlining and Health in Rochester, NY**

In 1933 the Home Owners' Loan Corporation Act created residential security maps of major cities that outlined mortgage lending risk; ranking neighborhoods as “best, still desirable, declining, and hazardous.” Neighborhoods considered “hazardous” were often redlined by lending institutions by denying them investment resources which worsened their housing and economic opportunities. This discriminatory practice wherein services are withheld from potential customers who reside in neighborhoods classified as hazardous to investment, referred to as redlining, has been a historic problem for the city of Rochester, NY. Most of the hazardous neighborhoods are those where racial and ethnic minorities, as well as low-income residents reside. Creating neighborhood rankings generated segregation between zip codes. This segregation has forged significant differences between territorial lines, especially speaking to health outcomes. Investigating how health outcomes materialize between zip codes is the research question at hand. This research acts as a tool for exploring health disparities produced by redlining practices. Using the social determinants of health as a framework for this research, the literature revealed the variability of economic stability, education, healthcare, neighborhood, built environment, and community context characteristics between the “hazardous” neighborhoods and the “best” neighborhoods. The findings outline clear health disparities when looking through this lens; people who reside within the lower ranked neighborhoods experience poorer health outcomes than those who live in the higher ranked neighborhoods such as. Redlined communities are more susceptible to mental illness, communicable and chronic disease, higher mortality, and lower life expectancy. These disparities have persisted for generations, creating a cycle of discrimination, poverty, and disproportionate health outcomes. A public health program, focusing on safe and affordable housing, is proposed for high-risk communities to mitigate the ill effects of redlining practices. By highlighting these inequalities and proposing this housing program, we strive to combat the larger issue at hand; systemic racism.

Abstract Name: **Next Generation Sequencing Analysis of miRNA Derived Musa sp.**

As the human population crosses 8 billion in 2022, food security has become a critical concern. Banana (Musa sp.) is a key crop for global food security as it is one of the few fruits that can grow year-round. It is under threat due to various biotic and abiotic stressors; it is imperative that we explore molecular metabolic regulators to develop resistance against the stressors and assist in crop improvement. Non-coding small RNA, especially microRNAs (miRNAs) in plants are known to regulate various metabolic processes in plants and play critical roles during their developmental phase and in responding to stress. Unfortunately, the small RNA library from Musa sp.is poorly explored and non-existent in miRBase, which is the most comprehensive miRNA library for various organisms. In this project, miRNA was extracted from the leaves of theMusa acuminata(AA) Higa cultivar and sequenced using Illumina next generation sequencing (NGS) technique. Raw sequencing data were cleaned and then analyzed with UseGalaxy and sRNAtoolbox to identify target genes, statistically analyze differentially expressed genes, and identify miRNAs unique to the plant. Sequenced miRNA data were annotated using the library of at least 90 plants present in the MirGene database. Data trends from the annotated species displayed high frequencies of mRNA or unmapped reads with a small subset of other RNAs left undefined. Reads were predominantly 17-18 nucleotides long and overall ranged between 15 to 39 nucleotides. The data was curated to analyze miRNAs within 17-25 nucleotides filtering out other non-coding RNA. Quantification of the raw genomic sequencing demonstrated successful hits with hundreds of thousands of reads mapped to mature and precursor miRNAs of various model plant genomes. Further quantitative analysis is underway to compare and contrast the results to the previously annotated miRNA derived fromMusa sp.

Abstract Name: **Soft Excess X-Ray Radiation from Black Hole Accretion**

A certain class of luminous galaxies hosting supermassive black holes (BHs) is known to exhibit the so called “soft X-ray excess” in their X-ray spectra. However, its physical identity and origin are yet to be understood. In this work, we systematically study a sample of 9 well-documented narrow-line Seyfert 1 active galactic nuclei (AGNs) by utilizing the archival XMM-Newton/Epic spectra in the context of general relativistic magnetohydrodynamic (GRMHD) model. In this scenario, thermal accretion disk photons (in UV) are Compton up-scattered by nonthermal energetic electrons in the hot downstream accretion due to shock compression, producing the observed soft excess. Our spectral model consists primarily of the shock Comptonization component and the underlying continuum including reflection from the accretion disk. Based on statistics, we successfully constrain the model parameters, most notably electron energy, effective disk blackbody temperature, and inclination angle θ, from which we would be observing the AGN, for a given BH spin. The disk temperature is commonly found to be ~ 10 eV and the electron energy ranges from ~ 75 - 160 keV (for Schwarzschild BHs) to ~ 126 - 232 keV (for Kerr BHs) depending on inclination. Our analyses imply that the characteristics of the observed soft excess are strongly dependent on the properties of the downstream accretion flow and BH spin.

Abstract Name: **Plant functional community assembly along a stress gradient in Northern and Southern Wisconsin forests**

Functional community assembly seeks to understand communities in terms of mixtures of functional traits. Stabilizing ecological selection can cause communities to have lower than expected trait diversity, while disruptive ecological selection can produce greater than expected trait diversity.Similarly, directional ecological selection can alter mean trait values. Environmental stress (e.g., low soil moisture) can reduce trait diversity, but the evidence is limited. Community assembly may be influenced by the spatial extent of the species pool and the spatial grain size of the sample plot. We sampled plants in 40 locations in Northern forests (mainly evergreen conifers) and Southern forests (mainly deciduous trees) across a strong gradient in soil moisture. Each location had three sample plots with three grain sizes: (0.1m^2, 1.0m^2, 10m^2). Four functional traits (two size traits and two leaf economic traits) were collected for every plant species. We used Monte Carlo simulations to estimate the amount of functional trait diversity and mean trait values that would be found if community assembly was caused by random ecological drift. The simulations used four species pool scales: regional (all observations), within Northern or Southern Wisconsin forests, within specific forest types, and within each forest location.With a large-scale species pool perspective, communities had lower than expected trait diversity, but with small-scale perspectives the pattern switched.Leaf size diversity was greater than expected using the smallest species pool.Moisture had significant effects on both trait means and trait diversities, but the relationships strongly differed in Northern versus Southern forests. Some results supported existing theory, for example dry forests tended to have more conservative leaf traits and also lower trait diversity in some cases. Functional community assembly differed in Northern versus Southern forests, and so there are unique assembly rules for each region.

Abstract Name: **Covid-19 Vaccine Hesitancy Among Latinas/os in the State of Arizona**

As the Corona Virus mutates, scientists are questioning how to effectively reach all communities and vaccinate the most vulnerable. I will be researching why the Latina/o population within the state of Arizona are hesitant to receive the vaccine and what can be done in order to reassure them to accept the vaccine and how medical racism within the medical system are to blame for the poor vaccination rates affecting the Latina/o population and covid misinformation. The vaccination of all groups is essential to ending the pandemic and preventing more potential mutations.This project will cover the sociological reasoning behind coronavirus vaccine hesitancy seen today among Latinas/os in the state of Arizona. Combining academic concepts on applicable theories to explain the current institutions in place and how they are failing Latina/os. These theories will delve into how the United States medical institutions bred environments for Anglo white Americans to advance medically at the expense of Black and Brown people. As a result of this past history of racist medical abuse, many are left traumatized and untrusting of institutions that had previously advanced at the expense of their lives. It will discuss intersectional issues within the social inequalities seen in the medical institutions of the state of Arizona. Next, this project will examine the findings of mixed method quantitative data on personal experiences and vaccine hesitancy among the Latina/o population focusing on fifty focus surveys and ten exit interviews. Finally, it will reflect on how the results and racist issues within the medical system are to blame for the poor vaccination rates affecting the Latina/o population and covid misinformation.

Abstract Name: **Nightcap**

This piece was composed over the past year for a trio consisting of clarinet, alto saxophone, and piano by recent UWEC alum Jack Ford. It was written for clarinetist Rafael Puga and saxophonist Nick Miskemen. Performing new works help move classical music forward by ensuring that fresh perspectives are being heard. It also celebrates the collaboration between composer and performers. The preparation of this piece goes beyond a practice room and rehearsals and requires communication by everyone involved. This piece has an unusual instrumentation as clarinet, saxophone, and piano repertoire is very limited, thus adding more music options for future musicians.

Abstract Name: **Planned Parenthood: Structural Evolution and Organizational Change**

If the voices silenced by Planned Parenthood could speak, what would they say? To address this question, the paper explores how the organization has continually centered the experiences of white women by placing stipulations on the definition of motherhood. Such definitions rely on models of Victorian domesticity. The work provides a historical analysis of the structures, both figuratively and literally, that the organization has implemented to bolster these ideals. This paper traces said values as they have transitioned out of once blatant white supremacist objectives into practices that have a more insidious effect on non-white women. By employing my first hand accounts, reviewing online reviews from Planned Parenthood patients, and delving into white feminist theory, this piece tells a tale that is wishfully forgotten. The research concludes multiple findings about the experience of women of color at the hands of Planned Parenthood. First, "educational" flyers, among other artifacts, produced by the organization permitted them to violate the reproductive rights of women of color by assuming sexual deviancy. Such an assumption was conversant with racial stereotypes of the era. Consequently, the establishment etched into the foundation of reproductive care the idea that women of color were fungible. This participated in other conversations about the role of said women in simultaneous contexts such as Jim Crow. Specifically, Margaret Sanger's population-control campaigns possessed rhetoric that resembled other problematic narratives about non-white women.By giving voice to the women who surrendered their reproductive rights to a non-profit that upheld white supremacy, society can better meet our moment. We can address our current desire to purify the nation, a desire that has shaped legislation into modern eugenics policy: the reversal of Roe v. Wade.The scholarship contributed to research on the history of Planned Parenthood and its role in current conversations around reproductive justice.

Abstract Name: **Shade and Flooding: How does it affect Mirabilis jalapa**

Environmental conditions, such as flooding and shade, have been suggested to have differential responses across species. Our study aimed to identify these favored conditions of the plant species Mirabilis jalapa. The treatments consisted of a combination of either regular watering or flooding, and shade or regular lighting; n=36. Results suggested that overall plant growth was diminished in the flooding treatment groups which included decreased plant height, shoot biomass and stem diameter, as well as significantly fewer leaves per plant. We also found that under the shading treatment group we saw increased plant height, shoot biomass and stem diameter, as well as more leaves per plant. Overall, we concluded that plants in the shading and regular water treatment group displayed increased shoot biomass and number of leaves. This evidence was supported in the study conducted by Raffo et al. who found that the leaf area and internode length increased in rosemary plants. This study may be further continued by shifting the focus to different types of soils including clay and sand as they will retain water differently and therefore interact with our regular watering vs. flooding treatment.

Abstract Name: **Modeling PCOS (Polycystic Ovarian Syndrome)**

Polycystic ovarian syndrome affects around 10% of women. Our project will expand on the existing mathematical modeling of female ovulation to create a model of abnormal ovulation, specifically looking at polycystic ovarian syndrome (PCOS). We are using mathematical modeling to learn about the real world and using a system of differential equations to study the properties of the mathematical expressions in our model. To do so, we are building on the research of Chen and Ward model and Hendrix model. Through differential and auxiliary equations, we have been able to graph the hormones involved with the menstrual cycle. Drawing a comparison between normal and abnormal ovulation will allow us to address the differences. Though a common treatment for PCOS is birth control pills, this is not the ultimate solution. There is not a definite biological cause of PCOS and not every person shares the same symptoms. Modeling the hormone system for PCOS has allowed us to make discoveries and recommend a different treatment, Metformin, to individuals of various age, race, and health status. This presentation will summarize the results of the CC-REU NSF summer REU experience (DMS-2050692) where these questions were explored.

Abstract Name: **The Effect of Immunotherapy on the Cardiovascular System**

Background: Target to background ratio of large arteries is an established method to study arterial inflammation. Immunotherapy in patients with cancer is known to induce inflammatory response in the body, and potentially can be detected using target to background ratio. Methods: We reviewed and analyzed 21 positron emission tomography (PET) scans of patients with cancer, both before and after immunotherapy. Values were obtained from the ascending aorta, descending aorta, superior vena cava, and left ventricle, using a method known as radiomics.Results: This study is still currently being conducted, as the data must be analyzed in order to make any further conclusions. The expected results would show stress being relieved on the heart once the cancer has been fully treated. Clinical Implications: This study will greatly influence the way physicians treat cancer patients, as well as help them understand the cardiovascular effect from immunotherapy.

Abstract Name: **Physiological Changes in Dienococcus aquaticus During Long-Term Stationary Phase Under Carbon Source Availability Stress**

There is a complicated interaction between a bacterium and its environment driving adaptation. Usually, bacterial physiology is studied during the exponential phase, but investigations during the long-term stationary phase are not as well understood. Here, we followed two strains of Deinococcus aquaticus in the long-term stationary phase in low and high-nutrient environments. The evolutionary trajectory was assessed through surveillance of cell viability, colony morphology, genomic content, and protein content over 54 days at three time points. We predicted that nutrient depletion and waste accumulation in the flask environment would result in phenotypic variation. Interestingly, there was an environmental shift toward a basic pH. Despite the shift in pH, cultures remained viable after 54 days. Differences among strains were observed in generation time, pigmentation, and colony morphology, among other phenotypic and metabolic characteristics. Divergence in extracellular protease activity was also observed throughout the study. Significant variation between samples equally subjected to the same growth conditions suggested that D. aquaticusis capable of short-term evolution under resource-scarce conditions.Our findings suggest that further research to evaluate variation in proteins as a carbon source is warranted.

Abstract Name: **THE IMPACT OF WESTERN FAST FOOD ON BMI IN CHINA**

Beginning in the 1980s, China has increasingly received Western influences over the last few decades, including the establishment and rapid expansion of American fast-food restaurants. This project will analyze the impact of two chains—McDonald's and Kentucky Fried Chicken (KFC)—on weight changes among China's population over a period of two decades. Previous literature used the China Health and Nutrition Survey (CHNS) to track several health factors, including increases in rates of overweight/obesity and body mass index (BMI), as well as changing diets and nutritional status of Chinese residents. Studies have also shown a positive correlation between the presence of Western fast-food restaurants and weight in certain neighborhoods. The data in this project will come from the CHNS, a longitudinal survey which involves the examination of food environments, physical health factors, and diet composition of the included participants, with a specific focus on the Jiangsu province. Data collection will involve mapping the locations of KFC and McDonald's from 1989-2019 in Jiangsu to visualize the development of those restaurants alongside any observed changes in BMI, overweight/obesity, and other health factors. This comparative analysis may reveal a correlation between the prevalence of Western fast-food restaurants and the shifting trends of weight and BMI in China's population. The results will guide future public policy approaches to improve the overall health of the population and to hopefully reduce the rise of non-communicable chronic diseases.

Abstract Name: **Advance in Mortality Modeling and Application to Life Insurance**

Life expectancy has generally increased worldwide: the global life expectancy at birth increased by an average of 6.5 years, from 66.8 years in 2000 to 73.3 years in 2019 (WHO, World Health Statistics 2021: A visual summary1). The longevity risk, from the perspective of an insurance company or a defined contribution plan, is the unexpected probability that individuals will live longer than anticipated and therefore potentially outlive their retirement asset. Improved models for mortality (and therefore life expectancy) forecasting give more accurate estimate of life expectancy and are undoubted steps in mitigating longevity risk.In this project, we first analyze several recent regression-based models for mortality and life expectancy forecasting (such as the Lee-Carter, the Renshaw and Haberman, the Age-Period-Cohort, and the Cairns-Blake-Dowd) using traditional extrapolative fitting techniques, such as principal component analysis, generalized linear models, and time series. In the second part of the project, we use advanced machine learning techniques such as neural network and decision tree to efficiently model mortality improvement and gain in life expectancy. Our future goal is to study the impact of mortality improvement on some mortality-linked financial products.

Abstract Name: **Data-Driven Real-time Infectious Disease Surveillance App and Dashboard**

With the continuous rise in the global threat of infectious disease, ad-hoc and active surveillance systems for have become powerful tools for monitoring the development and transmission patterns of fast-changing disease outbreaks, by public health officers. These surveillance systems typically track relevant epidemiological data such as number of cases, fatality rates, hot spots, and in most cases, evaluate the impact of public health intervention strategies in these locations. Currently, most disease surveillance systems are built by government organizations and are closed source. This study offers a modular, open-source, web-based dashboard program that is capable of visualizing and identifying epidemiological patterns for any infectious disease of interest, in real time. These visualizations can be in the form of GIS maps, bar charts, line charts, and metrics to track certain indicators. The program's source code is written in Python and uses the Streamlit library to manage both the frontend and backend of the application. Every aspect of this program is built with open-source software; allowing for other researchers and public health officials to adjust the surveillance system to track whatever disease they are focusing on. Given the systematic and timely availability of public health data offered by the CDC, this surveillance system is currently tracking the most recent Monkeypox outbreak in the United States. By visualizing the data related to the 2022 Monkeypox outbreak, the surveillance system can identify the relationship between public health interventions and the fall of cases in the US. Non-governmental organizations or other community-based groups can leverage on, and adapt this dashboard to monitor the spread of any new or quick-onset disease outbreak in their regions.

Abstract Name: **Assessment of the DNA damage and Cell Cycle Arrest of Saccharomyces cerevisiae exposed to Arsenic (III) Oxide.**

Arsenic is a metalloid that naturally occurs in the form of bioavailable compounds in many regions across the Rocky Mountain states. It is classified as an environmental hazard since its ingestion via contaminated drinking water may increase the risk of developing several types of cancer. The present investigation is a part of a project which utilizes a Saccharomyces cerevisiae-based model to study mechanisms of DNA damage and repair caused by exposure to arsenic derivatives. Our past research has demonstrated that a four-hour incubation of yeast cells with arsenic (III) oxide, administrated at 125Mand 250.0M concentrations cause moderate cellular toxicity. This was demonstrated by 44.0% and 70.0% rates of growth inhibition and approximately a 10.0% mortality rate. The goal of the present study is to investigate whether toxicity caused by arsenic (III) oxide treatment is associated with DNA damage. We further intend to analyze which genes and pathways are involved in the inhibition of proliferation that results from that exposure. DNA fragmentation will be examined using alkaline gel electrophoresis. The expression profile of selected genes of known role in cell cycle arrest will be assessed using Real Time-quantitative Polymerase Chain Reaction (RT-qPCR).

Abstract Name: **The Determination of Citalopram in the Kinnickinnic River from Milwaukee, Wisconsin**

Milwaukee Water Works in Milwaukee, Wisconsin last tested source water quality for pharmaceuticals and personal care products in 2005. According to the Safe Drinking Water Act, this testing is voluntary. In the current study, the concentration of citalopram in the Kinnickinnic River, one of three major rivers in the lake Michigan watershed, was investigated. Previous studies demonstrate low concentrations of these antidepressants affect aquatic life such as crayfish. To extract citalopram from the water samples, a procedure from the Journal of Chemical Health Risks (2013) was utilized. The procedure consisted of synthesizing magnetic nanoparticles (Fe3O4NPs) and modifying them with sodium dodecyl sulfate. The nanoparticles along with other solutions were dispensed into the water samples to allow for the extraction of citalopram. After separating the supernatant with a strong magnet, the clear solution was then analyzed at 239 nm with a UV Spectrometer. Although there was a concentration of citalopram detected, they had all been previously spiked with 0.78 ppm, in case the concentration of citalopram in the samples was not large enough to be detected with the UV Spectrometer. The data collected demonstrated concentrations of 0.27 ppm, 0.23 ppm and 0.31 ppm from three different locations. The spiked concentration was subtracted from the detected concentrations of each sample. After subtracting the spike, the numbers collected were negative, indicating a loss of the spike in each water sample. To conclude, the data came to be inclonclusive since there was some loss of the citalopram within the samples during the procedure. For future work, it would be recommended to investigate other extraction methods for citalopram from sample water.

Abstract Name: Impact of Caffeine Combined with Resistance Training on Post-Exercise Arterial Stiffness in Habitual Caffeine Consumers

Background/Purpose: Increased arterial stiffness has been shown as a marker of cardiovascular-related events. Previous research has revealed resistance training and caffeine consumption leads to increases in arterial stiffness independently. Therefore, the purpose of this study was to determine the residual effect of combining resistance training and caffeine on arterial stiffness in resistance trained females. Methods: This experimental study was conducted on 18participants between the age of 18 and 23yrs who were resistance trained in accordance to ACSM resistance training guidelines. All participants were habitual caffeine drinkers as defined by consumption of at least 200 mg/day, 5 days/wk. Pre-trial evaluation of 10-rep max was performed to determine individual training load for each exercise session. Subjects completed both caffeine and placebo conditions in a counterbalance fashion to avoid an order effect. Caffeine was administered during each trial a dose equal to 3 mg/kg body weight. Each condition was followed by an exercise intervention consisting of a full-body superset resistance training protocol. Measurements of arterial stiffness (pulse wave velocity, pulse wave analysis, and pulse pressure) were obtained using the SphygmoCor® system at 4 different time points (baseline, post-exercis, 10min post-, 20min post-, and 40min post-exercise). Results: A two-way repeated measure analysis of variance (within-subjects) did not indicate a significant difference in measurements of arterial stiffness between placebo and caffeine trials, but a time effect was revealed to be significant within both trials ($p = 0.008$). Conclusion: The results did not indicate a summative increase in measurements of arterial stiffness due to the combination of resistance training and caffeine consumption.

Abstract Name: The Impact of 12 Weeks of Adapted Dance on Balance, Gait, and Lower Extremity Function Among Persons with Dementia

Person's living with dementia commonly experience difficulty with mobility. Difficulties with these activities can lead to an increased fall risk, resulting in an increased loss of independence. Dance engages various parts of the brain including the cerebellum that is primarily involved in coordinating balance, posture, body positioning, and voluntary movement. An aim of this study was to assess whether 12 weeks of adapted dance improves balance, usual walking speed, and lower extremity function among persons living with dementia. An experimental design was used to randomly assign persons with dementia to either a 12-week adapted dance or social stimulation group. The convenience sample consisted of 12 participants, ages ranging from 62-97 years. The adapted dance is low impact where one foot is always in contact with the floor and is appropriate for older adults with cognitive and physical limitations. At baseline and at 12 weeks, measures of balance, gait, and lower extremity function were assessed. From baseline to posttest, the dance group had greater increased times for maintaining tandem balance (+47.5%) and faster times for usual gait speeds (+15.1%); compared with the social stimulation group tandem balance time (+0.98%) and usual gait speed times (+10.5%). A limitation of this study is the small sample size.

Abstract Name: Impact force due to a projectile passing through vibrating liquids

This experiment will analyze the effect vibrations have on an impact force of a spherical projectile passing through a liquid. The spherical projectile was dropped through water, olive oil, and linseed oil twice: once while the medium was vibrating, and once while it was not. The impact force is experimentally collected by a force sensor. The two impact forces with and without vibrations were analyzed to determine the effect of the vibrations on the projectile and the medium. The average force as the projectile passes through air was experimentally collected as 40.0±1N as the projectile passes through air and 13.8±1N as the projectile passes through water. The equations used to predict the impact force analyze the momentum at the time of impact, which relies on the viscosity of the liquid, the mass, and the radius of the projectile.

Abstract Name: Comparison of Epidermis Characteristics and Microbiome as a Result of Different Mask Type Usage in Young Adults

The Covid-19 pandemic has highlighted the importance of foundational disease control measures, including personal protective equipment; however, prolonged daily use of respiratory protective equipment can cause a shift in the skin's physiological properties. These changes are likely the root cause of “maskne,” mask-related acne, but not much is known about why these issues occur, and even less about the varying effects between mask types. This longitudinal study compares the effects of surgical masks and cotton masks on pH, temperature, moisture, oil, and microbiome of the facial skin in three areas (cheek, nose, and forehead). The epithelial characteristics of 12 individuals, 18-25 years of age, were analyzed before and after a duration of two weeks of wearing a mask for a minimum of four hours a day. A general trend of increases intemperature, moisture, and oil was found after the use of both surgical and cloth masks. Statistical analyses revealed statistically significant (paired t-test 0.05) increases in cheek temperature (+4.6% and +3.5%)in individuals that wore a surgical or a cloth maskrespectively. Moisture increased significantly at the cheek (+20.6%), nose (+15.8%), and forehead (+21.9%) with surgical mask use and only the cheek (+16.7%) with cloth mask use. The oil content increased significantly, as well, at the cheek (+21.6%), nose (+15.8%), and forehead (+21.6%) with surgical mask use and only the cheek (+17.3%) with cloth mask use. Neither pH nor microbiome quantity or diversity was shown to significantly change with regardto mask use. These patterns canexplain the physiology behind the increase in acne during the pandemic as well as provide insight intowhat can be done to prevent and treat these effects.

Abstract Name: Effectiveness of BAC Disinfectant or Probiotic bacillus Cleaner on Multispecies Biofilms

Biofilms on high-touch surfaces and water distribution pipes are a known contributor to bacterial transmission and infections. Biofilms are a mixture of bacterial cells encased by extracellular polymeric substances (EPS) and attached to surfaces. EPS can shield underlying cells from direct contact with disinfectants making these bacterial biofilms more tolerant than planktonic cells. Therefore, there is a need to understand how current cleaning procedures (treatment concentration, exposure time) affect biofilms formed on high-touch surfaces in workplaces and bathrooms. It was determined that the materials used to represent these high-touch surfaces would be polyvinyl chloride (PVC), acrylic, ceramic, and stainless-steel coupons. For this experiment it was essential to establish an effective, in vitro, and repeatable method of producing multispecies biofilms on the different coupons as they varied in material and size. This was done by fixing the coupons in agar and adding a multispecies media to the coupon and leaving it 24 or 48 hours to develop a viable biofilm. The purpose of this experiment was to determine the effectiveness of a benzalkonium chloride (BAC) disinfectant and a probiotic bacillus cleaner on a formed multispecies biofilm and if there is any regrowth on the coupon surface after treatment. The multispecies biofilm of three different pathogens that formed a suitable biofilm consisted of Staphylococcus aureus ATCC 6538 P, Pseudomonas aeruginosa PAO1, and Candida albicans ATCC 18804. The multispecies biofilm was removed either through sonication or Soya Casein Digest Lecithin Polysorbate (SCDLP) washing solution and then each pathogen was quantified on specific media after dilution. Treatment was found to be effective at reducing the amount of developed biofilm, but was not successful in its eradication which could be due to the treatment not effectively penetrating the biofilm and thus allowing for survival.

Abstract Name: Memory tests and microglia in a mouse model of Alzheimer's Disease

Alzheimer's Disease (AD) is characterized by amyloid plaque development and tauopathy, leading to crippling deficits in learning and memory. Most research has focused on how these amyloid plaques and tauopathy impact neurons in the hippocampus and cortical regions. The extent to which this pathology extends to other nervous system cells remains to be fully investigated. Microglia are a potential cell type contributing to AD pathology due to their accumulation around amyloid plaques. To investigate the changes that occur in microglia during AD progression, we compared wild type mice (JAX stock #101045) to 3xTg-AD transgenic mice (MMRRC stock #34830). This mouse line develops plaques and tauopathy beginning around 3-4 months. Mice were tested on an object location task and an object recognition task at early (7 weeks) or late (47 weeks) in development of the pathology. Briefly, mice were tested on behavior over three days, with one day for habituation to the apparatus, and then one day each for the object location and the object recognition tasks. Following behavioral tests, brains were removed and immunohistochemistry was performed to examine microglia (TMEM119 antibody) within the hippocampus and surrounding regions. Micrographs will be analyzed for the number and shape of microglia. Comparisons between wild type and 3xTg-AD mice and between the behavioral time points will be examined using T-tests and ANOVAs. This examination provides additional details on the development of the AD pathology in the 3xTg-AD mice and its contribution to learning and memory processes.

Abstract Name: **Jungfernhof: discovering a Holocaust burial pit using ground penetrating radar in Riga, Latvia**

Eleven kilometers south of Riga, Latvia, lies the remains of a former Holocaust concentration camp known as Jungfernhof. In December of 1941, ~4,000 Jewish people were transported to Jungfernhof to be killed and put into mass graves. What once was an execution site is now a well-used city park with no indication or memorialization of its past. Halakhah, a set of Jewish laws, forbid the disturbance of burial sites. Ground penetrating radar (GPR) is a nondestructive method of data collection, therefore, allowing research to be conducted while respecting Judaism. The main goal of the project is not to excavate, but to respect and commemorate those who brutally lost their lives at Jungfernhof.While conducting research at Jungfernhof using GPR, topography, 3D imagery, and survivor testimony, evidence of a potential mass burial pit was found. GPR emits electromagnetic pulses into the subsurface and when features such as pits are detected, the electromagnetic pulses reflect an anomaly in the data. A GPR grid 15m x 40m was laid down using tape measures. Using a Sensors and Software pulseEKKO PRO GPR system, 162 lines were collected every 0.25m. The data was collected with an antennae frequency of 500 MHz which triggered every 0.02m by an odometer wheel. The data was then processed using EKKO_Project software. The results show a pit anomaly 1.5m in depth. The 90° “corners'' of the anomaly indicate that the soil has been disturbed by humans.With the dramatic rise of antisemitism and Holocaust denial, it is vital that we use noninvasive methods to respect and commemorate those who brutally lost their lives during the Holocaust. The project will bring awareness to undiscovered evidence of the Holocaust and provide a sense of closure to those who never obtained it.

Abstract Name: **A Comparison of Alluvial Fills in Former Glacial Meltwater Stream Valleys in West-Central Wisconsin**

The Lower Chippewa River (LCR), a tributary to the Upper Mississippi River (UMR) in west-central Wisconsin, drained meltwater from the Chippewa Lobe of the Laurentide Ice Sheet and filled its valley with glacial outwash ca. 30 to 15,000 years ago. Then, as the region deglaciated, the UMR incised abruptly, initiating a wave of incision that progressed up the LCR in a prolonged and episodic manner (Faulkner et al. 2016). For this study, we examined the LCR’s two largest tributaries, the Eau Claire River (ECR) and the Red Cedar River (RCR), as part of an ongoing project to determine how incision propagated through the entire LCR fluvial system and to identify what controlled the incision process. The specific objective of our research was to ascertain the sedimentological characteristics of the alluvial fills in each river valley in order to determine if the fills are similar (as expected, given that both were meltwater streams that drained the Chippewa Lobe) or different. We accomplished this objective by kayaking each river, mapping the location of terrace cutbanks, and describing the alluvium exposed in them. Contrary to what we expected, we found the fills in the two valleys to be clearly different. While both are characterized by tabular cross beds of medium-to-coarse sand with rare gravel, along with planar interbeds of gravelly sand, gravelly sand interbeds are generally more common—and gravel-size clasts typically larger—in the RCR valley. We are uncertain why the RCR fills are coarser. One hypothesis is that the RCR was the larger meltwater river and able to transport coarser material away from the ice margin. Whatever the explanation, the differences in valley-fill sedimentology may have influenced the process of incision as it propagated up each valley. Future research should take these differences into consideration.

Abstract Name: **Social Perceptions of Suicide Among Sexual and Gender Minorities**

This is a replication and extension of Canetto et al.'s 2020 study on the normalization of suicide in sexual minorities. Suicide is one of the most prevalent causes of death in the LGBTQ+ community and thus we seek to examine what social messages are influencing this disproportionate rate. We also seek to gain insight into whether attitudes towards and experiences with suicide, suicidal ideation, and non-suicidal self-injury differ between sexual minorities and gender minorities. We have recruited over 2000 individuals (31.4% sexual minorities, 33.2% gender minorities) through social media advertisements, random email sampling, and snowball sampling. Following consent, participants read one of four randomly presented vignettes describing someone attempting and surviving a suicide attempt. Participants then answered a series of questions about their perspectives about the person in the vignette followed by a series of demographic questions. Approximately 45% of the sample reported having experience with suicide attempts or non-suicidal self-injury by themselves or others. Analyses will include running a series of ANCOVAs, controlling for social desirability, on participant views of the vignette individual's decision to attempt suicide and survival of a suicide attempt, and participants' degrees of sympathy and acceptability towards the vignette individual. Through this study, we seek to gain insight into whether perceptions of suicide differ between sexual and gender minorities and those who do not identify as a sexual or gender minority as that can inform public health campaigns focused on suicide prevention within this high risk group. Finally, we hope to gain insight into whether there is social pressure coming from the LGBTQ+ community to either engage in suicide, suicidal ideation, and/or non-suicidal self-injury, or alternatively if those actions can be attributed to outside factors.

Abstract Name: **Analyzing Data on Breast Mass Digitized Images using AI/Machine Learning Techniques to Predict Breast Cancer**

Breast cancer is the second leading cause of death in women. It develops in the glandular tissue of the breast, affecting the cells that line the lobules. The most crucial measures to stop breast cancer mortality are early detection and receiving cancer treatment. Despite the rise in medical research, there are still certain issues with cancer diagnosis. It is necessary to do a tumor's histological evaluation/microscopic examination of the image at the cellular level to determine its malignancy. The findings may vary depending on the subjective analysis/interpretation. Therefore, a computer-based diagnostic system is required for accurate diagnosis and early detection of breast cancer. In this study, we analyzed a breast cancer diagnostic data set from the Wisconsin Breast Cancer Database using the IBM Watson Machine Learning Platform. The data set consists of 569 digitized images of individual breast masses that contain cell nuclei information. Out of these 357, were classified as benign and 212 as malignant. The data set captured a range of cell properties, such as the radius, texture, perimeter, area, etc. that were employed as variables influencing the outcome. IBM Watson machine has the capability of developing models by using multiple algorithms. In this study, two algorithms with various enhancements were used including Snap Logistic Regression and Snap SVM Classifier with enhancements. Both algorithms reached an accuracy of about 97%. Some essential images' features include the product of various factors like area-worst, concave points, symmetry worst, smoothness mean, and perimeter worst. Since the overall diagnostic accuracy of the test is high, the model is very useful in predicting the diagnosis of a patient. This presentation includes a detailed analysis of the feature summary, ROC curve, and confusion matrices for various models and their implication in predicting the output results by categorizing the cancer cells as benign or malignant.

Abstract Name: **Exercising AI/ML Techniques to Determine the Likelihood of Developing Diabetes in Individuals**

Diabetes is a chronic disease characterized by elevated levels of blood glucose, damaging the heart, blood vessels, eyes, kidneys, and nerves. Preventive strategies and receiving medical treatments can mitigate the harms of this disease. AI//ML techniques can be utilized to predict the risk of developing diabetes to avoid further complications. Traditional analytical techniques may not be able to analyze large amounts of data related to diabetes, so AI/ML techniques are preferred. Among various platforms, IBM Watson Studio is readily available for developing ML models. In this work, we have used IBM Machine to develop ML models that can predict diabetes in individuals while taking into account their health features. The CDC dataset was collected from Kaggle; it consists of around 250,000 samples with 22 different features, such as BMI, smoking status, cholesterol, high blood pressure, etc. IBM Platform selects algorithms to model the problem in an automated fashion to provide optimized results. In this case, XGB Classifier and Snap Random Forest Classifier were selected to develop ML model. XGB classifier is favored when the dataset is large and performs well on structured data. Snap Random Forest is equally suitable for our dataset as it highlights for accuracy and is quick to build. The model based on XGB Classifier gave a prediction accuracy of about 85.4%, whereas Snap Random Forest Classifier predicted the outcome with an accuracy of 85.2%. This work aims to highlight the advantages of using Machine Learning and the specific models used to assist in diagnosing diabetes as well as predicting future outcomes considering different features of the patients. The final analysis will incorporate the medical aspect of various prominent features that were selected in this study and will elaborate on the confusion matrix, ROC curve, and related summary effects.

Abstract Name: **On Some Properties of Higher-Order Rectangular Numbers**

A pronic number is a number that is the product of two consecutive integers, that is, a number of the form n(n+1). The study of these numbers dates back to Aristotle. They are also called rectangular numbers. In our study, we explore some interesting properties of higher-order rectangular numbers. The n-th rectangular number of order h, Rh(n), is a number of the form n(n+h). In this terminology, the pronic numbers are rectangular numbers of order 1. Motivated by the properties of the first-order rectangular numbers, we investigate if similar properties exist for rectangular numbers of an arbitrary order n. Although both of these numbers share most properties, some properties of the first-order numbers are seen to be significantly different than their higher-order counterparts. In this study, we explore and motivate these results and propose a couple of conjectures to be studied further.

Abstract Name: **The Effect of Tactile Augmented Insole Stimulation in a Sequential Pattern on Healthy Walking**

The soles of the feet are the only body surface that make direct contact with the environment, thus are a critical source of information with respect to environmental navigation while walking. Several studies have indicated that plantar sensitivity is correlated with balance, which would imply that it plays an important role during gait. While research has been conducted to examine the effects of plantar cutaneous stimulation, very little research has investigated how specific patterns of tactile stimulation may affect walking balance and gait patterns. The aim of this study was to determine how sequential vibro-tactile stimulation to the plantar surfaces of the feet affects walking balance and symmetry during different walking tasks in healthy subjects. Various dynamic balance and gait characteristics were measured using force plates and a motion capture system. Stimulation patterns included no stimulation, sequential circle stimulation and reversed sequential circle stimulation, each collected at level incline, 5-degree incline, and 10-degree incline. Stimulation patterns could be causing a change in foot placement area but are not overly affecting other dependent measures. The reversed sequential circle stimulation caused the greatest decrease in foot placement area relative to the other two patterns at all inclines. With further investigation, these results will help to clarify which pattern of stimulation causes the greatest effect and how such responses could be beneficial in rehabilitation for individuals with decreased plantar sensitivity. Overall, this study will help in the further understanding of the effects of plantar cutaneous stimulation in healthy adults and potentially translate into rehabilitation methods for stroke survivors and other patients with decreased plantar sensitivity.

Abstract Name: **Critical Dynamics in the Emergence of Agency**

As adults we understand that our actions can affect the world. Less clear is how we become aware of our causative powers in infancy. This study aims to capture and describe the dynamics of the emergence of agency, action towards an end. The mobile conjugate reinforcement paradigm provides an experimental window into this process. Infants begin the experiment as detached observers, but when one of their feet is tethered to an overhead mobile, infants may discover their ability to move the mobile. A sudden increase in movement rate is proposed to mark a moment of agentive insight (Kelso, 2016; Kelso; Fuchs, 2016). Sloan (2022) collected 3D movement data at 100 Hz from 16 babies (age: M = 100.33 days, SD = 15.57) and calculated cumulative displacement of the tethered foot during infant~mobile interaction. This was differentiated twice across 1-min.-wide intervals with 10ms shifts (using the Matlab function movingslope.m) to produce 1-min. changes in movement rate (acceleration). We will apply linear regression to cumulative displacement in the minute preceding and following the infant's peak acceleration to explore dynamics related to agentive discovery. We predict that the magnitude of fluctuations will be greater before maximum acceleration than after since fluctuation enhancement is a hallmark of complex systems nearing phase transitions (Kelso, et al., 1992). Identifying mechanisms underlying the emergence of agency may help develop an array of novel treatments as aberrations in agency are involved in movement disorders (Kranick, et al., 2013) and mental illness (Szalai, 2016; Jeannerod, 2009).

Abstract Name: **Application of Gradient Boosted Decision Trees for Understanding Predictive Factors of Depression**

Background: Depression affects 300 million people globally and is a leading cause of disability1. Methods to identify patients with depression and understand predictive factors for its development are vital. Machine learning (ML) can be a powerful tool for this. XGBoost, which is an implementation of the gradient boosted decision trees algorithm, is particularly applicable. This study explores a unique application of classification-based XGBoost for understanding predictive factors of depression from nationally representative survey data.
Methods: This project utilized National Health Interview Survey (NHIS) data from 2020, with 31,568 responses. Data was preprocessed to eliminate features with excessive homogeneity. XGBoost was applied to create ML models that could predict the occurrence of depression in an individual (target variable), as determined by if the respondent was prescribed antidepressants. Feature selection was applied to determine which other respondent characteristics were closely correlated with depression. To ensure the best accuracy, randomized hyperparameter search was conducted. The results from confusion matrices assisted in guiding the optimization. The respondent features were selected on the basis of a feature importance threshold. Results: Figure 1 depicts how many respondents were accurately classified. The 1s represent the occurrence of depression, while the 0s represent the opposite. Those areas in which the true label and predicted label match significantly outweigh those in which the labels do not. The model has a Precision of 0.94, a Recall of 0.95, and an F1 Score of 0.94. Some features that the model relied on most to make its prediction were whether respondents: took anxiety medication, took sleep medication, received therapy in the last year, and could afford balanced meals. Discussion: Researchers can utilize this methodology along with these predictors to approximate whether patients have depression directly from medical records. This can be useful for guiding new provider-

Abstract Name: **Location of cartoid body oxygen sensors in the Alligator mississipiensis**

This research sought to identify the location of the carotid bodies in the Alligator missisippiensis. Biologists are interested in alligators due to their evolutionary success and distinct physiology. Their unique cardiopulmonary system has been researched, yet to date little has been published about the exact location of alligator carotid bodies. In humans, carotid bodies detect changes in blood levels of CO2, O2, and H+ and help maintain blood-gas homeostasis. Carotid body dysfunction can cause congenital central hypoventilation syndrome (or Ondine's Curse) and other forms of sleep apnea. Alligators are useful as a study model for understanding the evolution of blood-gas regulation in terrestrial vertebrates since they have changed little in the last eight million years. Further research on their vasculature and carotid bodies may help researchers understand how to treat certain human carotid body related diseases. Prior studies have determined that the carotid bodies in mammals are typically located at the bifurcation of the internal and external carotid arteries found laterally in the neck. The authors hypothesized that alligator carotid bodies would also be located at the bifurcation of the internal and external carotid arteries, although in alligators, this bifurcation is located on the posterior surface of the skull. Methods used in this study included vascular dissection of seven juvenile, female alligators, vascular casting, and Kluver-Barrera histological tissue staining for identifying myelin. The researchers' results showed that myelin was located at the bifurcations of the external and internal carotid arteries, indicating the likely presence of nerve fibers from the glossopharyngeal nerve and carotid body. Interestingly, as suggested by prior CT scans of alligator vasculature, the researchers also confirmed via direct dissection that the branching patterns of the left and the right carotid arteries were asymmetrical in the alligators studied.

Abstract Name: **The Intersectionality of Entrepreneurship and Latinx Critical Theory: Promoting Access to Credit for Latinx Entrepreneurs of Construction Companies with Alternative Methods of Financial Reporting**

Disproportionate outcomes exist in entrepreneurship based on the identity of the founders. While the Hispanic/Latinx population accounts for 19% of the United States population, Hispanic/Latinx owned businesses account for only 5.8% of all businesses. We are especially interested in understanding how a Hispanic/Latinx identity impacts entrepreneurial outcomes in the low-barrier industry of construction. Since many studies explore the obstacles and barriers in education for Hispanic/Latinx students, this paper explores the challenges in accessing start-up capital in the form of credit. This study collects data from the Utah Department of Occupational and Professional Licensing to estimate the number of contractor construction companies owned by Hispanic/Latinx founders. We also use the contact information in the dataset to distribute an IRB-approved survey on all construction contractors in Utah. The survey collects firm data and owner demographic data. Using Python, the firm and owner demographic data will be used as independent variables for a regression analysis to predictthe challenges forHispanic/Latinx construction companies to access credit. The findings of our research provide alternative methods of financial reporting and credit risk assessment for promoting Hispanic/Latinx entrepreneurship in construction and solving the shortage of affordable housing. Currently, our study is being reviewedby the Institutional Review Board (IRB) at the University of Utah.

Abstract Name: **The Literature of Siu Kam Wen and Julia Wong Kcomt: Disrupting Universalism in Perus Popular Narratives**

Peru has the largest population of Chinese people in all of Latin America. In Peru, “Tusán” describes the identity of Chinese Peruvians or Peruvians of Chinese ancestry. Many Chinese and Tusán writers, artists, and politicians have shaped the Peruvian historical and social landscape. Yet, Peru’s national narrative ignores Chinese contributions. Tusán families began emerging in the 1870s but would not be acknowledged or given racial category by the Peruvian government until the 20th century. Scholar Isabelle Lausent-Herrera argues that this lack of acknowledgment signified that Chinese-Peruvians had no real place in Peruvian society.Historians Elliott Young and Jason Chang argue that constructions of Latin American mestizaje and national belonging relied on anti-Chinese racism. My presentation aims to complicate popular narratives of what it means to be Peruvian and Tusán by engaging with the literature of two important contemporary writers: Siu Kam Wen (b. 1950) and Julia Wong Kcomt (b. 1965). While Siu Kam Wen explores the Chinese diaspora within the border of Peru through the “immigrant consciousness,” Julia Wong Kcomt’s poetry conveys her cosmopolitan vision between borders. Both authors explore diasporic identities, Peru’s xenophobic history, and disrupt Peru’s national Eurocentric narrative by presenting their own decolonial and alternative knowledge which has emerged from their Asian-Peruvian experiences. References: López-Calvo, Ignacio.Dragons in the Land of the Condor: Writing Tusán in Peru. Tucson: The University of Arizona Press, 2014, p. 5-8.

Abstract Name: Evaluation of prefrontal cortical circuits in an animal model of social phobia

Social phobia is a chronic anxiety disorder in which individuals suffer irrational uncontrollable fear during social interactions. Despite its high lifetime prevalence (~12% U.S. adults), little is known about the neuropathology of this detrimental condition. In this study, we are implementing a novel mouse model to evaluate the involvement of brain circuits formed by the prefrontal cortex (PFC), which have been previously shown to tightly regulate fear and anxiety. We already validated the mouse model, known as social fear conditioning (SFC), in which mice received mild punishment (0.40mA electric shocks for 1s) every time they social interacted with a social stimulus (another mouse confined to an adjacent cage). After a single training session with just a few punished social interactions, the experimental group developed a strong reduction in social behavior and a significant increase in anxiety-related behaviors such as freezing and avoidance, compared to the control group that did not experience social punishment. We are now examining the contribution of distinct subregions of the PFC – namely the infralimbic (IL) and prelimbic (PL) cortices – using an optogenetic approach which allows us to silence neural activity in the discrete brain regions. Preliminary results show IL silencing does not affect social fear learning. While IL seems trivial, a recent study suggests that PL may play a more prominent role for social fear learning (Xu et al., Neuron 2019). In addition, we are examining the contribution of key PFC inputs, such as the ventral hippocampus (vHPC), which has been implicated in several forms of fear learning, anxiety, and social behavior. Overall, this study has the potential to provide novel insights on the neural circuits promoting social fear learning and the development of social phobia in humans.

Abstract Name: Bringing Math off the Page with 3D Prints

The future of using 3D printers to improve visual learning is now. The constant struggle for educators to ensure that students are retaining information long term can reach a turning point by using manipulatives in the classroom setting. Using manipulatives in the classroom would promote active learning and have students further engaged in their courses. Harvard is the leading university into this idea by using 3D prints in their high-level math courses. Having math courses, especially Calculus, being the most failing subject in the country the proposal of 3D printed manipulatives to improve engagement and visual learning has shown promise in passing grades and long-term retention. This new way of learning can show students how math does not always have to be on paper but can now be in the palm of their hands. This can help achieve the goal of shifting from short-term memory to long-term memory in different level math courses. Active learning with 3D printed manipulatives is an essential part of any successful math course and that can be improved with this new growing technology.

Abstract Name: **Fostering Creative Inquiry on the Two-Year Campuses: A Discussion at the Confluence of Humanities, Sciences, and Academic Support**

As undergraduate research is a high-impact pedagogical practice, offering our students opportunities for meaningful and creative inquiry and guiding them as they undertake that inquiry is especiallyimportant on the two-year campus. Some of our students will graduate with an associate degree, meaning that this is the only chance they will have to do this work. Others will transition to four-year institutions, where they will need to be prepared for higher-level research when they arrive. At the same time, two-year colleges present unique challenges in supporting undergraduate research and embedding it into the curriculum. This panel will share some of the challenges faced by students, faculty, and staff in our two-year colleges from three perspectives—the sciences, the humanities, and academic support—then guide a discussion about strategies for meeting those challenges to enrich undergraduate research and creative inquiry. By bringing together these perspectives, we will examine undergraduate research on the two-year campuses at the confluence of the humanities, the sciences, and academic support with the goal of fostering creative inquiry and preparing our students to succeed in the next stage of their intellectual growth.

Abstract Name: **Effects of chronic exposure to the herbicides glyphosate and glufosinate on six spider species**

Glyphosate is the most used herbicide in the world. Due to the evolution of glyphosate-resistant weeds, it is often applied with the herbicide glufosinate ammonium. The individual and combined effects of these herbicides on beneficial agricultural species such as spiders have been poorly studied. Different spider species may vary in herbicide susceptibility due to size differences and microhabitat preferences. We measured mortality of six agricultural species of spider when chronically exposed to field-relevant concentrations of glyphosate, glufosinate, glyphosate and glufosinate or untreated control soils over a 15-day period (N=892). We tested the web-building spider Frontinella pyramitela, two plant-dwelling species, the crab spider Mecaphesa asperata and nurseryweb spider Pisaurina mira, and three ground-dwelling wolf spider species: Tigrosa helluo, Rabidosa rabida, and Pardosa milvina. Glyphosate showed no hormetic or toxic effect among any spiders, however glufosinate-exposed spiders showed significantly higher mortality than the control treatment for all tested species. For larger sexually-dimorphic spiders, male mortality was significantly higher than females among glufosinate treatments. We also found a significant antagonistic interaction between glyphosate and glufosinate for Pardosa, with spiders sprayed with both herbicides surviving longer than those sprayed with glufosinate alone. Our results indicate that glufosinate is a functional araneocide and recommend caution using it within crop systems where biocontrol is a significant component of integrated pest management.

Abstract Name: **Finding Better Solutions for Available MRI Contrast Agents - Fe(II) Complexes Exhibitng Temperature Dependent Spin Transition**

Studies have shown that existing contrast agents containing Gd that are used in Magnetic Resonance Imaging (MRI) are neuro- and nephrotoxic and can accumulate in the brain for many patients, especially those with renal complications. Our goal is to find a replacement for Gd contrast agents by designing an agent based on Fe(II) complexes that is dynamic, activatable, and targeted for thermal tumor ablation therapies. A key property of Fe(II) complexes is that they can undergo thermally induced spin-state crossover (SCO). However, finding an appropriate temperature range in which a SCO would occur for these therapies is critical for future applications.The behavior of numerous SCO complexes, particularly octahedral Fe(II) complexes, has been well described. Key to meeting the goals of this project is identification or chemical manipulation of currently known structures that undergo temperature-induced SCO without degradation at temperatures between 60 – 80 °C. Prior SCO complexes have been found to undergo spin transitions at much lower temperatures due to difficulties in stabilizing low spin states at room temperature. In the case of terpyridal Fe(II) complexes, the high stabilization of the low spin states results in SCO temperatures that are too high.Thus, to find iron complexes that meet the temperature SCO requirements for a contrast agent, we have synthesized a new type of tridentate ligand that contains a bipyridal unit along with a pyrazole, triazole, or an imidazole group. We will use these new ligands to explore their structural characteristics and feasibility towards MRI contrast agents and biological applications. The synthesis and characterization of all Fe(II) compounds, along with their magnetic susceptibility at various temperatures to determine their potential effectiveness as contrast agents, will be presented.

Abstract Name: **Funny Women, Changing Times: Differences In Feminism Between 30 Rock and Parks and Recreation**

Many critics agree that 30 Rock and Parks and Recreation are two of the best sitcoms that have come out of NBC. Both have garnered widespread critical acclaim, due to their storytelling, comedic chops, and feminist depictions of their 21st-century female protagonists. This essay aims to examine the ways and differences in which 30 Rock and Parks and Recreation portrayed their female casts, as well as how they portrayed the relationships between women and feminism overall. 30 Rock's cynical approach, bolstered by the post-9/11 cynicism present in George Bush's America, often took leaps that not many TV shows had attempted before, showing protagonist Liz Lemon as a career-focused woman who was unapologetically bad at many aspects of everyday life. Parks and Recreation started off with a similarly cynical tone (most likely informed by the creators' previous show, The Office) but made a dramatic change in its second season, with protagonist Leslie Knope not being characterized as a fool for her optimistic, perseverant, and unabashedly feminist nature. While neither show strayed far from the bounds of white feminism, Parks and Recreation, premiering three years after 30 Rock and less than one year after Barack Obama's decisively hopeful presidential win, had a gender-balanced cast and actively promoted the ideals of feminism; 30 Rock, on the other hand, did not have such a sincere attitude towards feminism, but allowed its female protagonist almost as much leeway in terms of makeup and styling as a male-lead show would allow its own main character. Both of these shows deeply influenced American pop culture, and their approach as different sides of the same coin allowed their feminist ideals to influence America as well.

Abstract Name: **Development of Technology Platform for the Integration of Several Micro-Sensors to Monitor Water Quality**

The demand for high-productivity agriculture has led to the increasing degradation of aquatic ecosystems - often due to fertilizer contamination. Because of this, water quality monitoring will be essential to guaranteeing high-quality consumable fresh water in the future. Unfortunately, commercial water quality measurement technologies are often expensive or -intensive and do not allow in situ measurements. Therefore, this project has sought the development of a low-cost technology platform that integrates several micro-sensors to monitor water quality over extended periods. This is based on previous research that showed that micro-fabricated conductivity and temperature sensors are of comparable accuracy to traditional benchtop alternatives. These sensors are paired with commercially available screen-printed pH sensors and integrated into a 3D-printed mechanical housing. The full platform fits within a 1-inch diameter tube and is fully watertight, allowing for deployment to waterside test sites. This platform has been characterized by using an LCR to understand the behavior of the sensors further. The platform design and operation will be further optimized using water samples from the Judith River Basin, MT. This will allow for the prediction of the platform behavior during future deployment. Ultimately, it is hoped that the platform will aid in developing and testing new sensor designs and selective materials under environmentally relevant conditions.

Abstract Name: **Understanding the Neural Circuits Responsible for Cognitive Flexibility in Health and Disease**

Neurons control many aspects of our brain, such as navigation, perception, and memory. Healthy neurons allow these basic human functions to work properly. In this project, we seek to understand how and why cognitive flexibility is impared in neurological and psychiatric disorders such as epilepsy and Alzheimer's disease. We do this by developing a high through-put automated task to evaluate the neural circuit mechanisms underlying these disorders.The lab performs numerous tests using mice and rats to document neurological data and analyze it. In this project in particular, the Feeding Experimentation Device version 3 (Fed3) is most commonly used to develop a cognitive flexibility task. The Fed3 allows for experimental flexibility because the user can tweak the precise behavioral design, allowing them to study the roles of different brain regions. The rodent is placed in the Fed3 and then trained on operant tasks which depend on what neurons or behaviors the user wants to analyze. The fully-automated Fed3 control system ensures that the animals are not distracted by interference from the experimenter, and can perform the tasks over long durations in their home cages. Every event detected by this device is stored in an SD card for offline analyses. In a subset of tests, we use high density electrodes to record the simultaneous activity of neurons in multiple brain regions.It is expected that the data will help researchers understand how healthy neurons in the brain compute different functions. The next step is to analyze the data and identify the neuronal subtypes in the frontal cortices that are chiefly responsible for supporting cognitive flexibility. By understanding how healthy neurons operate, problems in unhealthy neurons can be identified. These results ultimately would be used to therapeutically repair the damaged neurons and computations in individuals that suffer from neurological disorders.

Abstract Name: **The Impact of Far-Infrared Technology on Quality of Life in Older Adults**

Identifying various methods of pain amelioration to meet the unique demands of older adults (OA) may be crucial to increasing the quality of life (QOL) of this population. The purpose of this randomized, single-blinded study was to examine the effects of far-infrared heat (FIR) on pain management and QOL in OA. FIR utilizes a long light wavelength that simulates dry sauna-like conditions. Examining the relationship between FIR and pain is important due to the increased prevalence of chronic pain associated with aging and the corresponding impact it has on QOL and physical performance. Nine OA completed the study, eight of whom were women. Participants were randomly assigned to either a convective heat group (CON) or a convective and far-infrared heat (FIR) group, with convective heat set to 60℃/(140℉). Participants received six, 30-minute heat sessions over the course of three weeks. Pre- and post-assessments included physical measures such as range of motion, gait speed, timed up-and-go, and hand grip strength. Standardized questionnaires were used to determine pain severity and its interference with daily life, and the impact pain had on overall QOL, using a five-point scale. T-tests were used to compare the groups' pre- and post-assessment measures. Results indicated that pain severity was significantly reduced (from 3.31 to 2.5, 0.05) in the FIR group from pre-to-post, and that pain interference was significantly reduced (from 1.26 to 0.43, 0.05) in the CON group from pre-to-post testing. No other significant differences were found. Findings suggest that heat therapy was successful in reducing pain over time, but that FIR heat specifically, was not superior to that of convective heat alone. Our results couldn't discriminate between the independent effects of FIR and convective heat benefits. Further research is required to properly identify the relationship between QOL and the use of FIR.

Abstract Name: **Optimization of Pitch Angle and the Effect of Moment of Inertia on the Efficiency of Wind Turbines.**

With fossil fuels quickly becoming outdated due to the growing awareness of their negative impacts on the health of the general public and environment, clean energy is becoming increasingly necessary to ensure the survival and health of our planet. Wind energy, along with a multitude of other forms of renewable energy, is emerging into the foreground of clean energy options. Wind energy utilizes rotating wind turbines to transfer kinetic energy from the wind into electrical energy. This project's primary goal is to evaluate the relationship between the moment of inertia of wind turbine blades and the overall efficiency of the turbines, and to experiment with varying the center of mass of the blades, which in turn changes the moment of inertia, and how it can affect the power output of these turbines. It will also focus on altering wind speed, pitch angle, and moment of inertia together in order to find the most optimal combinations of these variables, both during constant wind speed and the lack thereof. Our findings support the theory that altering the moment of inertia of turbine blades not only affects the efficiency of wind turbines, but that altering the moment of inertia depending on the behavior of the wind will prove beneficial in increasing the longevity of rotation of the blades and the efficiency of remote braking systems. The data shows that the optimal moment of inertia for wind turbines is heavily dependent on the instantaneous wind conditions, which provides a potential for future research on designing and creating a system that will automatically alter the moment of inertia within the blades in real time, which will be the focus of future research for this project.

Abstract Name: **Improving the Strength of 3D Printed Material by Inducing Low Frequency Vibrations**

3D printing is a cost-effective option compared to other manufacturing methods but the printed parts from conventional materials (PLA+,PETG,ABS) often do not exhibit great tensile strength. The limitations come from the amount of the material and the fill factors used. Traditional methods to increase tensile strength include applying greater infill factors and thicker sample features but these methods may result in greater printing times/cost. To overcome this limitation, work at San Jose State university is inducing low frequency (5-10Hz) vibrations during the printing. For this purpose, a vibration motor (ERM/MTR/9000RPM-1.3V) was directly attached to the nozzle of the printer (Tronxy/X5SA). A special holder was used to hold the motor to attach it to the printer head to induce vibrations during the printing. For the overall dimensions of the specimen, ASTM-D638-Type-1 standard was adopted that gave the printed samples a thickness of about 7 mm. Different printing conditions included the variation of the fill factor (20%,60%,100%) with and without vibration. The printed samples were examined against the porosity and a fluid displacement method was adopted. Experiments show that induced vibrations were able to lower the porosity by 10 to 15% for identical fill factors. Initially samples were sent to Applied Technical Services (Gorgia) and the tensile strength for all printed samples (100% fill factor) with and without induced vibration was measured. The testing results indicate that for our 3D samples, induced vibrations did increase the tensile strength from 26.2 to 30.7MPa (~17% increase) for the corresponding applied loads of 4.1kN to 5.15kN respectively. The corresponding increase in the maximum stress was about 15.7% for 60% fill factor printed parts. New results from an inhouse testing machine at SJSU are being collected and analyzed. Final presentation will include full discussion on the impact of induced vibrations for various sample materials.

Abstract Name: **Caught on camera: Are humans a safety cue for mammalian vertebrates?**

Anthropogenic pressures are imposing environmental modifications at unprecedented spatial and temporal scales to drive ecological change. One provocative notion is that fear of humans (so called “super-predators”) in human-altered landscapes may substitute for predation pressures that were historically imposed by large mammalian carnivores. This project addresses the question of whether free-living mammals actively avoid or are attracted to human presence over space and time. We examined the impact of human activities on the assemblages of free-living mammals as part of a long-term behavioral ecology study at Briones Regional Park in California. Specifically, we characterized the presence of humans, their dogs, and native vertebrates by analyzing thousands of photos from automated-camera traps (e.g., trail cams deployed over the past several years). We tagged photos of coyotes, bobcats, deer, skunks, and ground squirrels using the image software organizer “digiKam” and analyzed the data using the R statistical package “camtrapR.” We report on variation in the visitation rates by mammals across space and time to uncover the interrelationships among multiple species within the park. Our data set documents the crepuscular activities of carnivorans (e.g., bobcats, coyotes, skunks) and offers insights into the potential effects of visitation by humans (and dogs) on the lives of these elusive mammals. This information about the activity schedule of these animals offers key insights into the behavioral ecology of these animals as well as useful information for wildlife managers as burgeoning human populations visit natural areas.

Abstract Name: Utilizing Machine Learning algorithms trained on Recent Music-Listening Activity in Predicting Big Five Personality Traits: A Novel Ongoing Investigation

Music has been important to everyday life since long before modern civilization and has been a subject of study for many years. It has been known to be a positive predictor of personality traits due to the individuality of personal preference. These personality metrics are typically evaluated using a Big 5 trait inventory that measures personality into 5 categories: Openness, Conscientiousness, Extraversion, Agreeableness, and Neuroticism. The study will attempt to assess the prediction quality of an individual's Big Five personality traits from a week worth of recent participant music listening activity from the Spotify Application Programming Interface using machine learning (ML). The created dataset will allow for correlating each of the 5 Ten Item Personality Inventory dimensions with music genres, artists, year, beats per minute, energy, danceability, loudness, length, acoustic, popularity, and other features in a vector. The dataset will be standardized and used to train on ML models such as Random Forest, Decision Tree, K-Nearest Neighbors, Logistic Regression, Support Vector Machine, etc. Prediction accuracy will be compared to previous works. Metrics include accuracy, FPR, TPR, and ROC/AUC scores. Both regression (continuous numeric value) and classification (Likert scale) will be used. A full literature review showed this is the first study to use both Spotify API data, rather than self-reported music preference, and ML classification, rather than traditional statistical tests and regression models, to predict the personality of a college student demographic. Applications of this study include custom advertisement recommendations and music therapy. Approval has been granted to administer the survey by Irvine Valley College's Institutional Review Board.

Abstract Name: Developing an Interdisciplinary Lesson on Microplastics using a Project-Based Learning Approach

Microplastics are a problem globally and in our local waterways. As such education on microplastics should not start only in college but as early as middle or high school. In 2019, aUniversity of West Florida (UWF)Biology Teaching major developed a microplastic lesson plan under the guidance oftheir STEM facultyadvisorand in partnership with alocalhigh school science teacher. This lesson planis in need ofrevision to keep abreast with changing standards, as well as updated protocols for microplastic sampling and analysis in ways that are inclusive and support of students and their needs.As such two UWF STEM Teaching majors – one Biology and one Environmental Science collaborated to undertake this task. The students reviewed local efforts to address microplastics such as the Florida Microplastics Awareness Project as well as other scientific literature on the scale of sand solutions to the problem of microplastics. The STEM teaching majors then utilized the 5E pedagogical model as well as Inquiry Based Learning techniques to develop a lesson plan on microplastics that integrated biology andenvironmental science content. The lesson is to cover a period of 5 daysand covers the water cycle, provides training on microplastics, lays out the procedure of filtration and using a microscope, and then concludes with a lesson and lab on biomagnification and bioaccumulation. By using a universal design approach to learning, this lesson plan ensures that STEM content is accessible and relevant to all students regardless of theirbackgrounds or abilities.

Abstract Name: **Characterization of auditory physiology in FXS in critical developmental timepoints**

Autism spectrum disorders are strongly associated with auditoryhypersensitivity. Fragile X syndrome (FXS), a common monogenic cause of ASD, results from transcriptional silencing of the Fmr1 gene and reduced expression of fragile X messengerribonucleoprotein (FMRP). FMRP directly impacts myelinproteins and various brain regions show reduced/delayed myelination in FXS, suggesting deficits seen in FXS may be caused by alterations to myelination. FXS is a neurodevelopmental disorder, therefore characterizing when during development auditory dysfunction arises in addition tounderstanding if these changes are myelin dependent is critical to elucidating the full etiology of FXS. Auditory brainstem response (ABR) measurements record 1-4 waves, each corresponding to part of the ascending auditory pathway; the latency of which could be directly related to myelination of auditory areas. To characterize the physiology of myelination deficits in FXS at developmental time points, ABR measurements were taken for transgenic Fmr1 mice and controls before (P8-10), during (P12-14) or after (P21-23 and adult) hearing onset in mice. This allowed us to study the developmental emergence of auditory disruptions in Fmr1transgenic mice and identify critical windows where underlying auditory pathways are established. We hypothesize that transgenic Fmr1 mice will have increased latencies in their binaural ABR waves (3, 4 & BIC) compared to the wildtype at different developmental time points. These data will aid in identifying the critical developmental windows of neural circuitry establishment in auditory sensory systems and potential myelination impairments that underlie auditory dysfunction observed in patients and mice with FXS.

Abstract Name: **Enhancing STEM identity among women through participation in community STEM activities: An ecological systems theory approach**

Alverno College is a designated HSI women's college serving primarily first-generation, and low-income students. Several lines of research strongly support the recommendation that community engagement can increase STEM retention for underserved students (Lozano, Franco, Subbian, 2017; Estrada, et. al., 2016). In addition, Estrada et al. 2016 found that showing students how to creatively link their STEM training to the needs of their communities is an effective strategy for increasing URM students' success in STEM. We extended this research by applying Brofenbrenner's model of human development to enhance STEM identity among women STEM majors. Our approach has been to place the individual student in a pro-social STEM community ecosystem to promote development and maintenance of their STEM identity (Miller, 2011). Alverno College's Truchan STEM Community Impact Program (T-SCIP) program funded by NSF IUSE HSI (award #2122903) applies evidence demonstrating that women and underserved students in STEM are motivated by directly experiencing ways STEM benefits the communities where they live. Specifically, the T-SCIP program provides multifaceted community based activities involving STEM peer mentoring, STEM faculty support, engagement with STEM community partners, the social support communities for the student (such as, family and friends), STEM alumnae, and the STEM professional community. We will report program organization and preliminary findings of the impact Alverno College's T-SCIP program has on STEM identity, sense of belonging, interest in pursuing research opportunities and graduate school study in STEM. Using a quantitative and qualitative study design, preliminary data suggests participants discuss the benefits of learning from each other, as well as having opportunities to develop personal leadership skills in science. Survey questions indicate participants gained confidence for doing science and being a scientist. We will also report retention and persistence to graduation rates in STEM.

Abstract Name: Examining biases in the measurement of a Gamma-ray Burst?s Isotropic Equivalent Energy caused by inconsistently derived T90 durations

The isotropical equivalent energy (Eiso) of a Gamma-ray Burst (GRB) is believed to be an estimation of the total energy released by the GRB's central engine in the form of X-rays and gamma-rays. This energy is treated as if it has both physical and cosmological implications, however, its measurement may be significantly biased by the individual analyzing the data.One way in which this energy can be biased is the method for which a GRB's T90 duration is determined. The calculation of Eiso relies on the time-integrated spectral modeling of a segment of data determined by the GRB's T90 duration. Thus, if the T90 starting and ending times are inconsistent between two different methods, then the spectral modeling results may return drastically different results. For example, if one analyst finds a T90 duration that starts later and/or ends earlier, then their spectral modeling results will likely find a Band function profile representing a harder spectrum.Just between the telescope instrument teams, T90 derivation methods have varied. The CGRO/BATSE instrument team's durations were derived by accumulating raw photon counts across time bins, the Fermi GBM instrument team's durations are found by accumulating the spectrally modeled fluences within these time bins, and the Swift BAT instrument team uses the Bayesian Block algorithm.In this work we explore bias in the value of Eiso caused by simply adopting the Fermi GBM team's T90 duration versus deriving our own T90 duration using the Bayesian Block algorithm. Our preliminary results have already shown that the Bayesian Block algorithm can find significantly different T90 starting and ending times, thereby leading to drastically different spectral modeling profiles and Eiso energies for the same GRB.

Abstract Name: Lake Eutrophication: Natural vs Anthropogenic Phosphorus?

Lake eutrophication in western Wisconsin results from excessive nutrient loading (P, N), and mitigation of the issue requires quantification of the ultimate nutrient source. Lake eutrophication events are not consistent across the region, but seem to vary with bedrock geology, hydrogeology, and land use. Lake eutrophication is assumed to be the product of nutrient overload associated with agricultural runoff. A regional surface water study shows elevated concentrations of P across the region. Seasonal values vary between peak agricultural months (July: ~160-180 ppb) and the winter months (November: ~20-95 ppb). The same study analyzes groundwater, documenting extremely elevated levels of P, which is problematic because it is believed that agricultural P does not enter the groundwater system due to absorption by the soil profile. The ultimate source of P in groundwater is unclear and discerning the role of anthropogenic vs natural P is difficult. Aquifers in the region are largely hosted in Cambrian bedrock, which hold more P (~2000 ppm) than groundwater (~ 0.5-1.6 ppm), and surface water (<.2 ppm). Sequential extraction demonstrates that P is bound with Fe-Mn oxides, which suggests that anoxic conditions in aquifers could lead to the influx of P from Paleozoic bedrock. Bedrock derived P may lead to elevated concentrations in groundwater, and therefore contribute to lake eutrophication. It is feasible that agricultural P may not be the primary driver of lake eutrophication.

Abstract Name: Preparedness and Comfort Levels in Providing Sexual Health Education on Vancouver Island

Sex trafficking and sexualized violence are increasing in communities across British Columbia (BC). Sexual health education has been recognized as a powerful tool to prevent children and youth from experiencing these devastating forms of abuse. The question then becomes: who is providing this sexual health education to British Columbian youth, and how well is it being provided? While parents and private consultants often play a role in teaching children the basic concepts involved in sexual health education, the quality and scope of their explanations can vary widely. As such, a key source of sexual health education is teachers in primary and secondary schools. Typically, sexual health education in BC begins in kindergarten and spans through grade ten. While the topic's content is regulated through the provincial curriculum, previous research has shown that teachers are not providing consistent and thorough education. The disconnect between the curriculum and educators appears to be hinged upon two concepts: first, educators themselves do not have enough knowledge on the topics to teach them effectively, and second, educators may not feel comfortable with certain sensitive topics within the curriculum. This project sought to investigate how prepared Vancouver Island teachers-in-training are to teach sexual health education based on their knowledge and comfort levels regarding the curriculum topics. A survey was created with three sections: individual demographics, a curriculum-based knowledge test, and a subjective section focusing on comfort levels regarding various sexual health topics. The survey was open to university students enrolled in the Bachelor and Master of Education programs at Vancouver Island University and the University of Victoria. By examining these future teachers, this project aimed to illuminate how prepared the next generation of teachers are and provide insight into the future of sexual health education.

Abstract Name: What does it take to change? Negative drinking consequences and willingness to change drinking behavior in college students

College student alcohol consumption remains a serious health problem despite frequent intervention and research. Excessive alcohol consumption among college students has been linked to various negative outcomes such as missing class, unsafe sex, accidental injury, assaults, and death (Hingson et al., 2009; White; Hingson, 2014). In a study of college students, more than half of alcohol drinkers report having a negative alcohol-related consequence in the past 12 months (Patrick et al., 2020). Despite these negative outcomes, college students continue to drink. These findings raise the question of what it takes for college students to change their drinking behaviors. There is evidence that college students do not always consider the consequences of drinking alcohol to be negative (Mallett et al., 2008). Since the interpretation of alcohol-related consequences varies, their impact on future drinking behavior may vary as well. This study aims to examine the relationship between the frequency of negative outcomes and willingness to change drinking behavior among college students. An online survey is in progress to collect health data from a mid-sized midwestern university. The survey will include the Young Adult Alcohol Problems Screening Test (YAP) and the Readiness to Change Questionnaire (RTC). It is expected to find associations between certain negative outcomes and readiness to change drinking behavior. Determining what specific negative consequences and what frequency of negative consequences impact readiness to change drinking behavior will help predict future drinking behaviors in college students with negative alcohol-related outcomes. Implications will be discussed.

Abstract Name: **Computation and Variation of Corrosion Initiation Time of Zeolite-Based HPC Mixtures**

The U.S. report card on bridges, conducted by the ASCE (2021) found that 7.5% of all the nation's bridges are structurally deficient, and approximately $125 billion is required for the rehabilitation of those structures. Without adequately functioning bridges, economic losses could be devastating. Corrosion of the reinforcement is one of the main concerns of the service life of reinforced bridges, as it can weaken the strength and durability of concrete. This research aimed to create a reliable and robust corrosion initiation model for reinforced concrete structures – from initial placement to when the corrosion process starts. Current models have limited resources for new durable, and sustainable cementitious materials and rebars.This study's factors of interest were rebar type, initial surface chloride concentration, cover depth, water-cement ratio, and percent replacement of cement. This research implemented the commonly used deterministic model, based on Fick's second law of diffusion, while including sustainable supplementary cementitious materials (SCM) and high-quality rebars. Ternary and binary-based high-performance concrete (HPC) mixtures were designed. Zeolite was used as the primary SCM in this study for its sustainability and availability on the west coast of the United States. In addition, fly ash, slag, silica fume, and metakaolin were used as other SCMs. Three resistivity testing devices measured the electrical resistivity of concrete as the durability of the HPC mixtures against corrosion. This data was then analyzed with the Nernst-Einstein equation and Fick's second law of diffusion to obtain the initiation time.This study showed accurate results for ideal concrete in low-corrosive environments. However, the inclusion of various SCM in HPC and the high-quality rebars in the model provided very high initiation times. This study shows promise in aiding research in enhancing corrosion initiation models in the step toward probabilistic modeling and the inclusion of durable and sustainable materials.

Abstract Name: **Exploring The Impacts Of Policing on Transgender Women In Chicago**

Transgender women are marginalized and often rejected by families, possible employers, and society in general.Stigma in society is pervasive and adversity experienced by transgender (trans) women often comes in the form of being mistaken for sex workers or actually being arrested as sex workers by police. As a result, transgender women are often wrongfully accused of sex work and incarcerated at disproportionate rates compared to the general population. Policies designed to prevent discrimination against transgender women, such as Chicago's Transgender Intersex Gender Nonconforming (TIGN) policy, are often not implemented. This qualitative study seeks to explore the effects of police discrimination and brutality against transgender women who are mistaken for or actually working as sex workers. Semi-structured, individual interviews will be conducted with a purposive sample of transgendered women. Intersectional Framework analysis will be used to identify key themes, patterns within themes between participants, and patterns across themes among participants. This data will provide the foundation to support the development and implementation of policies within law enforcement to reduce with the goal of preventing discrimination against transgender women and other marginalized populations.

Abstract Name: **Specific Work Organization Factors and their Relationships to Surgical Resident Fatigue**

Fatigue is a multidimensional construct encompassing physical and mental exhaustion with consequences ranging from impaired work performance to adverse driving outcomes. Workers in certain fields may be at high risk for negative outcomes associated with fatigue. Surgical residents specifically are at risk due to their schedules and training requirements. Previous literature has demonstrated certain job characteristics have affect fatigue, but specific work organization factors have yet to be examined in this population. Eleven surgical residents (Mage = 28.89 years, 64% female, 82% White) reported daily work organization factors (call type, number and duration of surgeries) and fatigue measured by the Daily Fatigue Impact Scale for approximately a week (Msurveys = 5.37). Residents reported how routine and ambiguous their day was and wore actigraphy devices measuring physical activity. A linear mixed regression indicated longer time in surgery, higher ambiguity, and being on 24-hour call were significantly associated with higher daily fatigue, while increased years in residency and greater percentage of time laying were associated with lower daily fatigue. Interventions regarding resident fatigue are commonly discussed in the occupational health and safety literature, primarily in the form of duty hour limit recommendations. These findings suggest considerations beyond time working are needed to address fatigue. To reduce fatigue, daily work experiences must be taken into account. This project's findings support further research into work organization factors and interrelationships among these factors and fatigue. Furthermore, a literature search exploring the existing interventions determined that "microbreaks" may be effective in reducing fatigue caused by amount of time in surgery. However, interventions that target other specific predictors of fatigue (e.g. ambiguity) have yet to be employed. Interventions designed to reduce fatigue should integrate work factors such as ethical, scheduling, instructional, and procedural ambiguity into recommendations.

Abstract Name: **Isolation, Characterization, and Host Range of Novel Microbacterium foliorum Bacteriophages**

Bacteriophages are viruses that thrive by infecting bacteria, using the host to replicate, and ultimately killing the host. Bacteriophages are essential viruses, and they can be found in different ecosystems and living organisms. Studies on bacteriophages have shown that these organisms have the potential to treat antibiotic-resistant bacteria, given their ability to infect and disrupt a variety of bacterial cells.3 Phage therapy has been a subject of interest in the medical field since the end of WW2, and clinical trials are being conducted to further understand the phage's antibacterial properties. This research focused on bacteriophage isolation, identification, and a host-range test. DNA extraction and sequencing were performed on three out of five phages, and transmission electron microscopy was also performed to identify the family type to which all five phages belonged. Since the phages were collected from different places, upon their successful isolation and purification, their lysates were diluted to the same titers for the host range test to reveal each phage's potential to infect different Microbacterium species, Staphylococcus epidermidis, and Escherichia coli. We found that the five phages have differing host ranges; some also infect S. epidermidis. Genome annotation of the phages Cedar Bank, Extercus, and Guetzie will reveal further information on why each phage has its unique host behavior toward different Microbacterium. Furthermore, genome annotation will also be used to analyze the spike protein, which allows the phages to adsorb to their host species. The genomes of the Microbacterium species will also be compared to elucidate what makes some species more susceptible to different phages, in this case, the Cedar Bank, Extercus, and Guetzie. Further testing is still needed to determine the isolated phages' potential uses.

Abstract Name: **The Effects of Poor Maternal Care on the Midcingulate Cortex and Social Behavior in Offspring**

Evidence from the literature suggests that early life stress (ELS) like social isolation causes prolonged biochemical and behavioral changes in social animals and their offspring. The midcingulate cortex (mCg) is an important brain region heavily implicated in cognitive control and social behavior, but the impacts of ELS on this region remains unknown. Thus, our hypothesis is that poor maternal care will disrupt the development of circuits involving the mCg by inducing an increase in the inhibition of the mCg and leading to behavioral deficits later in life. Using a mouse model, nulliparous female mice were raised in social or isolated settings for three weeks, and bred to produce offspring. The offspring underwent a social conditioned place preference (social CPP) test to measure behavior related to social reward during infancy (postnatal day 23), followed by immunohistochemistry testing for c-Fos and GABA in the mCg. Our data indicated that social isolation in dams failed to produce significant behavioral deficits in social CPP in the offspring. Interestingly, the data showed there are significantly higher numbers of GABAergic neurons present in male stressed offspring, suggesting that poor maternal care may accelerate the maturation of the inhibitory system in the mCg. Since we did not observe changes in social behavior at this age, this effect in the mCg may increase vulnerability to behavioral deficits later in life. This study can provide insights towards understanding the impact of poor maternal care in the development of neural circuits relevant for cognition and social behavior.

Abstract Name: **The Non-native Australian Pine (Casuarina equisetifolia) does not Appear to Affect Plant Species Diversity**

Australian pine (Casuarina equisetifolia) is an invasive plant species in many tropical and subtropical environments. This species is reported to accelerate erosion and limit native plant diversity. Therefore, we were interested in the plant diversity under the canopy of pines on San Salvador Island, Bahamas. We hypothesized that there would be a relationship between plant diversity and association with pine groupings. We predicted that Australian pine would reduce plant diversity under its canopy. Data was collected between 9 – 11 March 2022. San Salvador is a small island, so we divided it into six zones and randomly selected two pine trees in each zone. We paired each experimental plot with control plots (a plot with no Australian pine) by walking in a randomly selected direction away from the pine plot and collecting the same type of data at that plot. Plant species were recorded under pine canopy and in the similar sized control plots. Data analysis suggests no significant reduction of species diversity under the canopy of the pine in comparison to the control locations ($\chi 2=0.09$, df=1, $p=0.76$). This was a surprising outcome and could be a function of variable soil nutrients and a lack of allelopathy by the pine (which has been reported in earlier documents). Future studies should also consider nutrient content of soil, amount of solar influx, and distance to salty or saline water. This study can provide further insight into the effects of Australian pine as an invasive species as well as invasive plant species in general.

Abstract Name: **The effects of arbuscular mycorrhizal fungi on plant defense in Nicotiana rustica in response to simulated herbivory**

Plants have evolved various techniques by which they protect themselves from herbivore damage. In developing these defense mechanisms, plants allocate resources away from growth to increase chances of survival. In effort to compensate for this distribution of resources, studies have shown that plants can enlist the help of arbuscular mycorrhizal fungi (AMF), a mutualist that penetrates roots and exchangesinorganic nutrients for sugars. Prior research has indicated that under certain conditions both growth and defense increase inAMF-inoculated plants.Nicotiana rustica is one species that is associated with AMF. This tobacco species possesses both physical and chemical defenses, primarily in the form of trichomes and the alkaloid, nicotine. Through inoculation of this tobacco with AMF, we can investigate the mutualists effect on growth and defense mechanisms. In thisgreenhouse experiment, we will be looking at the effects of inoculation timing coupled with simulated physical herbivory.Plant mass measurements will betaken72 hours post herbivory. Nicotine levels and trichome density will be analyzed on select leaves of each treatment group. Based onprevious research, we expect to see increased defense in all herbivore damaged plants as well as heightened growth in all AMF inoculated plants. Higher levels of defense will be shown in all damaged inoculated plants, with the greatest levels seen in plants inoculated post germination.

Abstract Name: **Treating MCF-7 Human Breast Cancer Cells with Bisphenol A to Examine Effects on Inflammatory Pathways**

This project aims to examine the effects of the environmental estrogen, bisphenol A (BPA), on inflammatory pathways in human breast cancer cells. Environmental estrogens are found in a wide variety of plastics, food, and pesticides, so there are human health implications for studying the link between environmental estrogens and cancer cell inflammation and growth. Environmental estrogens mimic the effects of estradiol (E2) as they interact with the same receptor proteins. These interactions cause growth, differentiation, and proliferation in their target cells. One pathway that plays a regulatory role in inflammation-associated cancer development is the Mitogen-activated Protein Kinase pathway (MAPK). The MAPK pathway is activated by chemical messengers, which can include E2 or environmental stimuli. These stimuli activate regulatory proteins that mediate cell growth, differentiation, and proliferation. We are curious if BPA acts as an activator of the MAPK pathway specifically in cancer cells. To study this, MCF7 human breast cancer cells were cultured, treated with BPA, and lysed. The protein content was collected, quantified, and analyzed using Human Cell Stress Arrays. Upon comparing cells that received BPA treatment to cells with no BPA treatment, we will be able to see differences in the inflammatory response due to BPA exposure.

Abstract Name: **Adult Perception on Outcomes of Child Custody Cases**

Custody cases are meant to find the best possible option for the child, the process the child experiences lead to negative mental developmental outcomes.Throughout the family court process the families often face challenges that may consist of stress, role confusion, financial struggles, depression, anxiety and many transitions and changes to their everyday lives. One major obstacle for many families that have to deal with family court orders are the financial overloads placed on families. Private information often causes tension in families and households. This mixed methods study focuses on adults who have experienced a child custody case at any point during their childhood using a pre-developed Perception Survey. The survey consisted of 15 questions including demographic, multiple choice and open ended. Twelve articles were reviewed by the student researchers focused mainly on parental alienation, including factors associated with child custody cases and family court proceedings and how they affect the child involved.The student researchers used the literature review to aid in developing their research. This exploratory study explores the effects of child custody cases on mental development of children. The student researchers plan to study the impact of child custody cases by identifying the mental development outcomes of adults, who were a part of a child custody case. The student research group developed the following research question: (1) What are the mental development outcomes of children who were part of a child custody case? The study includes participants older than 18, who were involved in a child custody case when they were under the age of 18. Through purposive sampling, the researchers survey 75 participants to gain a better understanding of their perception of their childhood experiences during their child custody case.

Abstract Name: **Sustainability of Resources for College Food Pantries**

Over 40% of college students are food insecure. Students in need are 43% more likely to fall behind in classwork and drop out of college. Students with food insecurity are also more likely to develop severe mental health conditions like depression, anxiety, low self-esteem, and loneliness. This study seeks to explain what factors contribute to sustainability of resources in university food pantries. The purpose of sustainability research is to find new and efficient ways to meet the needs of students who are food insecure in college. The student researchers explore the issue of sustainability of resources within college settings and how it impacts the resources obtained by grants and donors. The student researchers developed the following question: What are the factors involved in the sustainability of resources within college food pantries? The student researchers used 16 scholarly journal articles to inform their research on the factors that contribute to the long-term sustainability of food pantries in institutions of higher learning. Researchers using purposive and snowball sampling to identify a minimum of 100 participants with the help of the public directories to complete the questionnaire.The student researchers identified three common concepts within articles: factors of sustainability of food pantries, barriers and obstacles to successful food pantry use, and pantry development. The information gathered from the articles assisted the student researchers in question development for their survey.This research aims to identify the factors in sustaining a college food pantry through increased use. This information is important in attaining the researchers' overall goal of aiding the Tarleton Purple Pantry in developing a plan to sustain resources through Tarleton State College's rapid growth in enrollment.

Abstract Name: **Roadmaps of Biochemical Knowledge: Analyzing Neural Networks of Nucleic Acids and Protein Structure Formed by Undergraduate Chemistry and Biochemistry Students**

Undergraduate biochemistry is an upper division course that can be difficult to understand, as it heavily relies upon visual representations. Improving students' ability to understand visual representations and incorporating this with content could aid in assimilating new information into pre-existing frameworks. Students form neural networks after observing visual representations, connecting topics with one another. As of now, there is little research regarding how students interpret biochemistry visuals or store the information they decode in their memory. There are also very few tools that allow researchers to assess students' neural networks, or how they organize the information they extract from visual representations. A study was conducted in an undergraduate general chemistry course where students ranked the relatedness of words and phrases to measure students' neural networks. This study created a similar instrument that measures students' organization of nucleic acid information. Rather than using words and phrases, students ranked the relatedness of biochemical representations. This study aims to determine if students' neural networks become more expert-like regarding nucleic acid vertical translation visual literacy skills as they progress through a sequential chemistry and biochemistry curriculum. In addition to nucleic acids, a sister survey was deployed for analyzing protein structure representational schemas. We analyzed data with Pathfinder, a tool that provides qualitative and quantitative aspects of students' neural networks, relative to an expert referent network. The quantitative data include eccentricity, neighborhood similarities, coherency, degree values, and path length correlations. These values allow us to quantitatively compare student organization of knowledge with expert neural networks. We also qualitatively analyzed images of the neural networks of students by identifying patterns and similarities with expert neural networks to identify chunking of knowledge in relation to the biochemical representation employed. Our findings may allow educators to better develop their courses for optimal student learning and retention of

Abstract Name: **A low-cost confocal microscope**

We demonstrate a simple and cost efficient scanning confocal microscope setup for use in advanced physics laboratories. Designed from convenient commercial products, the implementation of a 3D printed flexure stage allows for further cost reduction and pedagogical opportunity. Experiments exploring the thickness of a microscope slide and the surface of solid objects with height variation are presented as foundational components of undergraduate laboratory projects, and demonstrate the resolution of the setup on the micron scale. This system allows observation of key components of a confocal microscope including depth perception and data acquisition via transverse scanning, making it an excellent pedagogical resource.

Abstract Name: **Circle Packings from Tilings of the Plane**

Any circle configuration has a tangency graph, with a vertex for each circle and an edge for each tangency between circles. The well-known Apollonian circle packing can be constructed from a set of four base circles and a set of four dual circles, each of which has tetrahedral tangency graphs. The orbit of the base circles under the group generated by reflections through the dual circles is the packing, an infinite fractal set of circles.In general, one can start with a finite set of base circles whose tangency graph is the graph of any polyhedron and a finite set of dual circles whose tangency graph is the graph of the dual polyhedron. The orbit of the base circles under the group generated by the dual circles is known as a polyhedral packing, defined by Kontorovich and Nakamura.We study packings which originate from infinite configurations of base and dual circles, a further generalization. We introduce a new class of fractal circle packings in the plane and discuss its relation to crystallographic and Klenian circle packings. The existence and uniqueness of these packings are guaranteed by infinite versions of the Koebe-Andreev-Thurston theorem.The three main circle packings we study are the triangular, square, and hexagonal packings. We focus on their arithmetic properties--integrality, super-integrality, and quadratic and linear forms. We also give a broader class of examples (trapezohedron, cupola, and anticupola circle packings), with a focus on symmetries. We prove structure theorems which give a complete description of the symmetry groups for these packings and show that all 17 wallpaper groups appear in the symmetry groups of our packings. The infinite circle packings we study may reveal number theory and group theory properties of great interest, which remain to be further explored.

Abstract Name: **Synthesis of the Asymmetric Tridentate PCN Ligand and Derivatives for Organometallic Catalysis**

Catalysis plays a significant role in the world today within the polymers industry. Linear alpha olefins (LAOs) are short to long carbon chain molecules that are produced via selective polymerization of ethylene via transition metal catalysts. LAOs have an extensive outreach of uses in the industry, primarily in high performance plastics, motor oils, and synthetic lubricants. This project aims to develop a viable synthetic route to produce a ligand that can direct a metal complex to selectively catalyze the formation of LAOs. The ligand is labeled as a PCN-type ligand by the three elements that coordinate to the metal, phosphorus, carbon, and nitrogen. Our PCN ligand features a benzimidazole central carbene with asymmetrical opposing pendent arms featuring an imine and phosphine. Through a multi-step synthesis process using a combination of open-to-air and air-sensitive techniques, the pre-ligand has been verified and initial investigation into the isolation of metal complexes which are the pre-catalysts is underway. Presented here are the synthetic steps of this project to obtain the free pre-ligand, characterization of the molecules along this synthetic process, the crystal structure of a precursor molecule, computational analysis of predicted ideal complex geometries, and preliminary data on the properties of the target organometallic complexes. Structures of the pre-ligand have been verified using 1H-NMR, FT-IR and single crystal XRD. Future work will investigate the properties of the organometallic complexes of first-row transition metals and the catalytic ability for the selective formation of the desired LAOs via the PCN organometallic complex.

Abstract Name: **Lipid Modification of Cone Phosphodiesterase is Crucial for Color Vision**

Our vision is a vital part of our lives, but for some people that is not the case, disorders like achromatopsia cause color blindness and a lack of visual acuity. Color blindness occurs due to defects in the function of cone photoreceptor cells present in the retina. Cone photoreceptors mediate daytime and color vision and are compartmentalized with an outer segment and an inner segment. The outer segment is the light sensing organelle, and the inner segment is the part of protein synthesis. Thisresearch investigates the mechanisms behind achromatopsia related mutation leading to a loss of lipid modification in the protein cone Phosphodiesterase (PDE6). Our lab created a mutant mouse model modeling the mutation observed in humans, to address why a defect in cone PDE6 lipid modification causes impairment in cone photoreceptor function. We performed electroretinography (ERG) to test the photoreceptors' response to light. The ERG results showed that the cones in mutant mice were not functional, phenocopying the observations from human patients. To determine if the cone PDE6 protein was still being expressed in the mutant, we performed immunohistochemistry on retinal sections, which is a process to selectively identify proteins within a tissue sample. Our data showed that the mutant cone PDE6 protein is produced in the inner segment but is not localized or trafficked to the outer segment. Altogether, our findings show that the lipid modification of cone PDE6 is essential for its localization in the cone outer segment where it is required for cone-mediated vision. Our findings provide a mechanism to understand humans afflicted with PDE6 related color blindness.

Abstract Name: **Conformational Characteristics of Beta-Glucocerebrosidase and Alpha Synuclein Through Ion Mobility-Mass Spectrometry**

Gaucher's disease is a lysosomal storage disease characterized by three types in terms of severity. The current literature for Gaucher's disease indicates that there is an important missing understanding of how GCase interacts with ASyn. If there are significant structural relationships between GCase and ASyn, then those structural differences will be recorded and indicated in ion mobility-mass spectrometry by their overall shape/size and charge states. GCase and Asyn will be measured using IM/MS (Ion mobility-mass spectrometry), GCase will be produced via in-lab protein expression with E. coli. The primary focus will be on mobility and charge measurements to investigate the structures of the proteins and changes when they interact through ion mobility-mass spectrometry. Currently, this research has been focused on effectively producing the GCase protein through E. coli expression as the expression of the GCase protein is expensive and inefficient; preliminary results show that through a gel testing the expression of GCase, the most expression of GCase is at 18 hours for 0.1, 0.5, 1, and 5 mm IPTG for cultures grown at 30 and 37 degrees Celsius. This research seeks to provide structural and binding insights into the relationship between the two proteins with IM/MS.

Abstract Name: Acute Effect of a Pre-Workout Supplement on Power Expression and CrossFit? Workout Performance

A common CrossFit® (CF) workout structure is to have trainees complete the same circuit of exercises for 'as many repetitions as possible' (AMRAP) within a given duration. Performance is dependent on sustaining the power needed to complete each movement at a pace that also minimizes breaks due to fatigue. This ability is known to improve with training and CF experience. However, several individual nutritional ingredients are known to impact energy availability and/or assist with fatigue management, and these may collectively be found in a variety of pre-workout formulations. Thus, supplementing with a pre-workout formulation may provide a greater benefit to AMRAP performance than training and experience alone, but no study has investigated the acute effects of such formulations in experienced CF trainees. Therefore, the purpose of this study is to examine the acute effects of a pre-workout supplement on power expression and CF workout performance. Healthy, CF experienced (≥2 years) men (ages 18-45) are being recruited for this cross-over design, placebo-controlled study. After providing their written informed consent, participants must complete four, weekly experimental visits at approximately the same time of day in randomized order. Upon arrival, they are asked to consume either a pre-workout supplement (S) containing ingredients known to improve energy availability and manage fatigue, or non-caloric placebo (P). Then, they rest 40 minutes before completing either a 5- or 15-minute AMRAP of 9-calorie rowing, six 95-lbs. barbell thrusters, and three 24-in box jumps. Power expression will be measured during each set of rowing via the ergometer's microcomputer, and during each thruster (by PERCH; a barbell tracking camera) and box jump (by in-ground force plates) repetition, and these will be averaged across each round.Comparisons will be made between S and P, 5- and 15-minute trials, and their combinations on changes in power expression across each round completed.

Abstract Name: How Women Communicate and Fulfill Sexual Desires

Sexual desire has been recognized as the most universally experienced sexual response by men and women (Regan; Atkins, 2006), while also being one of the most subjective aspects of human sexuality (Mark et al., 2009; Meana, 2010). However, most of the research on sexuality is from a narrow lens that rarely highlights the positive aspects of women's sexual pleasure and desire (Jones, 2019). Additionally, there is no consensus on how to properly conceptualize and operationalize women's sexual desire (Brotto et al., 2009; Meana, 2010). Past research has assumed that women's sexual response cycle, and the ways they experience desire were identical to men (Brotto et al., 2009). Therefore, much of the research on sexual desire is through a heteronormative, male-centric lens, placing an emphasis on behavioral and physiological arousal responses to sexual desire. This has created a gap in the literature where women's individual and complex experiences with sexual desire may be overlooked or dismissed (Chivers; Brotto, 2017; Meana, 2010). Additionally, there is scant research on how women communicate desire to partners, which may be important in understanding how and if desires are fulfilled. The present study aims to understand women's lived experiences with desire through qualitative interviews. We are recruiting a diverse sample of 20-25 self-identified women.Using semi-structured interviews, women are beingasked about theirexperiences with sexual desire and the ways in which they communicate and fulfill desires. Through a feminist lens, we will be using thematic analysis to interpret the data. This study aims to offer new insights into women's desire and combat stigmatization around women expressing their desires.

Abstract Name: Feels Good, Man: Internet memes in the history of artistic reproducibility

In mid-2006, a collection of webcomics appeared featuring multiple characters including a frog and a dog. The plotlines are simple: Each of the uncolored MySpace panels contains its own simple plot line; in one the frog goes to the bathroom; the dog asks him why he does it. “Feels good, man,” he carelessly replies. But it is this particular, harmlessly lewd panel that has transformed, first into one of the earliest broadly recognizable Internet memes (Pepe the Frog), which has since been changed yet again into a racist and anti-Semetic symbol that its initial creator had never intended or imagined. All was made possible simply by a subversive reproducibility that both indelibly marks memeology and falls perfectly into historical context when placed in the history of artistic technologies.Philosopher and cultural critic Walter Benjamin (1892 – 1940) in his essay “The Work of Art in the Age of its Technological Reproducibility” theorized that different forms of art have their identities characterized by how easily replicated they are. This nature extends to their function: Just as the invention of film did away with the rare uneditedness of live theater, so too does the very nature of a meme distinguish it from its author’s intent. While I rely on Benjamin’s analysis, I also expand his account in two ways: by explicitly establishing how he sees a historical trend in the reproducibility of works, and by exploring the medium of internet memes as the logical conclusion of the processes that Benjamin first observed. Although Benjamin was not able to experience Internet culture himself, his analysis of the social impact of media transformations anticipated the tribalized fracturedness we now regularly experience through Internet communication.

Abstract Name: Manufacturing A Transparent Solution To Understanding Blast Trauma On The Ears

Numerous studies reported Poly Lactic Acid (PLA) as the most transparent and biodegradable polymer; however, further studies on PLA’s diverse visibility and flexibility are needed when manufacturing a transparent product. This study aimed to test the visibility and flexibility of 3D-printed PLA polymer ears by putting them through a blast wave created by the Oxy-acetylene shock tube to simulate the impact a person's ear could receive when being impacted by a blast. In a biomedical setting, this would allow doctors or researchers to see where the affected parts are and work to improve protection or faster treatment. To achieve this goal, computer-aided design and drafting software (AutoCAD) is used to draft a 3D human replica. Then the replica was transferred to a Raise 3D Pro 2 3D printer to trace the ear path and print it in 3 PLA filament styles, consisting of natural transparent, transparent clear, and crystal-clear. PLA filaments are used because of their flexible similarity to the human ear and transparency, allowing us to view the inside of the ear where the blast took place. Once the printing finalizes, an elasticity test will test the PLA ear’s flexibility and endurance through a pull and stretch procedure. Next, we compare the three PLA filament ears' results to conclude which replica will provide the best resistance when set in a high-tension environment. Subsequently, a residue visibility test performed by an oxy-acetylene shock tube blast captured by high-speed digital monochrome cameras tests and identifies where the blast wave impacts the ears. Thus, we can compare which PLA filament ear is better, illustrating the residue left on the ear replica. The current study improves visibility and future waste minimization, which can be incorporated into many industries, such as medical, military, and agricultural product selection when manufacturing equipment.

Abstract Name: **Remote Control of a High Energy Laser System**

High Energy Lasers (HELs) have become more prominent in defense applications, largely due to more precise, powerful beams that are capable of targeting small and quick moving targets. Typically, these lasers produce infrared light that lies outside of the visible spectrum and have multiple safety requirements that make them difficult to operate without extensive precautions. Due to the limited visual feedback and interaction, attempts to demonstrate the power and capabilities of HELs to observers are often unremarkable. In this work, I aim to address this problem by creating a more effective and satisfying experience of HEL demonstrations. To do this, I built an enclosed HEL control system that is easy to use and provides sensory feedback to the user through tactile buttons and switches. Additionally, multiple LEDs within the system provide visual feedback on the operating state of the HEL, allowing easy understanding. The system utilizes a microcontroller to receive, interpret, and execute commands based on user inputs. The microcontroller is programmed with a simple finite state machine to execute all available functions and communicates using ASCII commands over a serial interface connected to the HEL system. A shield was designed, printed, and mounted to the microcontroller to interface between the hardware inputs on the control panel and the microcontroller's digital inputs. Lastly, the control system is equipped with all necessary functions to operate the laser as well as multiple safety precautions, to include a hardwired emergency stop button.

Abstract Name: **Material Development - Attaining New Properties with Filled Polymers**

This research investigated the effects of adding filler material to Poly Ether Block Amide (PEBA) used in additive manufacturing. Glass bead (GB) filled PEBA composites were produced using selective laser sintering and were subjected to tensile, three-point bend, impact, and hardness testing. The composites tested had 0 wt%, 20 wt%, and 40 wt% GB. The results showed that elongation at rupture, tensile strength, and flexural strength decreased as more glass beads were added to the composite. However, the elastic modulus increased as with the addition of glass beads. Hardness remained invariant with variations of wt% GB. Impact resistance remained inconclusive due to time constraints.

Abstract Name: **Effects of caffeine and dbcAMP on expression of a vimentin-RFP reporter gene in human breast carcinoma MDA-MB-231 spheroid cells**

Breast cancer is the most prevalent type of cancer worldwide and the leading cause of cancer-related mortality. This study focuses on triple-negative breast cancer, which currently lacks a focused treatment option. The vimentin gene is an important marker of epithelial-to-mesenchymal transition (EMT) and is increased in tumor progression and implicated in cancer metastasis. To study the regulation of EMT, we developed a 3-dimensional (3D) cell culture model using the triple negative breast adenocarcinoma cell line, MDA-MB-231. More importantly, we used a specialized MDA-MB-231 (ATCC HTB-26) reporter cell line in which the vimentin protein has a C-terminal red fluorescent protein (RFP) tag that allowed us to track gene expression in vitro. We hypothesized that 3D cell culture would promote a mesenchymal phenotype characterized by increased vimentin-RFP expression compared to 2D cell cultures. In addition, we predicted that culture treatments with either 100 μM dibutyryl cyclic adenosine monophosphate (dbCAMP) or 100 μM caffeine to stimulate the cAMP/PKA signaling response would attenuate the 3D culture-dependent increase in vimentin-RFP. As expected, 3D cultures had increased vimentin-RFP compared to 2D cultures. Treatment of the 3D cultures with dbcAMP but not caffeine significantly decreased vimentin-RFP expression. These findings demonstrate that dbcAMP is effective in attenuating a marker of mesenchymal transition associated with tumoroid 3D culture growth and suggest that interventions targeting cAMP-dependent signaling may be useful as adjunct drug interventions for reducing triple negative breast cancer metastasis.

Abstract Name: **Computational Analyses of Myelin Protein Zero Interactions: A Data Science Approach**

Charcot-Marie-Tooth disease, the most common progressive hereditary neurological disorder, presents with symptoms such as muscle weakness and wasting in the hands or feet. Experiments have shown that these conditions correlate with the collapse of myelin sheaths in peripheral nerves. The molecular mechanisms for these symptoms is poorly understood, however one current hypothesis is that point mutations of Myelin Protein Zero (MPZ), the most abundant protein in the myelin sheath, may result in differing interactions with other MPZ proteins and neighboring membrane lipids. Our current research seeks to investigate this hypothesis by computationally probing the interactions between wild-type and select mutated forms of MPZ using molecular dynamics simulations. Specifically, we utilize coarse-grained simulations using the MARTINI forcefield to model multicomponent membranes containing MPZ in apposing bilayers. To compute the time- and spatially-averaged frequency and longevity of direct interactions between MPZ molecules in apposed lipid layers, we use coordinate positions generated from several microseconds of simulation time. Preliminary results from our simulations indicate differential interaction regions between MPZ proteins in apposing layers in wild-type verses mutated forms. Additional analysis may provide further details into the molecular mechanisms by which point mutations of MPZ disrupt myelin integrity.

Abstract Name: **Investigating Regulatory Mechanisms of Gap Junction Molecule innexin-19 in Neuronal Maturation**

While molecular mechanisms controlling early neurodevelopmental events like neuronal specification and migration have been the focus of much research, the molecular mechanisms controlling the maturation of the post-mitotic nervous system from birth to adulthood are not well understood. Electrical synapses are composed of gap junctions, created from connexins in chordate and innexins in non-chordate animals. Although the dynamic developmental expression of connexins/innexins have been suggested to play important roles in post-mitotic brain maturation, the mechanisms by which they control neuronal maturation and by which their dynamic developmental expression is regulated are largely uncharacterized. We used Caenorhabditis elegans (C. elegans) as our experimental model due to their stereotyped and fast developmental cycle, invariant cell lineage, and the ability to identify the expression pattern of any molecule in the entire nervous system to single neuron resolution. First, we characterized the downregulated expression pattern of inx-19, a gap junction channel, across post-embryonic development in single neuron resolution. Next, we investigated a heterochronic pathway regulator, the lin-14 transcription factor, as a candidate regulator of dynamic developmental inx-19 expression. lin-14 is important in promoting immature neuronal state in early C. elegans larval stages, and the downregulation of lin-14 expression is important for the maturation of certain neuronal phenotypes. We examined whether developmentally-regulated inx-19 expression was altered in lin-14 null mutants. Additionally, we will be characterizing the role of other members of the heterochronic pathway in regulating inx-19 developmental expression. Future studies will be devoted to determining the behavior and functional roles inx-19 plays in locomotion using the WormTracker. Identifying the regulation and role of inx-19 will allow us to better understand how dynamic gap junction expression across development regulates neuronal maturation, as well as uncover how dysregulation of these mechanisms may govern neurodevelopmental diseases.

Abstract Name: **Physiological and Behavioral Effects of Ocean Acidification on Two Species of Intertidal Snail**

Ocean acidification (OA) has been shown to affect organisms that use calcium carbonate to build their shells, such as marine snails. With the excess carbon dioxide in the atmosphere from burning fossil fuels, it reacts with seawater changing the water chemistry. The change in water chemistry increases the amount of bicarbonate and hydrogen ions and decreases the amount of carbonate. Not all calcifying organisms can extract the carbonate from bicarbonate which poses an issue of carbonate availability for shell building. The extra hydrogen ions in the water make it more acidic, which has been shown to cause adverse physiological and behavioral effects on certain calcifying organisms. If the excess hydrogen ions cannot find a carbonate ion in the water to bond with to make bicarbonate, they will bond with the carbonate already in the calcifier's shell, dissolving it. Other effects of OA include decreased shell strength and various reproduction issues. In this study, we will investigate the effects of lower pH on two snail species from Chincoteague Bay, Virginia that play an important role in the bay ecosystem: the common periwinkle snail (Littorina littorea) and the Eastern mud snail (Ilyanassa obsoleta). To determine the physiological and behavioral effects of OA on these two species, live snails and empty snail shells will be exposed to four levels of pH, 8.1 being the control value. Data will be recorded on weight, size, density, appearance, shell composition, shell strength, and movement behavior over the course of approximately five months. The results of this study will showcase how the data might differ between species and the likelihood of survival of these marine snails in an acidic ocean.

Abstract Name: **Effects of Nutraceuticals on Cardiovascular Health**

Cardiovascular diseases now outrank cancer as the number one cause of fatalities in the United States, with hypertension being the most dangerous factor linked to deaths. Despite medical efforts to develop pharmaceutical interventions to help individuals with cardiovascular disease, adverse side effects can outnumber initial presenting symptoms. In recent years, holistic medicine, also known as nutraceutical interventions, has been more prevalent in research. More specifically, the effects of herbal teas on lowering blood pressure and heart rate have been studied, exhibiting connections between tea consumption and improved heart health. Limited research has examined the effects of both dietary and herbal interventions. The aim of this true experimental, four-group design is to investigate the effects of herbal teas on human interventions, as well as the plausible benefits of the Dietary Approaches to Stop Hypertension (DASH) diet. Eighteen participants from various backgrounds and cultures were placed into either control, dietary intervention, herbal intervention, or dietary and herbal intervention groups. It was hypothesized that if participants implemented nutraceuticals into their daily regimens, they would experience decreased blood pressure, and heart rate, as well as an improved perception of overall personal health. Repeated ANOVAs were run to compare blood pressure and heart rate by week, and blood pressure and heart rate by the group. The results of the ANOVA tests did not show a significant impact on lowering blood pressure or heart rate. Although the data was not significant, participants reported improved health and adherence to daily routines. Additionally, there is qualitative and analyzable evidence to support the use of consuming hibiscus tea as part of a healthy diet. It is recommended that further research be completed to evaluate the plausible effects of herbal interventions on populations who have increased hypertensive risk factors needs.

Abstract Name: **Role of Motivation on Academic Success B**

The collegiate world is constantly discussing how student motivation is related to student success. How true is this correlation? Does the motivation importance change with the specific course or the format the course is taught in? Can the institution or instructor impact the student motivation level by understanding intrinsic and extrinsic factors that motivate students? The aim of this study is to determine what motivation is and how it impacts the academic success of college students. Factors that will be studied are intrinsic and extrinsic motivation factors, academic performance, familial college experience (1st generation studens vs non 1st generation students), and the role of the institution and faculty. The study will be completed through a survey with a battery of questions addressing all the key areas mentioned above. Demographics will also be collected to compare possible inter-group differences. Correlational analysis will be completed through data collection in the spring semester of 2023.

Abstract Name: **Improving Sustainability Awareness with K-12 Citizen Scientists Using Authentic, Interdisciplinary Project-Based Learning to Support an International Space Station Experiment**

Plastic waste disposal is a serious environmental challenge that is important to incorporate into K-12 curriculum. While the 3R's (Reduce, Reuse, Recycle) are commonly taught at this level, empowering K-12 students to contribute meaningful and authentic sustainability research data in efforts to increase awareness is needed. A potential plastic waste solution is Galleria mellonella (waxworm), a common beehive pest that can be easily incorporated into curriculum for K-12 classrooms. Waxworm larvae are capable of biodegrading low-density polyethylene (LDPE) films (e.g sandwich bags) into a reusable product, ethylene glycol. The A-State SPOCS (Student Payload Opportunity with Citizen Science) team was awarded a NASA grant to assess the plastic biodegradative properties of waxworm larvae in a microgravity environment on the International Space Station. A major component of this grant was partnering with Citizen scientists (CS) from two Arkansas K-12 intermediate schools who actively conducted preliminary experiments. Their classroom efforts optimized conditions for waxworm larvae plastic consumption, calculated mortality rates, and established the ability of waxworms to survive on minimal food stocks (beeswax only). CS contributed important data in establishing waxworm larvae' preference for the plastic type, Ziploc. This data was key to the final design of the ISS experiment and will be presented in various outlets. In addition, CS participated in engineering activities utilizing NASA constraints and independently manufactured the 3D-printed waxworm larvae habitats for the project. In July 2022, our team completed a successful launch of the experiment aboard the NASA resupply mission CRS-25. This project highlights efforts in finding innovative and sustainable waste management solutions for long-term space travel as well as bringing authentic, project-based learning opportunities in K-12 to increase awareness of this pervasive environmental problem.

Abstract Name: **Guided by Guidelines or Each Other: Social and Behavioral Mimicry During the COVID-19 Pandemic**

As Coronavirus variants mutate and evolve, it is essential to better understand the psychological mechanisms influencing adherence to guidelines such as social distancing, wearing masks, and other CDC recommended hygienic practices. Previous research suggests that people mimic perceived normative behaviors in the context of the COVID-19 pandemic. The present studies aimed to expand upon the original research by experimentally manipulating different levels of depicted guideline adherence through photographic imagery and doctored statistical polls. We predicted that because people are significantly more likely to mimic perceived normative behaviors, participants would likely adhere to guidelines when witnessing community members engage in similar behaviors. Study 1 was a randomized between-subjects design with one independent variable and four levels consisting of an empty city control, and images with different depictions of mask adherence (i.e., 40%, 70% and 100% adherence). Study 2 was a randomized between-subjects design with one independent variable and three levels consisting of a control graph from the National Highway Traffic Safety Administration, and statistically doctored graphs with varying levels of reported guideline adherence (i.e., 23%, 67%, and 92% adherence to guidelines). Researchers conducted a one-way ANOVA and found no significant effects for exposure to the manipulation and degree of willingness to adhere to guidelines for both Study 1 and Study 2.Keywords: Coronavirus, COVID-19, guideline adherence, social mimicry, social conformity

Abstract Name: **How First-Generation, Low-Income, Historically Underrepresented Students Perceive their Experiences while Pursuing a Graduate Degree**

This study focuses on how current and former McNair Scholars perceive their experiences in college when pursuing graduate school. Students in this program identify as first-generation, low-income, or are from an underrepresented/ historically diverse population, which historically have been underrepresented in higher education and even further underrepresented in graduate programs. There is a need to understand how students from these backgrounds find and utilize support to navigate higher education in pursuit of a graduate program.Through semi-structured interviewing this phenomenological study of current and former McNair Scholars found many forms of support that furthered students' educational goals. These experiences include faculty mentoring, familial support, and programs such as the McNair program. Participants in this study routinely mentioned that on-campus faculty support was crucial to their pursuit of graduate school. This research contributes to the general understanding of these student experiences and provides suggestions for best practices for support programs for individuals in these groups when pursuing higher education and graduate-level programs. These findings identify what current programming is doing to support students from this population in attaining their educational goals. While TRIO programs are benefitting the students they reach, there are more educational gaps that should be remedied. The findings of this study suggest that additional research is needed to better understand what each individual needs to be successful in their educational goals. This study is one step towards understanding the best educational support students who are first-generation, low-income, and historically underrepresented may need through the pursuit of a graduate program.

Abstract Name: **SUBDERMAL VERSUS EPIDURAL LONG-LATENCY AUDITORY EVOKED POTENTIALS IN RATS: A VALIDATION STUDY**

Event-related potentials (ERPs) are the summation of postsynaptic activity time locked to a stimulus which are recorded using electroencephalography (EEG). ERP's high temporal resolution reflects complex activation of neuronal networks in relation to particular events or cognitive processes. Notably, they also provide an analogous phenotypic measure between humans and animal models, and thus, are well suited for studying mental disorders and improving the validity of existing psychiatric animal models. Currently, except for auditory brainstem responses, ERP research in rodents has predominantly utilized relatively invasive EEG recording procedures like epidural electrodes. The purpose of this study is to validate the use of less invasive subdermal methods for ERP measurement. 20 adult, male Wistar rats will be implanted with subdermal needle electrodes while anesthetized with continuous isoflurane. Once fully awake, they will then be presented with a passive auditory paradigm consisting of a sequence of 5-tone trains with either 1- or 5- inter-train intervals (ITIs) presented at a frequency of either 8-kHz or 500-Hz. To assess temporal stability, subdermal needle recordings will be conducted twice for both frequencies separated by 2-3 months. Approximately 2-4 weeks following the second round of subdermal needle recordings, rats will undergo a craniotomy to implant skull screw electrodes for invasive recordings. We predict our findings will demonstrate the applicability of a semi-invasive method for recording ERPs in awake rats. Moreover, this work will allow for a better understanding of the comparability of findings between these epidural and subdermal approaches, which is vital to the replicability of findings within and across labs. Overall, this work has the potential to support the validity of an approach for measuring ERPs in awake rats that is less invasive and harmful than most conventional, invasive approaches.

Abstract Name: **The Symphony of the Cell: Using Data Sonification to Engage Students in Molecular and Cellular Biology**

As technology advances in all aspects of our lives, the demand for careers in science, technology, engineering, and mathematics (STEM) hasincreased exponentially. However, many students find STEM challenging, and further, lack key experiencesto gain a sense of belongingin STEM and consider pursuing it as a career. Thus, providing STEM learning modules that introduce key concepts while engaging students can make an impact in addressing this need. A particularly difficult topic for students to understand is the relationship between cells and how the sequence and structure of proteins ultimately contributes to their function. In order to introduce these basic principles to introductory students, our team has constructed a virtual authentic-learning tool that utilizes data sonification in which each amino acid in a protein sequence is assigned a musical note and rhythmic value based on its hydrophobicity. This allows a harmonious musical piece to be composed based on the sequence of a functional protein. Disease-associated mutations become disharmonious which allows users to auditorily identify disruptions in a protein sequence and understand how it impacts the cellular symphony. We will present our preliminary survey data supporting our hypothesis that this data sonification learning module helps students gain an understanding of the molecular basis of disease while improving students attitudes towards STEM.

Abstract Name: **Mental Health In Athletes**

Athletes who are in higher education, collegiate athletes, are individuals who can struggle with addressing concerns related to their own mental health. Athletes can develop these ailments due to their environment: self-esteem stigmatization, sport-related injuries like concussions, influences from coaches, their view on social status, and even overtraining. This research examines the effectiveness in outreach programs and the outcomes from having a mental illness as well as correlational factor of stress. In an attempt to analyze athletes and their stressors, a survey was directed to those who participated in sports. The search for a correlation between coaches and causes of stress, questions were asked in a survey related to athlete stress and relationship with the coaching staff. The participants responded with 'probably yes' and 'probably not'. This showed that athletes were prone to facing stress at an average and above-average level. Stressors and rehabilitation in athletes are reported to have been extremely difficult. Results reported back that athletes definitely struggle to reach out to others. The group also searched for solution rates regarding outreach encouragement with peers and coaches. The report shows a vast majority responded that they weren't encouraged by others. The results showed that mental illness is potentially still a hidden topic across the sports world. This study aims to help support the research that collegiate athletes do experience mental ailments and that these ailments are caused by many factors: the responsibilities of training and overcoming challenges, the consequences of injuries, and advice from coaches or peers.

Abstract Name: **Mindfulness Skills, Emotional Regulation, and Coping Mechanisms as Predictors of Academic Success and Wellbeing**

The goal of this research study was to determine the possible relationship between emotion regulation, coping, and three facets of mindfulness (acting with awareness, nonreactivity, and observing) in predicting perceived academic success and overall wellbeing. “Wellbeing" is a term that is often rated according to someone’s own perception of their mental and physical states. Academic success is determined by the individual’s own perception of what success should look like. Like Finkelstein-Fox et al. (2018) reported, “Understanding students’ intrapersonal resources that promote resilience and protect psychological well-being as they transition from high school to undergraduate life may provide useful directions for campus-based counseling interventions,” (2018, p. 639). Acquiring knowledge surrounding these variables and their relationship to individuals’ wellbeing could create pathways to decrease mental health issues in universities everywhere. The current study was conducted at a small, liberal arts university in the southeast. The Five Facet Mindfulness Questionnaire (FFMQ), a shortened form of the 60-item COPE scale called the Brief-COPE, The Emotion Regulation Questionnaire (ERQ), The Satisfaction with Life Scale (SWLS), and the Academic Self-Perception subscale were administered to 145 undergraduate students with a mean age of 19.52. The results were analyzed using a multiple regression analysis through SPSS. The results of this study revealed that acting with awareness was an overall predictor of overall wellbeing. A second multiple regression analysis revealed that the two variables of coping and acting with awareness were significant predictors of an individual's perception of their academic success. Emotion regulation and two facets of mindfulness (nonreactivity and observing) failed to significantly predict perceived academic success and overall wellbeing. Implications, limitations, and recommendations for future research were addressed.

Abstract Name: **Risky Behaviors: its Cycle of Victimization Against Women in Reentry**

Women who use drugs and are involved in the criminal justice system have been shown to be at an elevated risk of contracting HIV and other infectious diseases. This is of particular concern among women exiting prison, many of whom face numerous interpersonal and structural challenges upon release. While much of this risk is associated with injection drug use and unprotected sexual encounters, little is known concerning what factors affect the likelihood of engaging in these behaviors upon release from incarceration. Using the Reducing Risky Relationships for HIV (RRR-HIV), the current study examines 346 women who participated in a multi-site randomized clinical trial aimed at reducing HIV risk (and other risky behaviors) upon release from prison.Historically, interventions and prevention programs in prison have fallen short of reducing risk for women. It is a structure built upon a system constructed for white men, and what works for men does not always work for women. This, and the lack of research with reentry women as the subject, allow for the cycle of victimization to continue. This study examined numerous variables (drug use, living situation, abuse, partner satisfaction, race, mental health, perceptions of HIV) which may have an influence on a woman’s likelihood of partaking in risky sexual behaviors. It aimed to identify any potential factors that may have a particularly high risk for women engaging in these behaviors and examine potential intervention systems and prevention programs. Data was collected while women were incarcerated and 90 days following their release from prison. Multivariate regression results indicate that women who reported engaging in post-release drug use and had difficulty finding stable housing were significantly more likely to engage in risky sexual behavior. Policy implications will be discussed.

Riendeau, Liv

Institution: *WI - University of Wisconsin-Green Bay*

Discipline: Race, Gender, & Sexuality Studies

Author/Contributors:
Liv Riendeau

Abstract Name: **The Queer/LGBTQ+ experience within Social Virtual Reality**

Computer mediated communication (CMC) and modern-day social media applications have been an intuitive social space for minority advocacy and outreach for many marginalized groups. In relation to LGBTQ+; Queer individuals, the internet and its digital social spaces have created environments for inclusive activism, educational environments, and safe social spaces for these individuals to inhabit. As social technologies evolve, global interconnection creates new avenues for diverse identities to be represented and represent themselves through a complex, internet-based identity that can, at times, differ from their physical world identity. The aim of this research is to explore how Virtual Reality (VR) technologies and specifically Social Virtual Reality (SVR) applications (like that of VRChat, RecRoom, Meta Horizons, etc.) allow for LGBTQ+/Queer identity exploration on a far deeper level than traditional flat screen digital social spaces. Avatar embodiment, presence within VR (social, self,; world), and a slew of other social and psychological factors, gender/sexuality identity and orientation can be casually explored to profound results. However, since VR and SVR are newer technologies with a niche user base of dedicated enthusiasts, very little research has been conducted on social VR; especially regarding the LGBTQ+/Queer experience within SVR. How does avatar embodiment of a gender affirming digital body effect a trans* users experience within SVR? Does the digital SVR space create avenues for sexuality exploration in an inclusive setting that some individual may otherwise not be able to engage in? Does the SVR platform construct yet another digital space for LGBTQ+/Queer advocacy and representation akin to traditional social media platforms (Twitter, Facebook, etc.)? Finally, is VR, and by extension SVR, real? Do the events we attend, friends we met, and identities we engage with within VR/SVR constitute a genuine reality within a digital format rather than the physical reality we have come to know?

Abstract Name: **Evaluating the Differences Between Corewell Health Systems Enteral Nutrition Policies and Exploring Evidence-Based Practice Recommendations**

Adequate nutrition is vital to a patient's plan of care and overall health. Enteral nutrition may be recommended if a patient's nutritional needs are not being met, thus affecting their illness recovery. This project aimed to compare the enteral nutrition policies of two hospitals in a large health system in the Midwest and to explore evidence-based practice recommendations in the literature. Henderson's Nursing Needs Theory provided the foundation for this project, as it describes how individuals have basic health needs and may require assistance from nurses to achieve health, independence, and overall well-being. In addition, the theory's list of basic needs includes adequate nutrition, which, for some, can only be achieved through assistance such as enteral feedings. Multiple search strategies were used to determine adequate literature on the topic of enteral nutrition and best evidence-based practice guidelines. Keywords and phrases used in the search process included 'enteral feedings/nutrition,' 'tube feedings,' and 'alternative nutrition.' Subject matter keywords and phrases included 'systematic review,' 'best practice,' and 'evidence-based practice.' Implementation of Boolean Logic allowed for more concise searching and results. Databases included Primo, CINAHL, Google Scholar, and Elsevier. Inclusion criteria for articles included: 1) published within the past five years; 2) nurse as an author; 3) reputable source; and 4) focus on enteral nutrition. Organizational strategies were used to compare the policies, sorting findings into 'primary' and 'secondary' differences. Three primary differences were discovered for which a literature review of six articles was performed that revealed recommendations on gastric residuals, tube placement verification, and system changes. Limitations included a lack of diverse patient populations in the literature and a time restriction for the project that prevented the analysis of more articles. Overall, by implementing current evidence-based practice recommendations into enteral nutrition procedures, patients' nutritional status and overall well-being will be promoted.

Abstract Name: **Determining the Efficacy of a 4'-Thionucleoside Analog in the Sensitization of Glioblastoma Cells to Temozolomide**

The patient prognosis for Glioblastoma (GBM) remains poor, despite an aggressive standard of care. Therapeutically targeting epigenetic mechanisms, such as hypermethylation, may offer improved treatment options for patients. DNA methyltransferases, specifically DNA methyltransferase 1 (DNMT1), mediated hypermethylation of tumor suppressor promoters' results in altered gene expression and consequent tumor progression.. Prior reports determined that pretreatment with decitabine, a potent DNMT1 inhibitor, sensitizes glioma cells to the standard of care DNA damaging agent, Temozolomide (TMZ). Due to the limitations of decitabine, investigators at Southern Research developed 4'-thionucleoside analogs as DNMT1 inhibitors with lower off-target toxicity than decitabine. We hypothesize that 4'-thionucleoside analog will be more effective than decitabine in the TMZ sensitization of glioma patient-derived xenografts (PDX). Jx39P and D456 PDX models were treated over a 7-day period with hypomethylating agents at concentrations spanning 10 nM to 5μM. Upon completion of these treatments, cell viability was assessed using Cell Titer Glo, which measures ATP production. Additionally, Jx39P were pretreated for 48hrs with either decitabine or 4'-thionucleoside analog (200 nM or 30 nM respectively) and then subject to a singular treatment of TMZ (6 μM) followed by viability assessment. The IC50 concentration of 4'-thionucleoside analog was ten-fold lower than that for decitabine for Jx39P and two-fold lower for D456. In Jx39P, both hypomethylating agents in combination with TMZ are effective in reducing cell viability when compared to the treatment groups with single hypomethylating agents. Currently, we are optimizing experimental conditions to better predict the benefit of 4'-thionucleoside analog over decitabine in the sensitization of GBM PDX cells. We intend to determine the efficacy of 4'-thionucleoside analog in GBM PDX models resistant to TMZ, and the impact of both hypomethylating agents on DNA damage and repair pathways. Collectively, our data strongly suggests 4'-thionucleoside analog warrants further investigation as a single anti-GBM agent.

Abstract Name: **KidWind: Impacts of Engaged, Community-Based Learning on Elementary Education Majors**

Kidwind is an ongoing community-engaged project involving interdisciplinary teams of undergraduate elementary education and engineering students, to plan and implement a unit on concepts of engineering design process and wind energy in local 4th grade classrooms. Occurring over 3 years with separate participant groups, the lesson implementation was completed in person during 2019, hybrid in 2020, and virtually in 2021. As an elementary education student participant of the 2021 session of this study, I have strong interest in the impact that this engaged learning experience had on myself, my peers, and our 4th grade students. This interest led to two research questions: What are the impacts of Kidwind on elementary education majors' engineering teaching practice? How does this impact change depending on the modality of the lesson implementation? Participants completed pre- and post-tests, where the questionnaire items included Likert scale questions focusing on engineering teaching self-efficacy, and short response questions focused on assessing concepts of wind energy, wind turbine blade design, and the engineering design process. The Likert scale items were analyzed using Wilcoxon Ranking system and paired t-tests, and the short response questions were analyzed by identifying major themes that emerged within the participants' responses. The comparison between pre- and post-responses shows an enhanced understanding of wind energy concepts and an increased self-rating on engineering teaching self-efficacy. An analysis of both 2019 and 2021 elementary education participants' short answer responses shows an increase in knowledge of the key blade variables (pitch, size, shape, and number of blades) that affect wind turbines' performance. These findings inform effective engineering teaching approaches through engaging, community-based experiences which are incredibly valuable to learning and confidence for pre-service teachers.

Abstract Name: **Analysis of 1920 Bolshevik Propaganda Posters and the Representation of Women**

This research looks at the various ways in which women were depicted in, or left out of, Bolshevik propaganda posters and society at large in 1920. Class unity was often emphasized over gender relations in Bolshevik ideology and women's movements were often discouraged by the party. This stance differs from the Marxist ideology it originally grew from. The goal of this research is to show how women were viewed by the Bolsheviks, and by society at large, and how this reflected the facts of their place in society. This has been done by analyzing six propaganda posters to see how women were depicted and in what cases they were left out. Through showing this representation, this research highlights the place of women in early twentieth century Soviet Russian society as well as how the Bolsheviks chose to depict and therefore treat these women in society.

Abstract Name: **Poking Around: How does herbivory affect reproductive traits in Phytolacca americana?**

Plants often experience a trade-off when allocating resources for growth, survival, and reproduction. Additionally, herbivory, the consumption of plant materials by animals, can reduce the rate and amount of resources a plant can acquire. This loss of resources due to herbivory might result in plants suffering the cost in terms of reproductive allocation. My research addressed the question of where the balance between the cost a plant suffers from herbivory to theresources it allocates for reproduction. It is my prediction increasing levels of herbivory will have a significant negative effect on the reproductive efforts in Phytolacca americana. To examine these trade-offs, I simulated herbivory onPhytolacca americana in central Pennsylvania on Susquehanna University's campus. Each plant was categorized into three size levels: small, medium, and large. The treatment for the plants consisted of cutting off leaf structures down to the stem. Different treatment levels consisted of 0% leave mass removed, 50% removed, and 100% removed. Pre-treatment, thenumber of leaves and fruit racemes were recorded. Five weeks post-treatment, dead plants were noted as well as the number of fruits, fruit weights, and ripeness,plus the size and number of racemes between the groups. Smaller plants are not as resilient to the treatment and have resulted in numerous cases of extreme wilting or death. There is a correlation in the amount of underripe and overripe fruits between treatment groups.Understanding the interactions between herbivory and resource allocation in plants is important to further the knowledge of herbaceous plant populations as well as exploring the mechanisms in which resource allocation takes place.

Abstract Name: **Collection season effects ant diversity**

Ants provide valuable services to ecosystems, aiding in nutrient cycling, seed dispersal, and soil formation. The diversity of ant communities is often used to indicate the overall health of the environment. To explore how human impact affects ant communities on Bowie State University, students in BIOL 102 sampled ants in three locations on campus 1) on campus near buildings 2) at the edge of campus and 3) in the woods on campus. We used DNA barcoding, sequencing the COI gene, to identify the species of ants collected. Overall, 28 ants were successfully sequenced. We found a total of 5 ant species. The most common ant species was Prenolepis imparis, or the winter ant. The ant species diversity was ants collected much lower than the species diversity calculated from the Fall 2021 semester. Our results that the season impacts the diversity of foraging ants, with fewer ant species foraging in cooler temperatures. Ants are ecosystem engineers, providing many important functions. Temperature increases due to climate change could have large impacts on ant foraging and function, thus also affecting the overall environment.

Abstract Name: **Comparing the Proliferative effects of Pulsed Electromagnetic Fields (PEMF) and Capacitive Coupling (CC) Stimulus on Preosteoblasts**

In the US, more than 99 million individuals over the age of 50 suffer from low bone mass. Pharmacological drugs can reduce bone loss but come with serious side effects. Several non-invasive stimulators such as PEMF and CC have been shown to increase bone formation but the data have been inconsistent. Both L- and T-type Voltage Gated Calcium Channels (VGCC) mediate anabolic functions in osteoblasts and we postulate that these channels could be stimulated by PEMF and CC fields to increase anabolic function such as proliferation and elicit osteogenesis in osteoblasts. To test this hypothesis, we used MC3T3-E1 cells seeded at 2500 cells/well in 96 well plates to determine the effects of PEMF on proliferation after four days. To determine the role of VGCC's on proliferation we used nifedipine (5μM) or NNC-55 (5μM) to block the L-VGCC or T-VGCC, respectively. Additionally we used inhibitors to calcium binding proteins (CIB) calmodulin (W-7), CaMKII (KN-93), or Calcineurin (cyclosporin-A) to define the pathway for proliferation in these cells. We also stimulated control and inhibited MC3T3-E1 cells with PEMF or CC for 2 hrs each day for four consecutive days. Proliferation was determined using an MTT assay. In static controls, the proliferation of MC3T3-E1 cells was significantly decreased by inhibition of both L- and T-type VGCCs. Blocking downstream CIBs, resulted in a similar inhibition of proliferation. Application of PEMF significantly increased proliferation of non-inhibited MC3T3-E1 cells and was significantly suppressed by L-VGCC and T-VGCC inhibition. Preliminary data suggest that CC does not alter proliferation of osteoblasts. While inhibition of both L- and T-type VSCC's inhibited proliferation, preliminary results suggest that the T-VGCC may be important in reducing apoptosis. Defining the optimal parameters of both PEMF and CC stimuli in bone could provide insight into directed treatments of fracture healing, bone loss and osteointegration.

Abstract Name: **Graph Theory Analysis of Functional Brain Networks in Autism**

Autism Spectrum Disorder (ASD) is a neurodevelopmental condition with reported differences in behavioral and neurobiological characteristics. Previous studies have shown that autistic individuals differ from neurotypical (NT) individuals in brain connectivity (Kana et al., 2014), with some developmental differences as well (Bathelt; Geurts, 2021; Walsh et al., 2019). The purpose of this study is to use graph theoretical analysis to determine the differences in resting-state fMRI connectivity between autistic and NT individuals as well as between older and younger adults within those categories. Resting fMRI data from 58 participants were obtained from the publicly available Autism Brain Imaging Data Exchange (ABIDE II) database. The autistic (n= 29) and NT (n=29) groups were both divided into younger adults (ages 18-25 years) and older adults (ages 40-64 years). Functional connectivity analysis was followed up by ROI-to-ROI (region of interest) graph theoretical analyses using the CONN software (Nieto-Castanon; Whitfield-Gabrieli, 2021) to compare connectivity between diagnostic groups and age groups. Three measures were focused on: global efficiency, the measure of the connectedness of one node to other networks; local efficiency, the connectedness of the node to local nodes in the same network; and betweenness centrality, the involvement of the node in paths that run through the network (Smith et al., 2018). Global efficiency was found to be lower in the younger autistic group compared to the older for the right superior parietal lobule (RSPL) and the right intraparietal sulcus (IPS) (T=-3.03; 0.01 uncorrected). This is in line with earlier findings that found an age-related effect in connectivity of the IPS (Vinette; Bray, 2015). The autistic participants as a whole showed lower betweenness centrality in the left frontal pole than the whole NT group. These findings provide important insights into the brain network properties in autism.

Abstract Name: **Sustainable IoT Sensor Node for Energy Efficient Smart Building Applications**

The ambient parameters inside buildings, like temperature, humidity, and illumination level are valuable information that can be used to optimally control HVAC and lighting systems. Such optimal operation can significantly reduce energy consumption and improve the energy efficiency of buildings. Conventional sensor systems either use batteries or wired power supply. Wired power connections are expensive and limit the mobility and locations where the sensors can be placed. On the other hand, battery powered devices require frequent manual battery changes. Not only do batteries hold the hassle of continuous maintenance, but if not recycled properly, they pose a threat to human health and the environment due to their toxic chemical constituents. This research involves designing and prototyping a self-sustaining batteryless IoT sensor system for indoor environment monitoring suitable for smart building applications. Our designed IoT sensor is self-sustaining which powers itself by harvesting energy from ambient indoor light. Alternatively, it can be powered using a remote infrared laser beam in the absence of ambient light. The built-in energy harvesting circuit integrates a solar cell, a DC/DC converter, and an energy storage capacitor. When the capacitor charges to a certain voltage, the low-power STM32 M0+ microcontroller wakes up and sends sensor readings to a hub. The circuit is designed such that discharge of the capacitor from its charged state gives enough time for the microcontroller to complete sensor reading duties, and then transmit the data using an infrared transmitter to a nearby hub. The Wi-Fi enabled hub then uploads the data collected from all sensors to the cloud, which is then analyzed and can be used to control HVAC, power outlets, and indoor lighting of the building to optimize energy usage. We will present the circuit design, programming strategy, and the communication techniques used to develop this smart building IoT sensor.

Abstract Name: The Impact of Vector Fields and Topographic Maps in Life

Calculus is the introduction and foundation to higher level mathematical models. With the technological advances and the shift from material to intellect in the era of knowledge, I entail to analyze the impact and applications calculus has in present day. The universe is multidimensional, and calculus is math for multivariable functions. In daily life, society functions on data repositories, but few are aware of the degree their lives depend on mathematical equations. From the weather to their vehicles to GPS, technology uses multivariable calculus to analyze the data we collect. Technology quickens calculations, but even technology had to come from individuals applying mathematics. Some examples include topographical maps, which use cross-sectional areas to determine contour lines of elevation, vector fields, which analyze drag on F1 race cars or the aerodynamics of plane wings, and volume integrals, which can calculate the volume of irregular objects or terrain. Computers ease the labor of calculations, but they also allow individuals to learn and manipulate the lessons they're completing in calculus, such as the program GeoGebra, which allows users to visualize functions in 3 dimensions. There are many more use cases for calculus, and many in plain sight often overlooked by the common citizen which I hope to bring to the forefront of their minds with this research and presentation.

Abstract Name: The Inescapable: Overconsumption Encouragement Through Media - The Dichotomy of Tik Tok

Technology is what surrounds us, now more than ever. With reports of 98% of Generation-Z and Alpha individuals having an electronic device readily available at all times, it is no surprise that mass media is becoming the new way for users to consume information at a higher and faster rate than ever before. Most scientists have confirmed the damages of mindless indolent scrolling which media platforms such as TikTok provide. All, especially younger people, can turn off theirstimulation of the senses through 15-30 second content clips that require little intellectual processing and easily occupies hours of idle time.However, a surprising juxtaposition exists on TikTok. Although the app can be arguably useless it has also created its own subculture of users. Through a sophisticated algorithm, TikTok curates intellectual and academic content that produces surprisingly significant discourse. Generation-Z and Alpha now have access to a world of culture and connections creating a pathway for creators to use their online presence to create wavelength effects through debate, research, and discovery of new material.This paper will discuss the ways TikTok creates a circular void for itself, allowing for vacuous and substantive content to exists on the same platform. Are the days of drafting multiple arguments for your dissertation over? Imagine a 15-second video targeted to reach over 1 million people in less than a day, creating a trail of rhetorical breadcrumbs for discourse and debate to follow. Focusing on the future of academic work, this paper will analyze the way in which burgeoning intellectuals have already begun and will continue to use social media in innovative and professional ways.

Abstract Name: **AI for Autism: The Use of Artificial Intelligence to Classify and Count Challenging Behaviors In Children With Autism Spectrum Disorders**

Assessing challenging behaviors that are aggressive and self-injurious in children with autism can be difficult. These behaviors can also be physically dangerous to both the child and bystanders. Therefore, it is important for clinicians to account for these behaviors, in which to establish a baseline to measure goals of the implemented behavioral health plan. AI has been used to assist in the diagnosis, classification, and treatment of autism and can be an effective way to help characterize and count these behaviors. Convolutional Neural Networking (CNN) is an effective way to use AI to classify challenging behaviors. We found that the CNN model's adaptability would be suitable to recognize images of challenging behavior such as kicking, biting, and head striking. Characterizing these behaviors within their designated topography. In order to create an AI tool that recognizes challenging behaviors in children with autism, existing datasets need to be converted and grouped into distinguishable behaviors that are focused on specific actions. We collaborated with computational and behavioral scientist to increase the overall sensitivity and accuracy of the machine learning. In the future the model's algorithm can be revised and applied to larger datasets. AI can be beneficial in early childhood interventions for children who are experiencing severe forms of autism. It can provide clinicians a way to better understand this disorder and provide effective treatment by observing and quantifying the overt behaviors that are being displayed.

Abstract Name: **Exposition and Models for Nil Geometry**

Non-Euclidean geometry refers to any geometry outside of the standard Euclidean Geometry (uncurved space). Each non-Euclidean geometry has their own special properties. Nil Geometry is a non-Euclidean geometry derived using the Heisenberg Matrix group. This matrix group is most commonly used in quantum mechanics. Nil geometry's special characteristics include spiral geodesics (shortest paths), the x=0 plane is Euclidean, and there is rotational symmetry around the vertical planes.Nil Geometry is most commonly modeled two different ways, the Rotation Invariant model and a model derived from the Heisenberg Matrix group. The Rotation Invariant model is currently most commonly used for modeling the space due to ease of computation. The model based on the Hiesenberg group provides striking results when common geometric shapes, like a ball, are modeled through it. These shapes provide a simple demonstration of how a non-Euclidean geometry, like Nil, holds characteristic properties that distinguish it from Euclidean geometry.There is little readily-available information in the literature of why Nil Geometry was created, and there are not many examples of Nil geometry being used or modeled in the real world. The matrix used to derive Nil geometry has a lot of significance in the physics world, but this is not extended to the related geometry. Non-Euclidean geometries are also hard for many to visualize. The literature that is currently available on Nil geometry is made for graduate level mathematicians, with even fewer resources for undergraduate level students.This project will produce freely available exposition and 3d models explaining Nil Geometry and its applications, to help overcome the lack of such resources.

Abstract Name: **Postsynaptic Density Changes in the Trisynaptic Pathway in Schizophrenia: A Quantitative Postmortem Ultrastructure Study**

There is a staggering amount of evidence that the hippocampus is a key structure of dysfunction in schizophrenia (SZ). Neuroimaging and postmortem studies have revealed a positive correlation between hippocampal abnormality and degree of psychosis. Glutamatergic hyperactivity in the hippocampus is proposed to arise in multiple subregions and from specific cellular and morphological changes. In this study, we aimed to identify region-specific circuitry imbalances in excitation and inhibition via electron microscopy. Postmortem anterior hippocampus tissue was used from patients with SZ (N=10) and well-matched normal controls (N=10). Using the unbiased stereological disector method, we identified and measured the length, width, and area of asymmetric (excitatory) axospinous and axodendritic post synaptic densities (PSDs). We measured only the length symmetric (inhibitory) axospinous and axodendritic because the PSD of symmetric synapses is too miniscule to obtain the width and area. Measurements were taken in the dentate gyrus, CA3, and CA1 of the trisynaptic pathway in the hippocampus. We found an increase in the width of asymmetric axospinous PSDs in CA1 in SZ. We also foundan increase in the length of symmetric axodendritic PSD length in CA1, likely a result of long-term potentiation. These results are consistent with hippocampal glutamatergic hyperactivity literature andis the first region-specific quantitative analysis of PSDs in the hippocampus in SZ, providing novel insight to SZ hippocampal etiology.

Abstract Name: **Rheological and Water-Holding Properties of Lentil Protein Isolate for Use as a Plant-Based Yogurt Alternative**

Due to the increasing awareness of the negative impacts of animal husbandry, there is a fast-growing industry for plant-based alternatives. Weight by weight, plant-based alternatives generally use much fewer resources for the same amount of protein output than animal-sourced foods, indicating that without sacrificing nutrition, we should be able to produce more food of nutritional value using the same amount of resources. Currently, a majority of the plant-based alternatives on the market, other than soy products, lack a protein content that matches that of dairy products. Pulse-based alternatives have been recognized for their protein content comparable to that of dairy; however, undesirable textures limit their uptake into the mainstream. The purpose of this study is to optimize the texture of a yogurt-like product produced by the lactic acid bacteria (LAB) fermentation of lentil protein isolate (LPI) solution. To accomplish this, I experimented with the temperature at which I performed my fermentation and the protein concentration of my LPI solution. The fermented LPI solution was then subjected to rheological measurements and centrifugation tests to understand the gellification and water-holding capacity abilities of the yogurt-like product, respectively. The preliminary results show that due to its gelling properties, LPI has a high potential for future applications in other fermented plant-based dairy alternatives, as proved by the rheological measurements. However, more research is needed to determine the water-holding capacity of this fermented LPI solution. This presentation will present the complete results of the study. The implications of these results will indicate whether an LPI yogurt-like product would be able to avoid settling and separation during storage, improving its ability to enter the mainstream food industry as an environmentally-friendly alternative to fermented dairy products.

Abstract Name: The Effects of the Bank War: An Observed Causality Between Jacksonian Monetary Policy and Californian Settlement Based on Gold Demands

With an aim to understand the relationship between California's gold-centric settlement caused by the Gold Rush of 1848 and the monetary policy of President Andrew Jackson, this study investigates the Bank War and its impacts on the national gold supply while analyzing its subsequent effects on the growth of California following the Panic of 1837. Jacksonian policies made against the Second National Bank, such as the veto of the bank's recharter, the transfer of federal funds to state banks, and Specie Circular, are analyzed to ascertain their influence on national gold demands and any resulting impacts on the national economy. The consequences of this resulting demand are determined by investigating the statistics of California's population and manufacturing outputs at the time of the Gold Rush, which are derived from the Seventh Census of the United States in 1850. Results indicate that Jacksonian policy was the driving force of the gold shortages that caused the Panic of 1837 through a widespread default on land payments—consequently generating a demand for gold which incentivized the mass settlement of California undertaken during the Gold Rush. The initial mass migration caused by the discovery of gold created needs for otherwise unestablished markets, which in turn further stimulated the fledgling economy of the state. This assessment establishes a previously unexplored impact of Jackson's tenure as president and provides a more informed understanding of historical economics. Future research is needed to properly analyze the full impact of the Panic of 1837 and could include a comparative analysis of its similarities with other significant depressions in America, such as the post-war growth observed following the Great Depression and the housing bubble which caused the Great Recession of 2007.

Abstract Name: Impact of COVID-19 on an International Sample of Religious Leaders: Challenges, Sources of Resilience & Unmet Needs

The COVID-19 pandemic has placed unprecedented challenges on religious communities around the world and many have turned to their religious leaders for guidance but this places them and their houses of worship at a greater risk for stress and adversity. Religious leadership has a responsibility to guide and inform their congregants by answering remarkable questions while houses of worship offer a setting to practice faith. Nonetheless, leadership and houses of worship are also found at the center of controversy over ways to best mitigate issues stemming from the pandemic while also staying within tradition of the religion like taking communion, gathering at places of worship, and hosting ceremonies or proper burial, for instance. The data comes from a series of interviews with religious leaders from around the world from various backgrounds and denominations. In order to qualify, they needed to hold some responsibility for a congregation or community. During the interview process, we asked questions concerning the challenges that faced them, their family, their congregation, or the greater community they served. Next, we ask about their sources of strength and coping mechanisms to withstand or overcome hardships. Finally, we are asked about and later identified unmet needs: what do they, their loved ones, congregation, and community need to recover and move forward? Their answers suggested that various challenges arose from government policies to curb the effect of the pandemic. Moments of strength came from delving into scripture and becoming more involved with the local community and serving others. Meanwhile, families and houses of worship struggled financially and even entered a deficit. Among other challenges and overcoming some, the pandemic has left lasting effects on leadership, houses of worship, and the local community and brought new questions on how to combat similar crises in the future.

Abstract Name: **Rediscovery of the Self from the Outside in Kathy Jetn?il-Kijiners Iep J?ltok: Poems from a Marshallese Daughter**

Kathy Jetn̄il-Kijiner's poetry collection, Iep Jāltok: Poems from a Marshallese Daughter's, asks a western audience to consider the beauty of Marshallese culture, to recognize their destructive role in Marshallese history, and finally to act against anthropomorphic climate change to prevent the foreseeable destruction of the Marshall Islands. Its main title, Iep Jāltok, translates to "a basket whose opening is facing the speaker." In this figurative basket Jetn̄il-Kijiner places her own memories and experience as a member of the Marshallese diaspora. However, collected alongside her experiences are texts from external sources, some even from western perspectives. Jetn̄il-Kijiner transforms histories, linguistic fragments, and missionary songs into verse.This paper delivers a close reading of these "outside poems" to examine what their inclusions in the collection signal on a metatextual level, with poem originating from western sources providing particularly deep ironies in their role as reflections and distortions of Jetn̄il-Kijiner's Marshallese consciousness various stages of her self discovery. It also analyzes how Jetn̄il-Kijiner transforms non-verse text (e.g. dictionary entries, myths, historical accounts) into verse, as well as how she adjusts texts already in verse, and what meanings her choices in line breaks and meter convey. The paper concludes that it is through these "outside poems," that Jetn̄il-Kijiner traces her own journey of self understanding demonstrating not only the necessity of external changes in the world, such as combating climate change and protecting and learning from marginalized peoples and cultures, but also the necessary internal developments, using herself as a model, for the western audience to act on these changes without trampling on those for which the most is at stake.

Abstract Name: **Shining a Light on Experimental Theatre Practices: A dissection of Neo-Futurism as it is and how it is applied in a modern performance context.**

This project seeks to explore the tenets of an experimental style of theatre in a modern performance context while working with passionate students to help expand their means of artistic expression. Neo-Futurism is an active creative force and is continuing to evolve within the theatrical community. I will be basing my project on the work of The Infinite Wrench, a neo-futurist ensemble that is based in Chicago, Illinois. They are an ensemble of writers, directors, and actors that perform thirty plays in sixty minutes, all while following the four basic tenets of neo-futurism: no suspension of disbelief, speed and brevity, scripted and planned, reliance on chance. My goal is to create an ensemble of students at UWEC that mirrors this aesthetic of truthful communication between the audience and the performer. The main research questions I want to explore are 1. What exactlyisfuturism? 2. How did it evolve into neo-futurism? 3. How can we, as writers and performers, apply this specific style in a modern performance context and 4. How does a theatre practitioner develop this style of theatre? My objective for myself and the ensemble is to break out from the robotic tendencies of realism based writing and thinking and creating a new heightened theatrical sensibility. I want the audience to leave with a newfound appreciation for experimental theatre. In addition, I want our plays to evoke a particular atmosphere that challenges the audience to think for themselves. Moreover in executing this project, I want to gain dexterity in performing, writing, and directing within an experimental environment while also developing my skills as a leader amongst fellow creators. Lastly, I would like to develop this material into something suitable for a possible confrence presentation, a poster and/or a short performance at NCUR.

Abstract Name: **Understanding Musical Systems with Zn - Cayley Graphs**

It is well-established that music theory uses mathematics to explain concepts such as pitch, interval,rhythm, and counterpoint. Chord progression and pitch frequencies can be beautifully explained by mod 12 transformations and geometric ratios. Modern mathematical tools are used to advance concepts of music theory. This area of research is very active and answers the “how (music is born or can be created)” question; however, the “why (mathematics helps explain to some extent, music)” question is much more difficult. Possible answers will likely be unsatisfactory for different categories of researchers.In my research project under the guidance of mathematics professor Gabriel Picioroaga, I follow two avenues: one to show that the Cayley graph of the group Z12 with generators 3 and 4 explains the constructions of (most) major and minor chords. This is done by “walking” on paths in the graph originating at the root of the chord. The circle of fifths can be explained as “stepping” on both generators at once and recording the loop. Based on these considerations, with Z12 as model, a second avenue opens; we generalize Zn where n is a product of two relatively prime numbers. These are generators that help define chords as paths in the Cayley graph of Zn. We prove that a circle of fifths-like notion exists as well, which helps create harmonies. As a possible answer to a version of the “why (not other groups or frequencies)” question, we have written software in Maple to hear how these chords sound for Z6, Z10, and Z15. The tuning we consider is a generalization oftemperate tuning. Moreover, the frequency distance of the octave (which doubles from pitch C to next higher C) can be chosen to be a variable positive number.

Abstract Name: **Testing Effects of the Anti-diabetic Agent Acarbose in Mice with Renal Carcinoma: A Diet-Based Approach to Cancer Treatment**

Immunotherapies are the standard of care for renal cancer patients, but only ~50% of patients respond to treatment. Because renal cancer cells use glucose as an energy source to sustain their proliferation, our lab studied the connection between diet and renal cancer using acarbose, an FDA-approved glucoregulatory agent that prevents the breakdown of complex carbohydrates into glucose, thereby reducing the amount of sugar that makes it into the bloodstream after eating. In lean mice with renal tumors from the Renca renal carcinoma cell line, past research in our lab showed that acarbose blunted blood glucose elevation after meals and reduced renal tumor growth in a CD8 T cell-dependent manner. When acarbose was combined with anti-PD-1 immunotherapy, spontaneous lung metastases were significantly reduced. However, both obesity and type-2 diabetes – characterized by high blood glucose – are common comorbidities in renal cancer patients and tend to result in worse clinical outcomes. Thus, to emulate clinical patients, we worked to develop a BALB/c mouse model that would reflect both obesity and high blood glucose by using a standard high-fat diet plus streptozotocin, a toxic chemical that kills insulin-producing pancreatic beta cells. We found that using this approach, it was possible to generate mice with either obesity or high blood glucose, but not both. Low-dose streptozotocin produced unregulated type-1 diabetes, reducing body weight and survivability. We then tested the efficacy of acarbose in obese mice on a standard high-fat diet alone and found it to be ineffective at reducing renal tumors and spontaneous lung metastases. Surprisingly, acarbose was also ineffective at slowing renal tumor growth in mice fed a high-fat diet containing starch. Future studies will examine if acarbose improves immunotherapy outcomes in mice with obesity and evaluate acarbose efficacy in other tumor types.

Abstract Name: **A Pilot Study Exploring Veteran Identity Using Lyric Analysis in a Qualitative, Community-Based Participatory Action Research Framework**

Researchers attempt to define what it means to be a Veteran, but it is rare for that question to be directly asked of Veterans. Traditionally, experimenters define variables and ask the community of interest (CoI) to provide responses without the CoI being included in the research process or reaping any direct benefit from participation. There is a high degree of distrust and disenfranchisement reflected in Veterans towards the mental health care system and the scientific community. We aim to use the CbPAR model to amplify their voices and focus on what is important to them. We are seeking to allow Veterans to define their identity in their own words. Researchers serve as messengers to help amplify Veteran voices and disseminate their stories to the larger community. In the current study, we asked Veterans to identify songs that answered the question, "What does being a Veteran mean to you?" This study is part of a larger research project using both photovoice and lyric analysis to help define the "sights and sounds" of Veteran identity. Veterans worked individually with researchers through the process of lyric analysis, which is a music therapy intervention in which the client and therapist listen to a song together and discuss the connection the lyrics have to the client's life experiences. Transcripts of interviews will be analyzed to uncover common themes and elements that help researchers understand how they conceptualize their community identity as Veterans. External validity is addressed through member checking, in which participants will review transcripts, discuss identified themes, and choose representative songs to present as a part of an immersive, interactive gallery experience for the community to allow for their stories to be told. We assert that more research should be done with the Veteran community, not to them.

Abstract Name: **The Beloved Community: Creating a collaborative experience to explore Ethical Decision Making and Perspective taking using historical references**

The goal behind creating this experienceis to allow participants to engage with the decisions, actions, and perspectives of the governmental officials, college administrators, and student demonstrators during the 1960s student sit-ins for Civil Rights in Montgomery, Alabama. This project allows participants to see themselves in each of the moral leader comparators lived experiences as told by them, as well as engage with the original documents and newspaper coverage of the events. The events selected for this pilot spawned two landmark legal cases—the Dixon v. Alabama State Board of Education (1961) and the Sullivan v. NY Times (1964). This poster presentation outlines the metamorphosis of historical content into a collaborative, playable experience. Using content that was analyzed by previous teams, our goal was: to create archetypes of the people involved in the actual events; segment events into specific questions; and organize information access to individual players based on character perspective. Students then meet synchronously to debate the "Event Questions" from the perspective of their assigned archetype. At the end of the timed discussion, all participants propose and present to the group, a course of action based on their research and the impact of the discussion. This continues for four rounds. At the end of the experience, suggestions for actions are compared to the historical documentation of the events. Based on the game mechanics used in "The Situation Room Experience," students move from exploring contemporary events, back in time, where information is received through newspapers, flyers, radio and word of mouth, to better understand the context of decisions that still affect us today.In addition to understanding history, this experience can be used to promote the higher order skill development needed by college students - empathy, perspective taking, intercultural agility, and ethical decision-making.

Abstract Name: **The Metabolomic Analysis of Sjogren's Disease**

Autoimmune diseases result from the body's inability to distinguish between unknown and healthy cells. Sjorgen syndrome is an autoimmune disease that causes dryness in the eyes and mouth. The name for the autoimmune disorder was derived from Henrik Sjögren and can also be known as Sicca syndrome. However, the disease resembles the composition of Lupus disease due to the origin of connective tissues. The target of this study was to observe the difference in the metabolic makeups of t-cells. The experimental setup consists of methanolic extraction utilizing a liquid chromatography-mass spectrum to analyze the metabolites from the t-cells of a Sjögren patient and healthy control. My founding consists of significant differences in metabolomics in the Sjorgen patient sample compared to the healthy person control.

Abstract Name: **Role of Soil Moisture and its Assimilation on Streamflow Forecasting using Hydrologic Modeling and Remote Sensing**

Several studies have shown that skillful streamflow forecasts can improve management of water and agricultural operations. Monthly to seasonal streamflow forecasts are primarily dependent on atmospheric conditions, Sea Surface Temperatures (SSTs) and initial hydrologic conditions such as soil moisture. Soil moisture data assimilation has proven to enhance streamflow forecasting skills using hydrologic modeling. The goal of this study is to develop monthly updated streamflow forecasts and quantify the role of soil moisture on streamflow forecasting skills.
Forecasts were created using simulated soil moisture from the Variable Infiltration Capacity (VIC) model as well as using soil moisture estimated from remote sensing. These forecasts were compared to observed streamflow from 1-4 months lead time on monthly and seasonal basis. For a shorter lead time of 1-2 months, remote sensing data didn't improve forecasting skill. However, for a 4-month lead time, remote sensing data showed some improvements in forecasting skill, especially during summer seasons. During winter seasons, forecasting results didn't improve when using soil moisture was obtained from the ESA-CCI satellite. All forecasts, using both simulated and remote sensing information, showed poor performance during months of extreme flooding.

Abstract Name: **Genetic Modification of Saccharomyces cerevisiae Using ADE2 Screening**

Industrial yeast strains are used in the food and beverage industry to create products we consume on a regular basis. Genetically modified yeast can be used to create new products with unique properties, but Food and Drug Administration (FDA) guidelines restrict the use of antibiotic resistance genes to construct strains that will be in products for human consumption. To solve this problem, we are developing an industrial yeast strain that uses the ADE2 gene as a marker for genetic modification. When ADE2 is knocked out, the yeast cells accumulate a metabolic intermediate and turn red. By including a functioning copy of ADE2 along with our new genetic material, we can select for successfully modified yeast by looking for colonies that are white again. This approach to genetic modification aligns with FDA guidelines for ingredients that are “generally recognized as safe” and will allow us to create genetically modified yeast strains to be used in the food and beverage industry.

Abstract Name: **Political Party Affiliation and the Significance of Race: How Race Correlates With Political Party Identification.**

The 2020 Presidential election was one of the most historical elections in the United States. The world witnessed both Presidential candidates break and set a record for obtaining the most popular votes of any president in United States history. Controversies and speculations surrounded the election, but most importantly, the world observed that The United States is arguably the most divided that it has ever been. The Black Lives Matter movement and its countermovement, Blue Lives Matter, highlighted this division. The Black Lives Matter movement, composed largely of African-Americans, demonstrated alignment with the Democrat party, while the latter, composed of mostly Caucasians, aligned with the Republican party. In observance of this division, this essay asks: Is race a significant factor in determining one’s party identification? In this essay, the data collected from the American National Election Studies 2020 Time Series Study is evaluated and utilized to produce various graphs and tables evaluating the correlation between the independent variable, “Race,” and the dependent variables, “Party Identification”, “Democratic Feeling Thermometer”, and “Republican Feeling Thermometer”. In addition to the conducted research, literature review on the correlation of race and party affiliation was analyzed. For instance, various authors from the article Black Voters, Black Candidates, and Social Issues: Does Party Identification Matter? conducted research at Christopher Newport University to determine if race was more significant than ideologies regarding party identification. These authors found that the Democrat party identification is the biggest factor in Black voter decision making, validating that race was a more significant factor than ideologies. The findings of both the conducted research and the literature review reveal that Caucasians were more likely to vote Republican, while non-whites were more likely to vote Democrat. Both the primary and secondary research validate that race is a significant factor in one’s party identification.

Abstract Name: **False Memories: the Fear Factor**

Purpose: How does mood affect susceptibility to false memories? People are less likely to form false memories when sad, ostensibly because sadness encourages memory encoding of item-level information, while neutral moods encourage holistic processing, in favor of the gist (Storbeck, 2013). Though the protective benefit of sadness in avoiding false memories has been demonstrated, we investigate how both sadnessand fear–another important negative emotion– affect susceptibility to false memories. This is significant to investigate because when a negative event is experienced, people often remember vivid and specific details of the incident. In these traumatic scenarios, fear is likely the strongest emotion. From our work, we will be able to demonstrate whether fear, like sadness, protects against false memories.Procedure: Participants view movie clips validated to reliably elicit the desired emotions: neutral, sadness, fear (Gross; Levenson, 1995; Hewig et al., 2005) and rate their mood using the positive and negative affective schedule (PANAS). False memory susceptibility is evaluated with the Deese–Roediger–McDermott (DRM) paradigm in which participants study lists of words that are each related to a critical, unpresented lure, then take memory tests on the words. If a participant misremembers a critical lure as being presented, a false memory has occurred (Roediger; McDermott, 1995). The mean number of falsely recognized critical lures across the three mood conditions will be analyzed using ANOVA. This project has received IRB approval and data collection has begun. Expected Results and Implications: If fear, like sadness, confers a protective benefit against forming false memories as we hypothesize, participants in neutral moods will have significantly more false memories than sad or fearful participants. Of theoretical significance, we will determine if fear, like sadness, encourages detail over gist processing. Of applied significance, this study may add to our understanding of memory formation in traumatic situations.

Abstract Name: **Effects of Aromatic Prenal Chromene Oxime Derivatives on A375 Cancer Cells**

New anti-cancer drugs are in demand due to the undesirable side effects of pre-existing drugs and the tendency of cancer cells to become resistant to highly effective treatments. Oximes are highly selective kinase inhibitors, which makes them ideal for drug design. Six aromatic prenal chromene oxime derivatives were synthesized and examined for apoptosis induction when tested on A375 human melanoma cells. The compounds were compared to etoposide and dimethyl sulfoxide as positive and negative controls for their ability to induce apoptosis. A375 cells were cultured in DMEM supplemented with 10% FBS and passaged onto glass coverslips in 6 well plates. 50 micromolar concentrations of each derivative were added to two milliliters of cells in supplemented DMEM. After 24 hours in culture in the presence of the derivative, DAPI and Caspase stain were added to each well. After 1 hour of staining, live cells were imaged and then fixed with 4% formaldehyde for 15 minutes. To determine the percentage of cells undergoing apoptosis, cover slips were viewed under a fluorescent microscope. Cells that appeared green were scored as undergoing apoptosis, while the cells that appeared blue allowed us to identify the total number of cells. We calculated the percentage of cells undergoing apoptosis after exposure to each derivative. All 6 derivatives increased the number of apoptotic cells, relative to the DMSO control. The compounds M-Prenal oxime, oxime benzoate, and oxime cinnamate seem to have the strongest effects, although none of them were as effective as an identical concentration of etoposide. We are working to improve the consistency of results and to determine the concentration dependence of each derivative. Our initial results suggest that chromene oxime derivatives have potential as anti-cancer drugs and can induce apoptosis in a human cancer cell line.

Abstract Name: **An American Outcry - Using Music Composition as a means to discuss gun violence in American Schools**

Gun violence is very far from a foreign topic in our modern society. Unfortunately, America's youth are subsequently placed in the crosshairs far too often. Stemming from Columbine to Uvalde, active shooter incidents on school grounds has remained an ever present threat to the safety and well-being of students of all age ranges. Therefore, An American Outcry serves paying homage to the past victims of school gun violence. However, it also attempts to serve as a firm message that serious reform is needed, or else this is a conversation that will simply continue to happen over and over again. The piece, originally scored for wind ensemble, is centered around two core themes: fear and hope. The fear aspect is derived from the opening of the piece, which starts in a minor key, and is set up much like a traditional funeral march would. The remained of this section is a slow build to the violent climax that is meant to depict the pure tragedy that is gun violence. Following that section, the piece transitions into a major key and is begins to pull thematic material from the mid-nineteenth century ballad, "Annie Lisle". The tune, although having a historically grime meaning, is often found to be the basis for many school alma maters, thus making it the perfect setting for the theme of hope. The piece ends with the return of the fear theme, there to represent the failure our society has experience in gaining control over these travesties. The final page contains both themes playing offset from one another by one beat and is to serve as a reminder that work is still to be done if the safety of America's schools is ever to be guareented.

Abstract Name: **Role of Spinal Interneurons in Nociceptive Signaling Pathways in a Polytrauma Model**

Due to their differing responses post-injury, the central nervous system (CNS) and the peripheral nervous system (PNS) are often thought to be completely separate within our bodies. Neuronal regeneration does not normally occur in the CNS due to the surrounding environment whereas the PNS readily supports axonal regeneration. On account of a lack of effective treatment options to treat polytrauma in humans, the purpose of this research is to take a look at the mechanisms and interactions that occur post-injury in both of these systems. Currently we are characterizing central nervous system responses to a peripheral nerve injury. We have established a burn injury model in rats which led to increased thermal analgesia and mechanical allodynia in the group who received the peripheral injury. Immunohistochemistry using calcitonin gene-related peptide (CGRP), a neuropeptide that is correlated with pain, showed more axonal processes in the dorsal root entry zone compared to sham rats. These data suggest increased arborization in the dorsal root entry zone. Current experiments are designed to corroborate this by observing the upregulation of growth associated protein 43 (GAP43), a protein expressed during axon regeneration, using western blotting. In future experiments, we will do additional immunohistochemistry using various neuronal markers to determine what types of interneurons these new processes are synapsing with. Given that we are focusing on nociceptive spinothalamic pathways, we expect increased synapses with glutamatergic interneurons. Supported by Texas Woman's University Division of Biology, and grants from the TWU Research Enhancement Program (to DLH), Experiential Student Scholars Program (to MPH), Center for Student Research (MPH), and National Science Foundation Promoting Research and Innovation in Methodologies for Evaluation (to Diana Elrod, supporting JR, #1953448).

Abstract Name: **HCC Organoid Culturing and Drug Screening**

Liver cancer is the sixth most prevalent cancer and the third most common cause of cancer death in the world. Studies have demonstrated disparities in access to cancer care and outcomes for minority populations, including Latino patients. In San Diego County, liver cancer is an overrepresented malignancy, with mortality rates two-fold higher in Hispanic patients versus non-Hispanic white patients. In our lab, we are developing and refining a three-dimensional model, known as organoids, of the most common type of liver cancer, hepatocellular carcinoma (HCC). These patient-derived organoids are generated from human liver cancer resection and biopsy specimens. This was accomplished by establishing a pipeline in the electronic medical record (EMR) to identify patients who would be potential candidates for tissue donation via the biorepository while ensuring that Latino patients were enhanced in this cohort. Two tissue samples were collected to harvest into organoid cultures and to propagate for drug treatments in vitro to gather data for analysis. We are eager for the future workflow in the EMR that will allow us to identify all patients undergoing liver tumor biopsies at UCSD. For the upcoming academic year, our goal is to increase organoid specimens, while also looking for differences in molecular profiling and responses to different therapies in the Latino and non-Latino HCC populations.Research reported in this abstract was supported by the National Cancer Institute of the National Institutes of Health under award numbers: U54CA132384; U54CA132379. The content is solely the responsibility of the authors and does not necessarily represent the official views of the National Institutes of Health.

Abstract Name: **A Review of Dark Web: Trends and Future Directions**

The Dark web is regarded as the hidden layer of the vast world of web browsing. It is often labeled as malicious and a danger to the common user. In this research, we dive into the skeleton of what constructs the Dark Web and its contents. To conduct our research, we broke down published papers from several scientific Databases and explored different tools such as “Web Crawlers "which scrape Data through keywords, text data, and hyperlinks which are then stored by the crawler and visited at a later time alongside the Machine learning Techniques and Algorithms used by these Crawlers. The onion router (TOR) Browser, a favorable Web browsing tool for its privacy and anonymity settings, has become favorable and a top choice for any cyber-criminal attempting to mask themselves and hide their IP address through these layers of protection, making monitoring and controlling the dark web difficult for law enforcement. Our research has many routes that we can take as technologies and new vulnerabilities become more accessible and the surge of new marketplaces and offered services is bound to increase.

Abstract Name: Isolation of Secondary Metabolites from Antimicrobial Producing Bacterial Isolates

Antimicrobial resistance has become a major threat to public health in the 21stcentury. It threatens the effectiveness of treatments and prevention of illnesses caused by bacteria, parasites, viruses, and fungi not vulnerable to common medicines. The discovery of new antimicrobials can be a success to modern medicine targeting infections, including those present during surgery, and/or cancer chemotherapy (WHO, 2021). During this study, I focused on studying the secondary metabolites of 4 unique isolates (Jax1, Jax25, Wilson2, Wilson8) derived from soil that was previously demonstrated to exhibit inhibition against specific human pathogens. Two different tests were performed on each of the isolates. Primary testing using actively growing cells was performed on human pathogens known to acquire antibiotic resistance (tester strains): E.coli, S.epidermis, E.caratuvore, P.earuginose, E.aerogenes, B.cereus, A.baylyi, B.subtilis, and P.putida, to determine if the soil isolates inhibited the tester strains. Isolates that showed inhibition zones in the primary tests were chosen for the secondary testing. The overlay assay was performed to determine if the secondary metabolites produced by the soil isolates were able to inhibit the growth of the tester strains. Jax1 and Jax25 showed inhibition against gram-positive tester strains only (whole cell; 2* metabolite), while Wilson2 and Wilson8 showed inhibition against both Gram-positive and Gram-negative tester strains (whole cell; 2* metabolite). Currently, I am in the process of sequencingJax1 and Jax25, to determine their identity. Once their identity is determined, future work would include transposon mutagenesis to determine the genes responsible for antimicrobial activity.

Abstract Name: Investigating the Relationship between Academic Stress, Trait Self-Control, and Compulsive Behaviors in College Students

Stress amongst college students has been at an all-time high, contributing towards issues in coping, poor academic performance, and increased dropout rates. The American Psychological Association has even identified this population as vulnerable to high levels of stress. The current study aimed to explore relationships with academic stress, trait-self control, and various compulsive behaviors including disinhibited eating, cyberloafing, and compulsive online shopping. In total, 164 college students were surveyed utilizing convenience sampling to take part in this research by volunteering their time to fill out a 71-item survey. Survey packets included the Perceptions of Academic Stress Scale (PAS), the Brief Multidimensional Self-Control Scale (BMSCS), the Dutch Eating Behavioral Questionnaire (DEBQ), the Cyberloafing in Lectures Measure (CLM), and the Modified Bergen's Shopping Addiction Scale (M-BSA). In addition, several demographic questions and daily hours spent on Social media were asked. It was hypothesized that there would be negative correlations between academic stress and trait self-control. Furthermore, it was believed that there would be negative correlations between trait self-control and the various compulsive behaviors studied. Lastly, it was hypothesized that there would be positive correlations between academic stress and the compulsive behaviors studied. Results found significant moderate positive correlations between academic stress and cyberloafing and compulsive online shopping. Furthermore, a significant moderate negative correlation was found between academic stress and trait self-control. Trait self-control and the compulsive behaviors studied were unrelated. Correlations between academic stress and disinhibited eating were also not significant. Recommendations for future research, implications, and limitations are discussed.

Abstract Name: **Implications of COVID-19 on College Counseling Services**

Many aspects of college life were impacted by the restrictions set in place due to the Covid pandemic, especially when it came to mental health. During this time, the demand for counseling services increased and many students were reporting that the pandemic had negatively impacted their mental health (APA, 2020; Castonguay et al., 2021). Prior to Covid, studies have found that some of the most common concerns students present tocounseling with include anxiety, depression, and relationship difficulties (Cairns et al., 2010; Barr et al., 2011). It is unclear how the pandemic may have impacted the prevalence of these concerns on college campuses. One focus of our study was to uncover whether the most common presenting concerns have changed from pre-covid compared to post-covid. Another adjustment that was made due to Covid was the transition to treatment through an online setting. While these changes have been beneficial in managing depression, anxiety, stress, and other concerns, there have been mixed results when it comes to effectiveness compared to in-person treatments (Bambling et al., 2021). A second focus of our study sought to identify how satisfied patients of college counseling services were with online treatment. To complete our study, we looked at archival deidentified program evaluation data collected from a large Midwestern University System's counseling outcome evaluation tool including responses from our local campus. Our findings note that both at our campus and throughout thesystem, the most prominentpresenting concern both pre-covid (2017-2018) and post-covid (2021-2022) was anxiety, followed by stress and depression. Additionally, a majority (57%) of those who received counseling post-covid chose a telehealth appointment compared to an in-person appointment. Additional analyses examining group differences in satisfaction with counseling services are currently being completed. Implications of the results for counseling services on college campuses will be discussed.

Abstract Name: **ADE Classification in Quiver Representations, Lie Algebras and Cluster Algebras**

ADE Classification is a pattern that appears in several branches of mathematics. To understand ADE Classification, we will use Gabriel's Theorem from quiver representation theory. Quivers are directed graphs, and their representations are collections of vector spaces at vertices and linear transformations corresponding to arrows between each other. Gabriel's Theorem states quivers of finite type can be classified by ADE Dynkin diagrams. Additionally, Gabriel's Theorem allows us to determine a finite-dimensional algebra's properties by looking at its associated quiver representations. By using quiver representation theory, we can study the corresponding cluster and Lie algebras which share the same ADE classifications, creating a bridge among quiver representations, cluster algebras, and Lie algebras. Consequently, we will address more connections among these three theories.

Abstract Name: **Spider functional community assembly along a stress gradient in Northern and Southern Wisconsin forests**

Ecological communities are smaller subsets of overall larger species pools. Ecological selection can cause a community to have less than expected functional trait diversity, narrowing it to a small subset of features (trait clustering). There are also processes, such as competition, that can cause communities to have greater than expected trait diversity (trait overdispersion), especially where ecological stress is low (i.e., the stress-dominance hypothesis). Ecological selection can also alter the mean trait values of communities.There has been considerable work on the functional assembly of plants and fish, but little is known about assembly of terrestrial invertebrate animals. We placed three pitfall traps in 40 locations in Northern forests (i.e., mainly evergreen conifers) and Southern forests (i.e., mainly deciduous trees) across a strong gradient in soil moisture. We measured the size and asymmetry of spider body, leg, eye, and mouthpart traits because they are related to resource acquisition. We used Monte Carlo simulations to estimate the amount of functional trait diversity and mean trait values that would be found if community assembly was caused by random ecological drift. The simulations used three species pool scales: regional (all species), within Northern or Southern Wisconsin forests, within specific forest types. Overall, trait diversity was less than expected by chance, but the effect size was smaller when using smaller species pools. Spiders were larger in Southern forests, but mean trait values were unrelated to soil moisture.Size trait diversity increased with moisture in Northern forests, but not in Southern forests. This partially supports the stress-dominance hypothesis.Asymmetry trait diversity was also unrelated to moisture.Functional community assembly differed in Northern versus Southern forests, and so there are unique assembly rules for each region.

Abstract Name: **Nationalism, Religion, and Identity Formations for the Sri Lankan Diaspora in Staten Island, New York**

This essay argues the Sri Lankan diasporic community in Staten Island, New York negotiates narratives around “authentic” Sri Lankan identity and sense of belonging that encapsulates a romanticization of nationalism, religious identity, and history. In South Asian research emphasis has been on violent outbreaks such as the Sri Lankan civil war, however; an under-studied area is the memory and performance of the Sri Lankan diaspora community in Staten Island, New York in connection to nationhood and nationalism. Therefore, I aim to expand on South Asian research by surveying how mainstream Sri Lankan ideologies are transnationally assimilated to mediate parameters and artifacts around “authentic” Sri Lankan-ness in western spaces. Thus, my contribution will be to understanding how “authentic” Sri Lankan identity is formed and established in Sri Lankan coded spaces such as Lakruwana the restaurant or the Sri Lankan Arts and Culture Museum (SLAC) in Staten Island that legitimizes authority to Sri Lankan national and religious consciousness that is limited to the dominant experience and identity in Sri Lanka: Sinhalese Buddhist. Utilizing Marita Sturken’s Tangled Memories and Benedict Anderson’s Imagined Communities, I suggest through performance and narration, Sri Lankan identity is embedded within communal spaces such as the SLAC museum or Lakruwana restaurant as artifacts to memorialize nationalism, religious iconography, and traditions that authorize the Sinhalese Buddhist Sri Lankan Identity. As a result, these narratives limit the acceptance of who counts as Sri Lankan thus furthering ethnic hierarchy relationships transplanted from Sri Lanka and the erasure of experiences or narratives in Sri Lankan culture that are different than the dominant experience.

Abstract Name: **Capturing the Nuances of Written Language Learning in Five Beginning Writers**

The purpose of this study is to examine generative and narrative writing samples collected over a school year from five high school students with complex communication and learning needs and reveal elements of change/non-change in idea generation, vocabulary usage, and other evidence of word, sentence, or paragraph development. These five consented students participated, for the first time in their school career, in the daily classroom delivery of a comprehensive literacy curriculum piloted and co-taught by a special education teacher and a speech language pathologist. Before study, the five participants tested below the 1st percentile on standardized expressive and receptive language scores. The school team found the students eligible for individualized education program plans, and placed them in a more restrictive and separate learning environment. The five participants were learning foundational components of comprehensive literacy instruction in efforts to build their written language skills before graduation. All participants had access to a class-wide aided language system in the form of 36 highly useful core words along with access to relevant content vocabulary associated with the piloted instructional curriculum. The student's writing samples will be descriptively analyzed using the Developmental Writing Scale, the Readtopia Writing Rubric, and other SLP-generated informal assessments meant to examine change in the essential components of generative and connected text (narrative or expository). Analysis will include evidence/non-evidence of any progression in the students' narrative or expository writing over a school year. To date, 25 writing samples have been collected that represent these five student's beginning writing from September 2021 to December. Results of a systematic qualitative content analysis will be shared with conference participants.

Abstract Name: **Enhanced Wind Energy**

Wind energy is a source of inexhaustible renewable energy that utilizes wind turbines to produce electricity. However, the development of new mechanisms and techniques to improve the efficiency of this method is still a matter of interest for environmental researchers. Motivated by these questions, this research focuses on optimizing the amount of energy generated by windmills by creating a structure that concentrates the air currents. The rationale behind this proposal lies in the fact that the velocity at which the blades of the mill rotate increases, resulting in generating more electricity. To suitably concentrate the air currents, we considered two types of structures: cylindrical and conical. After creating different prototypes of the structure and conducting several experiments in which positions with respect to the windmill and magnitudes were evaluated, we noticed that the energy produced by the windmill varied as well. This proves that there is a correlation between the energy generated by the mills and the concentration of air currents. Therefore, we focus on determining optimal values for the parameters of the structure, namely, the diameters of the structure and its positioning. Our study indicates that the conical structure provides the highest concentration of air currents, thereby optimizing the amount of energy generated. Our findings can be used to enhance the efficiency of windmills around the world, placing wind energy as one of the most efficient types of energy.

Abstract Name: **Poverty Cycle: The Effectiveness of Government Intervention in the Phenomenon of Chronic Unemployment**

The Poverty Cycle is an intricate problem with an indefinite solution. Various attempts have been made by the government to mitigate and help eliminate the factors of poverty that keep individuals from climbing the socioeconomic ladder of the United States, namely unemployment. Thus, this study will explore the outcomes of TANF (Temporary Assistance for Needy Families) eligibility requirements and structure on unemployment and transition out of poverty. This research will review previous studies to better comprehend the possible challenges, setbacks, or irregularities during and after individual participation in TANF. These studies include existing social work research done to identify the employment and earning outcomes of TANF beneficiaries, existing research on different state implementations of TANF, and existing research on TANF turnouts in comparison to those who participated in AFDC (Aid to Families with Dependent Children) among other current studies. Several of these studies have employed data from the 1993 and 1996 Survey of Income and Program Participation as well as the 2002 National Survey of America's Families, with most studies being conducted after 2000. I will also be using information from Jonathan Gruber's textbook, Public Finance and Public Policy to help explain the importance of the phase-out portion of TANF; information such as budget constraints that explain individual behavior–decisions individuals make in the face of limited time and financial resources that determine their employment outcomes. By the end of this research, I anticipate the analysis of existing studies to yield a comprehension of factors that influence the success or shortcomings of TANF, with particular emphasis on long-term unemployment and transition out of poverty.

Abstract Name: **Primary Breast Cancer Communication with the Sentinel Lymph Node via Extracellular Vesicles Regulates Distant Metastasis**

Triple-negative breast cancer (TNBC) is a highly aggressive form of breast cancer that can be defined by the absence of estrogen, human epidermal growth factor 2, and progesterone receptors. With no effective targeted therapy for this dreadful cancer, it is an incredibly important area of research in order to reduce suffering and increase survival for TNBC patients. Metastasis is the major cause of suffering and death for TNBC. We are investigating the mechanisms by which the primary triple negative breast cancer can regulate distant metastasis at its local draining lymph node. Our novel approach is to examine the communication between the primary tumor and its lymph node mediated by extracellular vesicles (EVs) . EVs are lipid bound bodies that cells release under stressed conditions or during normal growth. Our data indicates that there are different kinds of EVs that are released by the primary tumor to enter the lymphatic drainage where they immediately go to the lymph node. These distinct types of EVs have a dramatically opposite effect on the lymph node and the establishment and growth of distant metastasis in an animal model of TNBC. We observed that when a certain class of large EVs, isolated by ultracentrifugation, enters the lymph node, it massively stimulates distant metastasis. In contrast, smaller EVs that were spun down at a much higher speed of 100K greatly suppressed the distant metastasis. Our results indicate that the mechanism is immunologically based, because the two types of EVs have remarkably different effects on the immune cell populations of the lymph node and the presence of immune suppressor cells in the distant lung metastasis via dendritic cells, macrophages, myeloid suppressor cells, and other anti-tumor immune cells. These data can offer completely new strategies for treating metastasis, the lethal aspect of breast cancer.

Abstract Name: Identification of Rotifer Cryptic Species in Chihuahuan Desert populations of the Genus Hexarthra

Previous studies have shown that many rotifer species, microscopic aquatic animals, that were believed to have cosmopolitan distribution are instead complexes of cryptic species. Cryptic species have undistinguishable morphological characteristics but have considerable genetic divergence. This study focuses on delimiting potential cryptic species of the genus Hexarthra, a monogonont rotifer, found throughout Chihuahuan desert aquatic habitats. Sampling sites were not hydrologically connected and are spatially separated. Hexarthra were sampled using two strategies (1) from active populations and (2) sediment egg banks collected from temporary rock pools. Diapausing eggs of Hexarthra are commonly found in these sediments and are the product of genetic exchange. Live individuals hatching from diapausing eggs were isolated individually to produce clonal lineages and maintained under laboratory conditions until DNA extraction was obtained. Similarly, individuals from active populations were collected following a rain event to maximize recovery of unique genotypes. For one population, 20 clonal isolates were sequenced to measure the infraspecific genetic variation of the population. The genetic marker sequenced was the cytochrome oxidase I (COI) gene. To identify unique evolutionary lineages within Hexarthra, the species delimitation methods Generalized Mixed Yule Coalescent (GMYC) and Poisson Tree Process (PTP). According to the results obtained, there are about 13 putative cryptic species within populations of Hexarthra found in 17 Chihuahuan desert populations. These findings will aid our understanding of rotifer biodiversity and cryptic speciation within the Chihuahuan desert.

Abstract Name: Isolation of Jumbo Bacteriophages

To date, there are relatively few known phages with genomes 200kbp or greater, which are classified as jumbo phages. This is likely due to their large physical size making them difficult to isolate using traditional methods as opposed to jumbo phages being rare. Their large size makes it difficult for jumbo phages to diffuse into typical top agar and allows jumbo phages to get caught in the filters used to remove bacteria from environmental samples. The goal of this project is to isolate jumbo phages from soil samples collected on campus. To overcome the barriers to isolating jumbo phages, several changes to the typical methods of isolation were tried. Larger pore filters and chloroform were used to remove bacteria from our samples without removing large phages. Low concentration top agar was also used during isolation and purification to better allow large phages to diffuse into the media, and we favored selection of pin-point plaques that could suggest physically large phages. Several phages have been isolated using these strategies and are being analyzed using transmission electron microscopy and gel electrophoresis techniques such as pulsed field gel electrophoresis. A selection of phages will also be sequenced to determine the length of their genome. At least one phage genome will be annotated using bioinformatics tools such as Glimmer, Genemark, BLAST, Phamerator, and HHPred.

Abstract Name: **Charcoal Analysis of a Sediment Core from Mud Lake, WI**

The Middle-Mississippian people settled in southern Wisconsin around A.D. 1050, near what is now Aztalan State Park. The site was occupied for two hundred years until it was abandoned around A.D. 1250, however little is known about why the Mississippian people chose to leave the site. A sediment core was collected from Mud Lake in Jefferson County, Wisconsin (43.05°N, 88.92°W) in January 2014 for the purpose of developing a climate record for the Aztalan site (43.08°N, 88.86°W). A charcoal record is currently being developed from the sediment core for the purpose of examining the links between climate, vegetation, fire, and anthropogenic activities in the region over the past 2,000 years. Different types of fires produce different forms of charcoal, and classification schemes exist to differentiate between the climate-driven and human-derived fires. Charcoal is analyzed in 1 cm increments and each centimeter of sediment is extracted from the core, treated with hydrogen peroxide and sodium hexametaphosphate, sieved through 125 µm mesh, and dried at 50°C for 48 hours. Samples are counted for the presence of charcoal using a stereomicroscope and 5-50x magnification. Dating of the sediment core combines radiocarbon and lead-210 dating techniques. Charcoal from the pre- and post-settlement of the Aztalan site will aid in differentiating between human and natural fires, and other geochemical analyses completed on the core will be presented to corroborate our interpretation. This will help us develop a better understanding of the role climate played in the abandonment of the Aztalan site.

Abstract Name: **Long-Term Impairments in Individuals with Chronic Ankle Instability and the Influence of Attentional Focus in Rehabilitation**

Lateral ankle sprains are one of the most common types of injuries among athletes. These sprains stretch or tear the ligaments in the lateral complex of the ankle. Once injured, these ligaments provide inadequate stability to the ankle; therefore, 40-70% of individuals who sprain their ankle will develop a condition known as chronic ankle instability (CAI). CAI negatively alters movement, decreases strength, and limits range of motion. Present rehabilitation insufficiently reduces these impairments thus requiring different strategies to break the cycle of repetitive injury. This study applies novel methods of movement-related feedback, specifically innovative internal and external focus of attention feedback (InFOCUS and ExFOCUS, respectively), to traditional rehabilitation to break the cycle of CAI. InFOCUS forces the individual to focus on their own bodily actions, which constrains movement, whereas ExFOCUS requires the participant to move based on cues in their environment, which increases adaptability. As part of an ongoing study, 12 participants were assigned to one of 3 groups: control, ExFOCUS (crosshair laser affixed to the foot), or InFOCUS (video camera). All participants received their respective feedback while completing the same strength, balance and functional exercises. Participants performed strength (inversion, eversion, dorsiflexion, and plantar flexion), dynamic balance (star excursion balance test [SEBT]), and range of motion testing at baseline and 1-week after a 4-week intervention. A repeated measures ANOVA indicated a significant time main effect for dorsiflexion strength and SEBT posteromedial reach. Participants showed less dorsiflexion strength regardless of group (baseline: 58.3715.35kg; follow-up: 50.7516.04kg; P=0.029) with improvement in SEBT posteromedial (baseline: 0.790.14; follow-up:0.870.82; P=0.031) and posterolateral (baseline: 0.710.13; follow-up: 0.810.10; P=0.023) reach directions at follow-up. This preliminary analysis suggests continued development of feedback strategies and modes of application to improve function in patients with CAI is warranted.

Abstract Name: **The Future of Plastic Waste: A Multi-Disciplinary Approach**

Approximately 300 million tons of plastic waste is produced every year worldwide; only ~7-9% is recycled.The result is harmful plastic waste accumulation that negatively impacts ecosystems and communities around the world. Polyethylene terephthalate(PET) is one of the most abundant plastics due to its transparency and chemical strength. While naturally occurring PET-degrading bacterial enzymes have been identified (i.e., PETase and MHETase), their physiological requirements make them ill-suited for industrial use. We attempted to address this problem by bioengineering a chimeric PETase::MHETase protein for enhanced PET degradation. Review of recent literature revealed a collection of PETase and MHETase-optimizing mutations shown to enhance temperature and pH tolerance. Building from this work, our approach was to combine these nucleic acid changes into a single modified open reading frame (ORF) to support even greater PET degradation capabilities. The synthetic plasmid DNA construct was transformed intoE. coliand expressed to produce a novel chimeric protein. The biomanufactured product was purified by nickel column chromatography and quality-tested using standard assays. Finally, functional assays allowed us to measure PET plastic degradation. Recognizing that typical practices in life science laboratories are part of the plastic waste problem, our team explored and implemented ways to make our laboratory—and others like it—more sustainable. Additional methodologies from the field of STS (Science, Technology and Society) were used to consider, imagine, and develop greater understanding of the implications of plastic waste and how a bioremediation-based solution might be implemented in the future.

Abstract Name: **Hugo Chavez and the United Socialist Party of Venezuela: Expropriations and Censorship**

Following Former Venezuelan President Hugo Chavez's coup d'état in 1999, Chavez's United Socialist Party of Venezuela began expropriating successful private companies and censoring media outlets that accused the political party of corruption in order to dismantle the country's democratic structure and instate a government-controlled economy. Examining the Bolivarian movement led by Hugo Chavez, this study analyzes Chavez's strategy to centralize the economy and isolate the country from unregulated media accessand how these have contributed to the country's current political atmosphere. In order to understand the factors that have contributed to Venezuela's political and economic conditions today, I examined scholarly journal articles published by Venezuelan and American scholars that discuss the effects Chavez's social and economic policies had on the Venezuelan economy. Specifically, how the politicization of the country's largest oil company, Petroleum of Venezuela, contributed to the country's economic decline. I found that the censorship of media outlets created a wave of misinformation and ignorance, particularly in rural areas of the country. This has led the people to justify the United Socialist Party of Venezuela's corrupt practices and continue supporting the party despite the decline in quality of life under Chavez's regime. The United Socialist Party of Venezuela appoints political elites to leadership positions in expropriated companies not because of their expertise but due to their loyalty to the Bolivarian revolution and its agenda. Thus, the Venezuelan economy has become centralized and stagnant, leading to hyperinflation and low exchange rates.

Abstract Name: **Characterization of Structure-Property Relationships of Stimuli-responsive Copolymers**

This research focuses on the characterization of structure-property relationships of stimuli-responsive copolymers for applications as dispersants in architectural coatings such as paints, primers, and stains. Stimuli-responsive polymers can dramatically change their physical properties in response to small changes in their environment. An important change in properties can be seen at the cloud point, the temperature where the polymer becomes insoluble in aqueous solution and indicates self-assembly or aggregation of the polymers. Copolymers with varying compositions were synthesized using Activator Regenerated by Electron Transfer Atom Transfer Radical Polymerization (ARGET ATRP), a synthesis technique that allows for narrow control of the molecular weight of the copolymers. Nuclear Magnetic Resonance Spectroscopy (NMR) and Gel Permeation Chromatography (GPC) were used to confirm the polymer structure and molecular weight dispersity. Polymer solubility and self-assembly were measured using Ultraviolet-Visible Spectroscopy (UV-Vis) and Dynamic Light Scattering (DLS) as a function of temperature, pH, ionic strength, polymer composition, and polymer concentration. These copolymers dramatically change solubility as a function of temperature and pH because of the tertiary amine. At low pH and low temperature, hydrogen bonding with water dominates behavior, so the polymers are water soluble. As pH or temperature is increased, the intramolecular forces control behavior, so the polymers become insoluble in water. The copolymer composition will shift at what specific temperature the solubility changes. Understanding structure-property relationships of these stimuli-responsive copolymers allows for optimization in applications. Stimuli-responsive polymers with these unique properties could be used as dispersing agents as a novel alternative to current commercial agents.

Abstract Name: **Reflections of illness identity in language choices among African Americans affected by Parkinson's Disease**

Background: Understanding how individuals from under represented communities form illness identities is fundamental to effective, culturally responsive nurse-patient communication. Purpose: To characterize patterns of language used by patients with Parkinson's disease (PWPD)and their caregivers, who identify as Black or African American, when discussing their experiences with PD symptoms and treatment. Methods: Using qualitative description, we analyzed verbatim text from remote interviews withtwo PWPD, one who had been diagnosed for 2 years and one for 14, both of whom held Master'sdegrees. Data were also analyzed from five PD caregivers ranging in age from at least 30 to over60 years old, with education levels ranging from high school to Bachelor's degrees. Their length of time caregiving ranged from three months to four years. Interviews about patients' and caregivers' experiences were coded and categories were generated to identify language patterns used when referencing PD. Results: There were two overarching categories of language used when referencing PD duringthe interviews: label-focused and emotion-focused. Label-focused language was explicit and spanned from acceptance to rejection of the medical diagnosis label of PD, often personifyingPD (e.g., "the silent killer"). Emotion-focused language reflected feelings of fear, loss of control,and confusion. These illness identities emerged within the context of discussion of PD disease progression and personal unfamiliarity. Participants also noted that concerns about privacy andfear of the unknown are common in their community. Conclusions and Implications: Disease progression and unfamiliarity may be acting to create feelings of confusion and fear, which are reflected in the language patterns of PWPD and their caregivers. Nurses should be aware of the potential for language choices (e.g., rejection of adiagnostic label) to reflect patient or caregiver's feelings concerning a diagnosis. Culturallyresponsive approaches are needed to promote effective communication among patients and caregivers from underserved communities.

Abstract Name: **Culturally Appropriate Fruits and Vegetables for Cardiovascular Disease in Hispanic/Latinx Populations**

The Hispanic/Latinx population is disproportionately affected by food insecurity and risks of cardiovascular disease (CVD), which can increase if individuals are acculturated to a Westernized diet. Few studies assess food preferences and medical nutrition therapy related to Hispanic/Latinx communities, resulting in difficulty treating individuals appropriately and effectively via nutrition interventions like the Dietary Approaches to Stop Hypertension (DASH) diet. The effectiveness of the DASH diet in research consists of predominantly western food choices conducted on white males. We aim to determine preference-based fruits and vegetables for nutrition boxes distributed to patients of a community health clinic in Minnesota who are uninsured and live within 200% of Federal Poverty guidelines. The objective is to promote adherence to a DASH diet, reduce markers of CVD, reduce food insecurity, and provide meaningful inclusion to medical nutritional therapy for immigrant, Hispanic/Latinx populations. Utilizing community-based participatory research practices, a 21-question survey addressing patient demographics, social determinants of health, and a literature review-informed fruit and vegetable preference list was administered to 46 patients of varying countries of origin who self-identified as Hispanic/Latinx. Of 36 women (78.3%) and 10 men (21.7%) surveyed, Mexico was the primary country of origin (n=30). A majority of the participants surveyed had an education level of high school graduate or below (58%). In the patient sample, 46.3% reported food insecurity within the last 12 months. The highest preferences for fruit were mango (57.8%), watermelon (51.1%), and banana (44.4%), and vegetable preferences included tomato (43.2%), cucumber (43.2%), and lettuce (38.6%). Food insecurity prevalence is high compared to the US average. These results informed the contents of DASH-diet focused medical nutrition boxes for a clinical trial to lower markers of CVD and tailor culturally appropriate interventions for Hispanic/Latinx individuals.

Abstract Name: **Quantifying the Relationship Between Arbuscular Mycorrhizal Fungi and a Native and Invasive Thistle**

Our research explored the relationship between arbuscular mycorrhizal (AM) fungi and two prairie plants – the native Pasture Thistle (Cirsium discolor) and the invasive Canada Thistle (Cirsium arvense). AM fungi associate with the majority of plants and assist in mineral nutrient uptake. In return, they receive photosynthetically fixed carbon from host plants. Their relationship with plants can be quantified by assessing dependence upon and responsiveness to AM fungi. Dependence is defined as the plant's inability to grow without AM fungi while responsiveness is the growth difference between inoculated and non-inoculated plants. We hypothesized that Pasture Thistle would have a stronger responsiveness and dependence on AM fungi than Canada Thistle because of the degraded mutualism hypothesis, which states that invasive species do not associate with local mutualists as closely as native plants. To test this hypothesis, we grew plants with and without AM fungi at ten different soil phosphorus levels, with twelve replicates per treatment. We measured the longest leaf length and height weekly, and after 10 weeks of growth, determined overall root and shoot biomass. We found that Pasture Thistle and Canada Thistle could both grow without AM fungi. Pasture Thistle was more responsive to AM fungi, growing 37% better when inoculated than when not inoculated, while Canada Thistle, showed a negative responsiveness. These results support our hypothesis that the invasive species would have a degraded mutualism with AM fungi. It is likely Canada Thistle lacks a strong relationship with AM fungi because it grows in disturbed areas where there is a low AM fungal presence.We also found that Pasture Thistle was most responsive at a soil phosphorus level similar to that in its native range, suggesting that it likely has a shared evolutionary history with AM fungi.

Abstract Name: **Abstract For the Proposal of Blended Housing**

In 2022, the Missouri House of Representatives criminalized homelessness with House Bill 1606. Street camping and tent cities were outlawed; concurrently,funding for nonprofits that provided permanent housing to the unhoused was eliminated. The researcher will propose a new model of housing blending transitional and permanent housing while also exploring past solutions to homelessness; the proposed model of blended housing ensures permanent housing providers of Missouri retainstate and federal funding that would otherwise be eliminated.The researcher's proposal is informed by preliminary research done with the unhoused, Bronta Chapman, Nate Schlueter, Alix Midgley, and other nonprofit leaders nationwide, and a control population of college students with no experience with the unhoused. Secondary analysis was done of existing research by the Cicero Institute ofAustin, Texas, the accompanying proposal, and the effects of the proposal in Austin, Texas where similar legislation was passed.

Abstract Name: **Are paleoecological reconstructions of zooplankton communities using chitinous remains biased?**

Chitin is a polysaccharide polymer that provides structural integrity to the exoskeletons of arthropod animals (e.g., insects, crustaceans) and is therefore one of the most abundant biologically-produced substances in the world. Because of chitin's strength and its resistance to degradation, the chitinous remains of zoo plankton and other arthropods deposited over time in lake sediments have been used by paleoecologists to understand how lake food webs have changed over long periods of time. While paleoecological studies using chitinous remains from dated sediment cores have the potential to reveal long-term changes in lake ecosystems, a critical assumption when interpreting these data is that the remains found in sediments of different age accurately reflect the circumstances that were present at the time that those sediments were deposited. However, if chitin concentrations in the remains differ among species and/or degrade differently over time, this critical assumption would be invalid, and could cause researchers to draw misleading conclusions about how ecological communities have changed over time. For this study, we used a colorimetric chitinase assay (the Schales method) to assess chitin concentrations of the remains of two types of freshwater zooplankton (Daphnia and Bosmina) from freshly-molted exoskeletons and from chitinous remains extracted from lakes sediments of known age. Based on results from a previously conducted paleoecological study, we hypothesized 1) that chitin levels in more recently deposited remains would be higher than for older remains, and 2) that the exoskeletons of Bosmina would be richer in chitin than for those of Daphnia. To date, we have successfully optimized the methodology for running the chitinase assay with consistent results, but have not obtained enough data on the chitin levels in the Daphnia and Bosmina remains to fully assess our hypotheses.

Abstract Name: **The role of COVID-19 in anti-Asian prejudice**

Terror management theory (TMT; Greenberg, Pyszczynski,; Solomon, 1986) states that reminders of death create the potential for anxiety, but a way to keep this anxiety managed is through cultural worldviews, self-esteem, and relationships. Cultural worldviews, like religion or political beliefs, involve having shared beliefs about reality that can provide a basis for self-esteem and a sense of immortality. TMT research demonstrates that reminders of death increase support for one's own worldview and hostility toward those with differing worldviews. For example, Germans reminded of death strongly preferred German products over foreign ones (Jonas et al., 2005). Reminders of death increase ingroup preference which increases one's sense of personal and group value. Recently the COVID-19 virus has caused both an increase in death reminders and prejudice, specifically anti-Asian prejudice due to stereotyped connections made between the virus and its origin in China. Comments tweeted by former President Trump calling COVID-19 the 'Chinese Virus' provide fuel for this prejudice. The present study investigates whether statements regarding the Chinese origination of COVID-19 heighten anti-Asian prejudice following reminders of death. To do this, half of the participants are reminded of their own death, while the other half are reminded of a control topic. Participants also read about the Chinese origin of COVID-19 or an article about COVID-19 that doesn't mention the origin of the virus. For the dependent variable, participants complete a measure of anti-Asian prejudice. The hypothesis for this study is that reminders of death will heighten anti-Asian prejudice for those participants who read the article mentioning the Chinese origin of COVID-19 compared to those not reminded of death or the Chinese origin of COVID-19. The results of this study will help us to better understand the causes and consequences of prejudice.

Abstract Name: **A Desire for Suffering: Escaping the Good Life through Camus and Sartre**

This paper explores the complex relationship between suffering and a person's optimism for the good life, defined for my purpose as a state of general happiness and prosperity. In Lauren Berlant's Cruel Optimism, they establish optimism as a complex series of promises provided by an object of desire. Optimism becomes cruel if some of those promises are problematic, and becomes dangerous when tied closely to political objects. From Berlant's work, I will argue that as an object of desire, the good life can create a state of mental suffering when its attainment is tied to political objects containing harmful promises. I propose that to escape this conflictive state of suffering, internally redefining what constitutes attaining the good life is necessary. Relying on the works of both Camus and Sartre, I attempt to prove the compatibility of their philosophies regarding freedom, and that the freedom they propose offers a route to internal redefinition. By accomplishing this redefinition through the freedom these two philosophers establish, the potential for escaping suffering becomes possible, so long as the new process of attainmentis no longer tied to problematic political objects. I conclude by arguing that, despite Camus and Sartre's philosophies placing heavy emphasis on the individual, they ultimately suggest the value of community and its place in attaining the good life.

Abstract Name: **Assessing the Tiny Earth ESKAPE Microbes for Toxicity in a Human Fibroblast Cell Line**

According to the National Institutes of Health, cancer was the second leading cause of death in the US from March 2020 to October 2021. Major treatment options for those diagnosed include surgery, chemotherapy, and radiation, which are expensive and stressful to the body. Improvements to those therapies have been made since their discovery, but they remain quite expensive and inaccessible to those who cannot afford them. One solution is the development of new therapies that focus on bacteria and their effects on cancerous environments. This was the focus of research conducted over the summers of 2021 and 2022. Findings from 2021 identified data that indicated a dose dependent decrease in colon cancer cell health as inactivated bacterial concentrations were added. Research from 2022 served to answer the question: “Is the dose dependent decrease in cell health specific to cancer cells only, or is a similar trend observed in non-cancerous fibroblast cells?” Fibroblast cells are the most common type of connective tissue cell, are found throughout the body, and serve as the control for this research. Testing on the fibroblasts utilized an MTT assay which measures a cell’s metabolic activity, or energy production. The cells take in a yellow compound, MTT, and turn it into a purple compound, formazan, with their mitochondria. Formazan can be measured using a spectrophotometer to determine its quantity based on how purple the solution is. More formazan is perceived to mean healthier cells because their mitochondria are more active and converted more MTT. Results for this research project indicated no harmful effects of the bacteria on the fibroblast cells, and instead showed increased health with higher rates of formazan production. These advancements provide support for further development of potential cancer therapies that are more accessible and less expensive than traditionally used therapies like chemotherapy and radiation.

Abstract Name: **Medical mistrust amongst ethnic minority adolescents and emerging adults.**

This paper examines two large overlooked minority young adult groups in America whom experience racial discrimination in healthcare.This paper argues that the effects of trust in a provider are associated with medication adherence, continuity of care, improvements in self-reported health, and decision making when seeking care. Racial discrimination in health care access and quality of care has resulted in a long standing and ongoing medical mistrust of health care providers and the health system for many racially demean groups. Adolescents and emerging adults are very important considering youth are beginning to become more independent and are taking on greater responsibility for their own health care. Medical mistrust studies have predominantly been studied in adult populations, but there has been a huge gap in the research studying medical mistrust in youth which is where early intervention can clearly be beneficial. Due to mutually dependent challenges that minority youth face such as racial discrimination, environments with social disadvantages, and medical mistrust they often have social complex. With this being said minority youth often have a lot of involvement with health care systems from multiple different access sites, but this leads to them often failing to achieve positive health outcomes. To gauge medical mistrust, surveys will be given to minority youth between the ages of 16 to 18 years old and 19 to 25 years old in clinic settings and in the community. The population the survey will be given to will include African Americans, Latinos, Arab Americans, and Bengali youth in metro Detroit,Hamtramck,and Dearborn. There are studies that look at the concept of adolescent trust in their providers, and also how it relates to the youths' health outcomes. It's shown that youth with higher levels of trust in their provider consistently receive more chronic illness care than those who receive medical mistrust.

Abstract Name: Smartphone Use and Well-being

How has Smartphone use impacted the general well-being of people today? The Smartphone usage has certainly increased over the past generation. The use is so prevalent that nearly everyone from 9-99 has one. Questions regarding how this intense Smartphonne use is impacting the overall health and well-being of society has been discussed across many different aspects of research. This research intends to study how Smartphone use impacts the physical, psychological, cognitve and social well-being of individuals across the generations. Previous research tends to focus on one aspect or another of well-being, for exmaple sleep or academic performance (cognitive functioning) or anxiety (psychological functioning). The research is lacking when looking at the global health of an individual and its association with Smartphone use. This study will also examine the specific ways individuals are using the Smartphones as well as how much of their daily life is consumed by the use. A correlational analysis will be completed in the spring semester of 2023 to determine what factors are most impacted by Smartphone use.

Abstract Name: An Updated Examination of Climate Change Views Among Wisconsin College Students Using Surveys Conducted in 2023

Climate change (CC) is perhaps the most important issue of our time. Citizen public opinion will likely be a significant determining factor regarding if/when CC mitigation policies will be enacted. Additionally, news media reports suggest that young people, including college students have been increasingly active in terms of calling for action to address CC. We will conduct surveys of Wisconsin (WI) college students in February 2023 with the expectation of receiving at least 600 completed surveys from at least three institutions to provide a current account of CC views among WI college students. A CC index (CCI) score will be calculated using responses to questions about if CC is happening and what are its primary causes as well as an understanding of CC science and concern about and obligation to act regarding CC. CCI scores range from -10 to 10 with higher scores indicating more alignment with the scientific realities of CC. This poster will present comparisons of CC views based on age, gender, major and political ideology as well as across the different institutions including ordinary least squares regression analysis. Because we have not collected the data yet, we cannot report any results at this time. For context, our poster will also compare the CC views from these 2023 WI college student surveys to the CC views expressed in previous surveys conducted among UW-Eau Claire (UWEC) college students in 2017, 2018, 2021 and 2022. Lastly, we will provide additional context by comparing the CC views from all of our WI college student surveys to similar work we have done comparing CC views between American and Chinese citizens from multiple survey years. This poster is connected to another submitted poster analyzing data from surveys conducted of both UWEC college students and also Chinese and American citizens in prior years.

Abstract Name: Investigating Trends and Patterns in Climate Change Views of UW-Eau Claire Students Using Survey Data from 2017, 2018, 2021 and 2022

Climate change (CC) is perhaps the most important issue of our time. Citizen public opinion will likely be a significant determining factor regarding if/when CC mitigation policies will be enacted. Additionally, news media reports suggest that young people, including college students have been increasingly active in terms of calling for action to address CC. Surveys were conducted among UW-Eau Claire (UWEC) college students in 2017, 2018, 2021 and 2022 (N=475) to provide a case study of college student views on CC. A CC index (CCI) score was calculated using responses to questions about if CC is happening and what are its primary causes as well as an understanding of CC science and concern about and obligation to act regarding CC. CCI scores range from -10 to 10 with higher scores indicating more alignment with the scientific realities of CC. Our poster presents CCI score comparisons across years as well as by age, gender, major and political ideology including an ordinary least squares regression analysis. We will provide additional context by comparing our UWEC student results to similar work we have done comparing CC views between American and Chinese citizens from multiple survey years. Our findings suggest that UWEC students are more aligned with the scientific realities of CC compared to both American and Chinese citizens overall. Moreover, although the variation in CC views among UWEC students is less than for American citizens overall, it is greater than what we see among Chinese citizens. Lastly, our results also show a similar political pattern in UWEC student CC views as what we find among American citizens overall with conservatives/liberals being the least/most aligned with the scientific realities of CC respectively. This poster is connected to another submitted poster analyzing new data from surveys conducted of WI college students in 2023.

Abstract Name: Examining the relationship between adolescent intercultural sensitivity and White identity development

Intercultural sensitivity refers to an individual's ability to step beyond their own culture and function with other individuals from diverse backgrounds.It has been proposed that intercultural sensitivity is a developmental process comprised of six stages, each of which fall into one of the two following categories: ethnocentric and ethnorelative. The stages in the ethnocentric category indicate a self-centered reality, while the stages in the ethnorelative category represent a multicultural acceptance approach. Much of the previous research conducted on intercultural sensitivity has not explored the concept within an adolescent population.This study looks at the relationship between stage of adolescence and intercultural sensitivity views. To investigate these relationships in older adolescents, 91 students were recruited from various psychology courses at a small Midwestern public university. Participants completed the 30-item Intercultural Sensitivity Index and the 60-item White Racial Identity Attitudes Scale.For the middle adolescent age group, participants will be recruited through local schools in early 2023 and will complete the same two measures.We predicted that younger adolescents would have intercultural sensitivity views that fall largely into the stages of ethnocentrism, while older adolescents would have more varied intercultural sensitivity views and will likely fall into the transitory or ethnorelative worldviews. The results of the analyses conducted for the older adolescent group did indicate that their views fell primarily into the ethnorelative category. Based on these results, it is anticipated that the analyses conducted for the younger adolescent group will likely reveal that their views fall mainly into the stages of ethnocentrism.This research gives insight into our current and future student population and serves as an incentive for improvement to intercultural competency within that population. Increasing underrepresented minority enrollment means that improved intercultural competency will be advantageous for all.

Abstract Name: **In silico analysis of the doublecortin domain containing 2B (DCDC2B) gene in pulmonary fibrosis.**

Lung fibrosis is an irreversible scarring of the lungs, which may lead to death in a matter of a few years if untreated. The pathophysiology of lung fibrosis implicates different and complex molecular pathways and is likely genetically driven. We analyzed whole exome sequences of 750 lung fibrosis patients and related and unrelated unaffected controls and have identified several genes that contain likely pathogenic variants in this cohort, some of these being novel variants. In this study, we characterized the role of one of these novel genes, the doublecortin domain containing 2B (DCDC2B) gene, in pulmonary fibrosis. DCDC2B is located on chromosome 1 and is broadly expressed in the lungs. We used Ingenuity Pathway Analysis (IPA)® (Qiagen) to conduct an in silico analysis of the role of this gene in the pathway of lung fibrosis. We contextualized the role of this gene in the pulmonary fibrosis canonical (i.e., established) pathway generated by IPA®. by conducting an in-depth literature review. We determined that this gene regulates endoplasmic reticulum (ER) protein folding and storage, causing 'ER stress' - a process already implicated in lung fibrosis, via different genes. ER stress in the alveolar epithelial cells type II predisposes the lung epithelium to an increased risk of injury and subsequent fibrosis in the event of a secondary insult like a viral infection, trauma, or exposure. Thus, our study is the first step in identifying novel genes implicated in lung fibrosis. Further studies will be needed to confirm the role of this gene in the molecular pathways of pulmonary fibrosis.

Abstract Name: **Magnetic Microparticle-Silicone Composites for Hyperthermia Therapy on Implantable Medical Devices**

Implanted medical devices such as joint replacements and implants following mastectomy have limited lifetimes, and their most common cause of failure is due to the growth of bacterial biofilms on their surfaces. One way to address this issue would be by heating the surface of the device within the body in order to eliminate the bacteria, preventing infection and inflammation. The heat, however, needs to be delivered directly to the surface without affecting nearby tissues. Localized heating may be accomplished by inserting magnetic particles directly into the implanted device. Our lab has developed a novel magnetic silicone composite that can be heated remotely with magnetic fields that are able to pass through healthy tissue with no effect. In this study, we have inserted the magnetic silicone into a material that mimics human tissues, known as a tissue phantom, which was then used to investigate the effect of magnetic heating on surrounding tissues using alternating magnetic fields to heat the particles and the internal surfaces remotely. The tissue phantom was constructed from polyacrylamide gel with a thermochromic dye incorporated to measure temperatures inside the tissue phantom. The thermochromic dye allowed us to visualize temperature profiles indicated by a color change occurring when a certain temperature within the tissue phantom was reached. These temperature profiles help determine if substantial tissue damage resulted from magnetic heating. Our expectation is that this research may contribute to a novel method of addressing bacterial films in implanted medical devices, leading to longer-lasting devices and better outcomes for patients.

Abstract Name: **Rehydration of Aged Latent Fingerprints on Non-Porous Surfaces**

In forensic science, fingerprints are an important resource for individualization. They are integral to linking suspects to crime scenes and therefore either convicting or exonerating individuals. However, our ability to develop fingerprints decreases over time due to the rapid evaporation that occurs as a fingerprint ages. Unfortunately, although there are methods to develop aged fingerprints on porous surfaces, there is not currently a method for developing aged latent fingerprints on non-porous surfaces. This is detrimental because the majority of fingerprints at a crime scene are on non-porous surfaces. The purpose of this project was to explore the effectiveness of and derive a method for the rehydration and development of high-quality latent fingerprints located on glass and plastic, two non-porous surfaces. This study sought to develop a technique for rehydrating aged latent fingerprints using a humidifier. Fingerprints were aged on the substrates for an hour before being placed in a sealed chamber with a humidifier. A range of 80-85% relative humidity was maintained within these chambers for the duration of the rehydration. Within the chamber, the fingerprints absorbed water from the air, thus restoring their quality. After rehydration was complete, the fingerprints were imaged and 4-8 ridge widths were measured per print. Those same ridges were measured in an image taken immediately after print deposition and compared to the post-rehydration widths to determine the degree of rehydration. The data revealed that peak rehydration occurred after 30 minutes on glass and 15 minutes on plastic. This research has important implications in overcoming the reporting, collection, and analysis delays that plague the forensic science community as it will allow forensic scientists to develop latent fingerprints from every case, regardless of how much time has elapsed since fingerprint deposition, and therefore ensure that all evidence at a crime scene can be collected and analyzed.

Abstract Name: **Investigating Observational Improvements For Future Gravitational-Wave Detectors Using Tuned Interferometry**

This project investigates the potential of extending the signal recycling capability of the current Laser Interferometer Gravitational-Wave Observatory (LIGO) configuration to enhance gravitational wave detectability at specific frequencies of interest. This method can be applied to planned future interferometers, such as A+, Cosmic Explorer, and Einstein Telescope. Still, it can also be implemented in the Advanced LIGO interferometer to improve astronomical examinations of GWs during the research and development of future instruments.By adjusting the position (tune-phase) as well as the transmissivity of mirrors located in the instrument, we find that we improve the sensitivity at specific frequency ranges. This allows for frequency-dependent sensitivity improvements for GW measurements – just like putting a filter on a telescope. In this work, we investigate tune-phase and transmissivity combinations and their respective ranges of improvement, with the aim of determining optimal configurations for application to gravitational wave astronomy. We expanded the pygwinc fundamental noise calculation package to calculate the effects of the various tune-phase and transmissivity combinations on the sensitivity of the interferometer. Additionally, we applied 196 usable pulsar spin-down limits from Abbott et al. 2021 to quantify the effectiveness of the tune-phase and transmissivity pairs. The optimal combinations demonstrate possible improvements on pulsars and open the project for comments and extensions on black hole binaries.

Abstract Name: **Compression and Contact of The Glenohumeral joint; a Cadaveric Study Comparing Angles of Internal and External Rotation**

Previous research has indicated that immobilization in external rotation for shoulder dislocation may reduce the recurrence rates of dislocation and instability of the Glenohumeral Joint (GHJ). The purpose of this research is to calculate the extent to which the humeral head is in contact with the glenoid fossa and the amount of pressure it applies in various positions of immobilization while comparing it to geometric analysis calculations. To accomplish this, we will be performing cadaver-based research using manipulation of the joint position as the primary independent variable. The joint will be positioned between 50° and 60° of internal rotation accompanied with adduction of the arm for the internal rotation measurements. For the external rotation portion, we will be measuring in multiple angles from 0° to 45° combined with abduction. The total contact and compression of the humeral head in the glenoid fossa will be measured using a Trill capacitive touch sensor. The geometric analysis involves measuring the superoinferior (SI) diameter of the humeral head, anteroposterior diameter of the humeral head, radius of curvature of the humeral head, humeral head retroversion, humeral head thickness, inclination angle, critical shoulder angle, glenoid width, glenoid length, and radius of curvature of the glenoid. Comparing our GHJ analysis with a geometric analysis will provide insight into possible reasons for the advantages of external rotation for anterior shoulder dislocation immobilization.

Abstract Name: **Analysis of Differential Equation Models of Kidney Bean Yield**

Current trends in farming are pressuring growers to generate higher crop yields with fewer resources. This pressure necessitates embracing precision agriculture, using data and science-based practices that are targeted at the micro-environments on the field level, to increase a grower's overall efficiency. Chippewa Valley Bean (CVB), located in Menomonie, Wisconsin is the world's largest processor of dark red kidney beans and works with growers all over Wisconsin and the Upper Midwest. Their agronomy team is looking to incorporate more precision agriculture to help their growers deliver higher yields of higher quality beans.CVB's agronomy team tasked us with determining the amount of water required to grow dark red kidney beans in different soil types. We developed a mathematical model consisting of three coupled differential equations that tracks water in the soil, canopy, and total reproductive biomass throughout the plant's life cycle. This model serves to predict the total yield of a plant given the irrigation levels as well as the characteristics of the plant and soil type. We then used numerical experiments to identify the irrigation levels that give the maximum kidney bean yield.

Abstract Name: **Evaluation of the Mechanical Properties of Cervidae Anterior Cruciate Ligaments, Patella Tendons, and Achilles Tendons**

The human anterior cruciate ligament (ACL) is in the knee joint and prevents the tibia (shin bone) from sliding in front of the femur (thigh bone). When the ACL is ruptured, the injury can be repaired using a replacement ligament in the form of an autograph, allograph, xenograft, or synthetic material. When replacement tissue is used it is important to understand and match the mechanical properties of the ACL tissue. In this study, deer tendons were tested to determine their ultimate strength, strain at fracture, and elastic modulus. These properties were compared across each tendon and with the physical properties of a human ACL. Cervidae (deer) tendons, including the ACL, patellar tendon, and Achilles tendon, were harvested from a local deer meat processor. The tendons were then frozen and tested later. To preserve the tendons after thawing, they were sprayed with a saline solution, and were tested for their tensile strength. The tensile test was conducted using an Instron universal testing machine. The machine recorded the force vs. displacement graph, which was used to determine the ultimate strength, strain at fracture, and elastic modulus of the tendons. The ACL had an ultimate strength of 20.7 MPa, a strain at fracture of 0.41, and an elastic modulus of 51.1 MPa. The Achilles had an ultimate strength of 16.6 MPa, a strain at fracture of 0.84, and an elastic modulus of 19.7 MPa. The Patellar tendon had an ultimate strength of 20.50 MPa, a strain at fracture of 0.467, and an elastic modulus of 43.89 MPa. It was determined that the ultimate tensile force for a human ACL was comparable to the maximum force for the patellar tendon, but higher than the Achilles or the ACL.

Abstract Name: **Suicide Prevention Among Oklahoma?s Student Veterans**

In 2020, the Governor of Oklahoma issued a statewide challenge to reduce and eliminate suicide among Oklahoma's service members, Veterans, and their families. As a result of this challenge, in 2022 a survey concerning suicidal ideation among Oklahoma's student Veterans was conducted. Multiple agencies were involved in the development of the survey, including the University of Central Oklahoma, and the Oklahoma Department of Veterans Affairs.The survey contained items concerning demographics, social support, military affiliation, and academic status.Additionally, to measure depression severity, the ten items from the PHQ-9 survey (Kroenke, Spitzer,; Williams, 2001) were included. To prepare for distribution, campus Veterans offices were contacted regarding their current outreach practices.The survey was then distributed through Veterans offices at campuses across Oklahoma, including career-tech centers, community colleges, primarily undergraduate institutions, public research universities, and private institutions. In all, 105 student Veterans responded. Chi-square tests and t-tests were performed to identify factors related to suicidal ideation and major depression. Following this, a multiple regression model for predicting the overall PHQ-9 score was developed. These results will be disseminated to Oklahoma higher education institutions to assist with their outreach efforts and to bring awareness to deficiencies in their current practices.

Abstract Name: **The Lesser Examined Coming of Age: Luchino Visconti?s Death in Venice**

This study is a combination of Simone de Beauvoir's phenomenological studies and Christopher Bollas' theories on object-relations psychoanalysis to contextualize the age-induced anxieties as revealed through Luchino Visconti's Death in Venice (1971). I will utilize Beauvoir's The Coming of Age, which focuses on the affairs of the elderly as they are disparaged by a society that problematizes and isolates their aging bodies to establish the situation of the film's protagonist, Gustav von Aschenbach (Dirk Bogarde), within a larger sociological climate. This conscious, lived-experience Beauvoir describes is the manifestation of what Bollas notes as the "generative state": a mood space that allows for a subject to regress into a former, childhood state to negotiate their current affairs, often brought forth by personal crisis. The subject, in this case, is Gustav – an aging composer who travels to Venice per recommendation of his doctor following a poorly-received concert which led to sickness. The anxiety boiling inside him becomes cooled over time with help from his generative state– communicated through the film's visual form and gesture– upon first sight of Tadzio; a boy who embodies the traditional Western standard of beauty found in the young. He further acts as Gustav's object of desire, that is a longing for both youth and the physical abilities it provides, which eventually allows for his recognition in the final sequence of life's inevitable: death. Death in Venice, in its simultaneous examination of beauty and decay, operates both as a reminder of the harm in denying one's age and a criticism of the societal antipathy that leads many, like Gustav, down a self-loathing-filled path fueled by agingand, finally, demise.

Abstract Name: **Exploring the Perceptions of Pre-Health Students who Engage in an Interdisciplinary Approach to Learning**

Background/Significance: Interprofessional education involves two or more health professions that collectively create and cultivate a collaborative learning environment with the goal of creating skills and attitudes that result in desired team behaviors (Buring et al., 2009). Minimal opportunities exist for interdisciplinary collaboration between pre-health students at liberal arts institutions, particularly nursing and athletic training. This may potentially hinder creativity and skill development essential for successful patient care. Creative pedagogical strategies that develop interprofessional collaboration abilities are needed at institutions where there is limited opportunity for actual interprofessional collaboration. Purpose: The purpose of this research study was to explore the perception of pre-health students who engaged in an interdisciplinary approach to learning. Methods: This qualitative study utilized Elo and Kängas' (2007) descriptive content analysis approach to complete a secondary analysis of group exam reflections from an unfolding case study. Ninety-three pre-health student responses were analyzed at one rural, liberal arts college in the Midwest. The reflections consisted of two open ended questions about working in groups, focusing on the effectiveness of the group, behaviors, and application to future professional roles. This study was exempt from IRB oversight. Findings: Preliminary findings indicate that open respectful communication, open mindedness, and working with a team with different skills/perspectives were behaviors that positively impacted collaboration. Students indicated the need to integrate these behaviors when working with other health care professionals to maximize learning resulting in comprehensive patient care.

Abstract Name: **Screening Microbial Secondary Metabolites for Anthelmintic Activity**

Schistosomiasis is a disease caused by parasitic flatworms which infects over 200 million people worldwide, primarily in underdeveloped countries. There is no vaccine for schistosomiasis and the disease is currently treated with one drug, praziquantel, which was discovered in the 1970s. The possibility of resistance is concerning, with only one drug for schistosomiasis control. Furthermore, there are some infections that do not respond to praziquantel even after repeated dosing. We are exploring microbial natural products as a source of potential new antiparasitic compounds (termed anthelmintics). Microbes have a proven track record as sources of anti-infective agents for other diseases. For example, the avermectin / milbemycin macrocyclic lactones produced by Streptomyces are frontline drugs to treat parasitic roundworms. In vitro screens have shown these compounds cause schistosome paralysis and death. Following this targeted screen, we have obtained an expanded collection of microbes to screen for additional bioactive secondary metabolites. In this project, we will screen this library to identify microbes that produce additional compounds capable of killing worms. Bacterial strains are grown in liquid culture for 5-7 days and fed to worms, which are tracked for a further week to score phenotypes such as death, slowed or impaired growth, or developmental abnormalities. Future work will involve identifying the structure(s) of active compounds produced by microbes that exhibit anthelmintic activity and optimizing culture conditions for increased chemical production.

Abstract Name: **Elucidating the Functional Role of Mouse Retrogene Phf8l by Mapping Protein-Protein Interactions Using Yeast Two-Hybrid Screening**

A major force driving the evolution of species is the acquisition of new genes. Typically new genes evolve as gene duplication events, such as retrotransposition, where the RNA of a gene is reverse-transcribed into cDNA and integrates into a different position in the genome. Most retrogene copies become nonfunctional, called pseudogenes. However, in cases where the retrogene remains intact and is expressed, it suggests the duplicate copy is important for the evolution of that species. We hypothesize that one such retrogene, Phf8l, along with its progenitor gene, Phf8, has enhanced male germline function after meiosis. While not much is known about Phf8l, Phf8 is a well-studied ubiquitously expressed X-linked gene encoding a histone demethylase. The focus of my research is to test how Phf8l has evolved from Phf8 by assessing whether they interact with the same or different sets of proteins. Previous in-vitro experiments have found that PHF8 interacts with WDR5 and Ash2L. I will test if PHF8L interacts with these two proteins and perform a yeast two-hybrid screen of mouse testis cDNA to determine which additional proteins PHF8L interacts with in the testis. Any proteins that PHF8L interacts with in the testis, I will then test if PHF8 also interacts with them. I will complement the yeast two-hybrid interactions with predicted interactions via AlphaFold computational analysis to pinpoint where the interaction domains are within the protein. Altogether, my studies will help elucidate how PHF8L has evolved from PHF8 with respect to the proteins they interact with. My studies will help improve our understanding of how PHF8L enhances male fertility and the basis for preservation of a functional copy of this retrogene.

Abstract Name: **Skill Assessment of Caregivers who Serve People with Intellectual and Developmental Disabilities**

This quantitative study assesses the knowledge and skill of caregivers who serve people with Intellectual and Developmental Disabilities (IDD) and explores the aspects of training they received prior and during their time serving the population. In order to test the skill of caregivers, studentresearchers created a survey with 15 qualitative and quantitative questions. There are 4 demographic questions that ask about age, gender, and ethnicity; and there are 11 questions that ask about prior experience, personal opinions of their training, and certifications. The collected data was received by sending out an electronic version of the survey to caregivers for people with IDD. Using 75 participants, this research aims to see how effective training is when used in practice. The research allows student researchers to explore solutions to maximize effectiveness. Once the data was received, it was entered into an excel coding sheet and copied into SPSS. This software provided student researchers with insight about their data based on correlations between prior training, certification and years of experience compared to their comfort level as caregivers. Student researchers used quantitative analysis such as Measures of Central Tendency, Chi-Square tests, and Correlations to find any statistical significance. The nonparametric testing that wasconducted for the research is the goodness of fit method. Student researchers thenran correlations between the variables of caregivers' age, gender, and education level.Overall, results indicate that participants felt the training they receive was beneficial, positive, and thorough (40%, n=30). The results also indicated that most of the participants had a high comfort level when it comes to caring for individuals with IDD (84%, n=63). The qualitative data is observed from open-ended questions. Student researchers intend to use these results to change training to maximize skillset and improve living conditions for people living with Intellectual and Developmental Disabilities.

Abstract Name: **Impact of Health Disparities and Prostate Cancer Among African American Men**

African American men are at higher risk of prostate cancer (PCa) compared to Non-African American men. This study identified health disparities such as socioeconomic status, education, and access to healthcare that may explain why African American men are more susceptible to this disease as well as what is being done to mitigate these barriers. A search was conducted to explore literature regarding health disparities African American men face pertaining to PCa. These articles were found using PubMed/MEDLINE, CINAHL, PsycINFO, and ERIC. Key search terms included: prostate cancer, African American men, screening, and health promotion. Year constraints were not used in the search. Reference lists were used to identify other sources from core articles. In this literature search, 35 articles were identified based on relevant titles. After reviewing each abstract, 15 articles were not relevant to the topic of interest and were discarded from the review. 20 articles were selected for a thorough review. The selected articles identified the health disparities and barriers contributing to the lack of knowledge and inaccurate beliefs pertaining to prostate cancer in African American men. Several studies indicated that African American men were less knowledgeable about the importance of early screening for PCa detection, despite African American men being at higher risk for PCa than men of other racial/ethnic groups. Studies identified the need for educational programs and interventions to encourage African American men to make more informed decisions regarding PCa screenings for early detection. Results showed a growing need for healthcare providers to encourage conversations with African American men regarding the important pros and cons of PCa screening. In summary, many African American men were unaware of their increased risk of PCa and did not have the knowledge to make informed decisions regarding early detection screening.

Abstract Name: Investigating Trends and Patterns in Climate Change Views of UW-Eau Claire Students Using Survey Data from 2017, 2018, 2021 and 2022

Climate change (CC) is perhaps the most important issue of our time. Citizen public opinion will likely be a significant determining factor regarding if/when CC mitigation policies will be enacted. Additionally, news media reports suggest that young people, including college students have been increasingly active in terms of calling for action to address CC. Surveys were conducted among UW-Eau Claire (UWEC) college students in 2017, 2018, 2021 and 2022 (N=475) to provide a case study of college student views on CC. A CC index (CCI) score was calculated using responses to questions about if CC is happening and what are its primary causes as well as an understanding of CC science and concern about and obligation to act regarding CC. CCI scores range from -10 to 10 with higher scores indicating more alignment with the scientific realities of CC. Our poster presents CCI score comparisons across years as well as by age, gender, major and political ideology including an ordinary least squares regression analysis. We will provide additional context by comparing our UWEC student results to similar work we have done comparing CC views between American and Chinese citizens from multiple survey years. Our findings suggest that UWEC students are more aligned with the scientific realities of CC compared to both American and Chinese citizens overall. Moreover, although the variation in CC views among UWEC students is less than for American citizens overall, it is greater than what we see among Chinese citizens. Lastly, our results also show a similar political pattern in UWEC student CC views as what we find among American citizens overall with conservatives/liberals being the least/most aligned with the scientific realities of CC respectively. This poster is connected to another submitted poster analyzing new data from surveys conducted of WI college students in 2023.

Abstract Name: Poetic Relativity in the Letters of Chevalier D'eon

The objective of our research is to study the ephemera and various letters written by 18th-century French, trans woman spy, Chevaliere D'eon, which we have found at the Houghton Library archives at Harvard University. Rather than focusing on the ephemera's historical significance, of which there is already a major shortage of research, we intend to study how these correspondences can be interpreted as poetry. We will be assessing whether something as conventionally "unpoetic" as a simple mailing address can be reread as something with its own inherent poetic value. The Whorf Hypothesis will be used to assess this linguistic relativism and the means by which we might classify poetics. Secondly, we will study how techniques such as the line break, enjambment, and majusculation can be found and classified as poetic elements, even when the context itself does not advertise itself as poetic. Finally, we intend to study the manner in which lines interact with one another and create a dialectical relationship between beginning and end.In relation to the Chevaliere D'eon herself, we intend to critically assess the concept of gender variance and how this affects the meaning of the poetic form. Gender identity is inextricably linked to how we see ourselves as individuals. Therefore, our research seeks to understand how that can influence writing and to what extent. Studying gender variance and language can lead us to a point of recontextualizing even the most seemingly inconsequential content. Locating Chevaliere D'eon "Opposite / the Adam and Eve," for example, gives us insight into the concept of positionality and the relationship between spatial poetics and gender identity. Understanding positionality in relation to poetics will allow us to create new ways of understanding through geographical planes and spatial relationships.

Abstract Name: **Examining distinct suicidal crisis triggers in individuals who struggle with substance misuse**

The Substance Abuse and Mental Health Services Administration (SAMHSA) estimates that 57.2 million people, or 20.8% of the country, struggled with substance misuse in 2019 (SAMHSA, 2019). Studies show that substance misuse plays a major role in suicide risk and confers ten times higher risk of death by suicide, when compared to the general population (Esang; Ahmed, 2018). Substance misuse and suicidality are common comorbidities, which highlights the importance of safety planning and crisis intervention. There is a lack of research regarding specific triggers prior to an emerging suicidal crisis in individuals that struggle with substance misuse. This study involved 522 individuals evaluated to be at risk of suicide throughout two healthcare facilities in Florida. A correlational analysis was used to determine if there was a significant relationship between substance misuse and twenty-four possible crisis triggers in patients at risk of suicide. Group differences between those that misuse substances and those that do not were examined to determine if substance use affects triggers leading to suicidal crisis. The results found through this analysis suggest a significant relationship between certain crisis triggers (increasing use of substances, feeling restless and fidgety, relationship break-ups, financial/legal problems, health problems, feeling humiliated and ashamed) and substance misuse. These results could prove valuable in developing safety plans for those struggling with substance misuse, as well as helping to identify an emerging suicidal crisis.

Abstract Name: **Exogenous alteration of DNA methylation affects the plants ability to assemble its soil microbiome**

Soils are a crucial component for sustaining healthy plants and are essential to a wide range of ecosystems. Microbial communities provide multiple benefits to their hosts, including better access to nutrients, enhanced growth, and improved tolerance to biotic and abiotic insult. Plants can modify the composition of such communities via the exudation of metabolites that enhance or prevent the abundance of certain microbial species. Epigenetic mechanisms, such as DNA methylation, have been proposed as one of the interphases that regulate the interaction between microbes and their hosts. Here, we used non-targeted soil metabolome analysis, metabarcoding sequencing, and labelled immunoassays to characterize and epimutant population of soybean generated using the demethylating agent 5-Azacytidine. We hypothesized that demethylated plants (epimutants) will present a unique set of mutant epialleles which will alter the plant's metabolic machinery, resulting in an altered ability to synthesize root exudates, and therefore a unique soil microbiome. In addition to the expected modification of the plant's morphological and developmental characteristics, non-targeted metabolomic analysis showed the metabolite profiles of soils sustaining epimutant plants are significantly different from those sustaining a wild-type. Importantly, next generation sequencing results indicate that exogenous plant DNA demethylation results in a) a partial loss of the plant's ability to alter the soil microbial communities (P=0.45; T-stat= 2.73; P-val= 0.005); b) an increased variability in the epimutants capacity to alter the bulk soil microbiomes compared to the wild-types; and c) a significantly lower ability of epimutants to prevent the growth of pathogenic bacterial species and promote the growth of beneficial taxa. Taken collectively, our results support the hypothesis that DNA methylation is involved in the ability of plants to direct the assembly of its microbiota. These findings signify the importance of epimutant plant populations as a resource for the identification of plant genes regulating soil microbiota assembly.

Abstract Name: Examining Use of a Standard Structured Meeting Agenda to Improve Learning Outcomes for Instructional Interns

BackgroundThe Instructional Internship (II) program at a Midwestern University was developed in response to the American Speech-Language-Hearing Association initiative to increase student recruitment into Ph.D. programs (ASHA, 2002) and designed to provide undergraduates with a teaching experience. This experience provides a glimpse into the daily life of a faculty member, including opportunities for teaching and mentoring students (Hemmerich, Hoepner,; Samelson, 2015). II roles are similar to that of teaching assistants. Typically, one or two IIs are assigned to a given course. IIs are undergraduate students that have already taken the course, earning an A-or better. Roles include leading weekly meetings, reviewing course content, responding to emails, and answering students' questions. IIs approach course content from a student perspective, increasing accessibility and reducing any power disparity. The experience changes II's perspectives on teaching and learning, has future implications for teaching clients/families, and develops interpersonal skills (Hemmerich et al., 2015). While associated with positive outcomes, individual experiences vary across instructors. Increasing consistency among instructors may increase consistency across II outcomes. Therefore, a standard structured meeting agenda was developed to increase inter-instructor consistency. The aim of the current study was to evaluate implementation of the structured meeting agenda.MethodsSpring 2022 IIs were recruited to participate in an online survey about their experiences with the structured meeting agenda. Quantitative results were analyzed through descriptive statistics. Open-ended responses were analyzed through collaborative qualitative analysis.ResultsMean ratings were calculated for scaled survey questions regarding use of the structured agenda. While no significant changes in approach to meeting agendas were noted, most instructors were already using a similar structured agenda. Open-ended responses were analyzed qualitatively. Instructors acknowledged that the structured agenda helped strengthen and guide the flow of the meeting, making meetings more focused, more interactive and supportive, increasing flexibility, and clarifying expectations.

Abstract Name: Whole-Genome Sequencing and Genomic Analysis of a Virulent Bacteriophage Infecting Providencia stuartii Bacteria

Drug-resistant infections caused an estimated 4.95 million deaths worldwide in 2019, and this number is projected to exceed 10 million by 2050. The most common method for combating antimicrobial resistance is the development of new synthetic drugs to which bacteria in turn evolve resistance. A potential alternative is phage therapy, which is the use of bacteriophages for the treatment of bacterial infection. Bacteriophages are a selective bacteria-infecting virus and one of the most common biological entities on earth. They are ubiquitous and found wherever bacteria exist. Bacteriophages are of an extremely diverse biological lineage, and their selectivity to the bacteria they infect make any uncommon bacteria a target of interest for bacteriophage research. The bacterium Providenciastuartiiis native to the western region of Wisconsin and has recently been isolated at the University of Wisconsin - Stout. Our research works to investigate potential novel bacteriophages that could infect this uncommon bacterium using locally collected environmental samples andProvidenciastuartiias a host for bacteriophage isolation and DNA extraction. These DNA samples will then be analyzed by whole-genome sequencing and bioinformatic methods.

Abstract Name: **Saving Brain: Progesterone and Dopamine Agonists as Potential Therapies for Secondary Neurodegeneration Following Ischemic Stroke in Men**

Secondary neurodegeneration (SND) is a phenomenon that occurs after a stroke, during which areas of the brain that were distal to the initial infarct site suffer from injury and tissue death, weeks or sometimes months after the initial incident. Current treatment of stroke and secondary neuro degeneration have limited success, and even more limited applicability, and the only widely-used drug therapy available is tPA, a thrombolytic drug effective in only 30-40% of stroke patients. I examined the mechanisms of SND, and the current research on potential novel drug therapies to minimize SND. I also researched the differences in response to treatment of SND between male and female subjects. My research shows that progesterone agonists and dopamine agonists each act on different mechanisms to limit the effects of SND, and minimize the loss of brain function in male ischemic stroke patients. Thus, further research and clinical trials should be conducted to explore the potential synergistic effects of both drugs used together.

Abstract Name: **Laying the Groundwork for Greener Solvents: A Study of Liquid-liquid and Solid-liquid Phase Behavior of an Imidazolium-based Ionic Liquid and Benzene**

In the past few decades, the scientific community has focused on substances known as ionic liquids (ILs) which have the potential to replace traditional organic solvents. ILs are low-melting point organic salts that lack the volatility, thermal instability, and handling risks of traditional organic solvents. Thus, ILs are deemed greener alternatives. Designing applications for ILs requires an understanding of their phase behavior, especially when paired with other liquid co-solvents. In this work, samples of the ionic liquid, 1-decyl-3-methylimidazolium bis[trifluoromethyl(sulfonyl)imide] (abbreviated C10mim) were mixed with benzene over a range of mass ratios. Individual samples were prepared in flame-sealed ampules. Liquid-liquid coexistence was measured with an automated laser light scattering setup and a stir-settle process was used for more accurate data analysis. The system exhibited partial liquid-liquid immiscibility with an upper critical temperature of 40.86 ± 0.06 °C. A critical composition of wC10mim = 0.1105 was determined by analyzing 90° light scattering data for critical opalescence. Solid-liquid phase transitions were determined using temperature control down to −40 °C in an insulated dewar. Samples were taken from a heterogeneously-mixed frozen state and were raised in 0.1 °C steps until transition temperatures were identified by eye. A system monotectic was identified at 5.35 °C consisting of a pure solid benzene phase in equilibrium with two liquid solution phases with compositions wC10mim = 0.011 and 0.29. A system eutectic was identified at −24 °C with a liquid solution phase at wC10mim = 0.78 in equilibrium with pure solid benzene and pure solid C10mim phases. The solid-liquid coexistence data were used to determine the enthalpy of fusion for the C10mim ionic liquid.

Abstract Name: **Development of an affordable UV detector for liquid chromatography**

Liquid chromatography systems are relatively expensive for undergraduate education and research. The price ranges are typically in tens of thousands of dollars. To more broadly introduce liquid chromatography methods and principles to education and research we are developing a modular open source chromatography system. In this presentation we describe our results on building and testing a UV detector at 280 nm for protein quantification. We used tinkercad, an online 3D modeling software with a simple and easy to learn interface to design structural pieces of a flow cell, and used 22 mm coverslips to provide UV-light access to the sample. We use an LED with a narrow emission spectrum centered at 280 nm to avoid costs and complications associated with using conventional mercury and deuterium lamps. The light intensity is measured with a UV photodiode and digitized with an Arduino board, and the single wavelength absorption allows us to avoid complex and expensive light focusing lenses or mirrors. The data is transferred to a computer in real time and analyzed with LabVIEW. To improve signal-to-noise ratio and minimize data transfer bandwidth limits we oversample our output, average 500 data points, and transfer the averaged data. A set of performance benchmarks has been completed. We estimate that the cost of our detector is approximately $70 vs.$2,000 for commercially available units. With this project we hope to provide easy to follow instructions for others to build their own UV spectrophotometers and to incorporate them into undergraduate curriculum and research.

Abstract Name: **Invisibly Here: The Future of Life Writing in Writing Centers**

In writing studies, Jonathan Alexander has employed the term “life writing” to describe the work of encapsulating the complexities of one’s lived experiences through writing (“Writing a Queer Life” 1). For us, such a theory extends the work of writing center scholars considering ways in which private and public struggles take shape through writing centers (Denny, Mundy, Naydan, Sévère, Sicari). These struggles remain increasingly tied to questions around agency and expression in the context of larger unstable social and cultural contexts. And so, we define “life writing” more broadly to encapsulate the work of helping students find meaning, voice, and agency within larger systems of inequity. Indeed, this roundtable starts by positioning life writing as a bridge between personal and academic. Yet, it builds toward offering life writing as praxis—as a writing center method for connecting with writers in a world torn apart, so often, these days. Questions around how students engage, and grow, are always tied to embodied struggles and histories they share with us, through conversation. These struggles manifest through traditional academic prose. At the same time, life writing recognizes writing centers as spaces that welcome creative fiction and nonfiction writing to process mental health and pain—that take seriously students navigating invisible struggles, including histories of shame and repression. We consider, too, how it enables us to better understand advocating for students navigating social anxieties. Presenters will begin by reviewing life writing as an emerging genre and lens we see taking shape in our writing center. Next, before opening for discussion, presenters offer what it might take—including community partnerships-- to develop life writing a genre, as a critical modality, and as a writing center method. We look forward to hearing ideas from other writing centers practitioners.

Abstract Name: **Avoidance Expression of Wistar-Kyoto and Sprague-Dawley Rats Following Overnight Fast**

Interoceptive feedback to the brain about the physiological internal state of the body plays an important role in guiding behavior. A single overnight fast can reduce anxiety-like behavior in rats, as assessed in the elevated plus-maze, open field tests, and acoustic startle and light-enhanced startle responses in rats. This reduction in anxiety appears to be an adaptive response to negative energy balance as it promotes exploratory and food seeking behaviors thus increasing the likelihood of body energy repletion. However, very little is understood about the biological and behavioral mechanisms through which physiological state influences behavior in the Wistar-Kyoto (WKY) rat, a model for stress vulnerability. The WKY rat exhibits behavioral inhibition (BI), a temperament characteristic associated with increased vulnerability to stress when compared to Sprague-Dawley (SD) rats, which serve as non-behaviorally inhibited (NBI) controls. Previous research has demonstrated that WKY rats exhibit superior avoidance performance in a signaled lever press avoidance task in which a tone conditioned stimulus (CS) signals a foot shock unconditioned stimulus (US) relative to NBI controls. The current study tested the hypothesis that an overnight fast affects lever press avoidance responding. We tested this by examining the effect of an overnight fast in female WKY (n = 8) and SD (n = 8) rats on signaled lever press avoidance. While the overnight fast did not impact avoidance behavior in WKY rats, fasting significantly increased avoidance performance in SD rats. However, total lever presses during the avoidance period was significantly increased in both WKY and SD rats following overnight fast. Our results support the view that physiological state plays an important role in influencing behavior and is the first demonstration that a single overnight fast can enhance avoidance responses in non-behaviorally inhibited SD rats to the level of avoidance demonstrated by behaviorally inhibited WKY rats.

Abstract Name: **Characterization of Npas1+ Interneurons in the Mouse Dentate Gyrus**

The dentate gyrus is a region of the hippocampal formation that is critical in learning, memory, cognition, and spatial recognition. Within the dentate gyrus, GABAergic interneurons, which release the neurotransmitter gamma-Aminobutyric Acid (GABA), are highly heterogeneous with multiple subtypes that have not been well characterized. These interneuron subtypes provide strong synaptic inhibition that enforces sparse neural activity of the principal neurons (granule cells) and dynamically gate the flux of neural information from the cortex. Our lab is specifically interested in neurogliaform (NGFCs) interneurons, a dendritic-projecting subtype with slowspiking properties that express neuronal nitric oxide synthase (nNOS). There are numerous Npas1-expressing interneurons (Npas1+) within this region, but they have yet to be differentiated into existing classes.Here, we used mouse hippocampal slices to characterize the morphological and physiological features of Npas1+ interneurons as well as their molecular marker expression to determine whether they can be differentiated from NGFCs. Our results show that Npas1 neurons co-express nNOS. While the physiological properties of Npas1 cells overlap with nNOS interneurons, the spiking pattern is not consistent with NGF interneurons. Together these results suggest that Npas1 neurons are a subset of nNOS-expressing interneurons that are not neurogliaform cells, but likely correspond to anatomically defined classes of either Total Molecular Layer (TML) or Hilar Commissural-Association Pathway (HICAP) interneurons.

Sabino, Dylaney

Abstract Name: The Creation of an Accessible Stage Performance

A live theater experience is traditionally considered to be made up of both visual and audio components, however for the blind or partially sighted audience member, sight is not a prominent part of their theater experience. In exploring the connection between the theatrical experience and the presence of inclusive audio environments, the author hopes to foster as inclusive and accessible an experience as possible through the use of audio descriptions and comprehensive sound design. Audio descriptions are the verbal additions made by a trained describer creating a mental picture of sets, costumes, characters and other visual elements of an onstage performance, both preceding and accompanying said performance, resulting in a more engaging experience for those who rely on their hearing.These audio descriptions are delivered to specific audience members via audio transmitters. These transmitters are individual devices meant to receive audio data sent through the sound board operator's system during a performance. These devices can be used both to transmit a separate signal containing audio descriptions for particular audience members, or can be used to simply boost the acoustic signal in the room from cast member dialogue. This secondary option helps to amplify the presence of natural sounds resulting from the show's writing and blocking.This work was inspired by the author's two-year employment with Young Sound Seekers, a Stetson University program partnered with the Conklin Davis Center for the Visually Impaired, geared towards exploring soundscapes in the natural world and inspiring efforts of conservation and active participation in environmental efforts. By implementing YSS's intentions of inclusivity into the world of theater arts, the author hopes to create a space where all audience members can feel comfortable and fully captivated by their theatrical experience.

Abstract Name: The impact of social media on the dietary choices of young adults in America

In recent years, social media has developed a strong presence in the everyday lives of young adults in America. Content specifically related to food, diet and nutrition often contain negative, unreliable information and can be harmful for young people who use these sites frequently. Due to the fact that young Americans are a vulnerable population, this is especially a problem to pay attention to. Exposure to this content almost daily can produce a profound impact on people's dietary choices. In my research, I will explore the impact that social media has on the dietary choices of young adults in America. Additionally, through the use of an online survey, I will be investigating young adults' personal motivations and influences for their diets. My primary claim is that social media does indeed play a large role in influencing the food habits of people who are exposed to food, diet and nutrition-related content.Social media is notorious for creating unrealistic beliefs and expectations in regards to body image and weight loss, creating a plethora of issues in relation to disordered eating, or eating habits in general. This content can cause issues with self-esteem and body image, and people may feel compelled to alter their dietary choices in order to achieve a certain image similar to one that they find online. In continuation to this, content related to food, nutrition and diet may generate eating disorders and convince viewers that weight is a significant sign of general health and self-worth.On the other hand, some positive ways in which social media may impact dietary behaviors may also exist. Images and videos of healthy foods and balanced meals that circulate on these sites could potentially inspire people to adopt healthier food choices.

Abstract Name: **Genocidal Counterinsurgency: The German Anti-Partisan War in Belarus**

The author took an interest in the history of the Eastern Frontin World War Two early in his life with a particular focus on Operation Barbarossa. Themyth of the “clean Wehrmacht” among other fallacies regarding the German Army demonstrated the necessity of critically studying the most destructive theater of the Second World War. By scrutinizing both primary and secondary literature, the author decided to add to the existing scholarship around the Eastern War by focusing onthe “counter insurgency” campaign in occupied Belarus. Through the lens of anti-partisan specialists such as Erich von dem Bach-Zelewski, the paper demonstrates the genocidal brutality of the guerilla war in the East and simple calculus the SS and Wehrmachtunderlined in their fight: to destroy the resistance, one must indiscriminately kill every man, women, and child regardless of the threat they pose.

Abstract Name: **A New Method for Counting and Identifying Water Molds in Field Samples**

Water molds (Oomycota) are aquatic multi-host pathogens that infect many species of amphibians and aquatic invertebrates. We developed a modified method for the quantification of reproductive propagules (zoospores) responsible for water mold transmission between hosts in aquatic habitats using Microwell Plates (MWP). We added 100 µL of potato dextrose agar to each well of a 96 microwell plate. We then added 100 µL of water from a serial dilution of water mold zoospores with known concentrations based on hemocytometer counts. We found that there was a close relationship between hemocytometer counts and microwell plate counts. When we tested water samples from a local wetland, the MWP method proved to be precise and repeatable when water samples from four field locations were assessed. To confirm that the quantified growths on MWP are the target species of water mold, Saprolegnia Sp. 2, molecular methods of identification such as using specific probes and primers in a quantitative polymerase chain reaction (qPCR), and restriction fragment length polymorphism (RFLP) in a restriction enzyme digest were tested. A DNA extraction method using squishing buffer and proteinase K was successful in reliably extracting water mold DNA for use in qPCR. Moving forward, the specific primers and probes that were created for the target species of water mold for use in the qPCR and the restriction enzymes that were selected for use in a digest will be tested on extracted water mold DNA to identify the growths counted.

Abstract Name: **Investigating the anti-inflammatory effects of Pomegranate Gold Nanoparticles on LPS stimulated THP-1 macrophages**

While inflammation is a crucial response to illness or injury, chronic inflammation has been shown to be a contributing factor to autoimmune diseases like multiple sclerosis, systemic lupus, and rheumatoid arthritis. The therapies currently used to treat these diseases focus on immuno suppression which can put someone at high risk for infection and many other opportunistic illnesses. Emerging therapies are targeting inflammatory cytokines by using plant-based derivatives. Several of these plant-derived molecules like curcumin, colchicine, capsaicin, and quercetin have demonstrated anti-inflammatory properties. The anti-inflammatory properties of pomegranates are correlated to a unique ellagitannin known as punicalagin. It has been hypothesized that Punicalagin is key in preventing the release of IL-6, IL-1b and TNF-a cytokines by inhibiting the NF-kB pathway. The objective of this work is to investigate the anti-inflammatory ability of pomegranate gold nanoparticles (Pom AuNPs) to reduce cytokine production from differentiated THP-1 cells. The use of pomegranate juice to mediate the synthesis with the gold chloride allows for the improvement of pharmacological activity and overall stability of the AuNPs. An XTT cell viability assay indicated that the Pom AuNPs have minimal cytotoxic effects at concentrations up to 100 mg/ml. Differentiated THP-1 cells were pre-treated with increasing concentrations of Pom AuNPs for 1 hour prior to lipopolysaccharide (LPS) exposure. LPS is a component of gram-negative bacteria that induces the secretion of pro-inflammatory cytokines by triggering the activation of the NF-kB signaling pathways. Preliminary results suggests that treatment of cells with Pom AuNPs resulted in a decrease in IL-6 production when compared to LPS only treatment but had no effect on the production of TNF-a.

Abstract Name: **Critical Dynamics in the Emergence of Agency**

As adults we understand that our actions can affect the world. Less clear is how we become aware of our causative powers in infancy. This study aims to capture and describe the dynamics of the emergence of agency, action towards an end. The mobile conjugate reinforcement paradigm provides an experimental window into this process. Infants begin the experiment as detached observers, but when one of their feet is tethered to an overhead mobile, infants may discover their ability to move the mobile. A sudden increase in movement rate is proposed to mark a moment of agentive insight (Kelso, 2016; Kelso; Fuchs, 2016). Sloan (2022) collected 3D movement data at 100 Hz from 16 babies (age: M = 100.33 days, SD = 15.57) and calculated cumulative displacement of the tethered foot during infant~mobile interaction. This was differentiated twice across 1-min.-wide intervals with 10ms shifts (using the Matlab function movingslope.m) to produce 1-min. changes in movement rate (acceleration). We will apply linear regression to cumulative displacement in the minute preceding and following the infant's peak acceleration to explore dynamics related to agentive discovery. We predict that the magnitude of fluctuations will be greater before maximum acceleration than after since fluctuation enhancement is a hallmark of complex systems nearing phase transitions (Kelso, et al., 1992). Identifying mechanisms underlying the emergence of agency may help develop an array of novel treatments as aberrations in agency are involved in movement disorders (Kranick, et al., 2013) and mental illness (Szalai, 2016; Jeannerod, 2009).

Abstract Name: **The Impact of COVID-19 on Recovery Communities in Appalachia**

COVID-19 led to an evolution in substance use disorder (SUD) treatment where service providers and persons with SUD have faced various barriers in giving and receiving treatment (Mellis et al., 2021; Palacio-Gonzalez et al., 2022; Radfar et al., 2021). Therefore, the purpose of this study is to examine recovery meetings pre- and post-COVID-19. Data was collected through phone interviews and emails that were coded to account for the current state of recovery meetings from 2018-2022. The data was analyzed using a chi-square test of independence and a chi-square goodness of fit test. In our sample of recovery meetings, there was a significant difference between the expected number of meetings before and observed number after COVID-19 X2 (4, N = 350) = 39.303, .001. Furthermore, there is a significant relationship between the number of meetings offered in the noncore, micropolitan, small metro, and medium metros and their meeting status. This indicates that most rural locations are related to lower frequencies of meetings (12, N = 350) = 44.983, .001, Cramer's V = .207. An overwhelming majority of the meetings have an unsure status (N = 118). This indicates the meetings could not confirm or deny their availability of transportation. Meetings that do offer transportation (N = 10) and do not offer transportation (N = 77) lacked sufficient sample size to analyze differences in locations. Thus, we can only tentatively support our final hypothesis. Based on our results, we can posit that recovery meetings and communities have been negatively impacted by the COVID-19 pandemic in Appalachia.

Abstract Name: **Shape Model and Boulder Clustering Analysis of Near-Earth Asteroid 2008 EV5.**

Near-Earth asteroids have Earth-crossing orbits that may presenta significant threat to life. Asteroid radar modeling aims to detect and classify hazardous asteroids to contribute to the efforts of planetary defense. We modeled the near-Earth asteroid 2008 EV5 using delay-Doppler radar images obtained by the Arecibo and Goldstone planetary radars during a close approach in December 2008 when the asteroid was within 0.022 AU. The SHAPE software was used to determine the three dimensional shape of the asteroid, its spin state, and other physical properties. The shape model of 2008 EV5 is a 2000-vertex polyhedra which reveals an equatorial bulge and a concavity on the equator. We estimate 2008 EV5 to have a pole direction of (λ , β) = (150°, -70°) ± 10° in ecliptic coordinates and an equivalent diameter of 445 ± 45 m. EV5's surface appears to be smooth over decameter scales. We performed clustering analysis on a sample of potentially high standing boulders on EV5's surface which correspond to bright pixels near the trailing edge of the radar images. The distribution of angular separations between the facets corresponding to the bright pixels were compared to the normal distribution of all facets on the model using a Kolmogorov-Smirnov test. The boulder clustering analysis reveals that the sample of boulders are clustered and may represent boulders larger than 10 meters on the asteroid's surface.

Abstract Name: **Fabrication of a Portable Pesticide Electrochemical Sensor: A Novel Label-Free Detection Of Glyphosate in Human Urine**

The increasing ambient toxicity levels and exposure to glyphosate, a widely used herbicide and desiccant, are significant public health issues. In this study, we aim to design a highly sensitive, label-free, portable sensor for the direct detection of glyphosate in human urine. The sensor platform consists of a portable, circular circuit platform with gold working and reference electrodes to enable non-faradaic electrochemical impedance spectroscopy. The sensing platform is comprised of an immunoassay-based electrode surface immobilized with a monolayer of dithiobis succinimidyl propionate (DSP), a thiol-based cross-linker, which was then modified with a glyphosate antibody (Glyp-Ab) through the bonding of the ester group of DSP with the amide of the antibody (Glyp-Ab). The sensor was tested electrochemically through two methods - the laboratory-based Gamry benchtop method and the custom portable sensing platform. Using the bench-top method for the glyphosate-spiked urine samples resulted in a dynamic response in the concentration range of 0.1–72 ng/mL with a limit of detection (LOD) of 0.1 ng/mL. This platform showed high selectivity in the presence of major interfering analytes in urine [malathion (Mal), 3-phenoxybenzoic acid (PBA), and chlorpyrifos (Chlp)] as well as high reproducibility with low inter-chip variation. Performance between the benchtop method and the portable platform were compared - creating a Pearson performance correlation of r = 0.994 between the two methods. This illustrates the development of a portable sensing approach that can be a highly reliable alternate sensor platform for the direct detection of pesticides in human bodily fluids.

Abstract Name: **Standard Flag Orders for Non-Complex Reflection Groups**

Galois orders were initially derived in 2010 and Futorny and Ovsienko and unify the study of the universal enveloping algebra, generalized Weyl algebras, shifted Yangians, and Coulomb branches. Since then easier methods were discovered for studying them, namely principal flag orders, which are essentially equivalent to studying principal Galois orders defined by Hartwig. They consist of an integrally closed domain Λ, $W \leq \mathrm{Aut}(\Lambda)$, and M a sub-monoid of $\mathrm{Aut}(\Lambda)$. To date, research on flag orders has been focused on those where W is a complex reflection group. We use techniques developed by Jauch in 2021 to examine standard flag orders with non-complex reflection groups such as the alternating group An and the quaternion group Q8. Additionally, we will construct maps from these flag orders to flag orders with the appropriate symmetric group as the group data. This takes the study of flag orders in a new direction and constructs algebras related to Hecke algebras with groups not normally associated with them.

Abstract Name: **Hydraulic efficiency of 3d printed static mixers**

Drainage practices are commonly used in Midwestern states to increase crop yield. While this method is very feasible for crop production optimization, it has some unwanted environmental effects. Unfortunately, water that is artificially drained from agricultural sites carries large amounts of nutrients to receiving waters and creates a pollution problem. There are several experimental engineering practices that suggested decreasing nutrient concentration. One of them ison-site treatment filtration of drainage water. Fast and efficientmixing of drainage water with treatment material ist he key to this practice.This goal may be achieved viastatic mixers.Static mixers are used in continuous practices, where they homogenize fluids with no moving parts, making them key components for filtration processes.There are different types, but we will focus on them here in the inline mixer.As they have for purpose to create turbulence that enhances the rapidmixing of the injected chemical into the water stream. We use them specifically for chemical treatment due to the fact they create an injection point for chemicals into water line.This research is devoted to determining the efficiencies of static mixers with different geometries.The goal is to improve filter efficiency by finding the adequate format of inline static mixerfor the right task. Hence, every filtration process differs and needsa different static mixer. Forthis, we are focusing on analyzing, characterizing, and designing a 3D line static mixer. In order to accomplish that we will be using a 3D printer to create models based on the design that we produced and test them based on specific criteria which are based on homogeneity and sediment retainment after mixing.

Abstract Name: **Location of cartoid body oxygen sensors in the Alligator mississipiensis**

This research sought to identify the location of the carotid bodies in the Alligator missisippiensis. Biologists are interested in alligators due to their evolutionary success and distinct physiology. Their unique cardiopulmonary system has been researched, yet to date little has been published about the exact location of alligator carotid bodies. In humans, carotid bodies detect changes in blood levels of CO2, O2, and H+ and help maintain blood-gas homeostasis. Carotid body dysfunction can cause congenital central hypoventilation syndrome (or Ondine's Curse) and other forms of sleep apnea. Alligators are useful as a study model for understanding the evolution of blood-gas regulation in terrestrial vertebrates since they have changed little in the last eight million years. Further research on their vasculature and carotid bodies may help researchers understand how to treat certain human carotid body related diseases. Prior studies have determined that the carotid bodies in mammals are typically located at the bifurcation of the internal and external carotid arteries found laterally in the neck. The authors hypothesized that alligator carotid bodies would also be located at the bifurcation of the internal and external carotid arteries, although in alligators, this bifurcation is located on the posterior surface of the skull. Methods used in this study included vascular dissection of seven juvenile, female alligators, vascular casting, and Kluver-Barrera histological tissue staining for identifying myelin. The researchers' results showed that myelin was located at the bifurcations of the external and internal carotid arteries, indicating the likely presence of nerve fibers from the glossopharyngeal nerve and carotid body. Interestingly, as suggested by prior CT scans of alligator vasculature, the researchers also confirmed via direct dissection that the branching patterns of the left and the right carotid arteries were asymmetrical in the alligators studied.

Abstract Name: **Genetic Contributions of APOE & TOMM40 to Mitochondrial Morphology & Alzheimer's Disease**

The strongest genetic risk factor of late on-set Alzheimer's disease, LOAD, is the apolipoprotein allele APOE ε4. APOE is an apolipoprotein that transports cholesterol and amyloid-beta proteins between cells and across the blood-brain barrier. Previous research suggested APOE ε4's relation to LOAD is tied to inefficient cholesterol; lipid transportation. Thus causing amyloid-beta protein accumulation and plaque formation in the brain. New research suggests that APOE ε4 affects other cellular functions, such as cellular glucose metabolism. TOMM40 rs2075650, a translocase of the outer mitochondrial membrane, is another single nucleotide polymorphism tied to Alzheimer's disease. Interestingly, genes APOE and TOMM40 are in proximity on chromosome 19 and share linkage disequilibrium. In order to study their effects on cellular level, HEK293 cell lines carrying combinations of these alleles will be created using Piggy-bac homology-directed repair method facilitated by CRISPR Cas9 technique. The Piggy-bac plasmid vector contains GFP, Puromycin resistance and hsvTK genes for cell selection. Once the cells are verified through sequencing, we will evaluate the effect of APOE ε4 on the distribution and transportation of cholesterol inside and outside HEK293 cells, glucose metabolism through mitochondria, and also to study its interaction with TOMM40 rs2075650.

Abstract Name: **Urban Economics and Environmental Design in Montgomery's Peacock Tract**

“When God gives the vision, provision follows.” - C.P. Everett, IV Mt. Zion A.M.E. Zion Church is a protected landmark found in the historically African American neighborhood of Peacock Tract, Montgomery, Alabama. Mt. Zion A.M.E. Zion Church’s restoration is part of ongoing efforts to revitalize the surrounding neighborhood. Charles P. Everett is the Director of Restoration for Mt. Zion A.M.E. Zion Church. In 2021, Auburn University College of Architecture, Design and Construction’s Environmental Design program approached Everett, to research and propose design-based solutions to economic and environmental disparities in the Peacock Tract. Parallel research on urban development in the Peacock Tract has been conducted by Auburn University, Columbia University, University of Pennsylvania, Tuskegee University, City of Montgomery, and local advocacy groups since at least 2012. The available research on the revitalization of the Peacock Tract has several limitations. These limitations include: - outdated statistical data (2010), - subjective and incoherent language, - low resolution data analysis, - lack of environmental documentation, - lack of social infrastructure analysis, and - lack of economic resiliency analysis.Urban Economics and Environmental Design in Montgomery’s Peacock Tract aims to address the limitations of current available research. To address the current research limitations, the project aims to: - update statistical data, - create a non-subjective model and coherentlanguage structure - increase data analysis resolution - document environmental conditions - document social infrastructure, and - conduct economic resiliency analysis. The guiding thematic questions are as follows:- How do transportation economics and environmental conditions in the peacock tract influence welfareoutcomes for its residents and workers? - How resilient is the transportation system of the Peacock Tract, and how might this impact welfareoutcomes for its residents and workers?In answering these questions, the preconceived notions of transportation planners around the world is carefully challenged.

Abstract Name: **Engineering and Project Manager Collaboration Expands Virtual Learning**

Lunar Languages is a free application developed by Embry-Riddle Aeronautical University upper-level software engineering students to provide an interactive and fun way to learn spoken languages and computer science components, including Python coding and vocabulary terms, Russian language vocabulary, and limited Mandarin vocabulary terms. Lunar Languages promotes educational growth via a hand-held,interactive gaming interface specifically designed to promote multi-purpose learning with endless applications.The Embry-Riddle Aeronautical University, Prescott College of Engineering (COE), in conjunction with the College of Business, Security; Intelligence (CBSI) are coordinating further updates of the Lunar Languagesapplication. Students from the COE specializing in software engineering and Games; Simulation partnered with project managers from the CBSI who earned the Certified Associates in Project Management (CAPM) to expand vocabulary, and develop graphics and support systems of the Lunar Languages application.This application provides students of all majors with free access to a digital database of vocabulary terms via gamification interface, promoting memorization and practical language-learning via interactive participation in augmented reality, accessible on the Apple App Store and Google Play. Recently, software developers expanded the functions of the application by adding Russian language vocabulary, randomizing the questions presented to the user, adding pinch and zoom functions, implementing sounds for correct answers, and creating a high-level class diagram for the developers to understand the processes of the app. Further application development includes collaboration with the College of Engineering to expand code for Mandarin vocabulary, expand map support to increase accessibility and range of the application, and update the sims and graphics designs for the app. Collaboration between project managers and the College of Engineering allows students to create a realistic plan to expand the digital infrastructure of this app and design diverse educational resources for individuals studying linguistics and computer science at all levels.

Abstract Name: **Limited Access to Rural Community Schools**

Sensitive topic agencies have limited access into the education system and are unable to inform school aged children on sensitive topics. Due to the limited ability agencies who facilitate sensitive topic programs contain in the rural community school systems, student researchers introduced a question pertaining to the issue. How do educators in rural communities perceive agencies who facilitate sensitive topic programs? This study aims to understand factors related to sensitive topic agencies. Through a survey, the student researchers collected mixed-methodological data with a concentration on quantitative data. The overall targeted sample size was 75 educators who have worked in rural community school systems. After speaking with individuals, researchers can reach out to schools as a whole. They can practice at a mezzo level by contacting the school about what individuals inside their facility believe is appropriate to be taught to the students. Reaching out to the school can allow researchers to obtain an approved number of topics that are allowed to be presented to the age group indicated. This will then allow agencies to provide some information regarding sensitive topics to schools. In terms of the macro level, agencies often branch out into counties. The student researchers found that a majority of female participants did report a positive perception of sensitive topic agencies, and male participants reported limited knowledge. They also found that age did not matter when looking at the perceptions the educators have on sensitive topic agencies.

Abstract Name: **The Orphic Journey: A Study of Mystery Cults Through Orphism**

One question mark within our knowledge of Ancient Greek religion is mystery cults, which carefully guarded their myths and rituals known only to initiates. One thing we know about a few of these cults is their application of Orphic literature. Modern scholarship defines Orphic literature as a collection of hymns, myths, and other narratives said to be written by the poet Orpheus that deal with themes of death and rebirth. Two texts bookend this research chronologically, The Orphic Gold Tablets, thought to have been written circa 400 BCE, and The Orphic Hymns, which were likely written in the second half of the third century (250 - 300 CE). Within this 700-year range, there is an opportunity to examine how mystery cults' beliefs changed by tracking variations in the composition of the Orphic corpus. To measure this, we have examined the death and rebirth myth of Dionysus, an underlying myth told in multiple Orphic texts because of Dionysus' role in the creation of mortals and as the successor to Zeus. For example, in The Orphic Gold Tablets Dionysus became a progenitor of humanity: after he is born, he is devoured by the Titans, they are then destroyed (by Zeus' lightning), and from the ashes, the first humans are created. This myth is also referenced by The Orphic Hymns where Dionysus is given the title "thrice-born" when he is reborn twice after his death referenced in The Orphic Gold Tablets. This project will acknowledge the connections to this myth in each Orphic primary source, identify how each source differs, and explore the reasons for these differences over time. Through variations in aspects of this myth throughout the corpus of Orphic literature, we assess how the perceptions of mystery cults had changed, which will give us new insights into a previously mysterious group.

Abstract Name: **Apparent activity in Aedes aegypti mosquito and its correlation with age and social environment**

Much work has explored the daily activity patterns of the yellow-fever vector mosquito, Aedes aegypti, yet both descriptive and experimental research has lacked cross-study uniformity in the most basic demographic variables. Such inconsistency in methods often produces differences in data and their interpretation. The underlying problem is that we don't know which of the many demographic variables are important determinants of activity behavior. We seek to correct this deficit in basic knowledge by quantifying the activity behavior of individual Ae. aegypti using "latent activity monitors" (LAMs) while systematically varying the most basic demographic variables: age, sex, and social environment. Our first experiment measures 24-hour activity patterns of individuals of separate sexes as they age. The second experiment compares 24-hour activity patterns within single-sex and mixed-sex environmental chambers. With the conclusion of these trials, a better understanding can be garnered of the possible effects of age, sex, and social environment on daily activity patterns. This work will guide future studies on the genetics that underly the activity patterns of Ae. aegypti. The findings will be relevant to public health issues resulting from temporal differences in human exposure to disease vector mosquitoes. Genetically modified mosquito technology might be improved by using this knowledge to better design experiments exploring the effect of genes that underlie activity.

Abstract Name: The effects of restoration projects on phosphorus concentrations throughout Manitowoc County streams and Lake Michigan

Phosphorus poses an ongoing challenge to Lake Michigan. Excess levels cause algae blooms resulting in degraded water quality in near-shore waters. As local tributaries serve as important phosphorus sources to Lake Michigan, we analyzed phosphorus levels in two streams in Manitowoc County, WI—Centerville Creek and the Little Manitowoc River.These streams have historically exceeded Wisconsin DNR surface water phosphorus standards of 0.075 mg/l phosphorus. Each stream has undergone restoration near where they enter Lake Michigan in order to slow stream flow and reduce phosphorus loading into Lake Michigan. Each creek showed a different trend in phosphorus concentration along its length. Centerville Creek showed lower phosphorus concentrations within the restoration area compared to the upstream branches, although all significantly exceeded the WDNR threshold. North branch averaged 0.510 mg/L phosphorus, and the south branch averaged 0.430 mg/L.Sites within the restoration project averaged 0.307 mg/L. In contrast, no difference in phosphorus concentration was noted between the upstream and restoration sites in the Little Manitowoc River.This may be because this restoration was more recently completed (2020 vs 2012), or due to the surrounding land use as the Little Manitowoc River runs through the city of Manitowoc, while Centerville Creek goes through agricultural land. However, overall concentrations across the Little Manitowoc River were lower than any of the Centerville sites, with an average concentration of 0.071 mg/L, below the WDNR threshold, and rain events did not increase phosphorus as much as in Centerville Creek. Future work will focus on identifying future sources as well as continued monitoring to evaluate the success of these restorations and inform land use decision-making.

Abstract Name: Characterizing novel mechanisms underlying serotonin dependent influences on behavior

Mood disorders, such as depression, affect over 40 million people in the US. Despite the use of an array of therapeutics for mood disorders, current understanding of the mechanisms underlying these processes and the specific targets of each therapeutic remains unclear. This results in variable success of the existing treatments, along with very little specificity toward an individual. More recently, there has been a deeper focus on understanding serotonin targets involved in mood and mood disorders. We use the nematode, Caenorhabditis elegans, to investigate the behavioral effects of serotonin and the neural mechanisms and intracellular pathways that mediate serotonin's effect on the brain. Our present study specifically investigates, 1) the novel targets of serotonin, and 2) how serotonin-dependent behaviors may vary across different species within the Caenorhabditis genus. We have found that known serotonin effects on worm behaviors including paralysis and stimulated egg laying, were significantly different across worm species that originate from distinct geographical locations. This implies the possibility of characterizing intracellular pathways and the factors that contribute to the differing behaviors, to understand the extent of pharmacological drug specificity toward an individual suffering from mood disorders. In further research, we intend to discover the targets of serotonin in nematodes across different genera to assess the fundamental variation in the alternate behavioral responses to both serotonin and serotonin targeting therapeutics, which continues to be of high importance in understanding human neuropsychiatric disease, like depression, addiction, and bipolar disorder.

Abstract Name: **Shadowing Rock Island's Coroner**

Over the summer of 2022, I shadowed Rock Island's Coroner-Brian Gustafson,where I saw autopsies being performed.I spent a total of 22 hours transporting and shadowing autopsies. Atotal of fivewere shot, with two overdoses and one natural death. While shadowing, I would typically observe and occasionally help handout tools. During my time shadowing, I got to see how complex autopsies truly are. They are very precise and done with much respect. The main objective of an autopsy, especially in forensics, is to find the cause of death, and they are performed by step-by-step examination of a deceased patient's external and internal organs. The forensic pathologist would allow the Rock Island Police Department to collect their physical evidence and thendo the autopsy where the primary organs:heart, lungs, liver, kidneys, and brain, would be weighed and cut into smaller pieces for further examination. Once the forensic pathologist examined all external and internal organs, Brian and I would transport the body to a local funeral home. The funeral home is where the mortician or funeral director would take the bodies out ofthe car and begin the funeral preparations.The most important takeaways from this shadowing opporrtunity would be to see and experience the utter respect these people have for the deceased and the deceased's family, the difficulty and complexity an autopsy consists of, and lastly, I received important information and knowledge from Brian and the other forensic pathologists I shadowed in the summer, and I'm forever thankful for this amazing opportunity.

Abstract Name: **Starving for Stability: Examining the Effects of Eating Disorders on Cognition**

People's food choices and perceptions of healthy food are affected by dominant cultural views on the subject and access to food. The present study focuses on the potential relationship between decision making, eating behaviors and impulsivity. It is hypothesized that decisions of individuals of color will be affected by their peers' or families' perceptions of their food behaviors, choices and definitions of "healthy eating". Given the heavy reliance on the Iowa Gambling Task in this type of research, an original survey was created for the purpose of this study. Participants registered for this experiment via the NEIU SONA system. After receiving the study link, individuals were provided with information necessary to decide whether to continue with the survey. Those that agreed were asked to complete a series of surveys, including the original scale and the Barratt Impulsiveness Scale (BIS-11). Participants were then asked to provide demographic information, debriefed, and allowed to exit the study. Analysis of the data will provide a better understanding of an individual's relationship with food and how they make decisions that impact this relationship. This study will shed light on the role factors external to the individual play their eating habits. Ultimately this and future research can lead to a better understanding of the factors surrounding how and why individuals suffer from eating disorders. Moreover, such research can improve our understanding of how these illnesses are connected to cognitive functioning.

Abstract Name: **The Relationship Between Salvadoran Immigrants' Perception of Corruption and their Civic Engagement**

Researching Salvadoran immigrants in the U.S. is important because of how the civil war in their country of origin pushed many of them out. This project analyzes the civic engagement of Salvadoran immigrants in the U.S. in terms of how the history of their country of origin has affected their trust in the government. Research shows a causal relationship between the perception of corruption and trust. A study found that 93% of people in El Salvador thought corruption in government was a significant issue. In light of the causal relationship established between the perception of corruption and trust, it can be assumed that most Salvadorans have low trust in their government. Furthermore, research shows how these perceptions and beliefs about the government are transferred over to the U.S. among individuals after emigration. It can be inferred that Salvadoran immigrants' lack of trust was brought over to the United States when they immigrated. This would then affect their civic engagement because it has been shown that those with lower trust in their government are less likely to participate in political activities. In addition, research has shown that those who immigrate to the United States from countries with "histories of state-sponsored oppression and lack of trust in government institutions" will be less likely to participate politically. That means Salvadorans' experiences with and perceptions of the government are likely to affect their engagement in the United States. I hypothesize that in comparing United States immigrants from El Salvador, those who perceive less corruption in the government in El Salvador will be more likely to engage civically in the United States than those who perceive more corruption in the Salvadoran government.This research is crucial, considering the growth of the immigrant and Latinx communities in the United States.

Abstract Name: **Gun Violence in Schools**

Gun violence has become a huge problem, especially when it comes to our schools. Just this year, as of October 31, 2022, there have been forty school shootings, twenty-eight of the victims were students and the other six were staff members. According to SIERP (Stanford Institute for economic policy Research) more than a hundred thousand students between 2018-2019 were involved in school shootings. School shootings have a major effect on students' mental health, academic performance, and enrollment ((Dodson, 2021,). School should be a place where children want to go to learn, make new friends, and a place where they can feel safe and secure. Sensible Gun laws need to be implemented in addition to school based interventions that address problems before shootings occur. One solution that has been tossed around and will not help this situation is arming teachers with guns. This literature review looks at the effects and impact of gun violence on students and offers some research-based approaches for creating safer schools and communities (McMillan, Jordan; Bernstein, 2022),

Abstract Name: Effects of Self-Monitoring and Visual Feedback on Mathematical Frustration with a Neurodiverse Learner

Mathematics is a content area that many neurotypical students struggle with, especially at the elementary level when learning the fundamentals of the subject. Neurodiverse learners may be predisposed to mathematical frustration, and past research has focused primarily on interventions involving motivation, self-monitoring, and visual feedback. A literature review was done to look at academic performance, curriculum issues, attributional style, mental health theories, school-based well-being, and frustration in mathematics. This study discusses an intervention involving self-monitoring with a creative visual feedback tool to increase motivation and decrease mathematical frustration in a neurodiverse 10-year-old male student, with diagnoses of autism spectrum disorder, attention-deficit hyperactivity disorder- combined type, disruptive mood dysregulation disorder, and sensory processing disorder. Over the course of 10 intervention sessions in class and in one-on-one work, the learner's frequency of frustration behaviors decreased significantly and his ability to ask for help when needed increased notably. Research across other grade levels along with more of a focus on mathematical performance in learners with specific diagnoses using creative visual feedback is needed to see if what the student colors matters or if online versus hand drawn coloring matters.

Abstract Name: AI Modelling for the Impact and Contribution of Various Factors on Heart Attack Casualties

Previous studies reveal that many prevailing health indicators/variables can play a significantrole in heart attack-based causalities. These variables include blood pressure, age, anemia,smoking, serum sodium, ejection fraction, serum creatinine, platelets, diabetes, and creatininephosphokinase. With the increasing computational power, it is now possible to use differentalgorithms to develop a predictive model that will take the input data related to various factorsto predict the outcome in term of survival or death of the patients. Developing these models istime consuming task that may take a lot of effort and resources. This can be eased by using machine learning tools that be able to develop a predictive model by incorporating multiplealgorithms for an optimized solution predicting the final outcome with a high accuracy. In the current work, an open-source data from Kaggle was obtained that incorporated multiple variables for 300 patients including the final outcome for these patients [https://www.kaggle.com/datasets/heart-failure-clinical-data]. We used IBM Watson platform to conduct this study. IBM machine model first analyzed each variable by conducting astatistical analysis on each variable. Then it used random Forest Classifier and LGBMClassifier with and without multiple enhancements including HPO-1/HPO-2/FE. Thedeveloped model can predict the outcome with an accuracy of 86.6%. Important variables contributing to the outcome predicted by LGBM forest included platelets-76%, EjectionFraction-58%, Creatine Phosphokinase-52%, Serum Creatine-49%, Serum Sodium-34%, andAge-27%. On the other hand, the corresponding variables contribution predicted by theRandom Forest included serum creatinine-50%, ejection fraction-30%, creatininephosphokinase-25%, age-19.00%, and platelets-18%.This presentation will highlight the medical implications for selected variables contributions and will provide information

Abstract Name: **Covert Resistance to #MeToo: The Uptake of Social Change and Public Anxiety in the Menøs Lifestyle Magazine Cover Genre**

The #MeToo social movement begun in 2017 raised voices and awareness around sexual violence and its role in masculinity, impacting individuals and institutions across the United States (PettyJohn, 2019). The extent to which #MeToo impacted the larger American culture and its masculine ideologies, however, is difficult to gauge. Employing an ideologically rich genre—the covers of men's lifestyle magazines—and concepts from Rhetorical Genre Studies (RGS), this presentation explores the larger impact of #MeToo on American culture. Reflecting the ideologies of the culture it exists within, the genre of men's lifestyle magazine covers plays a powerful role in the (re)production of masculine ideologies to be internalized by its audience. Focusing on the depictions of masculinity and looking for shifts, this presentation draws on analysis and comparison of two sample sets of the genre from before and after #MeToo (12 covers from 2007-2012 and 12 covers from 2017–2022) fromGQ, Esquire, Men's Health, Men's Journal, Playboy,andMaxim. Two shifts are identified in ideological (re)production of masculinity: (1) the replacement of traditional, clean-cut masculine aesthetics with a hyper-masculine "caveman" aesthetic; and (2) a dramatic decrease in representations of women as relational objects. The speaker will argue that these patterns represent a sidestepping of the issues raised by #MeToo and a covert resistance to the movement rather than a fundamental shift in American masculinity. While this presentation underscores the extent to which #MeToo may have provoked shifts in how masculinity is (re)produced in this magazine cover genre, it also more broadly considers the extent to which social movements and the resulting public anxiety can impact ideological (re)production in genres. Further, identifying these shifts in masculinity's (re)production through genre analysis allows scholars, activist communities, and individuals to witness the tangible impact of #MeToo on the ideologies that the movement sought to confront.

Abstract Name: **Role of CRF1 and CRF2 Receptors in Stress-induced Increase of Intestinal Permeability**

Stress has been proven to increase the permeability of the intestinal epithelial layer, contributing to the development of irritable bowel syndrome (IBS) and other intestinal diseases. Corticotropin releasing factor (CRF) has been known to mediate stress-induced increase of intestinal permeability and contribute to the etiology and symptom severity of IBS. Actions of CRF are mediated by two G-protein coupled receptors, CRF1 and CRF2, both are expressed in the intestine. However, the roles of the CRF1 and CRF2 receptors in stress-induced increase of intestinal epithelial permeability remain unknown. Since IBS is more common in females than in males, female mice were used in this study. Mice were restrained for one hour/day for five days. The selective CRF1 and CRF2 receptor antagonists were injected intraperitoneally 15 min prior to the restraint stress. Control mice were kept in their home cages without restraint. After the last restraint stress/control session, the proximal colon was removed and intestinal permeability was measured using the Ussing Chamber System. FITC-inulin (4kD) and horseradish peroxidase (HRP, 40kD) were used as tracers to measure paracellular and transcellular permeability, respectively, across the colonic epithelium. The results showed that restraint stress increased both paracellular and transcellular permeability in the proximal colon. Both the CRF1 and CRF2 receptor antagonists significantly reduced the effects of restraint stress on intestinal permeability, suggesting that both CRF receptor subtypes are involved in stress-induced increase of intestinal permeability. Targeting on both CRF1 and CRF2 receptors in the intestine may help to alleviate stress-induced increase of intestinal permeability and symptoms of IBS.

Abstract Name: **Comparison of Epidermis Characteristics and Microbiome as a Result of Different Mask Type Usage in Young Adults**

The Covid-19 pandemic has highlighted the importance of foundational disease control measures, including personal protective equipment; however, prolonged daily use of respiratory protective equipment can cause a shift in the skin's physiological properties. These changes are likely the root cause of “maskne,” mask-related acne, but not much is known about why these issues occur, and even less about the varying effects between mask types. This longitudinal study compares the effects of surgical masks and cotton masks on pH, temperature, moisture, oil, and microbiome of the facial skin in three areas (cheek, nose, and forehead). The epithelial characteristics of 12 individuals, 18-25 years of age, were analyzed before and after a duration of two weeks of wearing a mask for a minimum of four hours a day. A general trend of increases intemperature, moisture, and oil was found after the use of both surgical and cloth masks. Statistical analyses revealed statistically significant (paired t-test 0.05) increases in cheek temperature (+4.6% and +3.5%)in individuals that wore a surgical or a cloth maskrespectively. Moisture increased significantly at the cheek (+20.6%), nose (+15.8%), and forehead (+21.9%) with surgical mask use and only the cheek (+16.7%) with cloth mask use. The oil content increased significantly, as well, at the cheek (+21.6%), nose (+15.8%), and forehead (+21.6%) with surgical mask use and only the cheek (+17.3%) with cloth mask use. Neither pH nor microbiome quantity or diversity was shown to significantly change with regardto mask use. These patterns canexplain the physiology behind the increase in acne during the pandemic as well as provide insight intowhat can be done to prevent and treat these effects.

Abstract Name: **FRAMING A KILLER: HOW FICTIONALIZED VS DOCUMENTARY ACCOUNTS OF A FAMOUS SERIAL KILLERS SHAPE ONLINE CONVERSATION**

Stories allow people to engage with immoral minds. Yet, to be associated with an immoral actor is psychologically “threatening” because of the fear of being seen as immoral oneself. In everyday experience people distance themselves from immoral actors to remain unassociated with them; however, fictional narratives create enough psychological distance to allow people to identify with, and explore, the motivations of immoral actors. It is unclear whether this psychological distance occurs with stories about real-world individuals who commit extreme moral transgressions (i.e., serial killers), or whether it affects the characteristics of surrounding discourse. The current study examines whether people engage with “true crime” documentaries versus narrative retellings of the same stories differently. This will be done by scraping online platforms for comments about shows which examine the lives of serial killers (e.g., Jeffery Dahmer). The data will be analyzed using Natural Language Processing for moral content using the Moral Foundations Dictionary 2. Sentiment analysis will also be used to assess the emotional valence of the comments. It is expected that comments related to narrative retellings will have higher levels of moral content and fuller engagement throughout the valence spectrum. Despite having a large online viewership, the documentaries are expected to garner less engagement and exhibit specifically negative valence rather than positive. This is in line with the view that they do not create as much psychological distance between the viewer and the immoral actor. Nonfiction accounts of real-world atrocities may force people to grapple with the moral implications more directly and thus distance themselves from the main subject, whereas fictionalization may lead to more open engagement in online discourse.

Abstract Name: **Modeling a Bifacial Solar Panel for Characterization and Performance Evaluation**

Bifacial solar panels are gaining attention due to their superior performance that comes from their ability to generate additional output power (5-10%) by absorbing the solar irradiance from the back surface. Bifacial PV modules still need to be characterized for their overall performance. To evaluate the performance of the bifacial PV modules, attempts are underway at San Jose State University to develop a solar model along with a thermal analysis model that will be then validated by our experimental data. In the current presentation, a thermal analysis model developed for a bifacial PV model is included. For this purpose, a JJN Solar Panel 200 W bifacial PV panel was selected. Basic measurements include the short circuit current and open circuit voltages at various operating conditions. The thermal analysis model includes the basic structure of the panel by considering various layers of the PV module e.g., front surface with antireflection (AR) coating, followed by an emitter layer (P+ Si) and N type wafer that is followed by aluminum back surface layer with AR coating. Thermal conductivities and respective thicknesses of all layers were used to complete the thermal resistance model that was then used to find panel's surface temperatures by keeping a constant flux condition on both the front and back surfaces. Depending on the incident flux, surface temperatures were found varying from 50 to 60 C at the front side as compared to 35 – 30 degrees on the back side of the PV model. For he electrical modeling, five parameters equivalent circuit model proposed by MA et. al. [2019] was employed. Skockley diode equation was modified for the PV panel and IV characteristics were plotted by obtaining the data from the experiment. Final poster will include the details on our experiments and the associated results.

Abstract Name: **Combining Unsupervised and Supervised Learning for Credit Card Fraud Detection**

Due to potential risks as a consequence of the rapid growth of e-commerce, finding a proper method to detect credit card fraud becomes more important than ever. Supervised learning methods can find patterns within sets of credit card transaction data but can miss novel patterns of fraud and consumer patterns that have yet to be trained upon. Unsupervised learning, in contrast, can be used to find anomalies instead of specific patterns, but is limited due to variability caused by how different components are weighed. Solely using one form of learning for credit card fraud has limitations, which may be possible to correct with a combined approach. In this paper, we develop a way to combine unsupervised learning with weights discovered by prior supervised learning to improve credit card fraud detection. We use a decision tree to find the importance of different components of a credit card transaction in relation to fraud. This importance is then used to determine weights for distance used with the k-means clustering algorithm. To test our weighted k-means clustering algorithm, a dataset consisting of synthetic credit card transactions with over five hundred thousand transactions is used. Our algorithm improves clustering accuracy to 95.3%, compared to the normal k-means clustering accuracy of 90.5%.Due to audit requirements, the banking industry wants its models to be clearly interpreted. So, we present a k-means-based soft clustering algorithmto better apply to the banking industry. A method to find an optimal threshold for models using this simplified algorithm is also developed.

Abstract Name: **Simulation of Thin Film Growth during Magnetron Sputtering**

Sputtering is a fabrication technique for semiconductors. Thin film growth during plasma vapor deposition is a stochastic process which can be modeled by probabilities and randomly generated energies. The goal of this project is to use Monte Carlo methods to simulate the growth of thin films during magnetron sputtering. The Monte Carlo methods are a broad class of computational algorithms that rely on repeated random sampling to obtain numerical results. Python programming language was used to simulate the motion of constituent atoms to form a thin film during magnetron sputtering by applying the Monte Carlo methods. A random integer was generated representing the energy that each incoming atom has. The binding of the desired atom to the substrate to form a thin film was decided by the amount of energy each incoming atom has. Using python, the time taken to form a thin film of a desired thickness, was estimated. The formation of island growth in thin films was observed during the simulations. It was also observed that increasing the energy barrier and the size of the substrate resulted in longer run times needed to complete a matrix.Keywords: Monte Carlo Simulation, Python, Sputtering, Thin Film

Abstract Name: **The role of daf-12 in the post-embryonic neuronal development of C. elegans**

While significant advances have been made regarding neuronal development during embryonic stages, there is a gap in knowledge pertaining to the mechanisms that control post-embryonic neural development and maturation. Preliminary evidence suggests that vitamin D and its cognate vitamin D receptor (VDR) play important roles in these areas. VDR is an exciting candidate to examine as it responds to environmental stimuli by binding to nutritionally derived ligands, while its regulation is also under tight control by intrinsic genetic regulatory pathways. This project aimed to identify the mechanism by which VDR controls post-embryonic neuronal development and maturation. To examine this relationship, the temporal expression pattern of daf-12, a homolog of the VDR in C. elegans, was examined in the C. elegans post-embryonic nervous system using a GFP-tagged expression reporter, generated using CRISPR-Cas9. This was used to identify key neurons that were expressing daf-12 as well as the developmental stages in which this expression changes. Once these critical stages were established, the locomotory behavior of control worms was compared to that of daf-12 mutant worms, with early results indicating “juvenilization” of locomotor behavior in mutant worms. Since movement is closely tied to neuronal development, alterations in the maturation of locomotory behavior in daf-12 mutant worms suggest that daf-12 is involved in the regulation of neuronal maturation and gives direction to further studies of the mechanism by which daf-12 controls neuronal maturation. These directions include profiling the daf-12 mutant transcriptome to identify the downstream molecular targets of daf-12. Additionally, we are using a candidate approach to examine ins-6 and ins-9, as potential targets of daf-12. More broadly, the data gathered in this project aims to advance our understanding of neuronal development and how dysregulation of gene-environment interactions can contribute to neurodevelopmental disorders such as intellectual disabilities and autism.

Abstract Name: **Unity, Progress, & Activism in Milwaukee's Urban Neighborhoods**

For the third year in a row, Milwaukee has beaten its own homicide record. It is believed heavy policing is the answer to these societal problems, but many Milwaukee activists say that its investment in community programs would lower crime rates. With the guided help of Program the Parks director and activist, Vaun Mayes, we have been able to identify, investigate, and interpret these Milwaukee and Wisconsin racial-based issues in our documentary. It is with insight from these community leaders we have documented them creating events for youth, such as lock-ins, basketball tournaments, and park clean-ups. Through Vaun’s conversation with former Milwaukee police officers, Pamela Holmes and Ricky Burems, they discussed the need for police to form trust with the community itself. These solutions have come specifically from black police officers and have already been thought of, just not implemented. Some of the main topics we have chosen to focus on include urban crime being covered in the media while ignoring black success stories, the importance of leading youth with the help of community programs and leaders, and pushing local community members to run for office. The main solutions we have discovered and have encouraged are violence prevention, violence interruption, suicide prevention, incident de-escalation, social justice, and community building. Throughout our research, and now through the documentary we’ve created, we’ve been able to highlight community members who have their boots on the ground and are spreading awareness about these topics. By all of us continuing to put the work in, we can create a greater impact through unifying when trying to support these communities. These solutions can be beneficial for all.

Abstract Name: Stylistic Approach to Portraying a Realistic Romance on Screen

Night and Day, a 15-minute short thesis film, follows the romantic journey of a young couple. Emmanuel comes to Gabriella seven years after he unexpectedly left her on their anniversary. When his illegal activities from work began to have an effect on his personal life, Emmanuel knew he could not let Gabriella get involved with this. After years experiencing the harsh consequences of his immature actions, a changed Emmanuel returns, only to see Gabriella taking care of two kids. She has changed as well. As memories interfere with daily routines, the characters question whether their love deserves another chance. The reality of their present conflicts with the reality they used to have, as emotions gain control over their lives. My goals for this short film are to portray how complex love becomes with time, and to encourage young people to dedicate more effort into making relationships work. I express this stylistically by using telephoto lenses with high key lighting, and tilted angles. The editing will focus on capturing reactions, face expressions, getting an intimate insight into the mind of the characters, as the film's goal is to reveal the profound emotion revoked through heartbreak, separation, the loss of love, but also the process of finding it again and regaining trust in the one you love.Viewerswill experience a strong attachment to the characters as they discover the crazy things love makes people do.

Abstract Name: Medium Effects on Hydrogen Bonding and Proton Transfer in Fluoropyridine-HBr Complexes

Hydrogen bonding is a ubiquitous phenomenon in nature, it is the intermolecular interaction which governs many things such as the unique properties of water and the structure of biological macromolecules. This project involves using theoretical models and low temperature infrared spectroscopy experimentsto investigate hydrogen-bonding and proton transfer in a series ofcomplexes of fluoropyridines and hydrogen bromide (e.g., C5F5N-HBr). We are exploring two key issues in this context; i) the extent of fluorination and ii) interactions with chemical environment, specifically inert gas matricies (solid samples of noble gases at temperatures near absolute zero). Theoretical models provide structures (e.g., N-H distance), hydrogen bondenergies, H-Br bond frequencies which closely parallel hydrogen bond strength, and charge density. These can be compared to the respective experimental spectra in solid Ar,N2,Ne which reveal the medium effects. For the stronger systems, we predict proton transfer in the gas phase (C5H5N-HBr) or in inert media for weaker systems (F2C5H3N-HBr) and in the latter case we see a clear signature of this transition in the spectra. In addition, bonding analyses highlight shifts in the electron distribution that not only accompany the transition from hydrogen bonding to proton transfer, but also forecast it to some extent.

Abstract Name: The Canvas 2.0 Project

The Canvas 2.0 project focuses on building user-friendly and user-oriented functionality in a system that can work alongside the Canvas learning management system. The existingorganizationalfeatures for studentsare not user-friendly or do not do exactly what students would like these features to do for them to be successful in their college careers. A semester-long survey of portions of the UWEC student body resulted in a focus on two features in the initial version of the software system, which are: a grade calculator and a student task manager. The grade calculator determines grades a student would have to achieve to obtain a desired final grade in a course. The task manager allows a student to create and save both academic and personal tasks in one place, allowing them toavoid missed deadlines and appointments. These features were by far the most asked for during the survey process, mainly due to Canvas's existing systems either not being user-friendly or simply not functioning the way studentswould like. The system is a Maven-based Java project that incorporates JavaScript, CSS, HTML, and Database technologiesto create a web-based application with a runtime repository. The in-progress system now incorporates the grade calculator functionality and an architectural fulfillment of the task list functionality. The latter is slated for full completion in Fall 2022 and added functionality of creating a persistent database repository by end of Spring 2023. A persistent repository is important for the future of this project because it would allow users to track tasks even if they close the app, which aligns with the intended purpose of the Task List function. The Canvas 2.0 system is an ongoing project development, and we plan to continue to enhance the system's functionality to work alongside the Canvas LMS toward improving its student-centric features.

Abstract Name: Patterns and Contradictions of Gender Tropes within Contemporary WWII Espionage Film: How Modern Feminist Movements Impact Female Representations

World War II espionage thrillers have been around since the war itself and films continue to be made depicting this historical era. Although WWII spy and intelligence films can be considered their own genre, they arguably still fall under the larger umbrella of WWII films in general. Thusly, tropes and themes within a larger body of WWII films often carry over into the subgenre, including gender-related tropes and themes. In recent years, espionage films have tried to break female characters out of stock typologies, two notable examples being Female Agents (2008) and A Call to Spy (2019). These films succeed in reimagining a number of tropes, but many underlying themes related to women maintain conventional gender stereotypes. My research examines Female Agents, Black Book (2006), Enigma (2001), A Call to Spy, Allied (2016) and The Imitation Game (2014) in the context of a broader body of WWII espionage films in order to analyze changing gender representations and stereotypes in contemporary historical film. This study examines contradictions in the messaging of these films across a broad range of sources, such as the films, their scripts, interviews with various creators, and directors' notes. Their visual elements will be closely analyzed considering historic and cinematic citations, that is, references to key historic and cinematic images. I will analyze the films' representations of historical contexts and popular culture; additionally, modern feminist movements and theory will help guide examination of the films' executions and productions. A potential fourth wave of feminism began in the middle of this influx of WWII espionage film production, allowing for a consideration of filmmakers' motives and audience's perspectives at two distinct points in contemporary history. Overall, this study aims to detect patterns and contradictions in WWII espionage film's portrayals of women, gender, and cultural constructs in relation to modern feminism.

Abstract Name: **Social Media & Belonging/Conformity**

The 21st century has been described as the information age with knowledge and communications spanning globally at the push of a button. Social media platforms such as Instagram, TikTok, Snapchat, and Twitter have given all demographics access to express themselves through pictures, ideas, and beliefs. With the ability to obtain a wider audience in years proceeding, it should stand that social connectivity and the broadening of perspectives would come with it. Due to algorithmic processing, however, social media platforms curate and streamline information, advertisements, and profiles that seem to align with a person's interest. Because of this, diversification becomes limited and platforms do not provide the global perspectives they were once thought to achieve. It instead becomes an echo chamber: a confined corner of the internet where opinions, politics, and issues only align with the beliefs of the individual. Coupled with the fast-paced interaction of social media, the attention given to the information is finite and may not be internalized without proper education or mental consolidation. This ongoing study analyzes the correlation between social media usage and belonging/conformity. By interviewing people who use social media for over three hours daily, different demographics will be tested to see what beliefs they are passionate about, how they interact with those beliefs on a social platform, and if they allow other perspectives to be examined based on their site interaction. My prediction is that social media users will have an ineffective interaction with beliefs and political issues due to curated profiles and an inherent desire to align with said profiles. In examining this, my hope is to highlight the current issue with social media news consumption to educate the public about a willingness to diversify perspectivesthat should truly come out in an age of information.

Abstract Name: **Designing a Space to Support Sensory Regulation Within the Eau Claire Children's Museum**

With the recent rebuild and renovation of the Eau Claire Children's Museum, the museum's executive teamelicited the support of students and faculty within the Special Education and Inclusive Practices Department at the University of Wisconsin – Eau Claire to create a sensory room within the museum. The research team was comprised of student volunteers who previously took a class with Dr. Kirstin Rossi aboutplay and sensory pedagogy, as part of the Unified Special Education program. The team began the development process by meeting with executives from the museum and touring the designated space. During the initial visit, the executive team discussed the goals of the museum. The main goalwas to create a designated space for children to regulate themselves and re-enter the museum when ready. Previously, children who were dysregulated usually left the museum and ended their visit early. With these objectives in mind, student researchers used their learning from the aforementioned class and gathered further information on sensory integration to develop and design specific spaces in the sensory room. Within the design,all eight senses were supported through equipment, spacing, and materials. Additionally, a space was created toprovide a specific area for children to calm their bodies. The last project component was to identify materials and tools that would help children successfully reengage into the larger museumonce re-regulated. The sensory room was designed to be open to a variety of children while also providing tools and information for families to better understand their child's sensory needs, regardless of age or ability. Beyond the sensory room itself, informational materials were also created to share that increase community understanding of sensory needs and integration. This poster presentation will outline the research process and project development, including the final design and use of the space.

Abstract Name: Relationship of BATF3-Dependent Conventional DC1s to Type 1 T Helper Responses

Cryptococcal meningitis affects 150,000 people each year, killing 112,000 of them. Anti-fungal drugs are limited, and immunocompromised individuals are especially at risk for infection. Further study of dendritic cells–essential in host defenses–will help to develop new immunotherapies and vaccines to treat cryptococcal infection. Dendritic cells are heterogeneous and different subsets play different roles in the immune response.Our previous study showed that BATF3-dependent conventional DC1s (cDC1) are important for Type 1 T helper responses critical for fungal clearance. How cDC1s contribute to Type 1 T helper responses is still unclear. We are therefore interested in understanding how cDC1 promotes Type 1 T helper polarization. We hypothesize that cDC1 is the major producer of cytokine IL-12, which can stimulate Type 1 T helper polarization.Methods: Using intratracheal (IT) surgery, we will inject cryptococcus directly into the trachea of mice. They will be harvested 14 days post-infection. Through flow cytometry, we can identify cDC1 using XCR1 and SIRPa markers. We will then detect IL-12 cytokine production of cDC1s and other cells by intracellular flow cytometry. Expected results: We expect to find that cDC1 produces large amounts of IL-12 cytokine, supporting our hypothesis that cDC1 promotes Type 1 T helper polarization through IL-12 production. If so, we will administer IL-12 cytokine in cDC1 deficient mice and expect that Type 1 T helper polarization will be restored. We may see cells like cDC2 also secrete IL-12, suggesting that cDC1 is not the only source of IL-12 during cryptococcal infection. Our major conclusion from this experiment is that cDC1 promotes Type 1 T helper response through IL-12 production. Studying the role of cDC1 in Type 1 T helper polarization helps us better understand host defense mechanisms against cryptococcal infection. Modulating cDC1 and its pathway may be important for designing new treatments for cryptococcus.

Abstract Name: Stabilizing the Dimer of Non-Structural Protein 9 in SARS-CoV-2

SARS-CoV-2 is an RNA+ virus that is directly translated by the host cell to produce non-structural proteins (Nsp 1-16) essential to the replication of viral RNA.One interesting non-structural protein, Nsp 9, contains an unusual OB-greek key motif known in other viruses to bind single stranded RNA working with the helicase to allow efficient replication. Additionally, this protein is thought to dimerize for efficient RNA binding; however, the specific mechanism of dimerization and the interaction between this dimer protein and a cognate RNA sequence are currently unknown. To better understand the requirements for dimer Nsp 9-RNA binding, we have made a cysteine mutant to covalently stabilize this dimer. Tryptophan fluorescent studies have been developed to determine differences in binding affinities of both RNA and DNA sequences to help identify requirements of complex formation between Nsp 9 and, an as of yet, unidentified cognate RNA. Initial studies indicate binding of an RNA pseudoknot structure could aid in sequestering Nsp 9 to untranslated regions of the viral RNA.

Abstract Name: **Simulated Rooftop Prairie Plant Community Comparison to a Prairie Remnant Plant Community**

In 2008, in downtown Kansas City Missouri, a 14,000-square-foot rooftop prairie garden was established in a 4-inch coarse substrate. 15 years later, the garden consists of a self-organized community of native prairie plant species. In novel anthropogenic conditions, we compared this simulated plant community and its comparable ecosystem. A restored prairie remnant, Jerry Smith Park, served as a comparative community to the rooftop. We observed species richness and abundance via the Daubenmire Quadrat Method over three sampling plots: the rooftop garden, an unmanaged field in Jerry Smith, and a recently burned hillside in Jerry Smith. In a three-month sampling period, 77 plant species were observed. The three plots were compared using functional group percentages, Conservatism Coefficient (CC) means, and Floristic Quality Index (FQI) scores. The rooftop prairie Conservatism Coefficient means were similar to both prairie remnant sites. The rooftop prairie had lower FQI scores than the managed site, but similar scores to the old field site. The rooftop had higher abundance of native forbs compared to both Jerry Smith sites. While both remnant sites had higher abundances of grasses, sedges, and rushes, the managed plot had a significantly higher abundance of native graminoids. Within Jerry Smith, we observed higher abundance of native species overall. However, they varied throughout the sampling season. These differences are reflective of the abiotic and aesthetic pressures on the rooftop garden. Contrasts between the remnant plots are representative of the management they have received.Similarities found between the rooftop and remnant sites offer insight into the bridge between anthropogenic environments and reference sites. Further research comparing the biotic and abiotic structure and function of different prairie remnants to anthropogenic prairie communities is warranted.

Abstract Name: **(Im)Proper English: Exploring Identity with a Stigmatized Accent**

Contemporary research has focused on how English speakers perceive those with accents, but as the United States grows in diversity and societal expectations change over time, there are always new voices to be heard. My project centers on those with stigmatized regional and non-native accents who regularly have in the past or to this day face discrimination and prejudice due to their perceived accent. This study draws from published ethnographies that detail experience and ideology as perceived by those who use a stigmatized variety of non-standard English, supplemented by additional stories contributed by students and professorsfrom the University of Wisconsin La Crosse. This study relies on snowball sampling to acquire a select few knowledge-rich individuals who willparticipate in small focus groups and individual interviews. The space will be used to openly discuss linguistic discrimination and its effects on these individuals within their various identities as a student, employee, family member, and friend. Notes and recordings from each session will be coded with patterns assigned to themes relating to identity, community roles, and self-image. Upon conclusion, this project intends to determine themes that link individuals in their struggle with stigmatization and identity. These findings will provide insight into the perspectives held by those who experience accent discrimination and provide a stepping stone to further human rights in modern times.

Abstract Name: **Effects of Cognitive Priming on Problem Solving Ability**

Successful problem solving encompasses different cognitive mechanisms: executive functions, divergent thinking, and convergent thinking. Executive functions are generally defined by our individual capacity of: shifting, inhibition, and updating. Divergent thinking revolves around the ability to generate multiple ideas for potential solutions to a given problem. Convergent thinking is the mode of thinking associated with finding a singular, optimal answer. It has been found that a great deal of the failures on the Cognitive Reflexive Task (CRT)-the principal measure of an individual's ability to override an "incorrect gut response" (Frederick, 2005), are a result of a failure to properly explore a problem space (i.e, 61% of incorrect responses did not think about their answer (Szaszi, 2017). This failure to explore a problem space is why we hypothesize that individuals who are primed to think divergently will perform better on the CRT, and conversely that individuals who are primed to think convergently will perform worse on the CRT. Overall, there was not a significant difference between the priming groups on overall Cognitive Reflexive Task performance: $F(2, 48) = 1.68$, $p = .37$. The Convergent group had a lower CRT score than the Control and Divergent groups, however this was nonsignificant. While there was no statistically significant sex difference, a visual analysis of the line graph indicated that there were different trends for males versus females. As a result we conducted separate ANOVAs for males versus females. We did not find a significant effect for females ($F[2, 27] = .02$, $p = .98$), or a statistically significant effect in males ($F[2, 21] = .59$, $p = .57$). While we did not find statistical significance, it is possible that with a larger sample size statistical significance could be found, as evidenced by the difference in p values (.98 for females versus .57 for males).

Abstract Name: **PROPYLENE GLYCOL AND VEGETABLE GLYCERIN INHALATION EXPOSURE INCREASES CIRCULATING XANTHINE OXIDASE IN PREGNANT DAMS**

West Virginia has the sixth highest prevalence of electronic cigarette (e-cig) use in the country.An excess of circulating free radicals, highly reactive unstable molecules, from e-cig use may cause tissue and organ damage especially during gestation when the fetus is developing. Therefore, we examined the effects of propylene glycol and vegetable glycerin (PG/VG), the main liquid components in e-cigs, inhalation on maternal and fetal outcomes. Pregnant Sprague-Dawley rats were randomly assigned to sham-control or a PG/VG 50:50 ratio. Whole body e-cig inhalation exposures were performed (90 min/exposure; 30 W atomizer; 6d) during gestational days 10-19, with the last exposure occurring 24 hours prior to sacrifice. Mean exposure chamber aerosol concentration was 569 ± 56 mg/mL with particle size ranging between 100nm(ultrafine) and 1nm(fine).Plasma xanthine oxidoreductase activity was elevated 3-fold in PG/VG dams compared to sham-control (0.05). Additionally, placental xanthine oxidase activity was increased in the PG/VG group (6.50±0.51 mU/mg) versus sham-control (3.65±0.42 mU/mg; 0.05). Pup and placental mass were reduced in the PG/VG group (2.1±1.1 g;0.6±0.2 g) compared to sham-control (3.3±0.7g;0.7±0.1 g; 0.05).Placental efficiency (grams of pup/gram of placenta) was also reduced in PG/VG dams (3.7) compared to sham-control (4.4; 0.05).In maternal plasma, prolactin levels were decreased in sham-control (2.31±0.05 ng/mL; 0.05) versus PG/VG.PG/VG inhalation exposure during pregnancy may have adverse effects driven by free radicals on maternal and fetoplacental tissues.Support: WV-CTSI NIH-U54 GM104942-05; NIH-K01 OH12320 (ECB),NIH-R01 ES015022 (TRN)

Abstract Name: **Investigating a Local Elementary School?s Implementation of the Next Generation Science Standards**

Next Generation Science Standards (NGSS) are being implemented by K-12 schools throughout the United States. The Outdoor Discovery Center (ODC), a nonprofit education organization, partnered with a school in West Michigan to assist their K-5 teachers with implementation of NGSS throughout the 2021-2022 school year. The purpose of this research was to determine how effectively the elementary school teachers incorporated NGSS into their science lessons, how engaged students were during the lessons, and how comfortable the teachers were with the new standards. Researchers collected data using interviews, focus groups, and surveys from three sample groups: teachers (n=24), students (n=7), and ODC ambassadors (n=4). Qualitative data were analyzed with NVivo software using inductive methodology to determine major themes. Quantitative data were analyzed using a Wilcoxon Signed Rank Test in SPSS to determine if there were changes in teachers' attitudes over time. Qualitative results revealed that teachers often felt overwhelmed with integrating NGSS because of a lack of time, difficulties gathering appropriate learning resources, and a lack of content knowledge. However, teachers persevered and continued with implementation as they observed increased student engagement, gained experience with the new standards, and received support from the ODC. Survey data indicated most teachers felt more comfortable with this style of teaching by the end of the year, but they recognized there was room for improvement. Specifically, teachers wanted to develop more robust assessment tools, schedule more co-planning time with each other and the ODC ambassadors, and engage in more professional development to increase their content knowledge and gain experience with NGSS-based pedagogy. The research team also noted that more science and engineering practices could be incorporated into the elementary lessons. Nevertheless, the first year of implementation laid a foundation for the future of effective incorporation of NGSS in this elementary school.

Abstract Name: **Understanding Word Finding in Older Adults; Image Naming Norms Across the Age Range**

Introduction: Image naming tasks are used to better understand the linguistic processes of word finding in people without and with neurologic communication disorders such as aphasia and dementia. Neurologic communication disorders become more common with increasing age. However, word finding is affected in both, healthy aging adults and people with neurologic disorders. Therefore, norms for image naming in older adults are important for defining what constitutes normal performances and to refine markers for impaired word finding. To date, norms for image naming in older adults are lacking. The purpose of this study is to provide norms for older adults free of neurologic impairments on a large set of photographs of everyday objects, normed on younger adults, the Bank of Standardized Stimuli (BOSS).Methods: Thirty-five participants were recruited. All are native speakers of English, at least 50 years old, and free of neurologic deficits. Each participant was presented with 600 photographs derived from the BOSS on a computer screen and was asked to name each image as quickly and accurately as possible. The responses and response times (RT) were recorded. Accuracy, RT, modal name, and name agreement were analyzedResults: Preliminary results revealed a mean accuracy of 82.48% and a mean response time of 2.204 ms. Modal name agreement indicated an overall 66.34 % agreement across the 600 stimuli. The sample's demographic composition and an analysis stratified by 10-year age bands will be presented.This is one of few studies that provides norms for image naming for adults 50-80 years of age. We aim to collect data for60 older adults. Norms across the age range for image naming are a critical prerequisite for behavioral research that tackles theoretical as well as clinical questions.

Abstract Name: **Active Learning Pedagogy in Organic Chemistry: Analysis of Final Exam Data**

Organic Chemistry is a notoriously challenging course, required for pre-Health majors, with drop and failure rates commonly in excess of 30-40%. This project examined the effect of active learning on reaction mechanism pedagogy to increase engagement and decrease student failure rates. We studied two semesters with no active learning pedagogy, two semesters with half active learning pedagogy, and two semesters with full active learning pedagogy. Preliminary results suggested that student achievement greatly improved and drop/failure rates were halved when active learning was used, as shown by analysis of formative (ungraded) assessments. Upon review of final exam data of the studied semesters, we found that our analysis strongly supports the preliminary findings from formative assessments and drop/D/F rates. Taken into combination, the aggregate data provide strong support for the effectiveness of active learning in this “hardest college course”. In order to analyze the data in question, we developed rubrics that applied to 6 semesters worth of final exams. Students had better mechanistic understanding and knew how to portray a mechanism better when they were exposed to more active learning in their organic chemistry semester. In these rubrics, students were not given a grade, but rather scored based on individual steps in the mechanisms in question. These scores were based on logic and mechanistic reasoning rather than simple correctness, as our study seeks to analyze the effect of active learning on student understanding rather than memorization of mechanism steps.

Abstract Name: **Teaching Accurate and Age-Appropriate History to Elementary Students: Teaching Third Graders about Historic Thanksgiving**

This educational and historical research is based in teaching accurate and age-appropriate history to elementary students. Unfortunately, history in elementary classrooms is often taught inaccurately to avoid teaching children about the embarrassing and gruesome parts of United States history. When history is taught incorrectly, it can perpetuate stereotypes and it leaves students confused when they reach secondary and higher education and discover that some of what they know is incorrect. The purpose of this project is to investigate what really happened at the 1621 Harvest Feast, assess how to teach this information to children based on developmental appropriateness and create lesson plans for teachers to do just that. First, the research in this thesis consists of exploring the actual historical events of the 1621 Harvest Feast, through primary and secondary historical documents. Second, how Thanksgiving is currently taught at the 3rdgrade level, by reading teaching materials and books used in third grade classroom and an anonymous google form that Massachusetts teachers participated in. Finally, itincludes lesson plans and classroom activities for teaching about Thanksgiving using true accounts of history, based around the Massachusetts State Standards. This research has vital implications for not only how history is taught to elementary students and for helping teachers figure out how to do that; but also, a change in elementary education can positively change the United States’ cultural ideas of Thanksgiving.

Abstract Name: **The Mesoscale Conditions that Contributed to the development of the Morton, Texas Tornado on 23 May 2022**

On 23 May 2022, the participants of UW-Whitewater's Field Course on the Forecasting and Verification of Extreme Weather witnessed a tornado in west Texas. The official tornado report had tornadogenesis occurring at approximately 0007 UTC 24 May 2022 (7:07 pm CST 23 May 2022). Based on synoptic-scale (i.e., large scale) conditions most of west Texas from the US-Mexico border into the Texas panhandle were under the threat of severe weather on this day. While in the field and in the post-mortem analysis of this day it was determined the mesoscale conditions were the main factor as to why a significant tornado occurred in the west Texas region near Morton. Mesoscale conditions were evident during the course's morning weather briefing using various mesoscale forecast models. As the day progressed and conditions changed slightly, adjustments were made by the course participants that allowed them to witness the development of the thunderstorm that would end up producing a dust storm (with straight-line wind gust up to 80 mph) and large hail (1.5 – 2.5 inches in diameter). In the post-mortem analysis, a detailed analysis of the mesoscale conditions was performed with additional data from mesoscale networks around the west Texas region. This post-event analysis did find that a localized area of enhanced shear formed near the Morton area due to a surge of dry air out of eastern New Mexico. Preliminary results show that this surge of dry air interacted with an outflow boundary from the earlier developing thunderstorms. The interaction of these differing boundaries created a small area of enhanced lift and wind shear that allowed one of the on-going thunderstorms to intensify and produce an EF2 tornado that occurred 7 miles north of Morton, which the course participants witnessed.

Abstract Name: **Investigating Trends and Patterns in Climate Change Views of UW-Eau Claire Students Using Survey Data from 2017, 2018, 2021 and 2022**

Climate change (CC) is perhaps the most important issue of our time. Citizen public opinion will likely be a significant determining factor regarding if/when CC mitigation policies will be enacted. Additionally, news media reports suggest that young people, including college students have been increasingly active in terms of calling for action to address CC. Surveys were conducted among UW-Eau Claire (UWEC) college students in 2017, 2018, 2021 and 2022 (N=475) to provide a case study of college student views on CC. A CC index (CCI) score was calculated using responses to questions about if CC is happening and what are its primary causes as well as an understanding of CC science and concern about and obligation to act regarding CC. CCI scores range from -10 to 10 with higher scores indicating more alignment with the scientific realities of CC. Our poster presents CCI score comparisons across years as well as by age, gender, major and political ideology including an ordinary least squares regression analysis. We will provide additional context by comparing our UWEC student results to similar work we have done comparing CC views between American and Chinese citizens from multiple survey years. Our findings suggest that UWEC students are more aligned with the scientific realities of CC compared to both American and Chinese citizens overall. Moreover, although the variation in CC views among UWEC students is less than for American citizens overall, it is greater than what we see among Chinese citizens. Lastly, our results also show a similar political pattern in UWEC student CC views as what we find among American citizens overall with conservatives/liberals being the least/most aligned with the scientific realities of CC respectively. This poster is connected to another submitted poster analyzing new data from surveys conducted of WI college students in 2023.

Abstract Name: **Determining the Survivability Parameters of Mirror Satellites**

In the circumstance where a planet is tidally-locked it means that one side of the planet is constantly facing the sun whilst the other side is in perpetual darkness. An intelligent civilization could then attempt to expose the dark side of the planet through the use of orbiting mirror satellites that reflect light from the star onto the planet below. This light, or radiation would also exert a force on the mirrors and cause them to drift away from their gravitational orbits, jeopardizing their long-term survivability. Our research tests the survivability of these mirror satellites through the use of computer simulations in a variety of situations. We vary star type, the period during which radiation from the star impacts the mirror, the distance between the planet and satellite, and the orientation of the orbit. We showed that lower luminosity stars, radiation affecting the satellite only when the satellite is above the night side of the planet, and a smaller distance between the mirror and planet were more conducive to mirror survivability. These in addition, satellite orbit orientation of -XY, meaning the satellite is on the same orbital plane as the planet yet traveling in the opposite direction than the planet, tended to produce the longest mirror satellite survivability. The observed trends in mirror satellite survivability and how the aforementioned variables affect one another will be presented.

Abstract Name: **How does alcohol consumption affect life expectancy?**

Life expectancy is one of the most significant indicators for health-related issues. In order to asses the dependents of life expectancy at birth, I will examine the following research question: What is the association between alcohol consumption and life expectancy at birth?I used a panel-data from the World Bank of 217 countries over the period 2000-2021. In contrast to existing literature, it is a very long-term data set that also accounts for the distortions due to the COVID-19 Pandemic. After doing the Hausman test, I ran a fixed model regression with a linear functional form. Besides alcohol consumptions, I included important variables from other categories, like health care, education or socio-economics, that may have major influences on life expectancy. It turned out that an increase in alcohol consumption leads to a significant decrease in life expectancy per country on average over time.In order to assess the significance of the results, I ran several tests, like a t-test, and analyzed statistical parameters, like R squared.There are different limitations to the results. First, many missing observations about alcohol consumption question the significance of the results. Moreover, it needs to be examined in more detail if there are severe limitations such as an omitted-variable bias.

Abstract Name: **The Life and Music of Florence Price**

Born in Little Rock, Arkansas, Florence Beatrice Smith Price (1887-1953) was America's first significant African American woman composer. The purpose of this lecture-recital is to uncover how Price's compositions are a historic symbol for traditional black composers today, revisit her significance in music history, and provide a biographical overview of her life through the exploration of her piano compositions and experiences composing as a Black woman. Graduating with a double degree in solo organ and piano teaching from the New England Conservatory of Music in 1906, Price was deeply influenced by mentors who helped reinforce an African American identity in her music. While living through the Great Migration and the Great Depression, Price slowly gained recognition throughout her lifetime as a prominent figure in the black community by writing piano compositions that included the "juba dance" and other Afro-American characteristics. Linda Rae Brown's findings in The Heart of a Woman: The Life and Music of Florence B. Price, reveal Price faced issues with conflicting roles both as a woman and a composer. With increasing racial tensions in the late 1920s, Price was denied access to professional music organizations such as the Arkansas Music Teachers Association. Although she lived a moderately private life, analyzing gender and race-based marginalization through the lens of Black feminism illustrates how Price challenged prejudicial social structures and contexts. Price challenges these notions by advocating for herself as a Black woman composer, eventually paving the way by fusing Euro-American structures with elements of her own American cultural heritage by emulating plantation melodies and African American folk melodies in her music. This lecture-recital is part of a growing momentum to give further attention to Price's piano compositions and life, which deserve continued further attention from scholars, teachers, and pianists.

Abstract Name: **An Analysis of the 'Good Life' Through a Lens of Submission to Institutional Power**

The ideal of the 'Good Life' in the United States is a tool used by dominant institutions to encourage submission to their institutional power and, therefore, assimilation to the abstract of 'the majority.' Drawing on Foucault's Discipline and Punish, along with work by Emma Goldman, Paulo Freire, and studies into police violence, I will argue that punishment, being defined by Foucault as a solely negative action, has created the space into which discipline has stepped, shaping the norm of the Good Life on behalf of dominant institutions. Then, making use of Emma Goldman's idea of the majority in conjunction with Freire's view of populism, I will show that assimilation is presented as the only option to a 'reasonable citizen.' Additionally, I will examine Freire's concept of the 'banking method' of education in schools and policy around use of force in policing to further demonstrate that submission to institutional power is the narrative into which people are encouraged to conform. I conclude with a discussion of the revolutionary potential of power, specifically in an educational setting, in which the Good Life can be redefined as the questioning and subversion of authority.

Abstract Name: The Relationship Between Mindfulness, Directed Coping and Perceived Stress

With mental health becoming more recognized as a national problem, it is important to study the different aspects of how it affects lives and how it can be improved. Multiple studies have shown the positive effects of mindfulness to improve patients' stress levels through intervention. Studies have shown the preliminary effects of directed coping to also reduce perceived stress levels in people who are in consistently stressful environments. The current study sought to explore the relationship between mindfulness and directed coping skills among college students and their perceived stress levels. It was predicted that there will be a negative relationship between mindfulness scores and perceived stress levels; that there will be a negative relationship between directed coping scores and perceived stress levels, and that there will be a positive relationship between mindfulness and directed coping scores. Through a convenience sample, 183 college students were assessed through a voluntary survey. The survey consisted of the Perceived Stress Scale, the Directed Coping Scale, the Five Facet Mindfulness Questionnaire (Short Form), and a demographics section including age, academic level, and gender items. The results found a significant moderate negative correlation between perceived stress levels and mindfulness scores, a significant low negative correlation between perceived stress and directed coping scores, and a significant low positive correlation between mindfulness scores and directed coping scores. All hypotheses were supported. Recommendations for future research include replicating the research to include a wider range of cultural perspectives and differences in age.

Abstract Name: Legislative and Regulatory Responses to Houston-Area Flood Events Since 2015

This research investigates three NOAA-designated “billion-dollar” flood events in Houston, Texas, in relation to their influence on flood-specific legislation at state and local levels. A review of the literature, as well as flood related bills and laws between 2015 – 2021, indicates that the interrelationship between increased frequency of flood events and the volume of flood legislation following a significant event has received little scholarly attention. To investigate this relationship, two semi-structured interviews were conducted with Dr. Phillip Bedient, director of the Severe Storm Prediction, Education,; Evacuation from Disasters Center at Rice University, and Texas State Senator Brandon Creighton of District 4. The collected interview material elucidates the complex and political nature of storm event management and legislation pertaining to flood control and mitigation. This research reveals an upward trend in the issuance of flood-related laws and enhanced cooperation between governmental agencies; however, many substantial political barriers to proactive policymaking exist, such as the limited attention of lawmakers and complex intergovernmental relationships. The significant hurdles of organizational boundaries, political agenda—and the reactive nature of existing measures—call for more preemptive policymaking as flood-causing storm events continue to accelerate.

Abstract Name: **Exploring the effects of female power depicted in Chinese and Jewish mythology on identity in coming of age narratives**

Jewish and Chinese mythology is filled with stories exploring female power that directly inform literary representation. This creative project examines the intersection of racial, gender, and religious identity, by critically drawing from these Jewish and Chinese depictions. In recent years, the term intersectionality has been used to describe individuals or subsections of society who identify with a variety of social markers. Conversations about the overlap of Asian Jews —my primary identity— however, have not yet reached the forefront of scholarly or popular works. For instance, mythological beasts, power, sexual agency, and the role of women are explored in both canons. Using various genres, my final portfolio works to address this lapse in representation and give voice to diverse demographics by creating literature in predominantly white spaces. Through speculative fiction, poems, and narrative essays, this project seeks to examine the collision of personal identity by examining the depiction of power in traditional biblical and cultural mythologies. By engaging in conversations with these traditional portrayals, my writing strives to answer questions about personal, racial, gender, and religious identity. My research will culminate in a collection of works examining power and physicality through the lens of these identities and mythologies. I plan to give an oral reading of my work. By focusing my writing through an introspective lens, my work features stories that connect traditional myths to modern experiences, examining the both effects of the stories we tell and the types of narratives we promote.

Abstract Name: **Determining Limits of Re-Extraction Using Heated Passive Headspace**

Heated passive headspace concentration is the most common method used for extracting ignitable liquids from fire debris samples. The aim of this research is to determine if there is a limit to the number of times the chemical signature of a “positive” sample can be re-extracted from various matrices and successfully identified by analysts. This research analyzed a combination of substrates that are commonly found as flooring in residential and commercial buildings to determine if the interference from the pyrolyzed products would affect the results of the re-extraction. A standard 50%/50% mixture of gasoline and diesel was used as the standard ignitable liquid to broaden the visible pattern when analyzed by gas chromatography. Volumes of this combination of ignitable liquids ranged from 1 mL down to 30 µL. Unburned liquid standard was placed on Kimwipes to serve as a control while other samples contained typical building materials found in arson debris. The samples were burned using modified destructive distillation and extracted by passive headspace concentration. The re-extractions were performed, and analysis interpreted until the positive determination was no longer upheld by trained criminalists. Of the materials tested, the burned debris had the most difficulty in the determination of both ignitable liquids. The interference from the carpet and soft wood overlapped the identification pattern of the mixture which prevented the analysts from confirming both. The re-extractions of the other matrices were also analyzed and observed specific trends. Degradation of the alkane pattern occurred after several extractions of the Kimwipe while the unburned combination observed a skew towards the lighter compounds. In summary, the experiment showed that re-extraction produces repeatable results for at least three attempts in each condition; however, the complexity of the burn debris prohibits a universal statement on reliability beyond that number of re-extractions.

Abstract Name: Estimations, Ambitions and Achievements: An Examination of Parental Factors and their Effect on Students Educational Aspirations and Attainment

The impact that parental socialization has on a child cannot be understated, particularly as it relates to a child's educational experiences and outcomes. Research has thoroughly explored the relationship between parental factors, such as socioeconomic status and education-level, and theirchild's level of educational attainment as an adult. What is less understood, however, is what factors are most important in explaining the disparity between educational aspirations in relation to the actual education that a student completes. Utilizing data from the Youth Development Study, this study seeks to identify the relationship between students` educational aspirations in high school to their actual educational attainment collected at age thirty. Analyses will examine the difference between educational aspirations and actual attainment and which factors influence both. The Youth Development Study is a longitudinal panel survey that collected data from both parents and their children(N=1,010). Path analysis was used to identify the direct effect of educational aspirations on educational attainment while controlling for other demographic and structural factors and indicate the indirect effect of the exogenous variables on educational attainment through educational aspirations. The results indicate that parental aspirations and education level, along with specific individual level demographic measures, had the strongest effect on a child's educational attainment. The implications related to familial and educational policy will be discussed.

Abstract Name: Evaluation of esters of hydroxycinnamic acids as UVB-UVA filters in emulsion: A naturally sourced alternative to synthetic UV filters in commercial sunscreens

Synthetic UV filters approved for use in US sunscreen formulations have come under increasing scrutiny in recent years due to the suspicion of undesirable effects on human health and the environment. A growing body of research points to their potential for endocrine disruption, and recent state legislation in both Florida and Hawaii banned two of the most common of such filters — octinoxate and oxybenzone — upon evidence of coral bleaching and toxicity to marine life. Plant-based hydroxycinnamic acids (HCAs) and their corresponding esters have been shown to absorb in the UVB-UVA (290–400nm) region of solar radiation. This study sought to evaluate the UV-filtration potential of these compounds in emulsion, against existing commercial sunscreen filters.In the first phase of the project, three HCA derivatives (ferulic acid, sinapic acid, and 3,4-Dimethoxycinnamic acid) were each converted into their respective ethyl esters by Fischer esterification under microwave irradiation. The same process was used to synthesize isopropyl esters of the three HCA derivatives. Following isolation and purification by column chromatography, each ester product was incorporated by weight in combination with up to 3% avobenzone into a separate sunscreen emulsion and subsequently applied to a polymethylmethacrylate plate for UV-Vis spectrophotometric transmittance testing.Nearly all HCA-based sunscreens performed on par with or more effectively in blocking UVB-UVA radiation than a commercial sunscreen formulation containing a combination of synthetic UV filters (specifically homosalate, octisalate, octocrylene, and 3% avobenzone) at a much higher concentration. Ethyl ferulate- and ethyl sinapate-based sunscreens offered the best coverage across the UVB and UVA range, minimizing the need for avobenzone.The in vitro data generated from this study suggest that each of the naturally sourced HCA-derivatives has the potential to offer an exciting alternative to the cocktail of synthetic UV filters in sunscreens currently available in the US.

Abstract Name: **Impact of Recessions and Additional Government Funding on the price of Road Construction.**

Every year, the state of Iowa solicits bids for work needed to maintain or expand the roads, highways, and bridges in the state. During recessions, the federal and state governments tend to expand government spending for transportation projects to help stimulate the economy. As an example, the American Recovery and Reinvestment Act of 2009 allocated $839 billion for projects. However, there are a finite number of firms that can fulfill the specified project responsibilities. If the number of projects out for bid is too large, it can tax the available capacity of construction firms to complete all the projects and the cost of construction will be bid up. Providing clarity on the effectiveness of this spending is important when there are billions of dollars being spent. In this paper, using Iowa Department of Transportation Bid Data from 2007 through 2019, I examined whether bid amounts rise in years when the government expands the number of projects, and whether construction costs rise in recession years.

Abstract Name: **Radiation dose studies in fruit flies with 350keV electrons**

The effects of beta radiation on fruit flies (Drosophila Melanogaster) were studied using the Applied Nuclear Science lab AN400 accelerator modified for electron acceleration and extraction. Dose-dependent effects up to 800 Gy have been observed, with significant effects well below the LD-50 dose for 2-day old larvae. These effects include reduced larvae and aborted development to adulthood. The goal of establishing a population of viable adults in samples showing clear radiation dose effects to study inherent radiation resistance has now been met. The data gathered in the process of this experiment will be used to further calibrate the accelerator for future research.

Abstract Name: **College Students Understanding of Bias in the News**

As young voters, college students make up a key demographic during election season; Thus, it is important for them to be aware of current events in the world and potential bias in political news, particularly as studies have shown that bias is prevalent in the news and can impact voters opinions. This study is interested in investigating how well college students can detect and understand bias in the news. This will be studied by surveying a group of college students (target sample size = 100), showing them different stories from different news media organizations, and asking them about whether or not there is bias and for whom the bias favors. Comparing these results to the Ad Fontes Media Bias chart will show how well college students can recognize bias compared to a professional board of fact-checkers and journalists who regularly score news organizations on bias and reliability. These results will offer insight into if college students need further education on bias and how to recognize it. I plan to collect data through February 2023 and complete the analysis by early March 2023.

Abstract Name: **GCD of sums (and sums of square) of k consecutive terms of the Pell sequence and related sequences**

We explore the GCD of all sums of mthpowers (with m=1and 2) of kconsecutive terms of a sequence Snwith n greater than or equal to 0, where the terms Sncome from exactly one of following six well-known sequences: Pell Pn, associated Pell Qn, balancing Bn, cobalancing bn, Lucas-balancing Cn, and Lucas-cobalancing cn numbers. For brevity, we use the symbol Sm(k) to denote this GCD. We give a complete description ofS1(k) for all six sequences. These closed forms all involve certain braid sequences of Pell and associated Pell numbers in an intriguing manner. We further give partial results on S2(k) for some of the sequences. We collected data through Wolfram programming in Mathematica to gather conjectures and provide further evidence of the results that we inevitably proved.

Abstract Name: **?A Question of Defenselessness:? The Diverging Evolution of German and American Mennonite Communities, 1854-1945**

In the 1930s and 1940s, American Mennonites retained their traditional pacifism while their German coreligionists supported Adolf Hitler's Nazi regime. While most American Mennonites remained conscientious objectors, many German Mennonites joined the Nazi Party, Wehrmacht, and SS, and supported Nazi ideology. Through examinations of religious periodicals, letters, contemporary writings, and Mennonite World Conference proceedings, this paper examines and compares the evolution of German and American Mennonite identities from the mid 19th to the mid 20th century to identify the internal factors allowingfor this development. Though German and American Mennonite communities shared historical roots and developed closer international connections in the 19th and 20th centuries,differences in German and American societies contributed to differing understandings of Mennonite doctrine, practice, and identity. American religious freedom, ecclesiastical plurality, and celebration of individualism allowed American Mennonites to develop in a unique direction characterized by emphases on insularity, non-resistance, and non-conformity. By contrast, German militarism, nationalism, and church-state relations pushed German Mennonites to emphasize their identity as a non-state-supported free church and characteristics such as adult baptism, democratic church structure, and ethnic identity at the expense of uncomfortable historical doctrines like non-resistance. These differing self-identities provided a pre-condition for the two groups' differing responses to pressures in the 1930s and 1940s. Understanding these pre-conditions allows for a better understanding of church-state relations in German and American society leading up to the Second World War, the influence of nationalism, religious freedom, and cultural debates on sectarian communities, and the way in which historical identities and doctrines can be pushed aside or twisted to support evil.

Abstract Name: **Perception of Information and Source Reliability B**

The term misinformation is being used so frequently now that it has become an annoying word to represent almost nothing. The perception of whether information is valid seems to be very dependent on who is giving the information. There are many different factors that play a role in deciding whether a source is credible or not. In the US today we are seeing that individuals are siding with news sources that have a similar political ideology when deciding what is fact and what is misinformation. The purpose of this research is to determine what factors correlate with someone'ssuseptiblity to misleading information. The personal characteristincs being studied include racial/ethnic background of the messenger and receiver, political ideology of the messenger and receiver, news media source preference, expertise level of the messenger and receiver, and percieved trustworthiness of the messenger. The study will use information about controversial topics given by various sources and determine the level of confidence the subjects have about the legitimacy of the information. Demographics regarding the subjects will be collected. A correlational analysis will be made between traits of the message sender and receiver and the rating of the source information. Data analysis will be completed in the spring semester of 2023.

Abstract Name: Investigating the Folding of Intrinsically Disordered Cyclin-Dependent Kinase Inhibitor-Interacting Protein Using High-Performance Computational Simulations

Cyclin-dependent kinase inhibitor 1-interacting protein 1 is involved in the cell cycle regulation via mediation of the G1 growth arrest pathway for DNA damage-induced repair checkpoints. They fall into the group of intrinsically disordered proteins, which do not require a complete globular structure to perform their function. The intrinsic disorders of the class of protein allow alterations of its topology while conserving binding sites. Due to the absence of reliable three-dimensional structure, the folding and the conformational dynamics have remained poorly understood. In particular, a comprehensive understanding of the relationship between protein folding and other biomolecular crowders is absent. Herein, we report a classical mechanical simulation-based study of the protein using various-sized crowders of the polymers of ethylene glycol. The protein 3D structure was downloaded using AlphaFold - the database created by artificial intelligence-aided protein structure solving. Five systems were constructed: one in only water, one in ethylene glycol, and three more in polyethylene glycols of various molecular weights (600, 10k, and 20 k). A 50 ns molecular dynamics simulation data was used for further analysis. The effect of these crowders on the folding dynamics and energetics was studied in detail using visualization, computational, and statistical tools. Results obtained from these studies will be presented.

Abstract Name: Fostering collaboration between parents and speech language pathologists : What impact do motivational interviewing strategies have on parent-child reminiscing intervention?

The literature on parent-child reminiscing conversations from the various disciplines, including developmental psychology and communication sciences and disorders, indicates that these brief and routine conversations about shared, past experiences can have a positive impact on a child's developing language, cognitive, and socio-emotional skills. However, families can reminisce in a variety of styles depending on their culture. Motivational interviewing is a counseling style that aims toguide clients toward developing their own solutions as grounded in their personal values and priorities. With our project we ask the question, "What impact do motivational interviewing strategies have on the collaborations of parents and clinicians of different cultural backgrounds during reminiscing interventions?" To answer this question, we have thus far recruited two families- onemonolingual English speaking family with a preschooler diagnosed with a language delay.; one bilingual family (English and Japanese) with an adolescent boy diagnosed with ASD and TBI. We are video recording our collaborations and parent-child reminiscing. Inductive methods of analysis are employed to identify behaviors that contribute or interfere with effective collaboration between the clinician and parents. Collaboration methods will be refined after initial analysis and additional families recruited for further study. Understanding ways to foster better collaboration with families is essential to creating individualized and culturally sensitive interventions.

Abstract Name: **Tide Pool Mollusk Diversity Relative to Tide Level, San Salvador Island, Bahamas**

Tidal pools offer a unique environment due to fact that the water levels change twice a day. Because small tidal pool mollusks experience the flux of tides daily, I investigated if there were changes in mollusk diversity relative to tide level (high vs. low). I hypothesized that there is a relationship between mollusk species and the specific tide level. I predicted that there would be a unique suite of mollusk diversity at the two different tides. Data was collected between 9 – 11 March 2022 at Graham's Harbor Government Dock (San Salvador Island) during daylight hours and at different tidal times. Tidal pools were inspected and for each pool, mollusk species were counted and recorded. To keep my collection effort consistent, data was collected from the same area each trial, marked by a metal pole in the rocks. Data was analyzed using a $\chi 2$ test of independence. Data results suggests that there was a difference in mollusk diversity between high and low tide ($\chi 2 = 5.58$, df =1, $p = 0.018$). This implies that mollusks, despite having a muscular foot that can hold them in place in a pool, may not be as resistant to tidal water movement as previously thought. This research contributes to the knowledge base of tidal pool mollusk diversity as it shows that daily changes in tides can impact which species are present.

Abstract Name: **The Wisconsin Council on Undergraduate Research: Working Together to Promote and Support Undergraduate Research, Scholarly and Creative Activities**

Undergraduate research, scholarly, and creative activities (URSCA) have a long history in the University of Wisconsin System (UWS). Since 1999, various system campuses have hosted the UW System Symposium, an annual gathering modeled after the National Conference on Undergraduate Research. It brings together undergraduate researchers, their mentors, and program coordinators to showcase the accomplishments of and celebrate URSCA. With the support of a National Science Foundation grant awarded to the Council on Undergraduate Research to institutionalize undergraduate research at the system/consortium level, the Wisconsin Council on Undergraduate Research (WisCUR) was formally launched in 2013.The group initially consisted of URSCA program leaders and advocates from UWS institutions. Recently, its membership expanded to include private universities and technical colleges in Wisconsin. Its mission is to provide leadership to advance, enhance, and expand URSCA across the UWS and beyond in order to prepare graduates who can adapt and innovate for the challenges of the future. Since the inception of WisCUR, URSCA programs within the WisCUR network have made great strides. For example, three UWS schools (UW-Eau Claire, UW-La Crosse, and UW-Milwaukee) have won the Campus-Wide Award for Undergraduate Research Accomplishments (AURA). No other state system has received the honor of receiving multiple AURA awards. Partly due to its involvement with WisCUR, Concordia University developed an undergraduate research certificate program and Madison College created an undergraduate research program.Wisconsin higher education institutions have also faced a variety of challenges that require innovations and adaptations, and WisCUR has served as a resource and support in this area. In this presentation, we will share the organization and goals of WisCUR, typical activities (beyond UWS Symposium) we sponsor, and benefits of WisCUR to individual institutions and staff therein. We will provide suggestions on how to organize similar URSCA groups and invite attendees to share their experiences.

Abstract Name: **The Heather Cornell Legacy Project**

History is a complex gathering of information that often is marred with biases. Often the practitioners have little say in how they are remembered. This project is unique in that the artist is present. The Heather Cornell Legacy Project is multifaceted and international. Cornell has been a prominent figure since the tap renaissance. Her music/tap company, Manhattan Tap, led the global scene in the 80's and 90's. Next was an international solo career, fueled by her commitment to reconnect music and dance in North American culture. Cornell is one of the last living links to the original vaudeville tap masters and has the unique job of passing down this African American oral tradition. The Legacy Project is striving to preserve her work, searching for new ways to nurture the way forward. This project has three goals: 1) To digitize and organize Cornell's personal archives, which, though vast, represent a small fraction of her entire body of work. 2) To use these archives in concert with Cornell to educate the next generations of tap practitioners in the studio and on stage. 3) To disseminate the work through redefining tap pedagogy, rebalancing music, dance and theater and creating opportunities for intergenerational encounters through performance.
As Professor Cornell's intern, I began the digitization of her archives, including several forms of media: video, audio, and paper. I have also developed presentations to educate the community about the time sensitive nature of this work. Lastly, i have a created an original database to organize over 400 media forms that aligns with library standards in the US, facilitating usage by libraries and other sources, providing unique access to the work.

Abstract Name: **Reflections on Past and Present Coping Strategies for COVID-19 Related Stress and the Impact on Mental Well-Being: A Pilot Study in College Students**

The ongoing COVID-19 pandemic has left both physical and psychological scars. According to the CDC (2022), in 2021, 37% of high school students reported experiencing a decline in mental health during the pandemic. Many of these students are now enrolled in college, where we are seeing similar trends in increasing mental health concerns resulting from the pandemic (Ochnik et al., 2021). Social isolation, financial concerns, fear of loved ones or themselves getting sick, and food insecurity are some explanations for these trends (Knolle et al., 2021). At present, we are grappling with the long-term effects of the pandemic and processing what we have witnessed and experienced. We are interested in addressing two broad research questions: 1) How have college students been coping with COVID-19 related stress both in the past and presently and 2) What is the impact of different coping strategies on mental health during the COVID-19 pandemic? We are asking college students to reflect on the coping strategies they used to cope with COVID-19 related stress in the past, defined as from March 2020 to July 2022, as well as what strategies they are currently using, defined as from August 2022 to the present. We are using the 28-item Brief COPE scale, which contains fourteen different subscales, each measuring different coping strategies. We are grouping these items into two categories, adaptive and maladaptive strategies, for the purpose of analyses. We are measuring emotional, social, and psychological mental well-being using the Mental Health Continuum Short-Form. We predict that students who use more adaptive coping strategies, both in the past and present, will demonstrate higher mental well-being than students who use more maladaptive coping strategies. Our research is an important piece for building a better understanding of the impact of the pandemic on mental health in vulnerable populations.

Abstract Name: **Political Divide**

The current political climate in teh US is more than contentious. The current state of the us verses them attitude divided along the political lines is ever worsening. What information is fact and what is political rhetoric? How can the divide be bridged? What are the potential dangers of such a divide in a powerful country? This research is designed to study how the political attitudes across the US are shaped by unfriendly dialog and news media bias. The goal is to understand how the varying forces around the political disconnect predict the perspective of adults in the US. This research will focus on political knowledge, willingness to connect with people of differing views, commitment to current political views, and news seeking behaviors when identifying underlying reasons for the unwillingeness to accept others with different viewpoints and what can be done to mediate the negative behaviors creating an even wider divide between the groups. How does having friends with widely different political views impact inter-political discourse? What communication skill sets can be cultivated to foster necessary listening and dialogue techniques? Data analysis will be completed in the spring semester of 2023.

Abstract Name: **Hydrogen atom transfer and oxygen activation in polyoxometalate-alkoxide clusters**

Mixed-valent hexanuclearpolyoxovanadate-alkoxide clusters have emerged as stable hexavanadate alternatives with surface bridging alkoxide ligands. These species have a vast variety of applications in redox catalysis since they can function as redox reservoirs in multi-electron processes due to the VV/VIV redox couple. Their redox properties can be further expanded and tuned through the incorporation of multiple first row transition metal centers. Recently, a[(VIIIVV5-nVIVnO5)(O)(OCH3)12](4-n)+ cluster with a “vacant” metal cation embedded within the vanadium oxide cluster was identified, in which the vacancy can be filled by either water or oxygen molecules. Herein we present a computational study on the aqueous and non-aqueous hydrogen atom transfer and molecular oxygen activation catalyzed bypolyoxovanadate-alkoxides with differing redox states. The bond dissociation Gibbs free energy (BDFE) was used to evaluate the O-H bond weakening and the possibility of thermal H2formation. Finally, spin density distribution was used to identify the oxidation states of the various mixed valent species. Due to the nature of these vanadates, as well as the possibilities held within, the calculations have been repeated with differing metal centers from a similar family, those being Iron and Colbalt.

Abstract Name: Characterization of Stem Cell Regeneration in Schmidtea mediterranea

Animals rely on stem cells to repair tissue damage following disease or injury. In order to study stem cells, Schmidtea mediterranea is used as a model organism because of their unique ability to completely regenerate lost tissues through the use of stem cells. Previous studies have focused on how stem cells proliferate in response to injuries with large tissue losses where many cell types need to be regenerated at once. However, in the case of many human injuries or diseases, only one specific cell type is lost. This project aims to characterize how stem cells respond following destruction of specific cell types, particularly if the injury response mechanism is a general proliferative response or a specialized mechanism depending on the cell type lost. Work up to this point has allowed for destruction of pigment cells via light-induced pigment cell loss. This has allowed for measurement of mitotic index following destruction of pigment cells as compared to large tissue loss injuries. Collected data suggests that destruction of a particular cell type causes an increase in general proliferative responses. Additionally, measurement of pigment cells in an organism has been done using a riboprobe to detect the PBGD1 gene found in pigment cells using in situ hybridization. Preliminary data of the amount of pigment cells present following light-induced loss of pigment cells and large tissue losses suggest that stem cells send out a general proliferative response with many specific cell types in response to injury, rather than sending out only the specific cell types needed. Continued research will give insight about the molecular mechanisms behind regeneration following injury or disease involving specific cell types.

Abstract Name: Occupational Stress and Job Satisfaction: Differences among Racial/Ethical and Immigration groups

ProblemThe overarching goal of this study is to build a further understanding of the factors contributing to Long-Term Care Worker's (LTCW) job satisfaction by examining the association between occupational stress and job satisfaction, and the differences among racial/ethnic and immigration groups.MethodologyIn this study we utilized the National Nursing Assistant Survey (NNAS). First, means/standard deviations or percentages of all study variables were generated to describe the study sample. Second, bivariate analyses, including analysis of variance and Chi-square tests, were conducted to compare job satisfaction, job resources, and job demands among racial/ethnical groups and different immigration groups. Finally, a series of binary logistic regression models were conducted to examine the associations between occupational stress and job satisfaction, and such associations within different racial/ethnical or immigration subgroups.ResultsFindings indicate that White nursing assistants (NAs) are the least likely to be satisfied at work compared to other race groups and Resident/Alien workers have a higher likelihood of reporting higher job satisfaction. Among all racial/ethnic groups, there was a relationship between organizational resources and personal development. With respect to Naturalized NAs and White NAs benefits were crucial. For Hispanic NAs, job satisfaction was significantly correlated with high resident respect. Black, Hispanic, Naturalized NAs, and Resident/Alien NAs were less satisfied with high physical demands. Emotional demands were high for Black and Hispanic NAs, along with Resident/Alien NAs.ConclusionRegardless of race/ethnicity or immigration status, Nursing assistants have low-status employment, coupled with poor work conditions, challenging job tasks and low wages. Tailoring existing workplace environments to promote job resources among LTCW is a practical way to reduce the negative and costly consequences of occupational stress within the workplace

Abstract Name: **Effects of Foreign Imposed Regime vs Internal Imposed Regime Change on Its Populace**

Are international interventions that impose regime change effective in promoting human development in post-conflict societies? While existing literature has explored how foreign interventions shape conflict dynamics and duration, there is limited research on the effects of international interventions on human development after a regime change has occurred and conflict has ended. This study seeks to address this gap in the literature by examining the impact of 'foreign-imposed regime change' (FIRC) interventions and 'internally imposed regime change' (IIRC) on human development post-conflict. Specifically, I argue that although foreign interventions that seek regime change may have positive effects on creating stable conditions during conflict, their effects on human development post-conflict do vary. State-building structures and service institutions created during foreign interventions are viewed by local populations as illegitimate and therefore, are more likely to collapse post-conflict. In countries where regime change has occurred as a result of domestic processes, institutions created to improve human development are more likely to be supported by the domestic population and thus, remain stable after conflict has ended. Using data on education, equality, and income from the United Nations' Human Development Index to measure human development, I will estimate a statistical analysis to test the relationship between FIRC and IIRC regime change and human development for all post-civil war countries during the period of 1990-2009. I anticipate my findings to show that interventions that impose external regime change are ineffective in improving human development in post-conflict states. Additionally, I expect that post-conflict countries that have experienced internal regime change are more likely to exhibit higher levels of human development. In addition to making theoretical and empirical contributions to the literature on regime change and providing suggestions for future research, this study offers policy relevant insight into the consequences of foreign policy decisions on governance and development.

Abstract Name: **You?re Reading What, Now? The History of Book Banning in the U.S. and Its Societal Consequences**

Book banning is on the rise in the United States, with bands of parents and political groups protesting the exclusion of titles in classrooms. Parents are concerned about what their children are reading in school, at what age, and in what way—School Board meetings, as a result, have become literary bloodbaths. Our purpose is to understand what has brought on this latest surge of challenges; what the societal consequences of banning books in the U.S. may be; and, to create an applicable curriculum on Book Banning for classrooms. To gain a better understanding, we went to the texts themselves: By reading under-fire titles, we learned the arguments against them and discussed their controversies with students through our Subversive Book Club. Through our research and discussions, we found that books detailing the experiences of POC and LGBTQIA+ individuals, social issues, and historical events have been targeted most in recent years; however, the claims against them focus on explicit content and strong language. We believe this to be a way for parents and organized political groups to remove books that do not align with their ideological ideals or make them feel uncomfortable. But, this raises the questions of censorship and what we are "allowed" to teach students. Should we take additional measures to ensure their comfort at the expense of accuracy and truth? In the curriculum we are designing, we broach these questions as well as provide thorough background information on a number of banned and challenged books, along with companion discussion questions created to get students thinking more proactively about what they are reading. This work is significant because words have power, as do the stories we tell—to censor and remove them and their lessons are to withhold the most authentic education we can offer.

Abstract Name: **Oblique surfaces impact on aerosol jet printed line resolution**

Aerosol jet printing (AJP) has emerged as a valuable resource for its additive manufacturing abilities in printed circuits for electronics. AJP utilizes micron-size droplets to deposit electrically conductive materials onto a variety of surfaces and can create feature sizes on the order of 10-100um. The deposited inks are sintered creating a lightweight and precise electronic system. This process may be utilized in industries from aerospace to biomechanics. The research presented looks into how surface angle may affect line resolution (line width) and along with that, the conductivity of the final print as line resolution may affect conductivity. Unique among printed electronics techniques, AJP is well-suited to conformal printing on complex 3D surfaces due to its high standoff distance of 1-5mm. The work will explore the deposition physics of conformal printing, both surface normal and oblique. Process studies were performed employing both a traditional 3-axis aerosol jet printer, and a custom aerosol jet printer on a 6-axis robot arm enabling direct comparison between oblique and surface normal prints on non-horizontal substrates. Varying ink compositions were used to explore the relationship between droplet size and dispersion. Additionally, CFD modeling was used to simulate prints on angled surfaces.We found that with higher angles, the less resolution of printed lines. Additionally, one 45-degree sample was notably less conductive than expected which implies a decrease in impaction efficiency when the droplet sizes get too small. The results show the value of printhead position in relation to the print surface. The enhanced resolution from prints normal to the surface demonstrates the value of printing normally to a surface. For advanced non-planar surfaces, a machine that can maintain a printhead normal to the surface will help ensure accurate line resolution. Machines that utilize XYZ motion will have to account for angle variability to maintain precise resolution.

Abstract Name: **The Spiritual Realm in Hinduism in South India as Understood Through Localized Practices Connected to Western Christian Beliefs**

To enhance understanding and constructive conversation between individuals with a perspective of the spiritual realm from the idealogy of Hinduism in South India and Western Christianity, ideas about the spiritual realm in Hindu beliefs in South India were explored and connected to Christian ideologies. A Hindu conceptualization of the spiritual realm was explored through localized examples of worship and spiritual possession to understand the way religion is practiced and what that reveals about the beliefs of its adherents. Ultimately, understanding a perspective of the spiritual realm and spiritual possession is helpful for Christians to better understand how the spiritual realm fits with their idealogy and to strengthen constructive communication between Christians and Hindus. From a few localized examples of spiritual practice that were studied and informed by universal Hindu literature, the significance of the spiritual realm to Hinduism was revealed. Additionally, the manifestation of the spiritual through the manifestation of deities was understood as a significant component of Hindu worship. It was discovered that physical elements are used in connecting to the spiritual, at least in some cases of worship, and that a deity's presence is important in worship. Ultimately, there was a connection from the research between how Hindus understand spiritual possession and how it is related to Christan beliefs. Additionally, the Christian message is a spiritual message and communicates that when someone believes in Christ, the Holy Spirit dwells in them. This message requires some conceptualization of the spiritual realm. When Christian beliefs are shared with Hindus, components of Christian belief can be connected to frameworks that Hindus already hold. In this sense, understanding the shared frameworks between these religions can better inform communication between the two religions and challenge their beliefs from the differences in the other idealogy.

Abstract Name: Boys to Men: How Communication Forms Understanding and Talk about the Modern Feminist Movement

Using the method of grounded theory, I explored how young adult cis-gender men talk about, understand, and interpret the modern feminist movement. More specifically, I analyzed how young cis-gender men interpret and talk to each other about the modern feminist movement, as well as the messages they received growing up regarding the movement. I interviewed cis-gender men aged 19-24 (n=19) about their experiences growing up, along with how they talk about the movement today. I produced themes by using Owen's (1984) articulation of thematic analysis via recurrence, repetition, and forcefulness. Seven themes surrounding communication regarding the feminist movement emerged: "passive" feminist, role in conversation, everyone treated equal, strong female figures, limited power, women are powerful, and rare conversation. The findings demonstrated that men are hesitant to participate in the feminist movement despite identifying themselves as feminist. Findings show young cis-gender men feel as if there is a "box" they must fit into. Instead, they rarely choose to engage in conversations on the topics of feminism with their peer groups. They also believe that women's voices matter more concerning women's rights. In addition, young cis-gender men have received messages about women and women's rights through the female figures in their life. These findings suggest that men don't see a specific place in which they can speak on women's rights and when pushed to talk about women's rights they lean on close friends to provide that space. These findings also convey the impact of female figures onyoung men's viewpoints regarding women and women's rights . We can use this information to encourage young cis-gender men to speak up and engage in the feminist movement. Engaging young men in the conversation about equal rights benefits everyone.

Abstract Name: A scoping review on the association between long-term exposure to ultraviolet radiation and the risk of developing ovarian cancer

Introduction: There is a strong association in developing external cancers (e.g., skin cancer) due to excess exposure to ultraviolet (UV) light. However, there is limited research on the harmful effect of UV rays on ovarian cancer (OvCa), the deadliest gynecological cancer. Understanding the effect of UV rays may guide us in changing lifestyles to reduce the incidence rates of OvCa. The purpose of this review is to understand the association between long-term exposure to UV radiation and the risk of developing OvCa.Methods: We conducted a review using the following keywords: "ovarian cancer" AND "UV radiation" in PubMed. We excluded articles that did not investigate the direct correlation between UV light and the risk of developing OvCa (Figure 1). Population, study location, UV light exposure time, health outcomes, and confounding variables were extracted from the included articles. The second author (RS) confirmed the review process and results after the first author completed the review.Results: Eleven studies were included in this review. All studies showed an inverse correlation between UV rays and risk of developing OvCa. Eight articles had confounding variables related to the environment such as places of residence, air quality, and seasons. Seven articles presented dietary differences related to OvCa prevention: supplements (e.g., vitamin D), fruit, and vegetables. Five studies included ethnicity and/or racial information. Other cancers were also identified in all studies except one: colon, breast, prostate, bladder, endometrial, esophageal, gastric, pancreatic, rectal, renal, vulvar, Hodgkin's, and non-Hodgkin's.Conclusion: We found several factors involved in OvCa in addition to UV rays, such as vitamin D. Further studies may need to focus on specific confounding factors. Also, many confounding variables were unmodifiable and unavoidable. Future studies are needed to examine management strategies of non-modifiable factors in our daily lives.

Abstract Name: **Waxworm Larvae as a Potential Plastic Waste Management Solution for Long-Term Space Travel**

Plastic waste accumulation on Earth is an immediate and growing environmental challenge with similar implications for long-distance space travel. Current methods of waste disposal in space require jettison for incineration into Earth's atmosphere or costly shipment back to Earth. More sustainable plastic waste alternatives are needed as astronauts travel further into space and reach thinner atmospheric planetary bodies. Galleria mellonella larva, known as the waxworm, may be a possible plastic waste management solution in space. The waxworm has the unique ability to biodegrade low-density polyethylene plastics (LDPE) into ethylene glycol, a more useful byproduct, through its salivary enzymes and gut microbiome. Funded by the NASA SPOCS (Student Payload Opportunity with Citizen Science) program, an experiment run on the International Space Station (ISS) in July 2022 tested if waxworms were capable of biodegrading plastic in microgravity. Our interdisciplinary team of biologists and engineers (A-State), along with K-12 citizen science partners (CS) from local middle schools, designed a fully automated experimental module and collaboratively generated data establishing the experimental parameters to sustain waxworm biodegradation for three weeks on the ISS. These preliminary experiments defined optimal larval size (40-45 mg), a simplified diet (beeswax), and plastic (Ziploc freezer bag) to augment plastic biodegradation in microgravity. Onboard the ISS, waxworm survival and plastic consumption were confirmed through inflight imaging. Post-flight data collection shows plastic mass reduction in microgravity is not statistically different from plastic-fed Earth controls. Waxworm larvae and their excreta were preserved to enable future gut microbiome analysis and ethylene glycol detection (signature terminal product of LDPE breakdown) respectively to better understand the microgravity impact on plastic biodegradation by waxworms. This first successful ISS study with waxworms may lead to more sustainable methods of plastic waste management not only on Earth, but also for long-term space travel to the Moon or Mars.

Abstract Name: **An Analysis of the Effects of Globalisation on Far-Right Nationalist Ideology in Belgium**

From Donald Trump's victory in 2016 to Brexit to most recently Giorgia Meloni's victory in Italy, we are seeing a surge in the popularity of far-right ideology all across the West. Many scholars cite this as an effect of globalised capitalism and the subsequent economic, political, and social changes it has brought to many Western nations. While internationally, globalisation has helped reduce income equality between richer and poorer nations, domestically it has been detrimental to largely uneducated and unskilled workers in rich countries. The resentments and anxieties spawned by these economic disruptions have generated significant support for far right, ethnonationalist identity politics. Furthermore, globalisation has resulted in the large-scale immigration into both the United States and Western Europe. The subsequent population changes have given rise to what is known as the "Great Replacement Theory", where white majority populations believe that liberal elites are intentionally replacing them with the incoming migrants. This notion has been exploited by leaders of emerging nationalist and far right movements, who themselves have benefitted handsomely from early globalisation. Though many argue that the reawakening of far right ideologies is closely linked to the emergence of a globalist world order, this connection is one with many loose ends. By examining classic cases such as the United States and Britain – and comparing them to Belgium, an outlier of this popular theory – it becomes clear that globalisation by itself is not enough to account for this phenomenon. In Belgium, despite economic and social effects of globalisation being more prevalent in the region of Wallonia, far-right ideology is much more popular in the neighbouring region of Flanders. This project thus seeks to explore the different cultural and political factors that drive populations affected by globalisation to support alt-right ideologies.

Abstract Name: **Developing a 3D Printed Microscope for Imaging Cardiomyocytes in a Cell Culture Incubator**

Understanding the behavior and response of cardiomyocytes under external loading provides critical information for studying certain congenital heart diseases. An inflation chamber (bioreactor) is often used to introduce controlled stress and strain to cells. Continuous imaging of cells seeded in a bioreactor has proven to be challenging due to the lack of compatible microscopes. Our study aimed to fill the gap by developing a compact microscope using 3D printing technology and inexpensive electronic parts that met the following two requirements: 1) compatibility with a cell culture incubator and a bioreactor, and 2) capability of imaging cardiomyocytes under different testing conditions. The 3D printed microscope that we developed features adjustable focusing via a tunable lens, a programmable LED array for flexible illumination, and a long working distance compatible with the bioreactor. A Raspberry Pi single-board computer was used to control focusing, illumination, and image acquisition. The microscope is capable of performing bright-field, dark-field, and polarized light microscopy. These capabilities allowed us to acquire comprehensive information from the cells. Considering its working environment, the microscope was designed to be moisture resistant. We developed an intuitive GUI that allowed users to preview images in real-time and fully control the microscope with minimal training.
With the microscope, we quantified its imaging performance using a USAF 1951 resolution target and tested it on cardiomyocytes. We achieved a magnification of 10x and a spatial resolution of 228 line-pairs/mm, sufficient for imaging cardiomyocytes. Beating cardiomyocytes can be clearly visualized under the microscope and polarized light provided additional contrast. Our initial results suggest that the compact microscope is compatible with a bioreactor and cell culture incubator to study cell's responses to mechanical loading.

Abstract Name: **Increasing Conductivity in Gallium Nitride Nanocrystal Films**

As demand increases for renewable energy, it becomes especially important to develop alternative materials that will produce high-efficiency energy devices. The semiconductor gallium nitride (GaN) may be one of those materials for dye-sensitized solar cells. As such, this work attempted to synthesize GaN nanocrystal thin films with desirable electrical properties—specifically high conductivity. To achieve this, the power supplied to the reactor was varied during GaN plasma synthesis in order to induce nitrogen vacancies in the crystal lattice. These vacancies are believed to contribute to the free electron concentration of GaN. The plasma power varied from the standard 80 W down to 60 W and 40 W. The resulting GaN powder—normally colorless—became more yellowwith decreasing plasma power, indicative of defects. However, electrical conductivities were similar to that of the control sample, which implies that the desired defects (nitrogen vacancies) were not induced. Near-infrared absorption spectra did not reveal carrier absorption features due to free electrons, suggesting a low free electron concentration. This further supports a lack of nitrogen vacancies. Analysis of transmission electron microscope images eliminates amorphous crystal structure and unreacted Ga metal nanocrystals as the source of the induced defects. These results demonstrate that varied plasma power does not produce high conductivities in GaN nanocrystal thin films. Possible next steps include varying the amount of nitrogen during synthesis and doping with Si (via silane gas) or Zn metal to increase the free electron concentration of the films.

Abstract Name: **Geology of the Proposed Dreamer Segment of the Ice Age National Scenic Trail, Rusk County, Wisconsin**

The Ice Age National Scenic Trail (IAT) showcases Pleistocene glacial features in the State of Wisconsin. The Ice Age Trail Alliance has proposed a new Dreamer Segment trail to focus on landforms in the Blue Hills region of western Wisconsin. The Alliance commissioned a study the geomorphology of the proposed trail segment to create publication-quality materials (both text and figures) for a future interpretive guide. GIS analyses and field work have been used to study the proposed Dreamer Segment and the surrounding region. Published papers about the glacial geomorphology of the area were read. LiDAR-based shaded DEMs were used to evaluate glacial landforms in the region and determine potential interpretive stops. This was followed by five days of field work to determine the best locations for potential interpretive sites. Multiple geomorphic features are proposed as interpretive stops along the Dreamer Segment. Glacial landforms of the Chippewa Moraine are well represented, including kettles, hummocks, and ice-walled-lake plains. Precambrian Barron Quartzite is exposed in Gundy's Canyon. The most unique feature is the Blue Hills Felsenmeer State Natural Area. During the late Chippewa Phase of the late Wisconsin Glaciation, meltwater from the ice margin eroded a westward-dipping, subaerial "box canyon". Frost shattering and rock falls produced the angular "sea of rocks" of the Blue Hills Felsenmeer. The final product of this research will be interpretive text, publication-quality figures, and a research poster to be donated to the Alliance and the National Park Service.

Abstract Name: **Determination of the role of nucleoskeletal factors on mortality and seizures following traumatic brain injury (TBI)**

Traumatic brain injury (TBI) is a global public health issue affecting millions of individuals each year. One complication stemming from TBI is the occurrence of post-traumatic seizures (PTS), which affect up to 50% of individuals. Severe TBI, advanced age, and genetics are all associated with increased rates of PTS. However, these factors are poorly understood and the cellular and molecular mechanisms which initiate, drive, and maintain a PTS disease state are not known. These gaps in understanding hinder our ability to treat those suffering from PTS and prevent its development. Recurrent or lifelong PTS is associated with sustained changes in nervous system activity. Gene expression and nervous system activity are highly regulated processes. Central to gene expression are nuclear lamin proteins and associated binding partners. Interaction partners include the Linker of Nucleoskeleton and Cytoskeleton (LINC) complex which serves as a mechanical stress apparatus bridging cytoplasmic and nuclear functions. Lamins and the LINC complex are excellent candidates for factors which span contributions to aging, TBI outcomes, and PTS. We utilized the GAL4/UAS system in Drosophila melanogaster to drive RNAi-mediated knockdown of candidate genes. We specifically targeted the LINC complex factors consisting of fly Msp300, klarischt, klaroid, as well as the two fly lamins. Young flies were administered TBI via either a single, severe injury paradigm or a repetitive, moderate injury paradigm. Animals were then assessed for overall mortality, and also PTS via a simple behavioral assay. We found little evidence that genetic knockdown of candidate factors affected outcomes. Future directions include assessment of aged flies to understand if these factors are similarly negligible with advancing age.

Abstract Name: A Spatial Analysis of Cellular Signal Strength in Western Wisconsin

Across the United States, rural areas have lower levels of education, higher unemployment, and fewer economic opportunities compared to urban areas (Singh; Siahpush 2014). Rural residents have lower levels of access to health care and health services, and health insurance coverage rates are lower as well; as a result, the health of rural residents is poorer compared to their urban counterparts (Laditka et al. 2009).For Wisconsin, the disparities between urban and rural populations are stark. National estimates identify about 20 percent of the U.S. population as rural; in Wisconsin that number is even greater at 26 percent. The lack of healthcare providers, longer distances to healthcare, and lower economic status for rural populations places extra burdens for both providers and patients to meet and receive needed care. Telehealth, through synchronous and asynchronous remote appointments, provides health care providers opportunities to connect with patients outside of physical office visits, especially in rural areas. Coverage maps provided by major carriers are overall generalized, therefore the use of direct telehealth options using video cannot be properly assessed. This study will focus on measuring cellular telephone strength in rural areas through the direct collection of cellular phone strength for both AT&T and Verizon phones. Data will be used to interpolate strength for areas not along roads and a probability map will be generated using a Kriging method. Resulting maps will aid health care providers with more specific information to best provide patients the best possible telehealth option.

Abstract Name: Animals' Impact on Stress

The majority of today's students are stressed in some way, and research suggests that animals are a good way to manage stress levels. With anxiety and depression on the rise, programs are seeking support for students in the stress-filled school life. Some researchers have found that bringing in therapy animals has been a good way to lift the spirits of the students. Animals have been used in therapy as early as the 18th century (Chu et al., 2009) and have been shown to ease isolation. Over 98% of full-time students are stressed, and 86% of students find improvement in domestic animals. Animal-assisted programs are still being researched, but evidence shows that there is a positive influence towards stress in many students. This research attempts to disclose the relationship between pet interaction and the level of stress the person feels. The results show that a majority of students have reduced stress after interacting with a domestic animal.

Abstract Name: **The In-silico and In-vitro Characterization of Epigenetic Drugs (BET Protein Inhibitors and Related BET Pathway Targets) on a Colorectal Cancer Cell Line**

Bromodomain and extra-terminal domain (BET) proteins have been linked to increases in oncogene expression and tumor progression in a wide array of cancers. Previous research on BET proteins has demonstrated that BET inhibitors (BETi) and other drugs in combination can moderately reduce cancer cell proliferation in colorectal cancer. Limited treatments exist for colorectal cancer due to its malignant nature and existing treatments are often costly or ineffective. Our research centers around determining potential BETi in colorectal cancer through in-silico research and testing identified drug candidates in an in-vitro setting. While previous research has been conducted on BETi, few studies examine the effects of BETi in colorectal cancer. So far, we have created a list of one hundred possible BETi drugs. By utilizing a deep learning Cancer Drug Response (Deep CDR) prediction algorithm, we will further narrow down our list of potential drug candidates. We are also working on identifying additional targets in HCT116 cells that are related to the BET protein pathway to expand our research. In order to do this, we are analyzing gene expression datasets using R and ranking candidates related to the BET protein pathway. Once the in-silico analysis is complete, the drugs will be ordered/synthesized and tested on HCT116 colorectal cancer cells. They will be tested through MTT Assays, Western Blot and qPCR and the ones with the most BETi properties as well as the least harmful side effects will be selected. With more BETis available, we hope to increase the number of cancer treatment options for patients.

Souksakhone Sengsaisouk

Abstract Name: **Understanding Undergraduate Student Nurse Stress**

Background: In the results of a recent Iowa Nursing Demand Survey (2021), 71.6% of respondents said the nursing shortage in Iowa was either " Extreme" or "Great." Nursing students are prone to chronic stress, leading to attrition and contributing to the nursing shortage. Determining the extent of the stress in nursing programs is an important step in considering interventions to develop to impact the nursing shortage.Purpose: The purpose of this descriptive study was to explore the overall stress and stress per program level within undergraduate nursing students. Nursing programs can then use this information to consider opportunities to decrease student stress and attrition.Methodology: The Perceived Stress Scale - 14 was distributed to each undergraduate nursing cohort annually for a period of 4 years at a small, private liberal arts nursing program in NE Iowa. Students received a link to the survey via email from the nursing faculty. The Qualtrics online survey software was used to collect responses. SPSS software and Python Code were used to analyze data. The theoretical framework used in this study is the Lazarus Theory of Stress. Results: According to the data analysis, sophomore-level nursing students have the highest level of stress, but not significantly. All cohorts experience the same range of chronic stress as well as an equal possibility to have associated problems such as anxiety and other health issues. The literature informs us that nursing students' susceptibility to stress is due to both external factors such as clinicals, academic pressure, social life and intrinsic factors, like ability to cope. Conclusion: Information from the research can aid nursing programs in developing methods to assess their student stress and help to create programming to mitigate it. This will influence the attrition rate of students leaving nursing programs, which impacts nurse staffing levels.

Abstract Name: The Effect of Indomethacin on the Cytotoxicity of Phenylboronic Acid Nitrogen Mustards in Triple Negative Breast Cancer

Triple Negative Breast Cancer (TNBC) lacks hormonal receptors such as progesterone, estrogen receptors, and human epidermal growth factor (HER2 protein). TNBC is unaffected by hormonal treatments that target these three growth factors. After diagnosis, there is less time to treat TNBC than other breast cancers. Therefore, there is an urgent need for a better understanding of TNBC and development of better treatment options. Our previous study showed that the phenylboronic acid nitrogen mustard prodrug, FAN-NM-CH3 is effective in reducing tumor sizes without obvious toxicity due to the prodrug's enhanced activity in the presence of hydrogen peroxide (H2O2). This prodrug is initially inactive but can be converted into an active species upon metabolism in cancer cells with high level of H2O2. Many TNBC cells are under oxidative stress and produce high levels of reactive oxygen species (ROS), such as H2O2 that can act as a target for developing cancer-specific therapy for TNBC treatment. However, many challenges exist to the development of targeted cancer therapy based on a single agent, including tumor ROS heterogeneity, targeted delivery, selective activation, and therapeutic durability. We propose that these issues can be resolved by combining ROS-activated prodrugs with the agents that can create H2O2 selectively in cancer cells. Indomethacin is a ROS generating NSAID (non-steroidal anti-inflammatory drug), which can produce ROS selectively in cancer cells. Thus, we expect that combination of indomethacin and ROS-activated prodrugs can enhance the anticancer efficacy and selectivity, therefore reducing the effective drug doses, minimizing off target effects. Lower dose of prodrug would minimize adverse effects from the chemotherapy. My work is focusing on investigation of the cytotoxicity of indomethacin and its combination with FAN-NM-CH3 in TNBC cells and its correlation with ROS levels.

Abstract Name: Characterization of Antibiotic Resistant Providencia alcalifaciens: From Ecology to Genomics

Antibiotic resistance is a growing problem in environments around the world, but resistance rates tend to be greater near human populations. One such area is the Navajo Creek, a suburban waterway near southwest Chicago that flows through neighborhoods and forest preserves. Among bacteria isolated from the creek, resistance to six different antibiotics has been discovered, and metagenomic analysis of these populations shows diversity among the microbes. Water samples collected from suburban waterways over the course of several months indicate that Providencia alcalifaciens is widespread, both geographically and temporally. Whole-genome sequencing of P. alcalifaciens reveals a wide variety of resistance genes that allow it to survive in the presence of antibiotics, but the interplay between these genes and the corresponding antibiotics is still being determined. Bacteria are being grown in the presence of different antibiotics, and gene expression will be measured using qPCR. Growth assays are also being done to determine the bacteria's resistance in different concentrations of antibiotics. Overall, this project offers ecological and genomic analysis of a highly resistant microbe and potential pathogen that has been isolated from local waterways.

Abstract Name: Crafting the Truth Through News: Attitudes Toward the Russian Government, Nationalism, and Ukraine in Novaya Gazeta's Coverage of the 2014 Annexation of Crimea

Russia's annexation of Crimea in March 2014 was a moment in modern Russian history that consolidated narratives presented by media outlets in Russia while also dividing state and independent media further into an 'us' versus 'them' dichotomy. Utilizing Michel Foucault's concept of regimes of truth, in this paper I analyze the ways in which Novaya Gazeta, an independent Russian newspaper, crafts their own regime of truth that serves to oppose the nationalist, irredentist, and pro-state narratives found in the state media's framing of what truth is in Russian society. Additionally, I pair Foucault's ideas with the concepts of the "Russian World" and soft power as tools of analysis in exploring the modern landscape of Russian society, public opinion, and journalism.Novaya Gazeta, as an independent newspaper with a history of being targeted by the Russian government, is a particularly relevant media outlet to analyze in relation to their coverage of the annexation of Crimea as they express the full range of views that reject those presented in the state media's regime of truth. Their work in reporting on the annexation illustrates the limitations of journalism in a country with no freedom of the press and where self-censorship must exist as a protective measure against state violence. The Russian state simultaneously allows independent media such asNovaya Gazetato report on the annexation to create an illusion of democracy while also threatening its existence if it crosses the line of acceptable reporting. WhileNovaya Gazetais often bold in the language they use to oppose the regimeof truth crafted by the state media, its own regime of truth is limited in its ability to thoroughly report corruption and anti-state values due to the looming threat of coercion and violence on behalf of the state.

Abstract Name: Rare Bryophyte and Vascular Plant Survey: Diversity within the Devil?s Punchbowl, Dunn County, WI

The Devil's Punchbowl is a small preserve located in Dunn County along the Red Cedar River. It's most well-known for its unique waterfall and cliff geology. Rare plant surveys are important for the conservation of natural preserves like the Devil's Punchbowl, and for plant species conservation. These types of surveys help with research, monitoring, management, and citizen engagement.Since the Devil's Punchbowl is the most visited nature preserve in Dunn County, it is important to keep a record of the species present. To conduct this survey, Dr. Amanda Little and Idocumented vascular and bryophyte plant speciesweekly over the summer of 2022. We identified unknown specimens at the University of Wisconsin – Stout herbarium. Of the 206 vascular plant species found at the Devil's Punchbowl, about 78.6% are native and 13.1% are considered invasive. Notably, there were twelve different fern and three club moss species. Two of the clubmosses were regionally rare and county records but consisted only of a few individuals. The mean coefficient of conservatism (C of C) of the vascular species was 3.80 out of 10. We found a total of 9 different bryophyte communities within the Devil's Punchbowl with no rare mosses. However, the Devil's Punchbowl is a unique, small preserve with a high species density. There are many different natural communities, and the heterogeneity of the microhabitats creates high species richness. Despite the lack of rare species, the Devil's Punchbowl still provides valuable contributions to plant conservation in this heavily agricultural area of the state. Conservation actions like protecting the site from trampling and protecting fern and clubmoss areas are recommended.

Abstract Name: Assistive Robotic Platform Design for Non?Urgent Household Tasks

Humans overcome minor household inconveniences daily without fully recognizing how challenging these tasks could be for individuals such as elderly people or people with disabilities. Those people often times struggle to complete tasks, for instance opening a door or reaching for an item, leading them to rely on caregivers for help. During the COVID-19 pandemic, this caregiver support becomes an unsafe and unreliable solution that can result in a greater risk, thus the need for another solution arises: robotic technology. Recent developments in the robotics field have paved the way for this research, aiming to design a home assistance robot with capabilities to complete the basic household tasks. The designed robotic platform features four mecanum wheels that support a platform base, a lift mechanism, and a robotic arm. The omni-directional movement of the wheels is controlled by four DC motors, which allow the robotic platform to navigate to its commanded location. Further, the lift mechanism is controlled by a stepper motor vertically to adjust the robotic arm based on the requested height. The six-link robotic arm is used for manipulation tasks. The designed robot has a central computer that utilizes MATLAB and Simulink for the developed algorithms. The designed robotic platform's capabilities include autonomous navigation, object fetching, as well as face detection to interact with users. With these capabilities, the robot can aid elderly and disabled individuals in need of home assistance. Ultimately, this unique platform can drastically improve conditions for those who cannot independently perform household tasks. These activities are part of a larger effort to establish custom robotic platforms for helping people with non-urgent tasks in household environments.

Abstract Name: An Emotional Support AI to Assist Mental Health Disorders

Every year more and more people are struggling to handle a wide variety of mental health disorders. However, as the number of people in need of assistance increases, the number of resources available to them has continued to decrease. The goal of this research is to develop an Emotional Support AI (ESAI) system, an additional resource for those unable to obtain the help and information they need. ESAI provides users with a friendly user interface from which they can discuss their mental health concerns. The user can choose whether to communicate through typing or through real-time speech recognition. The ESAI has been trained to classify text based on the Naive Bayes Classification model. The model was trained using hundreds of thousands of Reddit posts, that were collected using web scrapping, where users have discussed their experiences with mental health. ESAI works by hosting 'sessions', in which it will log communications between itself and the user to check for any potential flags that may indicate the user is experiencing symptoms of one or many mental health disorder(s). These sessions can be used by the user for venting or to seek information regarding a variety of mental health disorders. If the probability that the user is experiencing a mental health disorder is higher than a specific threshold, the user is provided with general resources and contacts regarding the specified disorder. The user will also be provided with a mental health evaluation report at the end of each session upon request. Currently, results show that ESAI can classify mental health disorders with seventy-percent accuracy.

Abstract Name: Student Perspectives on Sustainability at Iowa State University

Today's university students will face unprecedented environmental, economic, and societal sustainability challenges upon graduation. The Sustainability in Curriculum Change Project (SiC-CHANGE) employed focus groups and a student body survey to understand Iowa State University (ISU) students' perspectives on how well the curriculum and extracurricular activities are preparing them to address the various sustainability challenges that society faces. Although ISU has incorporated sustainability language into its strategic plans and actions over the years, we are not aware of any systematic efforts to assess the adequacy of the university's efforts to increase student knowledge and skills related to sustainability. This research project is a rigorous effort to learn from students about their interest in and their experiences with sustainability at ISU. Twenty-one students from select colleges participated in focus group discussions between October 2021 and December 2021, and 1,206 students responded to a web-based survey of juniors and seniors conducted between April 18 and May 16, 2022. Our sample represents all colleges offering undergraduate degree programs at Iowa State University. Most respondents placed high importance on addressing environmental, economic, and social sustainability outcomes articulated in the UN sustainable development goals. Students at Iowa State feel empowered to solve climate change issues in the future, but they want more courses that integrate sustainability into their curriculum. Additionally, students believe that public universities should be leaders in sustainability. Our results show that most students don't think Iowa State prioritizes sustainability in education or that they are leaders in sustainability. Survey and focus group participants suggested many ways that ISU could incorporate this topic into the ISU experience to better prepare students with the knowledge and skills needed to face present and future sustainability challenges.

Abstract Name: Cardiomyocyte-specific Deletion of GSK-3? Promotes Ventricular Remodeling and Cardiac Dysfunction

Heart failure (HF) is a complex, major public health problem, so we wanted to investigate novel mechanisms that could lead to the identification of promising therapeutic targets to combat HF. Glycogen synthase kinase-3 (GSK-3) is a family of ubiquitously expressed serine-threonine kinases that consists of GSK-3α and GSK-3β isoforms. GSK-3α/β is critical to regulating many biological processes, including cardiac homeostasis. Previously, our research has identified cardiac fibroblast (FB) GSK-3β as a negative regulator of fibrotic remodeling in the ischemic heart. However, the role of cardiomyocytes GSK-3β (CM- GSK-3β) in the adult heart is not fully defined. To examine the role of CM- GSK-3β, we employed α-MHC promoter-driven, inducible CM-GSK-3β knockout (CM-GSK-3β-KO). At 10 weeks of age, mice were placed on a tamoxifen (TAM) chow diet for 15 days, followed by regular chow for an additional 30 days. After TAM protocol, echocardiography was conducted to assess cardiac function. Echocardiographic analysis suggested that CM-GSK-3β KO mice developed severe systolic dysfunction and dilative cardiac remodeling. Additionally, increased heart weight/tibia length ratio was observed in the CM-GSK-3β KO mice indicating adverse remodeling of the heart. Consistently, increased fibrosis in the KO heart was evident from Masson's trichrome staining. To further confirm CM-GSK-3β's role, we harvested the hearts at 45 days post-TAM diet and performed flow cytometric analysis. Consistent with the increased fibrosis, KO hearts demonstrated an increase in frequency of FBs, and COL1A1+ FBs. Furthermore, increased frequency of infiltrated CD45+ leukocytes and myeloid cell such as monocytes (CD45+CD11b+), macrophages (CD45+CD11b+F4/80+), neutrophils (CD45+CD11b+LY6G+), and dendritic cells (CD45+CD11C+) in KOs indicated the potential role of CM-GSK-3β in immune cells cross-talk. Our extensive flow cytometry analysis (IL-6+, IL-1β+ and TNF-α+ immune cells) suggested that CM-GSK-3β regulates pro-inflammatory subsets of immune cells in the heart. Overall, our finding reveals a critical role of CM-GSK-3β in maintaining cardiac homeostasis.

Abstract Name: **Developing a Framework for Implementation and Assessment of Transformative Mentored Undergraduate Research and Creative Endeavors**

This panel will describe the development and application of a rubric focused on implementation of mentored undergraduate research projects by professors at a public liberal arts college, CUR 2020 AURA award winner, Georgia College; State University. Panelists will include the Associate Provost for Transformative Learning Experiences, the faculty chair of the rubric committee, and the Faculty Director for Mentored Undergraduate Research and Creative Endeavors (MURACE) who will share insights from the process of conceptualizing the framework through programmatic implementation of it through the Office of MURACE. Two students will also discuss the effectiveness of the framework from their experiences in a course that incorporated the framework into the syllabus through a Course-based Undergraduate Research Experience (CURE). The value in identifying a common framework and the experience of this application from multiple perspectives will be discussed along with tools for assessment at the course-level and at a larger-scale programmatic level.We will share the definition of mentored undergraduate research developed by faculty at Georgia College; State University along with criteria for measuring how transformative components of this definition are, in practice. The framework serves as an excellent starting point for faculty new to developing effective undergraduate research experiences in CUREs and in individual mentoring experiences. It provides concrete considerations for creating a highly-transformative mentored undergraduate research experience grounded in data and best practices. In this way, our rubric can enhance both faculty/staff new to mentored undergraduate research as well as providing ideas for continuous improvement for those who are experienced mentors.

Abstract Name: **Impact of Biostimulants on Seedling Growth and Development in Tomato Transplant Production**

Biostimulants are an up-and-coming product in the agricultural and horticultural industry used to increase the health and vigor of crops. More information is needed on biostimulant use and benefits as there is a lack of research-based information despite increased interest from growers. This study assessed four potential biostimulants from Roquette America® (Soluys 048P, Potato Soluble, Pea Soluble, and Nutralys H85) for application in tomato transplant production. These potential biostimulants and a synthetic fertilizer were tested at three different concentrations and compared to an untreated control. Experimental design was a randomized complete block design with three replications, with 75 total seedlings per treatment. Each treatment replication comprised of a 25 seedling block of 'Mountain Fresh Plus' tomatoes planted in a peat-based organic growing medium. Biostimulants were applied 3, 4, and 5 weeks after seeding. Seedlings were grown in the ISU Horticulture Greenhouses where temperatures were maintained at 60 °F at night and 70 °F during the day. High-pressure sodium lamps were used to maintain a photosynthetically active radiation of 250 µmol.m-2.s-1. Transplants treated with biostimulants outperformed untreated transplants in stem diameter, plant height, SPAD level, and dried biomass. Nutralys H85 and Solulys 048 showed promise to be potential substitutes for synthetic fertilizers, as the treated transplants were similar in stem diameter, plant height, and SPAD levels to those treated with synthetic fertilizers. Further in field and greenhouse testing of these biostimulants may provide clearer insight into the benefits of these biostimulants.

Abstract Name: **Investigating the Folding of Intrinsically Disordered Cyclin-Dependent Kinase Inhibitor-Interacting Protein Using High-Performance Computational Simulations**

Cyclin-dependent kinase inhibitor 1-interacting protein 1 is involved in the cell cycle regulation via mediation of the G1 growth arrest pathway for DNA damage-induced repair checkpoints. They fall into the group of intrinsically disordered proteins, which do not require a complete globular structure to perform their function. The intrinsic disorders of the class of protein allow alterations of its topology while conserving binding sites. Due to the absence of reliable three-dimensional structure, the folding and the conformational dynamics have remained poorly understood. In particular, a comprehensive understanding of the relationship between protein folding and other biomolecular crowders is absent. Herein, we report a classical mechanical simulation-based study of the protein using various-sized crowders of the polymers of ethylene glycol. The protein 3D structure was downloaded using AlphaFold - the database created by artificial intelligence-aided protein structure solving. Five systems were constructed: one in only water, one in ethylene glycol, and three more in polyethylene glycols of various molecular weights (600, 10k, and 20 k). A 50 ns molecular dynamics simulation data was used for further analysis. The effect of these crowders on the folding dynamics and energetics was studied in detail using visualization, computational, and statistical tools. Results obtained from these studies will be presented.

Abstract Name: **Welcoming the Dear Neighbor?**

From 2000-2018, white homeownership in Minnesota remained constant at 70%, while black homeownership saw a decline from 31% to 21% (Turtinene, 2021). Even before this decline, disparities between white and black homeownership were stark on account of discriminatory practices including racially restrictive covenants, clauses in housing deeds blocking BIPOC citizens from purchasing property. Using data from the Mapping Prejudice project that catalogs covenants in Hennepin and Ramsey county and historical data from the US census, we investigate the relationship between upward mobility and neighborhood shares of racial covenants by running regression analysis to check for correlation. Preliminary results show that neighborhoods with high concentrations of covenants have higher upward mobility for white children but not for black children. Covenants are associated with a widening opportunity gap long after they became legally unenforceable. This research informs policies that remedy longstanding disparities such as changing zoning restrictions or amending first-time homebuyer grants.Reference: https://bringmethenews.com/minnesota-lifestyle/twin-cities-has-worst-racial-homeownership- gap-in-the-us-report-finds Melissa Turtinen

Abstract Name: **Speech-Language Pathology and Music Therapy: An Exploration of Collaboration**

Speech-Language Pathologists (SLPs) often collaborate and co-treat withother health-care professionals. From the perspective of clinicians, this type of interprofessional practice (IPP) is thought to improve outcomes for the clients they serve (American Speech-Language-Hearing Association, n.d.). Less is known about IPP in relation to the fields that are not a part of the traditional allied health professions such as Music Therapy (MT). SLPs and MTs work collaboratively with clients across a variety of communication impairments (e.g., autism, aphasia), ages, and settings (Geist et al., 2008). There are, however, controversial aspects related tothis relationship related to topics such as billing and clinical responsibilities. Although these types of disagreements exist, SLPs and MTs still collaborate. Unfortunately, little literature is currently available about this collaboration. Because of the potential clinical benefits of this relationship, the goal of this project is too understand the perspectives and experiences of SLPs who have co-treated with MTs. During Summer 2022, a series of 11 semi-structured interviews with SLPs who have co-treated with MTs within the past 5 years was conducted.During these interviews, topics that were discussed included what the collaboration was like, how often this collaboration occurred, and if there were any conflicts during their experiences together. Transcripts of these interviews will be analyzed using Thematic Analysis which consists of several rounds of reviewing and coding the transcriptions (Braun; Clarke, 2006). The results will allow for identifying key components of this collaboration across various environments. These findings will also be discussed relative to clinical applications and implications for future collaborations between SLPs and MTs.

Abstract Name: **Targeted Messaging about Food Storage in Social Media Posts**

Food waste is a major problem in the United States and around the globe. In the U.S alone, avoidable food waste exceeds 55 million metric tonnes per year, nearly 29% of annual production and it has been estimated that this waste produces life-cycle greenhouse gas emissions of at least 113 million metric tonnes of CO2 annually, equivalent to 2% of national emissions. Food waste by end consumers occurs for many reasons, including food being prepared and stored incorrectly, and misunderstandings of the “best by” date on foods. Food-related messaging is widespread on social media, with users posting comments and photographs of foods that they are preparing or enjoying. These messages are then viewed by millions of users. Targeted responses to such messages could correct some misconceptions and therefore reduce food waste. The main technical challenges for creating targeted messages are identifying food-related posts and automatically generating a relevant response. We have developed an approach that uses machine learning to identify if a social media post mentions specific foods. The approach is able to detect food entities in Twitter posts with a precision and recall of 0.8. This approach was also applied to identify foods in photographs posted on Instagram using object recognition in images algorithms. If a post is identified as likely to be about a specific food, a short message with information such as storing tips and methods to prepare that food is generated. We use the FoodKeeper dataset published by the U.S. Department of Agriculture which contains descriptions of foods and their storage methods to generate targeted responses. This approach could therefore be used as a tool for more targeted and real-time messaging of information related to food and potentially help reduce food waste by end consumers.

Abstract Name: Reducing Parkinsonian Gait Disturbances: The Impact of Yoga as a Type of Movement Therapy in African-American Males Aged 50 - 75 with Parkinson?s Disease

Older African-American males in the United States are increasingly affected with Parkinsonian Gait Disturbances, a cardinal symptom of Parkinson's Disease that causes slow shuffling steps and diminished arm swing and flexed posture. Although medicinal supplements and deep brain stimulation treatments have shown minimal improvement in gait issues, they generally tend to be ineffective and may lead to an increase of freezing gait -- brief, episodic marked reduction or progression of feet despite the intention to walk.Alternatively, a specific movement therapy may be able to address the lack of improvement of Pakinsonian Gait disturbances. A review of literature on movement therapy and neurology suggest that the timed intervention of yoga may be an auxiliary option for improving Parkinsonian Gait Disturbances in African-American male patients diagnosed with the condition. Studies on gait dynamics and functional improvements of yoga indicate that the combination of postures and breathing allows for an active-mind body component that increases awareness and proprioception and activates muscle spindles, leading to increased functional and decreased freezing gait responses. Based on the stated studies, this research proposes the consistent, weekly therapy of yoga. Yoga therapy may decrease a Parkinson's patient's gait disturbances on the basis that these individuals with hypokinesia and akinesia are susceptible to minimal changes because their bodies naturally follow the path of degradation. The correlation between yoga and Parkinsioan Gait Disturbances is a novel idea, and testing is needed to create further transparency in the biological and physiological impact of muscle spindles in relation to neurological signals.

Abstract Name: Modeling Individual Sleep Needs from Wearable-Device Data

An individual's natural sleep and wake cycle plays a critical role in nearly every aspectof their daily life. There are currently thought to be two processes that interact to regulate one's sleep/wake cycle: a sleep homeostat, which depends on the amount of time you have been awake; and the circadian rhythm, an internal 24-hour molecular clock present in nearly every cell of the body. Both processes differ between individuals, whether that's from a decision to pull an all-nighter one day or from a genetic inclination towards being an "early bird" or a "night owl". This project focuses on building a model that can predict how particular sleep disruptions impact an individual's sleep cycle, as well as their ability to recover from these disruptions. A "two-process" model with the capability to simulate a theoretical sleep-wake cycle with disruptions was built and is being tuned using actigraphy data. Actigraphy measures motion using a noninvasive accelerometer embedded into a wearable-device (e.g. FitBit), allowing for the study of sleep activity patterns in a real-world setting. The actigraphy data was collected from approximately 20,000 individuals, who reside in 121 different countries. Machine learning was used on synthetic data generated from the "two-process" model and on actigraphy data, to match the parameters in both. The algorithm was first trained and tested on the synthetic data, and our knowledge of the model was used to tune the algorithm. Then, this algorithm was applied to the actigraphy dataset to evaluate its prediction accuracy on real activity data. Our model has shown that recovery from sleep disruptions can be modeled mathematically, and can be individualized using actigraphy data. It will be useful to anyone experiencing sleep disruptions due to health, work, or family responsibilities, by providing information on how to get sufficient sleep regardless.

Abstract Name: **The Associations Between Prosocial Skills and Substance Use Severity in Justice-Involved Adolescents with a History of Depression and Anxiety**

Aims: Justice-involved adolescents (JIA) are more likely to have poor prosocial skills, worse substance use diagnoses, and a history of depression-anxiety. It's known that the presence of prosocial skills is a protective factor against substance use disorders and a history of depression-anxiety, but these relationships aren't established in a justice system context. Investigating whether the presence of prosocial skills protects JIA with a history of depression-anxiety against substance use severity is the first step to bridging this gap. The study hypothesizes JIA with a history of depression-anxiety that use prosocial skills willmore likely have lower substance use severity. Methods: The study examined cross-sectional data from the Florida Department of Juvenile Justice (FLDJJ), which comprised of 79,960 JIA that were assessed by the Positive Achievement Change Tool (PACT) between 2004-2015. Multivariable logistic regression analyses were used to examine the relationship between prosocial skills (no skills and uses skills) and substance use severity (DSM-IV-TR criteria: no diagnosis, substance abuse, and substance dependence) in JIA with a history of depression-anxiety. Controlled for race, age, gender, and income. Results: JIA with prosocial skills and a history of depression-anxiety had 1.38 (0.05) higher odds of being diagnosed with substance abuse and 1.77 (0.01) higher odds of being diagnosed with substance dependence than the odds of no diagnosis in JIA with prosocial skills and a history of depression-anxiety. JIA with a history of depression-anxiety that used prosocial skills had higher odds of a poor substance use diagnosis. Conclusion: The findings contradicted the hypothesis. Prosocial skills as a protective factor against substance use severity and history of depression-anxiety are likely untrue in a justice system context. Prosocial skills are integral to building quality relationships. These skills could indirectly provide easier access to substances in incarcerated facilities and contribute to higher rates of substance misuse.

Abstract Name: **Developing Rho1 into a Reporter to Determine Yeast GGTase-I Specificity**

Protein prenylation is a post-translational modification (PTM) of "CaaX proteins" which regulates their localization and function. Prenylation occurs to proteins having a C-terminal sequence that consists of a Cysteine (C), two aliphatic amino acids (a), and one of several amino acids (X). CaaX proteins typically undergo a coupled 3-step PTM pathway involving initial lipidation with a C15 or C20 isoprenyl group on the Cysteine, followed by endoproteolytic removal of the 'aaX' sequence, and finally methylation of the isoprenyl-cysteine carboxyl group. The 3-step PTM is documented for many CaaX proteins although emerging evidence indicates that some CaaX proteins are only subject to the first isoprenylation step. Ydj1 is an example of a CaaX protein that only undergoes isoprenylation, and it has been adapted as a genetic reporter to assess the prenylation potential of all 8000 possible CXXX sequences. Published results indicate that Ydj1 prenylation mediated by farnesyl transferase (FTase), which adds a C15 farnesyl lipid, extends beyond the traditional CaaX motif.Likewise, preliminary evidence indicates that Ydj1 prenylation mediated by geranylgeranyl transferase-I (GGTase-I), which adds a C20 geranylgeranyl lipid, extends beyond the traditional CaaL/F motif. These results suggest that the prenyltransferases, FTase and GGTase-I, have broader specificity than previously considered. Reliance on the naturally farnesylated Ydj1 reporter limits interpretation of these results for GGTase-I. This study reports on a method for assessing GGTase-I specificity through the naturally geranylgeranylated Rho1 GTPase that is a more appropriate reporter for GGTase-I activity. The method uses the essential nature of Rho1 and genetic recombination to create and assess the function of a plasmid library of Rho1-Cxxx sequences for insight into GGTase-I specificity. This study will refine the breadth of potential targets of the CaaX PTM pathway and provide insight into the implications of using GGTase-I inhibitors as human therapeutics in a variety of disease states.

Abstract Name: **Pathways to Seeking Mental Health Services Among Muslim Americans.**

What are the pathways that Muslim Americans have taken to utilize mental health services? What factors impact Muslim Americans' help-seeking behaviors? The research surrounding this topic found that acculturation to Muslim versus American values affected the likelihood of Muslim Americans reaching out to mental health services (Haque et al., 2019). The research demonstrates how Muslims who are less likely to seek help found services like group therapy, therapists of similar/same background, and therapy through imams and/or mosques the most approachable (McLaughlin, Ahmad,; Weisman de Mamani, 2022). The major gap in the literature is the lack of research on the populations that have successfully sought out mental health services and the pathways in which they did so. This study aims to fill that gap in the literature. The data will be collected using a survey distributed through Qualtrics online. Muslim Americans who are 18 years or older and have used some form of mental health services are our target audience and will be recruited through digital and print flyers and social media. The study's expected findings will be that those of the younger generations and those who are more acculturated will have utilized mental health services more than those of the older generation who are not as acculturated. Expected findings also see religiosity impacting the individual's likelihood of using mental health services. The survey will be distributed and data collection will occur in the winter 2022-2023. The data will then be analyzed in early Spring of 2023.

Abstract Name: **Changes in Parental Responsiveness across the Reproductive Cycle in the Biparental California Mouse**

In mammals, maternal behavior is activated by hormonal changes occurring during pregnancy and lactation. Females typically become highly attracted to infants at the end of pregnancy, whereas attraction to infants can wane across the lactational period. In many rodents, however, females gestate and lactate concurrently; it is not clear how maternal responsiveness changes in these species. Moreover, very little is known about fathers' responses to infants across their mates' reproductive cycle. We characterized the parental behavior of mothers and fathers across overlapping gestation and lactation periods in the monogamous, biparental California mouse (Peromyscus californicus), in which females are usually both pregnant and lactating and fathers perform comparable amounts of offspring care as mothers. Each parent was introduced to a young, unrelated pup for 10 minutes at four different time points across pregnancy/lactation, and behavior was compared across time points and between the sexes. Behavioral responses to pups did not change significantly across time points in either sex. At all four time points, however, fathers spent significantly more time than mothers performing parental behavior (i.e., licking, grooming, and huddling) toward the stimulus pup. These findings suggest that concurrent lactation might inhibit the rise in maternal responsiveness that would otherwise occur during late pregnancy, and that parental responsiveness toward infants is higher in breeding males than females in this biparental species.

Abstract Name: **Grameen Method of Microfinance as a Poverty-Alleviation Tool: Short and Long Term Effects on Women's Empowerment in Egypt**

Many people suffer from poverty globally, and economic tools used to combat it have varied from one country to another with some enacting noticeable change. The topic of micro-credit attracted attention after the Grameen Bank's microfinance method was recognized for decreasing poverty in rural Bangladesh by granting loans to women almost exclusively. This paper explores the application of the Grameen method of microfinance in Egypt. This is a review of the Grameen method, women's poverty as a universal issue and its significance, the specific conditions surrounding women's poverty in Egypt, and the economic and social outcomes of past Grameen microfinance efforts in Egypt. Research findings indicate that the Grameen method of microfinance successfully improved the economic status of Egyptian women. However, women from remote areas face obstacles in accessing and making use of these microloans. While the method had some favorable social outcomes by helping women build networks that provide support, it was proven to hold patriarchal structures in place by confining women to informal, domestic-managed work instead of challenging them. Further research is needed to research ways to improve women's access to microfinance in rural areas and to maintain the economic improvement guaranteed by the method while also challenging social norms hindering women's empowerment goals.KeywordsWomen'sEmpowerment; Poverty; Banking; Microfinance.

Abstract Name: **Feasibility of Virtual Exercise Intervention on Occupational Fatigue, Perceived Burnout, and Daily Sleep Time among Family Medicine Residents**

Background/Purpose: A career in medicine is a job of demanding hours by sacrificing one's own needs, causing an increase in mental fatigue and burnout syndrome. The purpose of the study was to examine the impact of a short-term tailored virtual exercise intervention on occupation-related fatigue, perceived burnout levels, and daily sleep time among family medicine residents. Methods: Thirteen participants were recruited and were asked complete two questionnaires related to occupational fatigue and perceived burnout level after which they were asked to wear three monitoring devices (thigh, hip, and wrist) for 14 consecutive days (one-week overnight shifts and another week of non-overnight shifts). Based on the feedback gained during a virtual interview with each participant on current exercisehabits and perceived exercise barriers, a three-week tailored exercise program was developed, and videoclips demonstrating the exercises were prerecorded. During the second and third weeks of the intervention period, participants were asked to wear the three devices. Post-intervention questionnaires on fatigue and burnout were completed. Paired samples t-tests were employed to examine the changes in outcome variables from baseline to during intervention. Results: One participant withdrew from the study due to injury; therefore, 12 participants were included in the analyses. As a result of the three-week intervention, chronic fatigue significantly decreased from baseline to during intervention (.05).Acute fatigue and intershift recovery slightly improved from baseline to intervention but did not show a statistically significant difference. No significant changes were seen in three subscales of the burnout inventory. Dailysleep time was also higher during day shifts than at night shifts for baseline and intervention periods (.05). Conclusion: Longer intervention period with a larger sample size is warranted to explore the effectiveness of the virtual exercise program on family medicine residents' perceived burnout, sleep patterns, sedentary behavior, and physical activity levels.

Abstract Name: Annotating Archival Recordings of Hoc?k

Hocąk (also known as Ho-Chunk or Winnebago) is an endangered Siouan language from the upper Midwest region of the United States. This project involves digital annotation of recordings of Hocąk made in the 1970s. Each sound in each Hocąk word is segmented based on spectrograms generated by the speech analysis software Praat. This is part of the first project to research the acoustic measurements of Hocąk phonetics, begun around 2010; previously, researchers have used their hearing instead of scientific measurements. This research will make phonetic data of the Hocąk language more accessible to researchers, facilitating future research on this endangered language. It can be used to compare historic sounds to modern equivalents and to further research into Hocąk's history.

Abstract Name: Inclusivity and Accessibility in the Arkansas Coalition Against Sexual Assault

Research shows that women who have experienced sexual violence experience less distress when they have access to a sexual violence advocate compared to when they do not. Further, research shows that marginalized groups are routinely underserved by formal sexual assault support systems as they face unique barriers such as lack of accessibility. This makes the work that the Arkansas Coalition Against Sexual Assault (ACASA) does very important. To determine how the Coalition can better serve its communities, this paper used a qualitative content analysis and an intersectionality framework to analyze the inclusivity and accessibility of the organization's communication materials, website, and social media pages. The findings showed that ACASA makes intentional efforts to be inclusive, accessible and supportive of marginalized communities. For instance, their brochures include translations for Spanish speakers and their website makes good use of descriptive links, which is especially helpful for visually impaired users who use their screen readers to scan for links. Some of the rhetoric in their communication materials, however, promotes negative stereotypes about individuals with disabilities. One example pertains to their brochure on sexual assault of people with developmental disabilities, which concludes with the quote "My ability is stronger than my disability." I argue that this quote frames disability as a weakness or obstacle, rather than as a difference that ought to be embraced. Also, videos on their social media pages do not have subtitles or any kind of closed caption option. This makes the videos harder to understand for the deaf and hard of hearing, as well as for non-English speakers who may be reliant on subtitles in their language. This paper provides recommendations for how the organization can improve problematic rhetoric in its communication materials and make its community and social media presence more inclusive and accessible.

Abstract Name: **Intercultural Competence of undergraduate students at American Transnational University in Uzbekistan**

Intercultural competence (IC) is the ability to function effectively across cultures, to think and act appropriately, and to communicate and work with people from various cultural backgrounds. Because of historical and recent events, Uzbekistan has a range of citizens from different nationalities. Uzbekistan is now welcoming more newcomers from Russia, Ukraine, Belarus, Kyrgyzstan, and more. Consequently, professionals are expected to be knowledgeable about various ethnic groups, to experience relationships with others, and to prepare for life in a multicultural society.This investigation examines the IC of undergraduate students in the Education Studies Program courses at a University in Tashkent. The investigator hypothesized that the students would be polarized in their orientation toward persons of cultures different than theirs. The research methodology is based on twenty current students who completed the Intercultural Development Inventory (IDI). Data analysis provided a 'snapshot' of their IC at this point.The findings suggest that Uzbek students have little life experience beyond their own home cultures. The University students do have a clear sense of their own values and practices, as well as a desire to preserve their own traditions. They see other persons as "others" without much definition or understanding.An undergraduate university program may promote IC skills to faculty as well as to students. University faculty may want to revise and rebuild the curriculum and policies in order to intentionally incorporate teaching and learning strategies to foster IC among their students. Additional research is needed in order to understand the IC development of undergraduate students in other settings, such as large public universities (e.g., the Tashkent Institute of Irrigation and Agricultural Mechanization Engineers).

Abstract Name: **Allocating Blame within Corporations through the Mind-Body Problem**

Allocating blame and the desire for someone to be punished for their actions are parts of human nature. But while someone may want to blame a finance company for a financial crisis, it is harder to assign responsibility to a corporation containing many people with varying specialized roles. My project explores how individuals allocate blame across organizations and how viewing responsibility through the "Mind-Body Problem" influences this blame attribution. Much like blaming a single person, which is easier than blaming an organization, the Mind-Body Problem allows the hierarchical structure found in organizations to be a single entity. As a CEO is at the top of the hierarchical structure of their organization, they would be the "mind" that controls their "body," or their subordinates. People would blame the "mind" the most for an event, while implementers of orders are not as blamed because they are not as pivotal and are mechanical. To test this, participants will read scenarios where a corporation's CEO decided with intent and asked their subordinates to implement their decision. Most mayblamethe boss for an event because their role is more pivotal and because they give out orders with intention. Because subordinates can be substituted and the outcome of an event is not affected by their participationspecifically, they maynot be as blamed. However, participants may blame subordinates when they act outside of the orders of their boss, though still not to the same extent as the CEO. These anticipatedfindings suggest that the mental state of an agent is important and that people rely on the fact that the "mind" controls the"body" when assigning blame.Surveyswill be conducted to gauge how participants interpretthe pivotality, intention level, and moral responsibility of multiple agents acrossscenarios demonstrating unique, fictionalizedethical failures within organizations.

Abstract Name: **OPERATION ENDURING FREEDOM: Improving Mission Effectiveness by Identifying Trends in Successful Terrorism**

This research examines how the characteristics of terrorist attacks predict the chance of an attack succeeding, where an attack is defined as successful if the intended attack type is carried out. Data from The Global Terrorism Database was analyzed across three geographical missions within Operation Enduring Freedom: Trans-Sahara, Horn of Africa, and the Philippines. The three models were able to distinguish between successful and unsuccessful attacks at 78.74%, 82.11%, 74.25%, respectively. Using predicted probabilities of success obtained from each logistic regression model, the medians were plotted to compare the characteristics of terrorist attacks across missions. The coefficients for each model were analyzed to compare the odds of success for each variable level to the odds of success of the reference level for that variable. The coordinates for successful and unsuccessful attacks as classified by the dataset were plotted to explore spatial patterns in regional maps. Many insights were gathered through analyzing Operation Enduring Freedom missions. For all three Operation Enduring Freedom missions, attacks involving Barricade Incidents, Unarmed Assaults, Infrastructure Attacks, and Incendiary weapons are predicted to have the highest probability of success. Additionally, the two most prevalent regional ethnic groups in the Trans-Sahara and Horn of Africa have higher predicted probabilities compared to jihadist organizations, in contrast to the Philippines, where attacks by Islamic Extremists have the highest probability of succeeding. Furthermore, attacks targeting private citizens, tourists, non-governmental organizations, and food or water supply, have the largest probability of success for the Trans-Sahara and Horn of Africa regions, whereas suicide attacks in the Philippines raise the chance of success. By determining the specific characteristics of attacks that produce the highest probabilities of success, the effectiveness of Operation Enduring Freedom can be improved by focusing counter-terrorism training and operations on the features that predict successful attacks.

Abstract Name: **Dietary preferences of invasive red swamp crayfish (Procambarus clarkia) from the Patuxent Research Refuge, Maryland**

Invasive species are a leading cause of environmental degradation in freshwater ecosystems. Invasive crayfish, for example, can displace native crayfish and consume large quantities of both aquatic macrophytes and native animals. While Maryland is home to three invasive species of crayfish, relatively little is known about their impacts to local food webs. Here, we collected invasive red swamp crayfish (Procambarus clarkia) from the Patuxent Research Refuge in Laurel, Maryland and performed a feeding experiment to understand their dietary preferences and likely influence on refuge food webs. Crayfish were housed in 20 x 12 x 10-inch glass tanks equipped with air stones and polyvinyl chloride pipes for refuge. They were offered native plants and animal matter in three separate week-long trials, and their diet preferences were quantified based on the percent of food mass remaining at the end of a trial. We also used the stable carbon and nitrogen isotopic composition of wild red swamp crayfish to understand how their dietary niche compares with that of a common, native omnivore, the eastern painted turtle (Chrysemmys picta picta). Our feeding experiment showed that on average, red swamp crayfish preferred smartweed (Persicaria sp.) over other species of aquatic plants and animal matter over native plants. We also documented substantial variation among individual crayfish – a finding echoed in wild crayfish's variable nitrogen isotope values. Finally, we observed considerable overlap between the red swamp crayfish's isotopic niche and that of the eastern painted turtle. These results provide insight into the impact of an invasive species within one of the largest green spaces in the Washington, D.C.-Baltimore corridor.

Sheehan, Martin

Abstract Name: **Influence of Dark Matter Particles During Interstellar Travel**

This paper examines the interactions between the scalar dark matter particles X and baryonic particles within the human body when a human is approaching near-light speeds. A scalar dark matter model in which X couples to photons only via loops is used to calculate the scattering amplitude between nucleons N and X. An approximation of the human body as nucleons is made to determine the luminosity. We consider all the possible interaction channels via elastic scattering. With the constraints from current dark matter data, we found the scattering amplitude of the channel XN→XN via the Higgs using the benchmark point of mx=100 GeV to be 9.9x10^47 cm^2. This value is close to the upper limit of 2018 Xenon1T and at the same order of magnitude.

Abstract Name: **Acute Effect of a Pre-Workout Supplement on Power Expression and CrossFit? Workout Performance**

A common CrossFit® (CF) workout structure is to have trainees complete the same circuit of exercises for 'as many repetitions as possible' (AMRAP) within a given duration. Performance is dependent on sustaining the power needed to complete each movement at a pace that also minimizes breaks due to fatigue. This ability is known to improve with training and CF experience. However, several individual nutritional ingredients are known to impact energy availability and/or assist with fatigue management, and these may collectively be found in a variety of pre-workout formulations. Thus, supplementing with a pre-workout formulation may provide a greater benefit to AMRAP performance than training and experience alone, but no study has investigated the acute effects of such formulations in experienced CF trainees. Therefore, the purpose of this study is to examine the acute effects of a pre-workout supplement on power expression and CF workout performance. Healthy, CF experienced (≥2 years) men (ages 18-45) are being recruited for this cross-over design, placebo-controlled study. After providing their written informed consent, participants must complete four, weekly experimental visits at approximately the same time of day in randomized order. Upon arrival, they are asked to consume either a pre-workout supplement (S) containing ingredients known to improve energy availability and manage fatigue, or non-caloric placebo (P). Then, they rest 40 minutes before completing either a 5- or 15-minute AMRAP of 9-calorie rowing, six 95-lbs. barbell thrusters, and three 24-in box jumps. Power expression will be measured during each set of rowing via the ergometer's microcomputer, and during each thruster (by PERCH; a barbell tracking camera) and box jump (by in-ground force plates) repetition, and these will be averaged across each round.Comparisons will be made between S and P, 5- and 15-minute trials, and their combinations on changes in power expression across each round completed.

Abstract Name: Conformity and Friendship Satisfaction Among University Students

The rhetoric around one's role in a friendship or relationship is largely shaping up to promote a lack of conformity. Adolescents and young adults are now regularly told to "stand out" and perhaps that fitting in isn't always the best option. This, however, prompts the question of what role conformity plays in impacting friendship satisfaction. This paper explores whether there's a correlation between an individual's level of conformity and their level of friendship satisfaction. Gender and relationship status are explored as potential mediators in this relationship. The participants' level of conformity was measured using the Elevator experiment, where participants enter an elevator and find 4 other people facing the rear end of the elevator. Participants accordingly make one of three decisions, they either turn and face the rear end (conformity), continue standing the same way (non-conformity), or hesitate (mid-level conformity). Participants then completed a questionnaire that assesses their level of platonic friendship satisfaction across three scales. This process was completed 75 times by participants, with 25 students conforming, 25 not conforming, and 25 mid. Results of the Anova show that there is no significant correlation between conformity and friendship satisfaction; however, there was a significant correlation between gender and friendship satisfaction, which indicated that girls are overall more content with their friendships. This opens lots of areas for future research, as it can be worthwhile to explore some of the other factors that result in girls being more satisfied with their friendships at this specific age.

Abstract Name: Investigation of the thermal stabilization of triplex DNA by flavonoids

Triplex DNA consists of a third strand, referred to as a triplex-forming oligonucleotide (TFO), binding to the double helix of DNA in the major groove via Hoogsteen H-bonding. The formation of triplex DNA follows specific base pairing rules. The binding of TFO to duplex DNA can interfere with the nucleic acid processing proteins binding to the same region and consequently regulate DNA replication and transcription. It has been recognized as a promising approach in anti-gene therapy. However, the downside is that triplex-DNA has a slower formation rate than its duplex counterpart. They are also known for being relatively unstable due to charge repulsion between three DNA backbones. Nonetheless, the stability of triplex-DNA can be enhanced by small molecules, which specifically bind to the DNA triplex and increase its stability. Our lab recently discovered that certain flavonoids exhibit a stabilizing effect on triplex DNA but minimal impact on duplex DNA. Such a phenomenon is pH-dependent. Flavonoids are natural products that can be found in fruits, vegetables, grains, etc., and have shown anti-oxidative, anti-inflammatory, and anti-carcinogenic properties. In the present work, we have carried out a full-scale study on the thermal stabilization of triplex DNA by commercially available flavonoids at different pHs monitored by UV. The effect of structure on the stabilization of triplex DNA will be discussed.

Abstract Name: **Preparedness and Comfort Levels in Providing Sexual Health Education on Vancouver Island**

Sex trafficking and sexualized violence are increasing in communities across British Columbia (BC). Sexual health education has been recognized as a powerful tool to prevent children and youth from experiencing these devastating forms of abuse. The question then becomes: who is providing this sexual health education to British Columbian youth, and how well is it being provided? While parents and private consultants often play a role in teaching children the basic concepts involved in sexual health education, the quality and scope of their explanations can vary widely. As such, a key source of sexual health education is teachers in primary and secondary schools. Typically, sexual health education in BC begins in kindergarten and spans through grade ten. While the topic's content is regulated through the provincial curriculum, previous research has shown that teachers are not providing consistent and thorough education. The disconnect between the curriculum and educators appears to be hinged upon two concepts: first, educators themselves do not have enough knowledge on the topics to teach them effectively, and second, educators may not feel comfortable with certain sensitive topics within the curriculum. This project sought to investigate how prepared Vancouver Island teachers-in-training are to teach sexual health education based on their knowledge and comfort levels regarding the curriculum topics. A survey was created with three sections: individual demographics, a curriculum-based knowledge test, and a subjective section focusing on comfort levels regarding various sexual health topics. The survey was open to university students enrolled in the Bachelor and Master of Education programs at Vancouver Island University and the University of Victoria. By examining these future teachers, this project aimed to illuminate how prepared the next generation of teachers are and provide insight into the future of sexual health education.

Abstract Name: **Determination of optimal feeding rates for juvenile Walleye (Sander vitreus) in tank-cultured systems based on growth performance**

Walleye (Sander vitreus) are a highly sought-after northern Midwest fish species known for their nutritional quality and recreational attributes; however, the population has been decreasing with the ever-changing climate of our lakes. The objective of this study is to determine feeding rates for walleye juveniles and provide baseline information on feed management for walleye aquaculture. We conducted three two-week trials in indoor systems run with flow through water at 18 to 20°C. Walleye were fed with a commercial diet at 6 different feeding rates (% initial body weight daily) ranging from 5.0 to 17.5 % in Trial 1, and 2.5 to 15% in Trial 2, with 30 fish per tank. In Trial 3, walleye werefed at 5 different feeding rates from 2.0 to 8.0 body weight daily with 15 fish per tank. The initial body weight was 0.95 g, 2.31, and 9.3 g for Trial 1, 2 and 3, respectively. Optimal feeding was estimated using polynomial regression method based on the percentage of weight gain during 2-week feeding. Our results showed that an optimal feeding rate was 22%, 12.5%, and 7.7% for fish ranging from 1-3 g, 2-5 g, and 9-17 g, respectively. The survival was significantly impaired (0.05) when walleye were fed at 5% body weight daily in Trial 1. Trial 2 and 3 showed minimal mortality impact based on diet. Condition factor, expressed as the ratio of body weight and the cube of length, was significantly lower for underfed fish compared to those fed at their optimal feeding rates or higher. The nutritional composition of walleye and feed is pending for analysis and will be available for the presentation. The result of this study will provide preliminary information for developing feed management of walleye culture and designing future studies on nutritional requirement.

Abstract Name: Integrating Undergraduate Research into Electrical Engineering Curriculum

Research and creativity are critical in the profile of a new engineer. One of our goals in engineering education is to have students experience design, creativity, and innovation. Thus, an exploratory innovation to integrate undergraduate research into electrical engineering curriculum is being conducted, which leads to an active learning for Computer and Electrical Engineering students at University of Wisconsin-Stout. Student research projects with state-of-the-art technologies are applied in engineering courses for embedding high-quality undergraduate research into teaching. The objectives of integrating undergraduate research into electrical and computer engineering curriculum include applying research skills and methodology on collaborative and industrial-relevant projects, teaching students all aspects of design of automatic control system and robotics, expanding knowledge base of new technology, and preparing future engineers to face real-world problems. The development of student research projects, such as robotics system design and intelligent control system design, is based on the application of hands-on instruments and software. Students are provided with research examples to teach them from the component level research to a complete functional system design. This research design process is prevalent in industry, which will be beneficial for students to practice and experience the design and research processes. It has been shown that the integration of undergraduate research into engineering curriculum has a great impact on motivating students in engineering and technology research, participating faculty-student scholarship activities, pursuing advanced graduate study in engineering, and embracing their responsibilities in active learning in engineering. Students are provided with more opportunities to work with their peers, faculty, and industry in research. Furthermore, students' skills with hardware and software, comprehensive application and hands-on abilities, and creativity can be better cultivated.

Abstract Name: Machine Learning to Develop Models for Analyzing Stress in an Academic Environment

This paper demonstrates the significance of readily available machine learning (ML) platforms like IBM Watson machine where the user can develop ML models to analyze the data and predict the outcome with high accuracy by using various algorithms. This platform provides a great opportunity to new users with limited computing and/or data analysis experience to run a machine learning problem. This is achieved by offering the user an option of automated selection of various algorithms and other relevant parameters (hyper parameter values) under both supervised and unsupervised learning. In the current work, we are analyzing the data collected from an academic institution in Pakistan to evaluate the impact of various parameters on students' average grades by developing ML models on Watson platform. The data was collected right after the COVID peak by distributing a questionnaire among students. The aim was to obtain information on various relevant parameters that were grouped in four sections as "General Information", "Perceived Stress Scale", "Cognitive Assessment", and "Social Dependency". Watson ML platform was used to develop a model under "supervised learning" option and by incorporating various algorithms including Extra Trees Classifier and Random Forest Classifier. The machine proposed two best performing pipelines corresponding to Random Forest Classifier that gave an accuracy of 66.4% (Cross-Validation) in which feature enhancements were performed including hyper parameter Optimization and feature engineering. The paper includes details on various aspects of using ML Watson-platform and the outcome of the ML-model for the analysis of the current data. Results shows that among all impacting parameters, cognitive performance, self-study hours, and number of class absentees played a dominant role in predicting the student's average score. This presentation will describe the questionnaire, statistics, and ML models employed to conduct the study. Suggestions to improve the model's accuracy will also be discussed.

Mike Sloane

Abstract Name: When is race a useful variable in research?

The use of race or ethnicity as a variable in social science and biomedical science research has had a long and tortured history. The history of social science research is replete with studies examining race as a variable. The issue of race and IQ is a notorious example where research has been co-opted to support racial stereotypes, structural racism, and policies driven by majority groups. Genetic and biomedical research have not been immune from similar abuses and misuses. Given more advanced understanding of the complexity of social issues that include disparities and injustices as well as advances in personalized genomic medicine it is useful to pause to examine under what circumstances should race or ethnicity be included as a variable in modern scientific research. Given the preponderance of biased media, increased levels of intolerance and racial bigotry, and the polarization of attitudes on most issues related to inequalities and disparities, one has to ask what are the responsibilities of researchers to incorporate race or ethnicity as a variable and what additional constraints might they consider in how such information is reported? The implications for using race or ethnicity in the social and behavioral sciences will be compared to the implications for its use in biomedical sciences and health-related research.

Abstract Name: Selective Functionalization of Leukocyte Subpopulations with E-Selectin Liposomes

Metastasis occurs when cells break off a primary tumor and enter the blood stream. This process can create secondary tumors at distant sites. To combat metastasis, an antimetastatic therapy uses the protein TNF-related apoptosis inducing ligand (TRAIL) to initiate apoptosis in circulating tumor cells (CTCs) in the blood stream. Liposomes with the protein E-Selectin (ES) attach to leukocytes in the bloodstream and are used as vessels to transport TRAIL to CTCs. Here, we investigate the influence that ES has on the binding of liposomes to subpopulations of leukocytes, specifically monocytes and granulocytes. Through flow cytometry analysis of monocytes and granulocytes from healthy patient blood, the concentrations of fluorescent ES-liposomes bound to the surface of these cells were investigated. It was found that as the average number of ES per liposome increases, the greater occurrence that liposomes are bound to granulocytes. The number of ES yields no correlation on the effect of liposome-monocyte binding. The influence of the liposome component DSPE-PEG was also investigated. When DSPE-PEG was removed from the liposome fabrication process, a specific subpopulation of higher fluorescence in flow cytometry measurements indicated more efficient binding to granulocytes. Imaging using fluorescence microscopy visually confirmed the binding of liposomes without DSPE-PEG to leukocytes using a DiI lipid dye and DAPI nuclei dye. A population of granulocytes did not bind to these liposomes, while most were bound to them in abundance, indicating there may be selective binding to specific types of granulocytes. There was little to no binding to monocytes with 0 ES, but with ES present, binding was found to occur to select monocytes. High binding to platelets was found in both leukocyte populations. The investigation of this topic can yield better results in the utilization of liposomes as a delivery system for TRAIL in antimetastatic therapies.

Abstract Name: **Rehearsal Visualization Therapy: The Test of Following Directions Evaluation**

Children with language and learning disorders often have co-occurring difficulties in remembering and following verbal directions. This is often due to the syntactic complexity of the directions along with the children's working memory limitations. Few research studies have examined the effects of therapy designed to assist children in improving their ability to follow directions. Due to the lack of research, speech-language pathologists struggle to find evidence-based practices for increasing children's direction-following skills. The current study examined the effects of a therapy called "rehearsal-visualization intervention" on children from 5.0-10.5 years of age. This intervention requires the child to repeat or rephrase the given instruction and to imagine the instruction as it was carried out and completed. Forty-five participants, who had been diagnosed with a language or learning disability, completed the intervention under the direction of speech-language pathology (SLP) graduate students in the public schools of Texas. Data collected by the SLPs was analyzed for changes in direction-following ability as measured by the Test of Following Oral Directions, an assessment to determine the difficulty of directions based on linguistic complexity. Pretest and posttest data from the participants indicated that 86.67% of the children demonstrated increases in the difficulty of the directions they were able to carry out. This suggests that rehearsal-visualization strategy training may offer an effective way to teach elementary-aged children to process and carry out difficult instructions.

Abstract Name: **Revisiting Stop Kiss 25 Years Later: What Has and Has Not Changed for the LGBTQ+ Community in that Time**

Following the height of the AIDS crisis,Stop Kiss by Diana Son tells the story of two women falling in love, exploring their identities, and fighting for one another despite the societal pressures pushing against them. Callie and Sara both have complicated histories with ex-boyfriends and have never been attracted to women before but find themselves falling for each other as they spend more time together. Stop Kiss deviates from a linear plot and instead opts to alternate between their relationship building up to a first kiss and what happens after that first kiss. The unseen moment connecting these two plots is a brutal hate crime against the two women after their first kiss, leaving Sara in a coma. This moment of hate is a crucial part of the story but is not a focal point of the play; this is a story about love prevailing, not hate. This was first performed in 1998, but the story is still strikingly relevant.Recent legislation and hate groups have shown that, while there has been progress in becoming more inclusive, the sentiments that existed then to harm and oppress LGBTQ+ identifying individuals still exist today and continue to cause harm. With the hate experienced in the community and seen in the news, stories of love and resilience are a powerful reminder that members of the LGBTQ+ community belong and are just as deserving of love and acceptance as anyone else is. I believe this play is important to perform because it focuses on the love of these two women while also acknowledging the cost that non-heterosexual relationships can have. This nuance is necessary when engaging with LGBTQ+ stories today and bringing attention to the in justices still faced by the community without forgetting to celebrate the victories, big and small.

Abstract Name: **Levels of Cytotoxic Rhodium and Platinum Compounds in Select Organelles within HeLa Cancer Cells**

Cisplatin, a well known and effective cancer chemotherapy drug, has many undesirable side effects. Complexes of rhodium, another transition metal with similar properties to platinum, are being explored in our laboratory to determine whether they are as effective as cisplatin. We have tested the cytotoxic effects of two rhodium complexes, Rh2(butyrate)4 and Rh2(acetate)4, on HeLa cervical cancer cells, and we aim to determine how well and into which cellular organelles these complexes enter. HeLa cells were treated for two hours with 100 μM of each compound, followed by cell lysis and quantification of rhodium or platinum levels by graphite furnace atomic absorption spectroscopy (GFAAS). In addition, we quantified the amount of compound relative to the total protein concentration within the cell (BCA assays) and to the levels of a specific protein (α-tubulin through Western Blotting). Preliminary studies of the whole cell lysates correlate to the IC50 values determined by our lab, demonstrating that compounds that are able to get into cells are most capable of causing cell death. We are now focused on measuring levels of rhodium and platinum complexes able to enter the cell nucleus through nuclear fractionation studies. We are able to isolate robust amounts of protein and DNA from nuclear fractions and are currently in the process of quantifying metal concentration by GFAAS. To ensure we successfully isolate the nuclear fraction, Western Blotting analyses using c-jun transcription factor as a nuclear marker and α-tubulin as a cytoplasmic marker have been performed. Taken together, these studies will help us to determine if the cytotoxicity levels of different rhodium complexes correlate with their ability to enter the cells and target specific organelles, such as the nucleus and/or the mitochondria.

Abstract Name: **Building an Atomic Force Microscope to Characterize Carbonaceous Meteorites**

How planets in our solar system formed is a major question that many scientists from different disciplines are trying to answer. Carbonaceous chondritic meteorites are considered some of the most primitive surviving materials of our solar system, and thus, these objects can provide valuable clues about planet formation, like thermal, barometric and temporal conditions in which these meteorites formed. This information can be obtained through their physical properties (e.g., structure, mineralogical and elemental composition, and morphology) which can be characterized using microscopy and spectroscopy techniques. In particular, atomic force microscopy (AFM) is a technique that can be used to analyze different properties of the surface of a sample (e.g., topographical, magnetic, chemical, electrical, optical and mechanical properties) through accurate and non-destructive measurements with very high resolution at the nano- and micro-scales. To the best of our knowledge, only a few works have been done on carbonaceous chondritic meteorites using AFM to examine their topography, while there no studies done using this technique to analyze their mechanical properties. In this work, we build and test an educational AFM system with different AFM tips and appropriate samples (e.g., CD/DVD/Blue ray surfaces, isolated carbon nanotubes on a substrate) with the final goal of characterizing fragments of carbonaceous chondritic meteorites by examining their topography and mechanical properties, such as adhesion and hardness. These properties allow us to investigate what structures are on the surfaces of the samples and how they have stuck together, which can provide important evidence to understand the origin of these relics.

Abstract Name: Family Perceptions of Care Provided to Children with Craniofacial Differences

Cleft lips and palates are common congenital disorders worldwide and can occur either together or separately. In America, roughly 1 in every 1,600 babies are born with both a cleft lip and palate (CL/P), 1 in 2,800 are born with only a cleft lip (CL), and 1 in 1,700 are born with only a cleft palate (CP). Previous research demonstrates disparities in access to CL/P care, with children from minoritized backgrounds, children without access to private health insurance, children from economically disadvantaged backgrounds, and children who lived in rural/geographically isolated areas more likely to experience delayed access to care (Broder; Wilson-Genderson, 2012; Harb et al., 2021). Despite its commonplace occurrence, there is little research as to what impacts parental satisfaction with their child's speech and medical procedures in regards to CL/P. The purpose of this research study was to better understand differing parental perceptions of medical/therapy interventions received by their child with CL/P. The author completed semi-structured interviews with six parents of children with CL/P in Wisconsin and Minnesota to better understand how perceptions of care differ between families. Demographic information related to socioeconomic status and geographic location was also gathered and information about these variables in relation to parental feelings about their child's care was elicited during the interviews. Interviews will be analyzed using inductive coding procedures as described by Merriam and Tisdell (2016). It is anticipated that aspects of the family environment (specifically, socioeconomic status and geographic location) may relate to parent perceptions of the quality of care. Understanding parent perspectives regarding treatment for CL/P helps clinicians understand the experiences they go through and will assist the field of Communication Sciences and Disorders (CSD) in providing higher quality services to families from all backgrounds.

Abstract Name: Invisibly Here: The Future of Life Writing in Writing Centers

In writing studies, Jonathan Alexander has employed the term "life writing" to describe the work of encapsulating the complexities of one's lived experiences through writing ("Writing a Queer Life" 1). For us, such a theory extends the work of writing center scholars considering ways in which private and public struggles take shape through writing centers (Denny, Mundy, Naydan, Sévère, Sicari). These struggles remain increasingly tied to questions around agency and expression in the context of larger unstable social and cultural contexts. And so, we define "life writing" more broadly to encapsulate the work of helping students find meaning, voice, and agency within larger systems of inequity. Indeed, this roundtable starts by positioning life writing as a bridge between personal and academic. Yet, it builds toward offering life writing as praxis—as a writing center method for connecting with writers in a world torn apart, so often, these days.Questions around how students engage, and grow, are always tied to embodied struggles and histories they share with us, through conversation. These struggles manifest through traditional academic prose. At the same time, life writing recognizes writing centers as spaces that welcome creative fiction and nonfiction writing to process mental health and pain—that take seriously students navigating invisible struggles, including histories of shame and repression. We consider, too, how it enables us to better understand advocating for students navigating social anxieties.Presenters will begin by reviewing life writing as an emerging genre and lens we see taking shape in our writing center. Next, before opening for discussion, presenters offer what it might take—including community partnerships-- to develop life writing a genre, as a critical modality, and as a writing center method. We look forward to hearing ideas from other writing centers practitioners.

Abstract Name: Wisconsin vs. Oregon: Community Justice Oriented Reform and its Effect on Recidivism

Wisconsin has made attempts in reducing the recidivism rates of those who have been incarcerated, but there is still a long way to go. Oregon is a model state with the lowest rates of recidivism in the United States, attributed to its practices of community-oriented rehabilitation backed by evidence-based programming. Our aim with this systematic literature review is to compare the policies and practices of social services in both Wisconsin and Oregon in their efforts to reduce recidivism. Systematically examining documents from scholarly databases and state government websites allowed for this comparison to review each state. With this review, we are searching for the gaps in Wisconsin's programming and practices in comparison to Oregon, so we may understand how to better serve this population and achieve lower rates of recidivism in Wisconsin. In creating such programming to achieve lower rates of recidivism in, we must first understand current practices enacted in the processes of rehabilitation. We aim to compare and contrast efforts to reduce recidivism of the incarcerated population in Wisconsin and Oregon. Our methods used to analyze literature were through scholarly databases and state government websites using an Excel Spreadsheet created to organize criteria of corrections programming and policies. We were able to find the vast differences in programming provided by each state, which concluded our findings and directed us to the importance of state-level involvement with private-sector organizations. Such practices built upon evidence-based programming assist those incarcerated and address the root of the continuous cycle of reoffending.

Abstract Name: Smartphones, Attention, and Brain Electrical Responses

Given concerns about how distracting smartphones can be, we are interested in how they affect attention-related brain electrical activity. Previous research suggests that the mere presence of one's smartphone can negatively impact behavioral performance on an attention-related task. The aim of our ongoing study is to investigate whether simply having one's smartphone present and visible (although shut off) influences attention-related EEG (electroencephalographic) activity. We are assessing this in two ways. First, subjects perform an oddball task, which requires attention and responses to occasional target stimuli ("oddballs") among many task-irrelevant stimuli ("standards"). The P3, a late component of the event-related potential (ERP), is typically larger to oddballs (which receive more attention) than standards; we predict an attenuation of this oddball effect in the presence of one's phone versus a control non-phone object (tile). Second, we are looking at EEG power in the beta range (13-30 Hz) as subjects passively view their phone versus the control object. Since beta activity is positively correlated with alertness and attention, we predict greater beta power in the phone condition. Furthermore, we predict a correlation between beta power in response to one's phone and attenuation of the P3 oddball effect by one's phone; that is, the more attention is garnered by one's phone the more we think their phone will distract from a phone-irrelevant attention task.Preliminary data suggest increased beta activity in the presence of the phone and replication of the classic P3 oddball effect, but are unclear about an impact of smartphone presence on P3 amplitude.

Abstract Name: Studying the Electrochemical Activity of Methanol Dehydrogenase in Lanthanide-Modified Methylobacterium extorquens

Recent studies have demonstrated that some enzymes in bacteria isolated from lanthanide-rich areas use lanthanides as metal cofactors in place of more common metals like calcium and that these lanthanide-enzymes have enhanced catalytic properties. For example, Methylobacterium extorquens is a methylotroph that conducts redox chemistry using methanol dehydrogenase (MDH). MDH is a type of quinoprotein that contains a pyrroloquinone and either a lanthanum (La3+) or calcium (Ca2+) metal cofactor. Here, the bioelectrocatalytic activity of MDH from M. extorquens grown in La3+ rich media is compared to MDH from M. extorquens grown in typical Ca2+ rich media. Biochemical assays have shown that La3+-MDH has higher activity than Ca2+-MDH. However, the bioelectrochemical activities from these bacteria have not been compared. If La3+ grown M. extorquens has higher bioelectrochemical activity than Ca2+ grown M. extorquens, then improved biofuel cells and sensors can be created. M. extorquens is grown in two separate cultures, one with La3+-rich media and one with Ca2+-rich media. Methylene blue is polymerized onto the surface of a glassy carbon electrode, then harvested bacteria or isolated enzyme is immobilized on the electrode by casting a mixture of the bacteria and tetrabutylammonium bromide (TBAB)-modified Nafion® onto the electrode surface. The bioelectrochemical activity for oxidation of methanol to formaldehyde is measured by cyclic voltammetry and amperometric i-t curves for various concentrations of methanol in a tris-HCl buffer. In addition to comparing the bioelectrochemical activity of the La3+-MDH and Ca2+-MDH, the activity of the whole bacteria and isolated enzyme electrodes will be compared along with the electrode lifetimes.

Abstract Name: Galaxy Morphology and it's Relation to Gas Content in Nearby, Star-Forming Galaxies

Stars are formed in galaxies from the collapse of gas clouds composed mostly of hydrogen. It has been previously shown that the amount of gas in a galaxy depends on its shape and structure (its morphology), and that spiral galaxies tend to host more gas. Measuring gas content is somewhat difficult to do, so it would be beneficial to use easy-to-measure quantities to estimate gas content in galaxies. Our gas measurements are taken from archival data, yielding a sample of 108 galaxies with molecular hydrogen (H2) measurements and 3,338 with atomic hydrogen (HI) measurements. We examine the correlations between HI and H2 gas content and different structural parameters that measure the distribution of mass within the galaxies. We find that gas content is correlated most strongly with the density of stars in the inner regions of the galaxies, especially within the inner 3,000 light-years. Our findings offer a method for astronomers to estimate the gas content using easily obtainable morphological parameters, which is very useful in situations where it is difficult or impossible to obtain direct gas measurements.

Abstract Name: **Changes in Chemical Oxygen Demand of Surface Waters in Dunn County**

Chemical oxygen demand (COD) is an indicator of the amount of oxygen required to oxidize organic and inorganic substances in water. COD testing is commonly done on samples of water contaminated with domestic and industrial waste. Discharge of wastewater by industries introduces organic materials that deplete dissolved oxygen available for aquatic life. In Dunn County, this wastewater disposal coupled with runoff from farms and residential areas can negatively impact aquatic ecosystems. COD analysis is an efficient way to determine the aquatic health of water sources, where increasing levels indicate an increase in substances susceptible to oxidation.To assess the susceptibility to oxidation, water samples were collected following a general timeline of herbicide, pesticide, and fertilizer application in the area. Samples were collected from three locations in Lake Menomin, two locations in Tainter Lake, and two locations in Red Cedar River.One set of samples was collected mid-July, a second set was collected at the end of September. COD analyses were conducted using the Open Reflux Method; samples were refluxed in a strongly acidified solution with excess standard K2Cr2O7 to oxidize any organic and inorganic components present, followed by titration with standard ferrous ammonium sulfate with ferroin indicator to determine the unreacted dichromate.Results of the analysis showed decrease in COD (ppm O2) of samples from one location in Tainter Lake (107.60±50.06 to 36.20±11.26), and two locations in Lake Menomin (97.53±44.01 to 41.80±8.09 and 249.27±31.40 to 83.80±6.94). An increase in COD was detected in an area by the Red Cedar River (20.73±9.45 to 36.07±4.69). These findings may indicate that pesticides, herbicides, and fertilizers from farm run-off, discharges from boats, and algae growth affect the COD levels in these surface water.

Abstract Name: **An exploration of inflation expectations**

This paper contributes to the discussion of inflation expectations in the United States and seeks to explore the dispersion of inflation expectations in the United States between consumers, firms, professional forecasters, and market-based metrics. The paper will examine the association of these expectations with realized inflation and potential shocks. Inflation expectations are a formative component of macroeconomic theory, as economists believe that expectations are a central determinant of forward realized inflation. The Federal Reserve utilizes inflation expectations as a forward indicator, making expectations integral to monetary policy. By keeping long-run inflation expectations anchored through inflation targeting and forward guidance, central bank credibility is maintained. However, there is no one metric for all inflation expectations, and there is a dispersion between the forecasts of different economic actors. This exploration will include time-series analysis of inflation forecasts from The Michigan Survey of Consumer Attitudes and Behavior (consumers), The Survey of Professional Forecasters (economists), and the FOMC Tealbook Dataset. We expect to find that policymakers are most accurate in predicting inflation when compared to professional forecasters and consumers, and that dispersion between consumers, firms, and market based measures increases in times of higher economic uncertainty. Additionally, the loss functions or informational inputs for actors may differ, inducing dispersion.

Abstract Name: **General Microbiology Students Searching for Antibiotics in Minnesota's Wetlands**

As antibiotic resistant pathogens continue to emerge, there is a dire need for the discovery and development of new antimicrobial agents. In Fall 2021,University of Minnesota Crookston General Microbiology students collected soil samples from wetlands of Northern Minnesota. They isolated and characterized the microbes to see if they have antimicrobial activity. Nineteen students were able isolate cultures that showed antimicrobial activity against the safe relatives of the ESKAPE pathogens. The current aim of the research is to conduct a longitudinal study to isolate and identify antibiotic-producing bacteria from bogs and fens collected from the previous student work. We hypothesized that some of the pure culture isolates would produce antimicrobial substances and show inhibition against the ESKAPE safe relative pathogens.Procedures followed the general protocols of the Tiny Earth-Studentsourcing Antibiotic Discovery Initiative. Soil samples were further analyzed using standardized techniques to identify the presence of potential antibiotic-producing microorganisms. Bacteria from these samples were transferred to isolates and tested against ESKAPE pathogens to show signs of antibacterial activity. Streak plates were created for all isolates showing antibacterial activity and incubated at room temperature to further separate the microorganisms to purity. This process was repeated until cultures reached purity. Pure isolates were then tested against ESKAPE pathogens to demonstrate inhibition. Pure isolates that showed inhibition underwent chemical fixation using acetone. Further testing is needed to isolate and extract the antimicrobacterial component. Further characterization of the twelve pure isolates that have antimicrobial activity will be reported. Findings from this research could aid in the development of antibiotics with new antimicrobial properties that can fight off pathogens resistant to current medications.

Abstract Name: **Search for Antimicrobial Producing Strains in Minnesota Bogs**

Microbes in Minnesota bogs are a largely underrepresented area of study in the search for new antibiotics. New or unstudied species of Minnesota bog bacteria have the potential to combat the current and worsening problem of multi-drug resistant pathogens. The purpose of this study is to identify if lower pH levels are more suitable for different bacterial colonies as opposed to normal pH levels, and determine if these microbes exhibit antimicrobial properties against safe relatives of the ESKAPE pathogens. Methods used reflect the protocols from the Tiny Earth - Studentsourcing Antibiotic Discovery Project. Soils were processed and microorganisms were isolated from the different locations of bogs in Minnesota and grown on various media: 10% Tryptic Soy, Glycerol Yeast Extract, Nutrient Broth, and Actinomyces media at two pH levels (3.8 and 4.8). More acidic pH levels were selected as Minnesota bog soils are more acidic than other soils. Selected colonies were tested on pathogen plates. Microbes found to have antimicrobial properties were further purified on appropriate media and incubated at room temperature. Microbial growth and isolates are compared to ongoing experimentation of soil microbes isolated on “regular” pH media. Characteristics of the pure cultures of the isolates grown on “low pH” media that demonstrate inhibitory activity will be reported. This research will aid in the process of developing new antimicrobial agents that can be used for advancements in the medical field. This study will serve as a baseline for future antimicrobial research in Minnesota bogs.

Abstract Name: **Electrochemically Grown Gold-Nickel Multi-Segments Nanowires and Network Formation**

Transparent conducting films (TCFs) are both optically transparent and electrically conductive, and indium tin oxide is currently the most widely used material for TCFs. The thin film consists of the network of nickel-gold nanowires offer a few advantages for TCFs, including great conductivity and low cost, compared to our current technology. Therefore, the electrochemically grown gold-nickel multi-segments nanowires is a promising material to replace the indium tin oxide for TCFs. In this research, the nickel nanowires with both gold ends can be fabricated via electrochemical growth in porous alumina (AAO) templates, and the nanowires is used to build a nickel-gold nanowire network that can be used to produce transparent conductive glass.

Abstract Name: **Synthesis and Characterization of Cyclic Peptoids Against Cryptococcus neoformans and Candida albicans**

Antimicrobial resistant strains of fungal pathogens such as Cryptococcus neoformans and Candida albicans have risen to concerning heights, necessitating the discovery of a safe and effective novel antimicrobial agent. Antifungal peptoids, or peptidomimetic N-substituted glycines, have great potential when it comes to acting as antifungal agents due to greater bioavailability and stability towards proteases compared to their peptide counterparts. RMG8-8 and RMG9-11 are two peptoids recently discovered in the Bicker Lab with observed antifungal activity against Cryptococcus neoformans and Candida albicans, respectively, with comparable antifungal activity in vitro to current antifungals on the market (1.56 µg/mL MIC against Cryptococcus and 6.25 µg/mL MIC against Candida). This study attempts to optimize antifungal activity by cyclizing the aforementioned linear peptoids with the hope that increased rigidity due to a locked conformation will increase the antifungal activity of the antifungal peptoids without affecting the observed permeability. Additionally, peptoids are synthesized via solid-phase synthesis, a relatively inexpensive method that eliminates intermediate purification. To characterize the extent of efficacy, cyclic RMG8-8 (RHS3) and cyclic RMG9-11 (RHS6) have been tested for minimum inhibitory concentrations (MIC) against Cryptococcus neoformans and Candida albicans which will be reported. Should the cyclic peptoids display improved MICs, there is potential for a novel therapeutic that could eliminate the growth of the aforementioned fungal pathogens of interest. Future analysis will include mammalian cytotoxicity on HepG2 liver cells and hemolytic activity against human erythrocytes (red blood cells) to determine whether these peptoids are viable options moving towards animal studies and clinical trials.

Abstract Name: Using Photocaged Nitric Oxide Donors to Study Cellular Systems

Nitric Oxide (NO) is an endogenous regulatory molecule that potentially affects a multitude of cellular systems, including mitochondrial signaling pathways. Given its high reactivity, NO can be either beneficial or harmful and has been implicated in both biogenesis and the triggering of pathways that lead to neurodegeneration. However, unearthing the specific effects of NO on mitochondrial dynamics and cellular systems has proven challenging in part due to the limitations of current methods of intracellular monitoring. Hence, the development of a tool for studying this relationship is imperative and can elucidate crucial details on morphological changes in mitochondria as well as other cellular processes. Here, we delineate the synthesis and applications of NOD550, a novel nitric oxide donor that is highly localized in mitochondria. Once photoactivated, NOD550 releases a fluorophore and two NO molecules, allowing for the observance of the dynamics and response of the mitochondria. Microscopy done in tandem with NOD550 serves a major advantage by enabling the study of intracellular signaling in physiologically-relevant conditions. Based on these studies, NOD550 could serve as a valuable tool for further study to be done regarding the release of NO on mitochondrial dynamics and cell signaling systems.

Abstract Name: The Effect of Synthetic A? on Ciliary Membrane and Axonemal Proteins

Primary cilia are immotile microrganelles present in all eukaryotic cells including neurons and astrocytes that regulate fundamental neurophysiological activities in the brain. Defects in the primary cilia lead to a myriad of diseases known as ciliopathies. Ciliopathies have symptoms including a decline in cognitive function and neurogenesis; also seen in patients with Alzheimer's disease (AD). Alzheimer’s disease, a progressive neurodegenerative disorder, is one of the leading causes of death in the United States according to the CDC. AD is a common form of dementia that becomes progressive in older patients (age 65+), it can be characterized as plaque formation in the brain. The hallmarks of Alzheimer's disease are the development of extracellular amyloid- β (Aβ) plaques and tau tangles leading to neuronal death, Aβ is the by-product of the proteolytic cleavage of the amyloid precursor protein, APP. Accumulation of Aβ leads to a cascade of events, ultimately resulting in memory loss and cognitive decline, which are major symptoms of AD. Previously in Dr. Saunders lab, it was observed that APP localizes to the primary cilia in the presence of both extra-cellular and synthetic Aβ, leading to the disruption of the primary cilia. In this study, we aim to delineate the localization of major ciliary proteins, membrane (ARL13B)or axoneme (Tau; pTau), in the primary cilia affected first in the presence of synthetic Aβ. This was observed through immunofluorescence and imaging software to count cells that had specific ciliary proteins. There was a greater decline in axonemal proteins than membrane proteins in a 24-hour incubation. A decline in both types of proteins was seen in a 48-hour incubation.

Abstract Name: **Moving from Is to Ought: The Relation Between Primals and Moral Foundations**

Researchers have recently proposed the concept of primal world beliefs (primals) as a primary determinant of many psychological phenomena, including well-being outcomes and personality. Primals are views about the characteristics of the world that seem to be developed early in life and remain fairly constant throughout (e.g., good—bad). In our research, we ask whether the ways in which we view the world also influence our views on how we should behave in the world. In other words, are primals related to moral foundations? A secondary question is whether primals are related to moral foundations above and beyond the contributions of religion, as research has demonstrated the importance of intrinsic religiosity and fundamentalism in predicting moral foundations. In an online sample of 298 Christians living in the United States, it was found that some primals are related to some moral foundations. Seeing the world as Alive was the primal most predictive of moral foundations, and was associated with the foundations of care, loyalty, authority, and purity, as well as adding incremental validity beyond the religious variables to all these moral foundations. Seeing the world as Good and as Enticing were also individually associated with care, while a sense of the world as Enticing also added incremental validity to the moral foundations of care and loyalty. Primals were not related to fairness in the zero-order correlations or the incremental validity analyses. Thus, how we think we should behave seems to be influenced by what kind of world we think we live in, and primals may have a part in the development of moral reasoning. We discuss potential ways in which primals may interact with religiosity in shaping moral reasoning.

Abstract Name: **Adverse Childhood Experiences, Resiliency, and Help-Seeking among Undergraduate Students**

Adverse childhood experiences (ACE) are an unfortunate occurrence that have affected countless children worldwide. Previous literature has shown that those who had an adverse childhood experience of any kind would likely have some long-term physical or psychological health outcomes as they aged. Previous literature suggests that those who had an ACE in their childhood had increased chances for suffering from psychotic episodes later in adulthood (Mętel et al., 2018). Furthermore, research has shown that those who had an ACE in their childhood also had increased risk of poor help seeking behaviors in the form of substance abuse disorder (SUD) in their adult lives (Watts et al., 2020). There are gaps in literature regarding ACE in undergraduates, however. Most notably, there are few studies on the associations between ACE and other variables such as resilience, help seeking behaviors, mental health, depression, and stress, which we plan to discover. Our hypothesis states that those who suffered from more severe cases of adverse childhood experiences would have higher rates of depression, stress, and other negative attributes. An online Qualtrics survey was distributed to 101 undergraduates (74F, 23M, 4 non-binary). Participants partook in multiple scales including the Brief Resilience Scale, National Survey of Children's Health, ACE scale, and the Depression, Anxiety, and Stress (DASS) Scale. Results indicated a positive correlation between ACE and levels of stress, depression, and anxiety, but no significant correlation between ACE and help-seeking behaviors or resiliency. Limitations include a small sample size and an uneven number of female participants. Additionally, there was a low distribution of people of color and non-white ethnicities. Future research and a larger and more diverse sample size could infer what interventions could help alleviate the poorer mental health of those who had an ACE.

Abstract Name: Determination of the role of nucleoskeletal factors on mortality and seizures following traumatic brain injury (TBI)

Traumatic brain injury (TBI) is a global public health issue affecting millions of individuals each year. One complication stemming from TBI is the occurrence of post-traumatic seizures (PTS), which affect up to 50% of individuals. Severe TBI, advanced age, and genetics are all associated with increased rates of PTS. However, these factors are poorly understood and the cellular and molecular mechanisms which initiate, drive, and maintain a PTS disease state are not known. These gaps in understanding hinder our ability to treat those suffering from PTS and prevent its development. Recurrent or lifelong PTS is associated with sustained changes in nervous system activity. Gene expression and nervous system activity are highly regulated processes. Central to gene expression are nuclear lamin proteins and associated binding partners. Interaction partners include the Linker of Nucleoskeleton and Cytoskeleton (LINC) complex which serves as a mechanical stress apparatus bridging cytoplasmic and nuclear functions. Lamins and the LINC complex are excellent candidates for factors which span contributions to aging, TBI outcomes, and PTS. We utilized the GAL4/UAS system in Drosophila melanogaster to drive RNAi-mediated knockdown of candidate genes. We specifically targeted the LINC complex factors consisting of fly Msp300, klarischt, klaroid, as well as the two fly lamins. Young flies were administered TBI via either a single, severe injury paradigm or a repetitive, moderate injury paradigm. Animals were then assessed for overall mortality, and also PTS via a simple behavioral assay. We found little evidence that genetic knockdown of candidate factors affected outcomes. Future directions include assessment of aged flies to understand if these factors are similarly negligible with advancing age.

Abstract Name: Evaluating School Professionals' Knowledge of Dyslexia

Speech-language pathologists and educators play a vital role in the academic success of students with dyslexia. Due to the common misconceptions that have surfaced, school professionals may experience confusion regarding what dyslexia is and what their role in remediation may be. Researchers have found that pre-service students and in-service school personnel fall victim to myths about dyslexia or lack knowledge of the topic in general. The purpose of this study was to evaluate and compare the accuracy and confidence of dyslexia knowledge among various groups of educators (N = 199) including speech language pathologists (n = 68), K-12 teachers (n = 62), and reading specialists (n = 69). To our knowledge, no other studies have assessed dyslexia knowledge and confidence among the previously mentioned groups. Using a Likert scale formatted survey, this study qualitatively assessed educators' knowledge of common dyslexia characteristics. Item analyses revealed that reading specialists were most accurate in their responses when compared to the literature. Consistent with item accuracy, reading specialists also reported higher confidence in their abilities to effectively work with children with dyslexia. Even though reading specialists' confidence levels were high, there was a lack of confidence among all groups in formal education preparation for dyslexia. The findings indicate an increased need for in-service training and modification of educational curriculums to include explicit dyslexia instruction.

Abstract Name: **Examining the abundance, distribution, and behavior of Gray Seals (Halichoerus grypus) in the presence of white sharks (Carcharodon carcharias) off of Scatarie Island, Nova Scotia**

Great white shark (Carcharodon carcharias) migratory patterns within the Atlantic Canada waters have been tracked and studied by the OCEARCH research team since 2018. As part of their migration, adult sharks typically spend most of the summer in the coastal waters of the Northern United States and Atlantic Canada. During this span, the gray seal (Halichoerus grypus) serves as an energy-rich food source for these apex predators. Gray seals form dense colonies on rocky outcrops near shore, but must travel to deeper water to forage. While traveling to deeper water, foraging, and returning to the colony, these seals are vulnerable to predation.Gray seals often congregate on “launch pads”, or shallow areas offshore of the colony, which they use as staging and return areas for their foraging expeditions. To examine the abundance of gray seals at a well-established colony in Nova Scotia, as well as the influence of nearby predators on seal behavior, small unmanned aerial vehicles (UAVs) were deployed off of Scatarie Islands. These UAVs were used to assess the abundance of seals, identify shallow water launch pads, and observe seal behavior. Data collection via drone surveillance provided high-resolution imagery of animal locations and behavior within the research area without disturbing the seal colony. The information gained through this study was then provided to OCEARCH to enhance their understanding of this popular white-shark feeding ground and assist with future fishing efforts.

Abstract Name: **County-Level Factors Associated with COVID-19 Vaccine Uptake in the U.S.**

Since the onset of the COVID-19 pandemic and the emergency approval of vaccines, different areas of the United States have seen differing rates of vaccine uptake among their residents, and we have seen a concerning trend of vaccine hesitancy among many Americans. In our research, we explore the relationships between county-level demographic, socioeconomic, and political factors and the rate of uptake of the COVID-19 vaccine in the United States. While previous studies have used a cross-sectional approach to explore factors related to intention to receive a vaccine, we aim to identify key factors that help to explain why counties differ in their residents’ rates of COVID-19 vaccine uptake using a longitudinal mixed-effects logistic regression approach. We obtained data for vaccinations by county over time from the Centers for Disease Control and Prevention (CDC) and obtained data for potential predictor variables from the Office of the Assistant Secretary of Planning and Evaluation (ASPE), the United States Department of Agriculture’s Economic Research Service (USDA ERS), the MIT Election Lab, and the United States Census Bureau, all of which we merged to create a single analysis dataset in SAS. This analysis dataset includes a diverse array of county-level variables, such as voting data, median household income, racial and ethnic makeup, region, and vaccine hesitancy estimates. Preliminary results show that many of our selected variables are, in fact, significantly related to vaccine uptake over time, with one of the most significant results being the positive relationship witha county’s proportion of votes for the Democratic presidential candidate in 2020. As we continue to build more complex models, we expect to find meaningful results that identify the ways in which several demographic, socioeconomic, and political factors interact to impact vaccination rates.

Abstract Name: **Creating a Pseudoscience Scale: Identifying Gaps in Critical Thinking in Acceptance of Pseudoscience Topics**

Pseudoscience pervades discourse across the world. Acceptance and consideration of pseudoscience was especially highlighted during the COVID-19 pandemic, demonstrating the threat of pseudoscientific beliefs to public health and the prevention of disease. Teovanović et al. (2020) conducted a study that revealed those who were less likely to participate in guidelines such as hand washing or physical distancing were more likely to believe in pseudoscience practices. Additionally, a study by Desta and Mulugeta (2020) revealed that the spread of pseudoscientific beliefs related to COVID-19 had a negative effect on the containment of COVID-19. Across the world, researchers recognize the importance of understanding the origins of pseudoscientific beliefs. García-Arch et al. (2022) created a validated psychometric tool to measure a range of pseudoscientific beliefs, though this scale was developed and validated in Spain. Our goal is to create a pseudoscience scale focused on specific medical beliefs within a United States sample. This is particularly important as pseudoscience beliefs can vary significantly across cultures. We aim to investigate how pseudoscientific beliefs about health and medicine in the United States correlate with intelligence and critical thinking. We created a survey which was distributed electronically to college students, with a goal of obtaining at least 100 responses across different school levels and other demographic characteristics. We began data collection in fall 2022 and plan to continue throughout winter and spring of 2023. This study will contribute to knowledge about what gaps in logic or critical thinking contribute to acceptance and belief in pseudoscience. We hypothesize that individuals with lower levels of critical thinking and intelligence will indicate higher agreement with pseudoscientific ideas. The analysis will aid us in more effectively targeting people with pseudoscientific beliefs in an effort to reduce the acceptance of pseudoscience.

Abstract Name: **Manifest Space: Creating the future or repeating the past?**

With the rise of the space industry, are we attempting to escape our planet's severe environmental problems in the hopes of scientific advancement, or are we inadvertently accelerating the death of the Earth? As we enter the new age of space exploration and colonization, we are seeing a massive increase in interest in space, a jump in the number of spacecraft launches, and a crucial switch from federal to privatized control regarding the future of space. Although the prospect of colonizing other planets, facilitating a golden age of scientific discovery, and expanding humanity's reach across the stars is enticing, we must consider the ethics and potential environmental impacts of our actions in trying to reach these goals. Throughout my research, I am analyzing questions pertaining to (1) environmental topics such as the difference between existing and alternate rocket fuels and their respective impacts on human health, ecosystems, and climate change, (2) the cluttering of the space environment, and (3) space mining, resource extraction, and the associated environmental concerns. I continue by exploring the concept of space as a global commonality and how our past actions can warn us that we are heading towards a "tragedy of the commons". Furthermore, I am examining how the 16th-century age of imperialism and the associated exploitation of resources could apply to the future of space development and how we can avoid repeating our previous mistakes with Earth. In approaching these topics, I am analyzing scientific journals, emerging space technologies, opinion pieces, and interviewing professors and professionals from different fields regarding their opinions. I am also interpreting various pop culture sources and audience responses from movies such as Don't Look Up and determining how they can influence the future of space exploration and development.

Abstract Name: The Role of the Acyltransferase Gpc1 in Anti-fungal Susceptibility in Candida albicans

Candida albicans is a prevalent fungal pathogen listed among the World Health Organization fungal priority list among the critical priority group (1). Most treatments for C. albicans target aspects of lipid metabolism making membrane synthesis a relevant area of research in the organism. One of the most abundant membrane lipids is the glycerophospholipid, phosphatidylcholine (PC). PC is synthesized by two major biosynthetic pathways. These include the phosphatidylethanolamine (PE) methylation and the CDP-choline (Kennedy) pathways. However, we previously identified a third PC synthesis route, denoted the PC de-acylation reacylation pathway (PC-DRP). PC-DRP begins with the deacylation of PC by phospholipases to form glycerophosphocholine (GPC). GPC is also robustly imported into C. albicans through the Git3 and Git4 in C. albicans. GPC is then acylated by Gpc1 to form lysophosphatidylcholine (LPC), followed by a second acylation by Ale1 to form PC. In these studies, we used growth assays to examine the sensitivity of a strain lacking the committed step in PC-DRP, gpc1Δ/Δ, to antifungal agents. We observed sensitivities to drugs targeting membrane synthesis, including ketoconazole, myriocin, and miltefosine. These results indicate that inhibition of PC-DRP via loss of Gpc1 increases the susceptibility of C. albicans to a variety of membrane perturbations.

Abstract Name: Relationship Between Margin of Stability and Joint Kinematics During Gait in Children with Cerebral Palsy

Cerebral palsy (CP) is a neuromotor disorder characterized by abnormal tone, posture, and movement, causing limitations in physical activities such as walking, or gait. For children with CP, previous research studies have suggested an altered ability to control their stability. Margin of stability (MoS) is a unique, dynamic measure calculated from the center of mass trajectory and is utilized to assess the margin an individual has to maintain stability if a perturbation were introduced. Compared to typically developing children, children with CP exhibit a greater MoS in the lateral direction during gait which may be a compensatory method to keep them from falling. This compensatory method may be associated with the body's orientation, which is reflected by joint kinematics. It is plausible that greater MoS in the lateral direction during gait is related to discrepancies in ankle and knee kinematics. The purpose of this study is to determine if there is a relationship between MoS and ankle and knee kinematics during gait. Kinematic data will be collected through three-dimensional motion analysis during a 5 m gait study using retroreflective markers placed on bony landmarks and motion capture software. It is hypothesized that the greater MoS in the lateral direction during gait in children with CP than typically developing controls is related to ankle and knee joint kinematics, such as joint angles in the frontal and sagittal planes.

Abstract Name: **Physiological linkages in eating disorders via variance in preproglucagon**

The brain plays a crucial role in feeding behaviors through the activation and inhibition of various neural circuits. Properly understanding these mechanisms allows us the ability to create therapies and treatments for diseases relating to feeding and motivation, including obesity related illnesses and various eating disorders. One particular hormone that regulates the mechanisms of feeding is Glucagon-like peptide 1 (GLP-1), a peptide hormone produced by the intestinal cells through the processing of proglucagon. It is known that GLP-1 acts by activating GLP-1 receptors on the pancreas and brain which increases the release of insulin while simultaneously decreasing the release of glucagon, causing a decrease in appetite. Despite its well known function in the pancreas, this phenomenon is still being explored in the brain and is the focus of our study. We performed an anatomical characterization of GCG cells (GLP-1 producing cells) in the nucleus of the solitary tract (NTS) looking at two different cohorts of mice. For one cohort, we used non-transgenic mice and performed fluorescence in situ hybridization for that cohort, and for the other, we crossbred GCGicre mice with L10EGFP mice. We imaged horizontally sliced sections as well as coronal sections of the NTS and then analyzed those cell counts using software that aids in interpreting cell images. Potential sex differences in the distribution of the GCG cells was unknown, therefore this led us to the analysis of the density distribution separated by sex. In our study, we observed no sex differences in the density distribution of GcgNTS cells; however, future studies using this data will be important in understanding the impact GcgNTS cells have on feeding and motivation and what roles they play in advancing current therapies of obesity related illness.

Abstract Name: **Using low-cost sensing technology to assess ambient and indoor air quality in Queens, New York during and after the COVID-19 Pandemic**

Air pollution is a leading cause of death in the U.S. Although ambient air quality improved during the COVID-19 pandemic, indoor air pollution (IAP) remains a concern yet data are seriously lacking. Understanding the role of In respiratory illnesses is critical. Americans generally spend about 90 percent of their daily lives indoors. With no indoor air quality (IAQ) health standards, high IAP levels imply greater health risks among vulnerable groups especially children, the elderly and persons suffering chronic respiratory and cardiovascular diseases. This study utilized the AirBeam2, to measure concentrations of particulate matter with a diameter of 2.5 micrometers (PM2.5) to investigate the differences between indoor and ambient PM2.5 levels in Queens, New York during the COVID-19 pandemic in winter, spring and fall of 2020 at six private homes, and in fall 2022. Meteorological parameters: temperature and relative humidity were monitored simultaneously. IAP levels were more than two times greater than ambient levels. Indoor spaces with little or no ventilation and direct emission sources such as smoke from cooking, particularly in kitchens and basements, resulted in higher PM2.5 levels that momentarily exceeded outdoor levels and those in more ventilated areas. Indoor PM2.5 concentrations were significantly higher than outdoor levels, $p = 0.05$. High ambient PM2.5 levels were attributed to vehicular traffic at street-facing sampling sites. Even under normal conditions, infiltration of PM2.5 through ventilation systems could further degrade IAQ. The identification of PM2.5 sources in this study can be useful in devising control strategies for improvement of IAQ and consequently, the alleviation of respiratory health effects. Further, these findings may be used as a basis for in-house modifications including natural ventilation and the use of air filters to reduce exposures, mitigate future risks, and prevent potential harm to vulnerable residents.

Abstract Name: Lo Shen region of Venus: mapping and interpretation of impressive lava-flow feeder systems with implications for Large Igneous Provinces on Venus and Earth

The Lo Shen region is located on the southern margin of the eastern Ovda Regio (likely an area of ancient continental crust). The Lo Shen name comes from frozen lava rivers that are more than 225 km long.I am using detailed radar from the 1990-1994 NASA Magellan mission to Venus in order to produce a detailed geological map of the Lo Shen region. The research goals are to establish links between subsurface magma (liquid rock) chambers and these channelized lava flows ('lava rivers'). Amazingly, there is no water erosion on Venus because there is no flowing water due to the extreme surface temperatures (450C). In the absence of erosion, the lava sources are recognized by shallow depressions representing surface collapse above an underlying magma chamber. Some depressions are small and sub-circular while others are elongated to irregular in shape. We suggest that the reservoirs with elongated shapes are associated with underlying dykes (sub-vertical cracks filled with magma) while the irregular shapes are sill-like (horizontal pancake-like reservoirs). There are also lines of pits (that appear like sinkholes) and representsurface collapse above dykes.These surface depressions and their channelized flows were emplaced onto a smooth surface, which represents a lava flooding event that suggests flooding of a broad topographic basin. However, the area of lava flooding corresponds to a topographic high (about 140 x 80 km, and about 300-500 m high), which suggests that uplift must have occurred after regional lava flooding. We speculate that this elongated domical uplift was caused by the filling of an underlying sill-like magma reservoir more than 50 km across and 100s meters thick.These features on Venus are analogous to huge volcanic events on Earth called Large Igneous Provinces, which can lead to abreakup of supercontinents and dramatic climate change.

Abstract Name: Geology of the Archean Nonconformity in Michigan and Wisconsin

The Lake Superior region is home to ancient crystalline rocks that are part of the larger Canadian Shield. Dating back to nearly 3 billion years, these Archean rocks are overlain by a much younger sequence of sedimentary rocks of roughly 1.9 billion years from the Paleoproterozoic era. The eroded surface on which this sedimentary sequence was deposited is known as a nonconformity. This nonconformity tells of over a billion years of erosion, and the Paleoproterozoic rocks provide a record of the environment of deposition.Locations, where this nonconformity is exposed, are few and far between, and two locations in Michigan and Wisconsin have been studied for this project. In Republic, Michigan, mud deposited on a solid planar granite surface transformed into amphibolite schist when it was later metamorphosed. In Pence, Wisconsin, granite Archean blocks, angular pebbles, and cobbles, were buried in fine sand and then later metamorphosed and deformed into a fine-grained quartzite-enclosing granite breccia. Regardless of the elusive nature of the nonconformity, our research using petrographic thin sections from the two sites was able to determine that the two locations' basement rock bodies below the contact did not experience chemical weathering, for if it did, metamorphosed saprolite would have formed 'saprock.' Instead, the fragments of granite intermixed with the quartzite are evidence of an environment in which physical weathering dominated over chemical weathering.

Abstract Name: Cas 9

CRISPR/Cas9 gene editing provides researchers with the ability to target virtually any location in a genome for disruption. Since its description in 2012, the system has been modified by labs around the world to carry out functions as diverse as gene insertion and COVID-19 testing. This project's goal is to clone, express, and purify Cas9, the restriction endonuclease enzyme component of the CRISPR/Cas9 system, using a bacterial expression vector. The Cas9 gene will be tagged with a 6-histidine sequence to streamline purification. Using IPTG induction with an inducible lac promoter and a pET expression vector, expression levels can be visualized on an SDS-PAGE gel. Cas9 protein is then purified from cell lysates using a nickel resin. After designing guide RNAs, the enzyme will be tested for activity and accuracy to cleave DNA.

Abstract Name: Cross-priming as a Strategy to Improve Drought Stress Tolerance

Water deficit stress due to heat, drought, and/or salinity is one of the major environmental factors affecting the survival rate and productivity of plants/crops. Seed priming, stress priming, and Cross-stress tolerance(all of which are based on plant stress memory) are promising methods to improve plant/crop tolerance to water deficit stress. Seed priming is when seeds are soaked in water or a solution containing a substance that has the ability to produce improved stress tolerance. Stress priming is when the plant/crop is exposed to a mild form of the stress they will encounter later in their life cycle. Cross-tolerance is when a plant/crop are exposed to a mild form of stress that results in improved tolerance to a different stress that might trigger similar adaptive responses by the plant/crop.Although there is substantial evidence in the literature suggesting the benefit of seed priming or stress priming or cross-stress tolerance to improve water deficit stress tolerance in plants/crops, there is very little evidence of whether seed priming and stress priming together improves stress tolerance, and if so, is there improved stress tolerance compared to seed priming or stress priming alone. The same is true for seed priming and cross-stress tolerance together. In this experiment, Arabidopsis thaliana are seed primed with 10 microM Abscisic Acid (ABA) and exposed to a mild drought or mild salinity stress before being exposed to more severe drought conditions. We anticipate that compared to control samples (no seed priming andno stress/cross-stress priming, no seed priming withstress/cross-stress priming, seed priming but nostress/cross-stress priming), cross-primed samples will demonstrate improved drought stress tolerance via a higher relative water content in the leaves and lower levels of hydrogen peroxide, a common reactive oxidative species that is increased during stress exposure.

Abstract Name: **Using CT scans to create 3D skull puzzles as open access pedagogical tools for anatomy classes.**

As the digitization of museum specimens becomes more widespread and access to affordable 3D printing technologies increases, the use of Computed Tomography (CT) technologies in biological research of anatomical features is well positioned to contribute to the advancement of pedagogical experiences through the creation of physical models for teaching. Such complementary efforts may enhance broader impacts associated with biological research in anatomy by simultaneously boosting the education system with a more hands-on experience for students and providing an alternative to expensive taxidermy and other artificial models. Using an existing dataset of µCT scans of chameleon specimens originally collected to examine the comparative skeletal anatomy of the family, we created a 3D puzzle of the skull of one chameleon specimen to aid in teaching squamate cranial morphology. We then created a 3D puzzle of the skull of a human from a donated scan to aid in teaching human skeletal anatomy. After segmenting all the bones from each respective skull and lower jaw, the individual skeletal elements were 3D printed to create disarticulated skulls that students can learn to reconstruct. The elements were individually dip-dyed to color code the different bones and small magnets were inserted into the printed components to enhance the overall learning experience. We used this 3D puzzle of a human skull in an upper-level anatomy course and surveyed the students about the effectiveness of this physical model in learning the bones of the skull. Following additional refinement, these models will be broadly disseminated to educators worldwide by uploading them to an open-access online database with instructions on preparing the 3D puzzles.

Abstract Name: **"From Doctors to Your Doorstep: A Feminist Analysis of 1970s Reproductive Rights Activism in the Greater Boston Area"**

My project examines feminist activism in the Greater Boston area during the 1970s, focusing on the reproductive rights movement. I define feminism as the social and activist movement toward gender equality. The project aims to understand how reproductive health information shifted from being solely in medical professionals' hands to being readily available to the masses. During this era, many women felt that medical professionals and gynecologists were unsafe and did not respect them. Doctors tended to be straight, male, and white, making it difficult for them to understand the plight of women and thoroughly examine intersectional identities. There was little access to information about female autonomy, and illiteracy surrounding women's bodies was rampant. After the 1970s, there was an explosion of information and increased public dialogue surrounding reproductive rights. I examined how these shifts occurred and how activism developed to broaden access to reproductive health care during this period.I used a mix of archival and oral history sources in my project. I conducted archival research at the Snell Library at Northeastern and The History Project in Boston. I examined posters, fliers, and meeting minutes from various feminist organizations. I also completed nine oral history interviews with various feminist activists from this period. My narrators were members of organizations such as the Cambridge Women's Center, Gay Community News, Bread and Roses, and the Women's Community Health Center.During my research, I had a few significant findings. During the reproductive rights movement, activism did not solely focus on abortion access. Instead, they used a lens of reproductive justice that included discussions surrounding motherhood, sexual assault, homophobia, and disability. Feminists during this time also engaged in coalition building that allowed them to get their message to a broader audience. It was coalition building that promoted the shift of information.

Abstract Name: **Investigating microbiomes of colored nectars: Characterization of isolate growth and inter-species interactions**

Pollination is the transfer of pollen from one flower to another that leads to the formation of fruits and seeds. Pollinators are insects or animals that transfer the pollen amongst flowers. Nectar is a sugar-rich reward that plants produce to attract pollinators. It is a complex liquid that contains sugars, proteins, amino acids, lipids, and various other specialized chemicals to help pollinator health. Recent studies have unlocked new understandings of the microbiomes of nectar. There have been multiple microbial species reported to exclusively inhabit certain nectars. Their roles in pollinator health and outcompeting other harmful plant pathogens are an active area of study. We focused our research on the microbes in two colored nectar producing species- Nesocodon mauritianus and Melianthus sp. Colored nectar is rare in nature and attracts specialized pollinators such as birds, rodents and lizards by providing visual cues. Recent studies have revealed novel pigments mediating colors such as red and black in these species. We investigated the microbes in the nectar of these species by serial dilutions of the nectars on various microbial media, ranging from rich (Tryptic Soy Agar and Yeast Mannitol Agar) to minimal (Reasoner's 2A Agar). Species identity was confirmed by DNA extraction of the bacterial colonies and sequencing of the amplified 16S rRNA gene sequence and alignments. We consistently found at least four different culturable microbial species growing in the red nectar of Nesocodon mauritianus and ten microbial species in the nectar from Melianthus sp. Ongoing investigations include testing the interactions between these species and other known nectar microbe generalists such as Metschnikowia reukaufii. We are also testing for the antimicrobial activities of these nectars. This will hopefully lead to more sustainable ways to prevent plant diseases, especially the ones where pathogens gain entry via the flowers.

Abstract Name: **Mercury Exposure in Migrating and Breeding Wood Ducks in Central Wisconsin**

Wood ducks (Aix sponsa) are an emblematic waterfowl species that have faced trials and tribulations such as habitat loss and overharvest, resulting in low population numbers in the mid-1800s to early 1900s. Successful conservation and management practices have resulted in population increases across their range, yet there has been a recent shift in these trends in Wisconsin, and wood duck abundance has become annually variable. Exposure to environmental contaminants is a rising concern for wood ducks due to their use of forested wetlands and diet ofaquatic invertebrates. Mercury is a widespread environmental contaminant increasing globally because of human activity. Mercury has been found to magnify through food webs, resulting in higher concentrations with increasing trophic positions. While there is growing concern about mercury exposure in wetland birds due to its bioavailability and toxicity in aquatic environments, little is known about mercury exposure in wood ducks in Wisconsin. Mercury exposure can have negative health effects on waterfowl such as immune suppression and neurological changes. The objectives of this study are to 1) examine mercury exposure in wood ducks that use wetlands in Wisconsin and 2) investigate factors influencing feather and blood mercury concentrations in wood ducks. We captured 49 wood ducks in central Wisconsin utilizing swim-in traps, walk-in traps, cannon nets, and nest box checks. After capture, we collected blood samples in addition to breast, flank, and axillary feathers from birds for mercury analysis, and took morphometric measurements. We hypothesize that blood and feather samples collected in this study will have mercury concentrations associated with negative health effects on wood ducks, specifically high parasitic load, high white blood cell count, and poor body condition, measured in a concurrent study. This study aims to fill a knowledge gap and inform wildlife managers of mercury exposure in wood ducks.

Abstract Name: An Investigation of Muscle Thumb-tip Movement Patterns: Application to Restoring Lateral Pinch Grasp Following Tetraplegia

It is believed that 65-75% of the persons diagnosed with tetraplegia would benefit from reconstructive surgery to regain the ability to perform activities of daily living. This surgery would improve their functional independence and reduce the annual assistive care costs ($80 million) in the US. Tendon transfer surgery, a reconstructive surgical procedure involving surgical transfer of a healthy muscle–such as the pronator teres (PT) or the brachioradialis (Br) muscle–to the paralyzed flexor pollicis longus (FPL) muscle of the thumb, is commonly performed to restore lateral pinch grasp. Functional outcomes, however, have been mixed. Previous simulation studies in our lab have shown that attaching Br or PT to multiple thumb muscles, rather than to just FPL, could improve pinch force characteristics. In particular, we found 64 such muscle combinations (13 muscle pairs and 51 muscle triplets). The goal of this present work was to determine whether these muscle combinations could generate natural lateral pinch movement. For this purpose, we used a Jacobian-based framework to develop a planar, 3-DOF model of the thumb consisting of 3 hinge joints and 3 bones. Execution of the model determined whether individual muscles and muscle combinations could begin to move the thumb from an extended posture to the index finger in a natural way. We found that only muscle combinations, and not individual muscles, have the capacity for the desired movement. Moreover, muscle combinations should consist of both a flexor and an extensor, and one of those muscles should be the FPL. Taken together, these model findings reduce the possible 64 muscle combinations from our previous study to 10. Further computational modeling and in-situ cadaveric simulation work will further refine these muscle combinations by considering natural lateral pinch movement in 3D and throughout the full range of grasp motion.

Abstract Name: Anti Indian Propaganda and American Expansionism in the 18th and 19th Century

This research examines how racist anti-Indigenous propaganda leading up to, during, and after the Revolutionary War contributed to the mass land dispossession of Indigenous peoples in the nineteenth century. I examined newspaper databases, most prominently Americas Historical Newspapers, to find examples of anti-Indigenous imagery and articles that cultivated an anti-Indigenous sentiment among revolutionary era readers. Secondary resources such as Robert Parkinson's work titled "The Common Cause" acted as a guide for finding useful authors, newspaper publications, and dates for the primary research. Prior to the revolution, the thirteen colonies had little to do with one another and all placed negative labels on each other. Colonial leaders knew that they could not win a war for independence if the colonies could not unite. Revolutionary leaders built a common cause among colonists by stoking their fear and hatred of Indigenous peoples who inhabited the land. Capitalizing on this fear, elite and wealthy colonists printed mass propaganda that portrayed Native Americans as a savage British ally who would threaten the safety of the colonies. Such imagery was widely utilized by printing newspapers full of misinformation and manipulation tactics. Following Independence, the leaders of the new nation had an opportunity to end the racist lies that they had used as a tool for victory and seek peace with their Indigenous neighbors. Instead, they doubled down on this propaganda and ensured that new generations of Americans would grow up being indoctrinated by the same racist rhetoric that was used to win the war. The Revolutionary War propaganda that villainized Indigenous peoples as violent and savage enemies that helped win American Independence was strategically and intentionally upheld to play a role in justifying American expansion and land theft in the nineteenth century.

Abstract Name: **Materials Characterization of Foam for Insulative Use to Optimize Tumor Ablations**

Tumor ablation is a minimally invasive surgical procedure in which a needle-like probe is injected to apply extreme heat or cold to solid tumors in areas such as the liver, kidneys, and lungs. Ablation is a common and highly effective cancer treatment method; however, oftentimes, healthy surrounding tissue is damaged in the process. Saline or carbon dioxide is currently used to insulate healthy tissue, but these tend to sink or rise in the body, respectively, and lose insulative contact. A biocompatible foam has been created using FDA-approved materials and promises to offer better stability and stiffness in order to maintain optimal contact with target tissues. Detailed lab studies of the foams have been conducted using rheology and pendant drop tensiometry. Characterization of these properties is valuable in assessing the foaming capabilities of the materials used and quantifying the physical behaviors of the foam. Rheology was used to determine the viscosity and viscoelasticity of the solutions and foams, and pendant drop tensiometry was used to measure the solution's surface tension and interfacial tension. The data collected from these methods was used to optimize foam stability such that it would be a more ideal insulation method for the tumor ablation procedure. Material characterization of the foam and data on its insulative properties is necessary for publication of the results and IRB approval for human trials. The potential applications of the foam could reduce side effects, complications, and hospitalization for patients following tumor ablations and improve an already effective cancer treatment.

Smith, Ella

Institution: *GA - Kennesaw State University*

Discipline: Communication/Journalism

Emily Scheinfeld,
Ella Smith

Abstract Name: **Does End-of-Life Communication With Parents Impact Self-Esteem and Relational Satisfaction?**

According to previous studies, death is taboo, and families usually underestimate the dire need to talk about final wishes and wills, among other end-of-life (EoL) related issues (Nickels; Tenzek, 2022; Omilion-Hodges; Swords, 2017, Prince-Paul; DiFranco, 2017). Having EoL conversations allows final wishes to be better satisfied, alleviates needless suffering, and can allow an opportunity for a good death (Tenzek; Depner, 2017; Zadeh et al., 2018). Healthy EoL communication can also impact outcomes for family members and caregivers alike. For example, personal growth allows family members to say goodbye, connect, show love, and explore their own identities (Generous; Keeley, 2022; Keeley, 2007; Keeley; Generous, 2017; Shames; Barton, 2003; Yingling; Keeley, 2007). Additionally, EoL conversations can reduce levels of guilt (Scheinfeld; Lake, 2019) and can contribute to personal growth (Generous; Keeley, 2022) and coping mechanisms following the death of a parent (Generous; Keeley, 2021). Therefore, the aim of this study is to explore the role of final conversations in a survivor's identity post-parental death. Data is currently being collected via convenience snowball sampling within a large southwestern city and university community. Participants will complete an anonymous online survey using quantitative measures to assess the independent and dependent variables and to collect demographic information. From the results, we hope to show that having a final conversation that covers the survivor's identity is not only important but also leads to higher levels of self-esteem and relational satisfaction. Understanding the role of final conversations in a good death experience for survivors advances the field of end-of-life communication. Moreover, these results may help healthcare practitioners in supporting families experiencing the end of life or their loved ones and help guide them through the bereavement process.

Abstract Name: **Coping with a Partner's Death due to COVID-19: The Impact of Coping Styles on Posttraumatic Growth and Complicated Grief**

A loved one's unexpected death from COVID-19 relates to higher levels of prolonged grief (Eisma et al., 2021). Prior to COVID-19, unexpected loss research suggests that avoidant coping (e.g., denial) significantly predicts complicated grief (Schnider et al., 2007), while problem-focused (e.g., positive reframing) and emotion-focused (e.g., support) coping predict posttraumatic growth (Fisher et al., 2020). Our study examined what coping styles predict complicated grief and posttraumatic growth for individuals whose partner unexpectedly died from COVID-19.Participants (N=37; 36 females; Mage=52.57 years) completed an online survey (MTimeSincePartnerDeath=9.74 months). Measures included Inventory of Complicated Grief (Prigerson et al.,1995; α=0.89), Post-Traumatic Growth Inventory (Tedeschi; Calhoun, 1996; α=0.95), and Brief-COPE (Carver, 1997; α=0.74), comprised of problem-focused, emotion-focused, and avoidant coping facets. Table 2 presents target variable correlations.Analyses included simple and multiple linear regressions controlling for age, education level, and time since death. Specific to avoidant coping, denial (β=7.71,p=.001) significantly predicted complicated grief (R2=0.40, F(1,31)=24.29, p=.001). Specific to emotion-focused coping, acceptance (β=-5.24, p=.008) and self-blame (β=5.23, p=.009) significantly predicted complicated grief (R2=0.39, F(2,30)=12.01,p=.001). Specific to problem-focused coping, active coping (β=12.41, p=.001) and positive reframing (β=10.29, p=0.006) significantly predicted posttraumatic growth (R2=0.58, F(2,30)=20.72, p=.001). Specific to emotion-focused coping, acceptance (β=13.02, p=.001) and religion (β=8.60, p=.005) significantly predicted posttraumatic growth (R2=0.60, F(2,30)=21.89, p=.001). Findings support previous research suggesting problem-focused coping and religion lead to grief management and posttraumatic growth (Fisher et al., 2020; Zara, 2020) and avoidant coping predicts complicated grief (Schnider et al., 2007). Future research shouldfurther examineemotion-focused coping facets, as they predicted both outcome variables in this sample.

Abstract Name: **Kinetic-Energy Harvesting Floor Tiles**

Today, over half the world's population lives in urban environments. Each day, hundreds of millions of pedestrians walk through city centers en route to work, school, or their respective homes. Walking is a repetitive action, and thus each step is seen as an opportunity to contribute to the world's energy needs. This project seeks to design and manufacture an energy-harvesting floor tile that converts the kinetic energy of a human step into electricity efficiently and cost-effectively while maintaining an easily implemented product. While similar tiles exist, none of them can combine all of these benefits. Our unique design combines electromagnetic induction with an effective linkage of gears and a flywheelto cause continuous rotation of the DC motor shaft when stepped upon, which consequently leads to the harvesting of energy. This generated electricity may be stored in a capacitor or connected to a device for immediate consumption of the energy, depending on the needs of the client. The tileproduced 10.2 W/step cost USD 181.38, and it was easy to implement. Our approach led to our design outperforming other tiles in the sector by a factor of 1.4-24in terms of cost per unit of power and was cheaper to manufacture than other tiles. The ultimate purpose of this research is to pursue and discover alternative approaches to the energy-harvesting tile and create a more viable solution for working towards a more sustainable world.

Abstract Name: **Polycyclic Aromatic Hydrocarbons and Their Analysis Using GC/MS**

Polyaromatic hydrocarbons (PAHs) are a family of over 100 different chemicals formed during the incomplete combustion of substances like coal, oil, natural gas, garbage, tobacco, and charbroil meat (Rios et al., 2007). These PAHs are toxic organic contaminants composed of two or more benzene rings. USEPA has classified 18 of these compounds as priority pollutants based on their toxicity to human health. There are two main origins of PAHs, petrogenic (from petroleum) and pyrogenic (incomplete combustion). PAHs are often introduced into waterways by oil spills and urban runoff and are semipersistent toxic compounds. The main goals of this research were to investigate PAH concentrations from samples collected after the Husky Oil Refinery event in April 2018 and compare these concentrations with historic PAH concentrations in the same study area. The second goal was to change the He gas to H2 gas in the Gas Chromatography / Mass Spectroscopy (GC/MS) analytical instrument. Calibration of the GC/MS was completed using standards of known percent of concentration recovery. Experimental samples were extracted by liquid-liquid extraction using hexane as a solvent. These samples were tested before the analysis of the unique samples from 2018. The average percent recovery of standards was 84% using the H2 gas. The change in gas type was evaluated to obtain the correct signal from the GC/MS analytical instrument.

Abstract Name: **Observational Astronomy in Contemporary Art: How the Stars Inspire Us**

As humans, we have admired and observed the night sky and astronomical events throughout history. With the inventions of the Hubble and Webb Telescopes, we have captured spectacular landscapes throughout the night sky and deep within the expanding space. We have also been able to capture many amazing and spectacular astronomical discoveries using photographs. However, there are not a lot of studies being done on the significance of observational astronomy in contemporary art, especially with how the two relate. Therefore, in this study I will be focusing on the works done by the artists and astronomers Chesley Bonestell, Chris Impey, and Heather Green. With those artists and astronomers in mind, I will first be exploring what connects astronomy to art. As well as, whether or not observational astronomy can be considered an art. Why do we find astronomy interesting? What inspires us to capture the night sky or astronomical events? Have any artists helped with astronomical pursuits? Were there any astronomical pursuits that have inspired any artists? Lastly, how has art and science worked together through STEAM? By using art historical research and studies on astronomy, this study demonstrates that the close relationship between art and science broadened the notion of contemporary art and brought knowledge of observational astronomy to a wide audience.

Abstract Name: **Exploring the Disorder in von Hippel-Lindau Tumor Suppressor Protein by Molecular Dynamics Simulations**

The von Hippel-Lindau tumor suppressor protein is known to cause tumors in multiple vital human organs such as the spinal cord, retina, and varying blood vessels within the brain. It belongs to the class of intrinsically disordered proteins, which lack stable secondary or tertiary structures and their flexibility allows them to engage in a wide variety of interactions with other molecules making them biologically efficient. The folding of these proteins is still a mystery, and the conformational dynamics have remained elusive due to the absence of reliable three-dimensional structure. A simulated study of structural dynamics in the presence and absence of crowders could provide valuable insights of the conformational flexibility of the protein. The structure of the disordered protein was taken from Alphafold database - the database was created by artificial intelligence-aided protein structure solving. Five different protein systems were built: one in only water, one in ethylene glycol, and three more in the presence of varying sized polyethylene glycol ($C_{2n}H_{4n+2}O_{n+1}$) crowders (molecular weights ~ 600, 8k, and 20 k). A 50 ns molecular dynamics simulation was performed, and the data was used for further analysis. The effect of these crowders on the conformational dynamics and energetics was studied in detail using statistical tools. Results obtained in these studies will be presented.

Abstract Name: **Monks, Animals, and Discernment from the Third to Eleventh Centuries**

Friendship with animals in the lives of desert hermits are portrayed in two prolific texts of Western Christianity: John Cassian's Conferences, written in 420, and Sulpicius Severus' Dialogues, written around the same time. Cassian is important for establishing rules of living for monks in the early days of monasticism, and Severus is also known for writing about desert monks and the life of Saint Martin of Tours. The human-animal connections in their writings are paradoxical; they write about the rigorous ascetic practices of desert monks, yet these same monks learn from their animal companions whose instinctual natures are the opposite of their lifestyle. A parallel literary tradition, the medieval bestiary, can help unravel this paradox. The medieval bestiary is a text which describes traits of animals, and sometimes, plants and stones, writing their natural characteristics as an allegory for living virtuously and avoiding vice. The first bestiaries originated in the third century, but the tradition grew in the Middle Ages. I argue that, in one bestiary text, the eleventh century Physiologus Theobaldi, the descriptions of animals educate readers on choosing good habits and relationships. Examining this bestiary in concert with monk-animal friendships in Cassian and Severus highlights the importance of discretio, or discernment, a virtue which allows one to choose the right path or course of action throughout one's life. Not merely fantastical, individuated portrayals of animals,I contend that the Physiologus Theobaldi invites medieval readers into a worldview in which following the right path is not a matter of rigid rule following, but one of case-by-case, animal-by-animal discernment. Ultimately, an appreciation for animals' natural traits does not mean shunning rationality; rather, it is indispensable to the medieval Christian's life choices that lead where one needs to go to become who one is called to be.

Abstract Name: **The Non-native Australian Pine (Casuarina equisetifolia) does not Appear to Affect Plant Species Diversity**

Australian pine (Casuarina equisetifolia) is an invasive plant species in many tropical and subtropical environments. This species is reported to accelerate erosion and limit native plant diversity. Therefore, we were interested in the plant diversity under the canopy of pines on San Salvador Island, Bahamas. We hypothesized that there would be a relationship between plant diversity and association with pine groupings. We predicted that Australian pine would reduce plant diversity under its canopy. Data was collected between 9 – 11 March 2022. San Salvador is a small island, so we divided it into six zones and randomly selected two pine trees in each zone. We paired each experimental plot with control plots (a plot with no Australian pine) by walking in a randomly selected direction away from the pine plot and collecting the same type of data at that plot. Plant species were recorded under pine canopy and in the similar sized control plots. Data analysis suggests no significant reduction of species diversity under the canopy of the pine in comparison to the control locations ($\chi 2=0.09$, df=1, p=0.76). This was a surprising outcome and could be a function of variable soil nutrients and a lack of allelopathy by the pine (which has been reported in earlier documents). Future studies should also consider nutrient content of soil, amount of solar influx, and distance to salty or saline water. This study can provide further insight into the effects of Australian pine as an invasive species as well as invasive plant species in general.

Abstract Name: **Perception of Information and Source Reliability B**

The term misinformation is being used so frequently now that it has become an annoying word to represent almost nothing. The perception of whether information is valid seems to be very dependent on who is giving the information. There are many different factors that play a role in deciding whether a source is credible or not. In the US today we are seeing that individuals are siding with news sources that have a similar political ideology when deciding what is fact and what is misinformation. The purpose of this research is to determine what factors correlate with someone'ssuseptiblity to misleading information. The personal characteristincs being studied include racial/ethnic background of the messenger and receiver, political ideology of the messenger and receiver, news media sourcepreference, expertise level of the messenger and receiver, and percieved trustworthiness of the messenger. The study will use information about controversial topics given by various sources and determine the level of confidence the subjects have about the legitimacy of the information. Demographics regarding the subjects will be collected. A correlational analysis will be made between traits of the message sender and receiver and the rating of the source information. Data analysis will be completed in the spring semester of 2023.

Abstract Name: **Country-Level Factors Associated with International COVID-19 Vaccine Uptake**

In March 2020, the World Health Organization declared the COVID-19 pandemic. Since then, healthcare professionals around the world have worked to develop vaccines to alleviate symptoms and slow the spread of the disease. Although multiple vaccines have been approved for use, much of the world's population has yet to be inoculated because of inequitable distribution of the vaccines. Of particular concern is the rate of uptake in low-income countries, which have experienced the highest morbidity and mortality rates during the pandemic but have the lowest vaccination rates. The current study aims to investigate what factors at a country-level are related to the uptake of these COVID-19 vaccines internationally. To explore this research question, we first aligned and merged publicly available data from multiple online sources, including Our World in Data, the CIA World Factbook, and the World Bank. We are using longitudinal mixed-effects modeling to analyzevaccine uptakeover time. Our models include country-level factors such as GDP per capita, income group, geographical region, and maternal mortality rate, among others, as potential explanatory variables with vaccine uptake as measured by percentage of the country's population that has received at least one dose of a COVID-19 vaccine as the response variable. Preliminary results indicate that income group, healthcare spending, GDP per capita, and life expectancy are positively associated with the percentage of a country's population that has received at least one vaccine dose, while unemployment rate, child mortality rate, and maternal mortality rate are negatively associated with the percentage of the population having received at least one dose. Moving forward, we will continue to fit more complex models that investigate associations among multiple variables simultaneously.

Abstract Name: **Synchronizing 120 Cameras and the One-Client-Many-Server Architecture of the PARSEC Photogrammetry Rig**

The PARSEC project sought to construct a rig of connected cameras and develop software to maintain and control them for the purposes of photogrammetry. The final rig consists of 120 Canon cameras all surrounding and pointing at a single target. The cameras are each connected to one of four computers and an ESPER trigger box. They are controlled by a program we developed using a JavaScript wrapper of Canon's EDSDK. To create a model of the target all cameras are fired via their trigger boxes and the images are sent through the computers to be saved in a single network storage for processing through specialized photogrammetry software. The "Canon Camera Control Client" we developed utilizes a few techniques to minimize the hindrance to users while managing the large amount of processing required to control so many cameras. To split up processing, the system uses a nontraditional architecture with a single client running many servers. Each of the four computers on the rig run one instance of our server side program and control only a quarter of the cameras, but all the servers are synchronized and controlled from a single client running on our primary workstation. When a task needs to be run on all cameras, the client sends instructions for a bulk task to each server via HTTP. However, large tasks like image downloads can take too long, causing the HTTP request to timeout while awaiting a response. For this reasonwe also use socket.io to subscribe the client to later messages from the server. This waythe HTTP can resolve instantly indicating that the task was started, and the client will wait for a later socket message to confirm the final results. These techniques allowed for much faster task processing and smoother user experience while controlling the rig.

Abstract Name: **Quantifying organic phases in coral skeletons at the nanoscale**

Nanoscale mineral structures of coral are not well understood. When corals build their skeletons, they are composed of nanoscale crystalline structures. It is known that coral skeletons are affected by ocean acidification and climate change at the macroscale. However, understanding how the coral skeleton-building process functions at the nanoscale would allow for better modeling and prediction of how coral might fare under varying ocean conditions and climate changes. Specific isotopes in coral skeletons can mark the organic or mineral parts of the skeletons, and thus can be used as indicators of different phases in the coral skeletons. Our goal is to statistically investigate quantitative relationships that exist between different organic and mineral associated isotopes in coral skeletons. Multiple corals were lab-grown under various controlled conditions at St. Olaf College, and they were analyzed at the nanoscale by a mass spectrometer to extract concentration data for specific isotopes present throughout the skeletons. We use Pearson correlation to measure the strength of the relationship across coral isotopes and Mander's coefficient to measure co-occurrence. Co-ocurrence looks at the high concentration clusters of isotopes across isotope pairs. Knowing the quantitative co-occurrence of isotope pairs in the coral skeletons helps in understanding the spatial distribution of organic molecules within the coral skeleton, which in turn can help us better understand the growth process of the coral skeleton itself.

Abstract Name: **Illuminate cellular organelles via fluorescence microscopy**

An ability to interpret the inner workings of cellular machinery requires an advanced knowledge of subcellular architecture. The goal of my research is to illuminate cellular organelles within mouse macrophage cells using fluorescence microscopy. Organelles are targeted with different reagents utilizing several fluorophores. For example, green fluorescent protein (GFP), Texas Red, and4′,6-diamidino-2-phenylindole (DAPI)can be used to examine different regions of a cell. Fluorescent microscopes produce stacked images of these fluorophores revealing their internal organization. Once organelle localization is established,fluorescently tagged proteins can expand analyses to other functions like protein trafficking and protein-protein interactions.Advanced staining techniques are built upon a foundation of cell culture skills. Sterile technique while handling cells, media preparation, cell passaging, and cell counting using a hemocytometer, are all essential techniques for cell-based research. This project builds on these skills to produce illuminating fluorescent images of the cellular landscape.

Abstract Name: **Site-Selective Nickel-Catalyzed C-H Nitration of 8-Amidoquinolines**

C-H functionalization reactions provide greater efficiency than many traditional methods of synthesizing compounds. These reactions are often capable of producing only one isomer or a small number of isomers in cases where traditional methods may have produced many isomers. Therefore, C-H functionalization reactions are essential to pharmaceutical engineering, agricultural chemistry, and materials science. C-H functionalization reactions also provide the possibility of limiting the amount of waste that is associated with the synthesis of compounds of vital importance to society. Previously, noble metals like palladium were primarily used by synthetic chemists due to the versatility of palladium as a catalyst for C-H functionalizations. Because palladium is rare and expensive, much recent focus has turned toward first-row transition metals. One such metal is nickel which is of interest because of its relative abundance and low cost compared to many noble metals such as rhodium, ruthenium, and palladium. Site-selective C-H functionalization reactions are often difficult to accomplish because of the possibility of functionalizing undesired C-H bonds when many are present within a molecule. In the case of 8-amidoquinolines, there are at least 6 C-H bonds that are open to functionalization; however, the nickel-catalyzed C-H functionalization reaction described in this poster only produces two isomers: 5-nitro-8-benzamidoquinoline (71% yield) and 7-nitro-8-benzamidoquinoline (20% yield). This poster will describe the development of this nickel-catalyzed C-H nitration reaction of 8-(N-quinolinyl)amides, as well as the selectivity observed in this reaction and the substrate scope of the reaction.

Abstract Name: **A green chemistry project: catalytic reactions in supercritical carbon dioxide**

Green chemistry is a development and practice of environmentally friendly and safe ways to carry out chemical processes. “Greening” of the chemical industry can be achieved by adopting new alternative methods with less toxic materials involved, less wastes produced, less energy required, and altogether safe to humans and environment. One of the big challenges in the current chemical industry is the use of volatile organic solvents. Solvents are used to mix multiple reagents to react, and when the reaction is over, the solvent is removed by evaporation. This convenience comes with a price: the vapor easily escapes to the environment and causes air pollution. Furthermore, most volatile organic solvents are either flammable or toxic, or both, and is a hazard to workers. Supercritical carbon dioxide (scCO2) is a possible environmentally benign alternative to traditional organic solvents. ScCO2 is abundant in nature, non-toxic, and a renewable resource, unlike common organic solvents, which are mostly produced from non-renewable petroleum. CO2 is gas at a regular temperature and pressure, and a solid at a low temperature below -77 degrees Celsius (known as dry ice). When CO2 is placed under high pressure (1071 psi) and a moderate temperature above 31 degrees Celsius, it becomes a supercritical fluid. Supercritical fluid is dense like a liquid and can dissolve solutes, but it is also like a gas with low viscosity, which makes solutes move fast and collide to react efficiently. We are testing scCO2 as a reaction solvent for chemical reactions involving different types of catalysts: zeolites, immobilized enzymes, and homogeneous transition metal catalysts. We are examining whether the reactions catalyzed by these catalysts are as efficient in scCO2 as in traditional volatile organic solvents, or better, and whether scCO2 has effects on the selectivity of the reactions.

Abstract Name: **Physiological Changes in Dienococcus aquaticus During Long-Term Stationary Phase Under Carbon Source Availability Stress**

There is a complicated interaction between a bacterium and its environment driving adaptation. Usually, bacterial physiology is studied during the exponential phase, but investigations during the long-term stationary phase are not as well understood. Here, we followed two strains of Deinococcus aquaticus in the long-term stationary phase in low and high-nutrient environments. The evolutionary trajectory was assessed through surveillance of cell viability, colony morphology, genomic content, and protein content over 54 days at three time points. We predicted that nutrient depletion and waste accumulation in the flask environment would result in phenotypic variation. Interestingly, there was an environmental shift toward a basic pH. Despite the shift in pH, cultures remained viable after 54 days. Differences among strains were observed in generation time, pigmentation, and colony morphology, among other phenotypic and metabolic characteristics. Divergence in extracellular protease activity was also observed throughout the study. Significant variation between samples equally subjected to the same growth conditions suggested that D. aquaticusis capable of short-term evolution under resource-scarce conditions.Our findings suggest that further research to evaluate variation in proteins as a carbon source is warranted.

Abstract Name: **Student Organizations as a Means to Effectively Develop Safety Culture Within Undergraduate Chemistry**

Safety education for college-level chemistry labs can be adequate for minor incidents of broken glass and small spills, but the chemical industry and graduate programs are often under the scrutiny of environmental health and safety departments that have far more stringent requirements than an average undergraduate student will encounter. Students who graduate with a bachelor's in chemistry often find themselves with a job where chemical hygiene is practiced at a level they aren't used to. Considering the professional and personal implications that poor adherence to chemical safety can have, more could be done at the undergraduate level to develop the skills and mindset associated with chemical safety. The Chemistry Student Safety Team (CSST) is a student-led, mindset-focused organization working to foster a safety culture at UWEC. The CSST is mentored by UWEC faculty and the UMN-Twin Cities Joint Safety Team (JST). The CSST uses safety demonstrations, awareness campaigns, PPE sales, and safety themed merchandise to promote safety culture. To track attitudes in the UWEC department of chemistry, the CSST uses an annual safety survey along with a system to report near miss incidents anonymously. Student safety organizations at an undergraduate level are an innovative way to promote safety-culture through peer education. With faculty support, student-led safety organizations such as the CSST can be an integral part of disseminating safety information to other students within undergraduate chemistry programs. Involving students in education and safety initiatives at an undergraduate level can lead to more effective researchers, more productive employees, lower organizational costs, and a more safe and equitable learning environment.

Abstract Name: **The Excellence Capsule (NExT)**

Transformational leadership is a leadership style that can inform our high-impact educational practices by serving as a better capacity builder for students. Inspiring positive changes in those who follow, transformational leaders are generally energetic, enthusiastic, and passionate. Not only are these leaders concerned and involved in the process, but they are also focused on helping every member of the group succeed. The Nonprofit Excellence and Transformation (NExT) Program makes for a great capacity-building opportunity by focusing on the progression of professional development. We hypothesize that the NExT program serves as an excellence capsule not only for the non-profit organizations that they partner with but for the student by expanding their knowledge, professional skills, and cultural awareness, through a gradual process that prepares them for their next step in the real world.

Abstract Name: **Utilizing Machine Learning algorithms trained on Recent Music-Listening Activity in Predicting Big Five Personality Traits: A Novel On-going Investigation**

Music has been important to everyday life since long before modern civilization and has been a subject of study for many years. It has been known to be a positive predictor of personality traits due to the individuality of personal preference. These personality metrics are typically evaluated using a Big 5 trait inventory that measures personality into 5 categories: Openness, Conscientiousness, Extraversion, Agreeableness, and Neuroticism. The study will attempt to assess the prediction quality of an individual's Big Five personality traits from a week worth of recent participant music listening activity from the Spotify Application Programming Interface using machine learning (ML). The created dataset will allow for correlating each of the 5 Ten Item Personality Inventory dimensions with music genres, artists, year, beats per minute, energy, danceability, loudness, length, acoustic, popularity, and other features in a vector. The dataset will be standardized and used to train on ML models such as Random Forest, Decision Tree, K-Nearest Neighbors, Logistic Regression, Support Vector Machine, etc. Prediction accuracy will be compared to previous works. Metrics include accuracy, FPR, TPR, and ROC/AUC scores. Both regression (continuous numeric value) and classification (Likert scale) will be used. A full literature review showed this is the first study to use both Spotify API data, rather than self-reported music preference, and ML classification, rather than traditional statistical tests and regression models, to predict the personality of a college student demographic. Applications of this study include custom advertisement recommendations and music therapy. Approval has been granted to administer the survey by Irvine Valley College's Institutional Review Board.

Abstract Name: **Patient Satisfaction for Suicide Care in the Emergency Department**

Self-inflicted injuries continue to be major public health concerns in the United States with 312,000 related emergency department visits in 2018 (CDC, 2022). Patients with self-inflicted injuries often report to the emergency department to seek help, where staff must accurately assess the patient's lethality and manage their care. Admitted patients for self-inflicted injuries present variation in satisfaction across departments. Satisfaction is commonly rated lower in the emergency department compared to other units where they may have received care. (Hutchison, Brian et al., 2003). Patients who receive poor care during this time are not only more likely to report lower satisfaction but also may leave with an increased level of risk. The purpose of this study is to compare responses on the Hospital Consumer Assessment of Healthcare Providers and Systems (HCAHPS) of patients visiting the emergency department with self-inflicted injuries to patients visiting the emergency department without self-inflicted injuries. Permission to access the deidentified data from patients presenting to a local hospital emergency department between January 2021-December 2022 has been granted and we are awaiting the data. Continuous satisfaction variables will be analyzed using independent sample t-tests and Chi-Square analyses for Categorical Data. We expect patients who visit the emergency department with self-inflicted injuries to report less satisfaction on the HCAHPS than patients who visit the emergency department with other injuries. Implications of the results will be presented and shared with the selected hospital emergency department to guide care quality improvements.

Abstract Name: **Breaking the Walls: Mapping the Islamic State's Use of Recruitment by Force**

This project analyzes the impact of Islamic State (IS) recruitment on vulnerable Syrian communities. Jihadi groups frequently use prison breaks and attacks on camps for internally displaced persons (IDPs) to free detained fighters and recruit new members en masse. The Islamic State's use of the tactic I refer to as 'recruitment by force' has been widely documented in open-source media and news reporting, but understudied in an academic context. Recent major attacks include the battle at Al-Hasakah prison from January 20-30, 2022, that freed thousands of IS prisoners(Seldin and Civiroglu 2022), the attack on Kuje Prison in Nigeria that freed over 900 inmates(Adetayo 2022), and the attempted suicide attack on al-Hol on September 22, 2022(Liebermann and Starr 2022). Since the IS's defeat at Baghouz in 2019, the group has been shifting its operational focus from the Middle East to sub-Saharan Africa, meaning that a solid understanding of the ways in which the group acquires new recruits by force is key to maintaining robust counterterrorism capabilities (Bacon, Doctor, and Warner 2022). This work examines how the Islamic State's use of prison breaks has changed diachronically and geographically since October 2006. This research aims to map the IS's attacks on prisons, detention centers, and IDP camps over the past 16 years and analyze how the group targets vulnerable communities to recruit in larger numbers. In this case study, I will: (1) use spatial analysis techniques to identify trends in attack distribution, (2) use discourse analysis to analyze the way the Islamic State talks about targeting specific locations in its primary source material, and (3) use quantitative analysis to identify new relationships between the project's original dataset and existing data on Islamic State attacks and displaced Syrian communities.

Abstract Name: **Differences in DNA Damage due to Reactive Oxygen Species in Hybrid Lizards**

Hybridization can occur between some species but may lead to reduced fitness in hybrids. Reduced fitness may result from decreased mitochondrial function in the hybrid offspring. Analysis of mitochondrial function found that hybrids of the lizards Urosaurus graciosus and Urosaurus ornatus have increased ATP production rates. This can have negative effects because of increased reactive oxygen species (ROS) production. Hybrid lizards appear to maintain reproductive fitness despite having dysfunctional mitochondria; however, the underlying biological mechanism is unknown. The purpose of this study was to assess the difference in DNA damage due to ROS for the liver tissue in the two parental types and their hybrids. Hybrid lizards should have the least amount of DNA damage because previous research found an increased melanin content in their liver tissue, which can act to absorb ROS. Comet assays were used to assess DNA damage. Isolated liver tissue cells were treated with hydrogen peroxide (H2O2). DNA damage was visualized after 1 hour of single-cell electrophoresis. Images of DNA damage were analyzed using OpenComet. Each liver tissue sample resulted in analysis of roughly 1,000 cells. DNA tail percentage, tail moment, and olive moment were measured for the control, 1/50, 1/100, and 1/1,000 dilutions of H2O2. Hybrid tissue showed significantly higher damage (0.01) for DNA tail percentage, tail moment, and olive moment when compared to U. graciosus and U. ornatus. There was no significant difference between the two parental species. Despite tending to have increased melanin content in their liver, hybrid DNA is not as well protected from ROS as each of the parental lizard species. These results indicated that hybrid lizards may not be able to deal with oxidative stress as well as either parent species.

Abstract Name: **A Loss of Pb2 Sensilla Across Cactophilic Drosophila Species?**

Olfaction is a primary sensory modality used by insects for identifying host plants. Shifts in host plant use can result in changes in the insect olfactory system. These can take the form of changes in sensitivity of individual primary sensory neurons, and/or a gain/loss of these neurons. The present study documents changes in the olfactory system of the Drosophila repleta group that accompany shifts in host cactus species. A previous study found no evidence for one of the three expected sensillar subtypes, the maxillary palp basiconic 2 (pb2) subtype, in 3 of the 12 repleta species measured, based on recordings of individual olfactory sensory neurons. Given that this lack of evidence may have resulted from a simple failure to locate existing single sensillae, we recorded global responses of populations of neurons in the maxillary palps to odors diagnostic for each sensillar subtype. Included were the three Drosophila species with putative sensillar loss, plus a Drosophila species known to have all three sensillar subtypes (positive control). Results reveal the presence of pb1 and pb3 sensillar subtypes in all four of these species. However, no responses to odorants diagnostic for pb2 sensilla were found in the three species hypothesized to lack this sensillar subtype, which is consistent with previous work on single sensillae.

Abstract Name: **Connect-4 via Min-Max algorithm and Monte Carlo Tree Search**

Games have been around people for a long time. As study in machine learning is proceeded, unbeatable programs are frequently observed such as AlphaGo. AlphaGo is a computer program that plays a board game called GO, developed by DeepMind Technologies in Google and implemented with reinforcement learning. Reinforcement learning is the area of machine learning which focuses on computer algorithms that can improve automatically through experience and data by computer itself such as self-driving robots/pilots and search engines. The objective of the research is to implement reinforcement learning algorithms into a program which plays connect-4 and enable it to make the best move by learning itself. There are two algorithms implemented: Min-Max Algorithm and Monte Carlo Tree Search (MCTS). Min-Max Algorithm is an algorithm that finds all possible cases and makes a winning move while MCTS is a major component of AlphaGo algorithms that simulates a lot of random games, evaluates every move, and makes a winning move. However, due to countless number of cases Min-Max Algorithm can find, NegaMax Algorithm is implemented which simplifies the Min-Max Algorithm; additionally, a limit on the number of recursions is set. Also, The MCTS algorithm's winning ability is controlled by how many simulations it performs before picking a move. The further step is to build a 6x7 grid of connect-4 board using Python, create 3 players: RandomPlayer, NegaMaxPlayer, and MCTSPlayer which use the specified strategy. After simulating hundreds of battles among the 3 players, the data shows that the larger upper bound of NegaMax, the stronger move it makes, the more simulations in MCTS, the stronger move it makes. Whether MCTS is stronger than Negamax depends on the two hyperparameters.

Abstract Name: **Exploring The Impact Of Educational Exchange Activities Between UWEC And CIT Project**

With the development of educational internationalization, more and more Chinese students choose to study abroad. While ample studies discuss international students, less research examines exchange programs. To better understand the impact of exchange activities on international students and scholars, this case study explored the positive experiences and challenges faced by students and exchange scholars in the University of Wisconsin Eau-Claire (UWEC) and Changshu Institute of Technology (CIT) 1+2+1 program.The research team adopted surveys and interviewers to collect data from exchange students, visiting scholars, and administrative personnel. The results revealed both external and internal factors that accounted for the participants' experience, such as students' perceptions of values in speaking up, sense of fitting in, and the importance/lack of a multilingual classroom environment. The participants shed light on gender, identity, language, culture, education, and communication style. Additionally, results showed that the study abroad experiences influenced students' networking with diverse friends and a better understanding of their own cultural values and prejudices. This project aims to offer implications for future exchange programs between Chinese and American universities, advocate for thoughtful and mutually beneficial cross-cultural communication, as well as offering suggestions for exchange students.What made this research project distinctive and meaningful was that the entire research team consisted of international students and a faculty mentor from China. Both the topic of the project and the background of the researchers represent an effort to promote equity, diversity, and inclusion locally and globally. The research team was able to bring in an authentic, culture-relative, and empathetic lens to examine the gains and challenges experienced by the participants. This project hopes to inspire more international students to engage in faculty-student research experience, enhance their professional and career skills, and amplify their voices.

Abstract Name: **An Examination of the Vocal Tract Dimensions in Children with 22q11.2 Deletion Syndrome**

22q11.2 Deletion Syndrome (22q) is the most common microdeletion known in humans. Individuals with 22q have an increased risk for the development of speech and language impairment such as hypernasal speech and nasal regurgitation during swallowing. Adequate functionality of the vocal tract (VT), which is bounded superiorly by the posterior nasal spine and inferiorly by the base of the epiglottis, is required for normal vocal production since the shape of the VT determines articulatory possibilities. Irregular vocal tract dimensions, such as a wider pharynx, can lead to inadequate velopharyngeal closure (Titze, 2001). No studies to date have analyzed the VT volume in a non-sedated pediatric population with 22q. Thus, the aim of this study was to investigate the relationship of the volumetric VT measures and resonance disorders among children with 22q using a novel, non-sedated 3D imaging protocol.MRI data were obtained on 30 participants (4-12 years old), 15 with a confirmed diagnosis of 22q and 15 control subjects. 3D MRI data were collected while the velum was relaxed as the participants lay in the supine position. The 3D scan involved a 0.8 in-plane isotropic resolution with an acquisition time of less than 5 minutes. MRI data were transferred into Amira 6 Visualization Volume Modeling software (Visage Imaging GmbH, Berlin, Germany). Linear measurements were taken of the pharyngeal depth. Volumetric measurements of the adenoid volume (AV) and VT were also examined. Two sample t-tests were used to assess differences between the control and clinical groups.Preliminary results indicate that VT port dimensions are significantly different in children with 22q compared to the non-syndromic group (.05). This syndrome-specific quantitative anatomical data in children with 22q can be used to tailor surgery to provide a more personalized treatment approach to enhance speech and surgical outcomes in the 22q population.

Abstract Name: **String in Switch ? Usage Analysis and Maintainability**

The release of Java 7 in 2011 introduced the capability of using character sequences, hereby referred to as String objects, in switch expressions and their corresponding case statements. This String in Switch language feature allows producing readable and better-performing code when compared to commonly used alternatives like if-else statements, often nested and difficult to modify and maintain. As a consequence, code maintainability can be simplified by incorporating this feature into a project. Our research focuses on the usability analysis of this new language feature, with the goal of observing its usage over time across selected Java-based open source projects. In addition, we perform a comparative analysis between sample String in Switch statements and equivalent if-else expressions to discuss the maintainability of the code as it relates to the advantages of String in Switch. For analyzing a project, we perform a file expansion that generates revisions for every commit in the project's repository. Subsequently, we build Abstract Syntax Trees (ASTs), allowing us to identify the presence of String in Switch statements present in a target file. With this information, usage-over-time plots are derived, allowing us to observe the occurrence of String objects in switch expressions throughout a project's development history. Of the analyzed projects, our research shows that the String in Switch feature is not widely used, despite its capability of generating cleaner and readable code. We conclude that some of the analyzed projects may be mature, which reduces the need to rewrite functional code into equivalent String in Switch statements. These findings are useful not only for programming language designers in understanding the tendency to utilize new features, but also for instructors in teaching programming languages in a limited amount of time.

Abstract Name: The Humanitarian Crisis Due to Fast Fashion

In the United States of America, more than 97% of apparel that's sold is made somewhere overseas, according to the American Apparel; Footwear Association. Currently, the fast fashion industry is one of the fastest growing industries that continues to exploit their workers in order to maximize profits. International governments like China fail to properly monitor regulations due to the high profit these products bring. Brands like Shein continue to grow in sales but the product is created at the expense of long hours and little pay for workers, and environmental destruction. Creating discussions and pushing for change within our communities is the first step to create a better future for those outside of our borders. Implementing systems and spaces for slow fashion, an ethical way of shopping and distributing old clothes, and international labor laws can spread awareness for workers and the environment. Therefore, a survey will be sent out to students at John Brown University that will ask to evaluate their clothing decisions by choosing their favorite clothing items and listing what countries these clothing items are made in, brand, and where it was purchased. Information on well-known fashion brands and their impacts will be given with links at the end of the survey in hopes that the surveyed group may have an informed opinion on the fashion industry. These students, as consumers, are what keeps these corporations afloat and educating them of the crimes that are done for their money is critical. Consumer awareness is an integral step for the reformation of the current fast fashion industry. One step at a time, the implementation of domestic social change and international policy regulation can bring upon a future that no longer globally exploits garment workers to maximize profits.Keywords: Fast fashion, labor workers, slow fashion, multinational corporations

Abstract Name: The complete mitochondrial genome of the Indochinese jackal (Canis aureus cruesemanni) and its relationship to other subspecies of golden jackal

The Indochinese jackal (Canis aureus cruesemanni) is a subspecies of the golden jackal (Canis aureus) found in Southeast Asia. While this species has been genetically studied in Europe, the Middle East, and India, current research is lacking on the population(s) in Southeast Asia. Using a genome skimming approach, we assembled the first complete mitochondrial genome for an Indochinese jackal from Thailand. The mitogenome contained 37 annotated genes and is 16,729 bps in length. Phylogenetic analysis with 21 additional canid mitogenomes, along with analyses of a cytochrome b gene-only data set, supports the Indochinese jackal as a distinct lineage, and therefore subspecies, among golden jackals.

Abstract Name: Variations in Microbial Populations in Metropolitan Houston Wetlands

In recent years, the number of chemical industries near bodies of water have increased and pose a threat to the environment and microorganisms within the water supply. In order to minimize the damage being done to the natural environment, restrictions have been set in place for how chemical industries dispose of waste. Houston has a multitude of chemical industries, which gives opportunity to study and monitor changes within the bodies of water near this metropolitan area. The microorganisms within the water can be an indicator of its quality. The foundation of this research is based off two areas within Armand Bayou Nature Center, a nature reserve that shares water with chemical plants within the Houston area. One area sampled was a pond within the nature reserve while the other was from the bayou which is in closer association with wastewater. The microbial diversity present in each water sample was explored to see differences between the two environments. Five prokaryotic microorganisms were obtained from each sample and testing was performed to show similarities and differences between the two ecosystems. This research is baseline sampling that can be used for future comparisons and collaborative work. The continuation of this study will broaden our knowledge of the relationship between the chemical industries and microbial diversity.

Abstract Name: Investigating Undergraduate Students' Engagement in Systems Thinking Using Causal Maps

Undergraduate biology classes must prepare students to engage in an increasingly interdisciplinary field where they need a foundation of scientific understanding to make informed decisions about the science they will encounter in their careers and everyday lives. To study how undergraduate students engage in systems thinking, we conducted a pre-post study with students in an undergraduate botany course. Students were asked to complete a causal map at the beginning and end of the course. Students were also asked to answer two questions about their causal map: (1) Explain how your causal map demonstrates the relationships of plants and the environment? and (2) If someone, a non-scientist, asked you to explain how plants connect to everyday life or situations, how would you answer using your causal map?To evaluate the questions students answered, we used open coding to determine common topics among the answers. We also used the framework for systems thinking developed by Mehren et al. (2018) as utilized by Mambrey et al. (2019). This framework is defined by three stages. At Stage 1, students provided a vague level of understanding when comprehending the benefit of causal maps. At Stage 2, students made moderate connections between plants and the environment but did not elaborate with specific examples that would help them create broader connections. At Stage 3, students identified multiple different complex connections and identified specific examples. Ultimately, results showed that most students did not draw upon specific connections, but rather leaned more toward broad areas of connection.This work highlights the difficulties undergraduate students have with engaging in systems thinking but provides insight into areas in which students do engage in more complex thinking and areas in which we can target with intervention. As such, it will be of interest to NCUR attendees and the broader science education community.

Abstract Name: **Evaluation of cytotoxic and apoptotic effects of several regional plant-based extracts on human squamous cancer cell lines**

The south has always been a place where home remedies and scientific-based medicine go hand in hand. Throughout time, natives and other groups have used homemade salves and ointments for what could have potentially been carcinoma or other forms of skin cancers. Through literature study, certain plants of interest have been identified. Plants used in various assays were either grown in the ABAC greenhouse or collected from local areas. Two extracts of interest have been used in the application of cell cytotoxicity assays, cell proliferation assays, and a cellular invasion assay using skin cancer cell lines. The cytotoxicity assay demonstrated cytoprotective properties when applied to cells. The cell proliferation assay confirmed this observation by showing increased cellular proliferation in cells treated with the extracts. The wound healing assay demonstrated increased cellular invasion into an area of artificial damage. Overall, these extracts have been shown to demonstrate increased cell survival, increased cell proliferation, and increased cellular invasion when used to treat subcutaneous cancer cells in vitro. In summary, the extracts demonstrated a prosurvival phenotype indicative of enhanced wound healing.

Abstract Name: **Catalyzing Creative Inquiry via Faculty Led Study Abroad: Entrepreneurship through the Arts**

Undergraduate students enter higher education with 12-14 years of formal education, generally prescriptive in nature. The creativity that children may have displayed in pre-school and elementary school has often been tempered by conformity. Rules, reified, often become the basis on which students learn and are assessed.Creative inquiry, necessary for the application, analysis, evaluation, and synthesis of research, can be catalyzed outside of traditional education environments. Research demonstrates that inquiry requires the disruption of 'comfortable' environments and the subsequent disruption of fixed mindsets.This presentation offers a faculty-led, study abroad course curriculum, sample itinerary, and tools designed to inspire students from across disciplines to encounter and thrive on ambiguity, stretch their ways of thinking, and inspire artistic creativity via a 3-week course to Scandinavia. The course is designed to increase research and presentation skills via real-world scaffolding that fosters a natural curiosity about their fields of study and enables them 1) to compare earlier learning with new experiences, 2) to formulate research questions based on new perceptions, and 3) to articulate their research aims and objectives with greater clarity. The students are predominantly from programs in the arts, industrial design, gamification, and business. The course is designed to support students who have begun or are about to begin their senior thesis and capstone projects. Vis-à-vis samples of student business journaling and evaluation survey data from this course led in 2019 and 2022, the presentation provides a case from which others can build their own faculty-led courses to strengthen creative inquiry and research readiness.Studying abroad increases creative and cognitive inquiry. The students in this program experience a breadth of activities that, in addition to the cultural dissimilarities with their home country, expose them to cross-curricular professional and academic environments that challenge their zones of comfort.

Abstract Name: Effects of Social Media

Social media has become one of the biggest aspects of our everyday lives. They allow us to share our lives with loved ones, research our interests, and expose ourselves to all kinds of new things. Due to how ubiquitous the sites are, they inevitably will have a profound effect on mental health. Existing literature shows that there are many ways that social media can affect people's lives. It shows that social media can affect people's health choices and personal lifestyle decisions. Research also shows that people tend to compare themselves to others more when using social media often, which can lead to a multitude of mental health and self-perception issues. This research focuses on mental health and social media use. Using a survey implemented to a diverse sample of individuals through various social media outlets, a wide variety of different trends emerged. The main focus of the research was to determine whether social media was linked to self-esteem. The research shows a wide variety of ways social media is affecting people's mental health and their assessments of their own physical and intellectual attributes.

Abstract Name: Investigation of Cancer Biomarkers Using SERS

Surface Enhanced Raman spectroscopy (SERS) can be used to detect changes in the composition of human saliva that may indicate the presence of cancer biomarkers. Cancer is a prevalent disease that affects many people. By using SERS with human saliva, a painless and possibly more effective way to detect cancer can be created. Like blood, saliva can show changes in proteins and concentrations of certain molecules that occur due to cancer. The method that our group will focus on is SERS which is an extremely sensitive spectrophotometric method. This is necessary when using saliva samples as many analytes are in very low concentrations. Our group is still in the preliminary stages of using the Raman spectrophotometer and optimizing SERS conditions. Moving forward, our group hopes to successfully run treated saliva samples on the Raman.

Abstract Name: Analysis of LNS2 protein domain conservation through bioinformatic annotation of Lpin in Drosophila species

Evolutionary relationships between species of an organism can provide insight into how the genes within each organism have changed in structure in order to maintain function. At the same time, similarity between gene structure as seen through conservation can point to certain evolutionary relationships. The Genomic Education Partnership's (GEP) Pathways Project aims to use this concept to examine how the evolution of a gene's regulatory region relates to the position of the gene in a network. The Pathways Project focuses specifically on the gene network that regulates the insulin signaling pathway. The insulin signaling pathway is a good candidate for a model pathway to study because it is critical for growth and central metabolism. A pathway with this magnitude of importance maintains high conservation throughout evolution to an extent where slight changes in genetic structure can be mapped out over time, creating a potential for organizing the phylogeny of a group of species of an organism. One of the genes within the insulin signaling pathway is called Lipin, abbreviated as Lpin. In this study, Lpin was annotated in 25 different species of Drosophila to contribute to the GEP's Pathways Project. Lpin is a gene that encodes for a protein that works as a phosphatidate phosphatase to aid in fat body function and energy metabolism in the insulin regulatory pathway. It is hypothesized to have one functional domain, the LNS2 domain. The Lpin annotations were compared between distantly related species in order to identify conserved functional domains. These conserved domains were then compared to computational predictions of the LNS2 domain. The annotations supported one computational prediction, suggesting that conservation between species may improve the predictions of functional domains.

Abstract Name: The State of Dissolved Oxygen in the Longhurst Ecological Provinces

The purpose of this study is to determine the current state of dissolved oxygen in regions defined by the Longhurst Ecological Provinces and compare those results to dissolved oxygen measurements as early as 1965. Dissolved oxygen is an important variable to consider when assessing the conditions of an ecosystem. Therefore, a comprehensive study of the state of dissolved oxygen in the world's oceans is important to understanding the physical and biological processes occurring in each region. Specifically, it can reveal how physical processes, such as mixing, climate change, and upwelling, can affect primary production and the ecosystem as whole. A part of this study is to also compare dissolved oxygen concentrations to chlorophyll-a concentrations to investigate the relationship between dissolved oxygen and primary production in each Longhurst Province. This study uses dissolved oxygen data from biogeochemical Argo floats and the World Ocean Database in the Longhurst Ecological Provinces. Chlorophyll-a, temperature, salinity, and potential density are other factors that were considered when analyzing the state of dissolved oxygen. The findings are that in many of the provinces studied, the trends in dissolved oxygen are not consistent with previously observed concentrations, and there is a direct relationship between dissolved oxygen concentrations and chlorophyll-a concentrations.

Abstract Name: A Glimpse Into the Romantic Era: Henryk Wieniawski's "Romance"

The Romantic Era is a musical movement lasting between the years of 1820 and 1900. Composers of this era utilized music as a means of individual, emotional expression, incorporating longer, more heartfelt melodies, a broader usage of dynamic contrasts, and more intense passion within their works than in previous years. Many composers drew influences from art, literature, love, death, and war in composing their works. Henryk Wieniawski, a Polish composer, pedagogue, and violin virtuoso, was a prominent figure during this time period. During his lifetime, Wieniawski composed over fifty works for solo instrumentalists and ensembles and was considered, by critics, the reincarnation of violin virtuoso Niccolò Paganini for his impeccable technique and performance skills. Wieniawski's Violin Concerto No. 2 in D minor, Op. 22, is highly regarded today as both a staple piece of solo violin repertoire and as one of the most popular Romantic Era violin concertos, notable for its colorful and passionate melodies and harmonies. The second movement of this work, Romance, is gentle and flowing, yet its central climax is fervent and intense, demanding the full attention of the audience and of the solo performer alike. The movement's repeating melody is presented in a simple 12/8 time, changing tonic pitch at various points throughout to emphasize the movement's melodic contour and to provide a contrast to the listener's ear. For the soloist, paying attention to the movement's intricate melodies and articulations is crucial for how it is performed, and, more importantly, for how the movement's intended message is conveyed. Usages of intense vibrato, legato bow strokes, and an awareness of the sounding point between the bow and the string are crucial for the soloist. From its main theme to its utilized techniques, Wieniawski's Romance provides a glimpse into the central ideas and characteristics of the Romantic Era.

Abstract Name: Simulation of the Shear Flow Dynamics of Suspended Microscale Particles

Understanding the shear flow dynamics and wall interactions of non-spherical particles suspended in fluid media is important in a number of fields, from large scale phenomena like coastal erosion to mesoscopic and microscale applications such as additive manufacturing with fiber-reinforced composite filaments and shape-based separation of particles and biologicals.In particular,focusing on the geometric orientations of high-aspect ratio fiber-like particles suspended in low- and high-viscosity fluids transported through precision engineered pores with radially asymmetric geometries. This includes usinga combination of analytical methods and numerical simulations withcomputational fluid dynamics solvers ANSYS Fluent and STAR CCM+ to evaluate the ability of customized microscale pores with tapered sidewalls to orient and align fibers suspended in fluid media. We believe these results to also provide valuable insights into nanoscale applications such as the wafer-scale printing of aligned carbon nanotubes for microelectronic circuits.

Abstract Name: Activating Learning in Out-of-School Youth Science & Engineering Programs: Activation Lab Survey Findings

According to the U.S. National Science Foundation 2022-2026 Strategic Plan, as globalization and knowledge-based economies grow, scientific and technological innovations become increasingly important and thus enhance the importance of STEM education opportunities. Since 2019, the Caruth Institute of Engineering Education (CIEE) has offered a variety of week-long engineering summer camps to students. The camps are grouped by grade levels (7th& 8th, 9th&10th, 11th&12th), gender (all girls, all boys, co-ed), tuition-based, scholarship, and residential options. In addition, the CIEE began offering camps to 5thand 6thgraders in 2022. The Institute offers Hamon Foundation camps for underrepresented and underserved youth in South Dallas, e.g., Jubilee Park Community Center, and West Dallas, e.g., Voice of Hope Ministries. The types of engineering activities over the years have included designing an irrigation system, designing, and building a wind turbine, a pollinator house, a water filter, and solar ovens. To assess learning and engagement, the CIEE utilizes the STEM Learning Activation Survey, developed by Rena Dorph, MatthewCannady, and ChristianSchunn, as apreand post-camp to measure the interests, confidence, scientific sensemaking, and emerging identities in STEM disciplines. The STEM Learning Activation Lab/Survey has prompts that assess individual's responses across four dimensions of science learning activation: Fascination, Values, Competency Beliefs, and Innovation Stance. The presentation will present a factor analysis that examines connections across these four dimensions as well as a discussion of findings examining correlations with other factors such as age, gender, socioeconomic status, and the domain/contexts of science and engineering that framed the activities the campers completed.

Abstract Name: Experimental and Computational Analyses of Drop Motion in Straight Microchannels

Droplet-based microfluidic systems have become quite prevalent in recent years, especially so for applications such as lab-on-chip systems, single cell assays, and high-throughput microreactors. Such systems often take the form of straight segments with rectangular cross-sections, which is the focus of this investigation. Studying the motion and deformation of droplets travelling through straight microchannels allows for more informed design of such systems. It is important to quantify how physical and geometrical parameters such as the capillary number (Ca), viscosity ratio (λ), drop size, and channel geometry affect the motion of a droplet flowing through a straight, rectangular microfluidic channel. This investigation leveraged numerical simulations and experiments to study the motion of droplets. Typically, viscous droplets are quite computationally intensive to simulate, so our simulations utilize a boundary-integral algorithm coupled with a moving-frame method to efficiently simulate a droplet's motion with given physical parameters (droplet size, viscosity, etc.). Through our simulations, we have found that increasing the Ca results in a faster and more deformable droplet, whereas increasing λ results in a slower droplet. Our simulations are verified through the use of an experimental flow-cell setup, which we've scaled up to a macroscopic scale for ease of visualization. We've scaled up the flow-cell in such a way that all relevant nondimensional parameters are preserved, and so we can witness microfluidic, low-Re, laminar flow at a scale which can be imaged with a cell phone camera. The experimental data are analyzed using computer-vision algorithms and postprocessing to quantify droplet trajectories, centroid motion, and tail deformation; our initial results have shown promising qualitative agreement with our simulations.

Abstract Name: Preventing Adherence of Candida spp. with Pre-Therapeutic Drug - Filastatin

Candida yeasts are the most common human fungal pathogens. These primarily opportunistic pathogens can infect a variety of tissues and cause a variety of infections. They are also a common cause of healthcare-associated infections (HAI) in immunocompromised individuals. Candida yeasts usually form biofilms upon adhesion, which then increases their pathogenicity due to their lack of response to conventional treatment. Candida auris is an emerging fungal pathogen with nearly a 57% mortality rate. Filastatin is a drug not yet approved for human use but has been found to uniquely inhibit adhesion of C. albicans to the surface of several biomaterials and human cells. This study will assess if Filastatin is also able to inhibit the adhesion of three other pathogenic Candida species, C. albicans, C. glabrata, and C. auris. 96 well polystyrene microtiter plates will be used to assess the inhibition of fungal adhesion using various concentrations of Filastatin. After incubation, cells grown in the wells will be stained with either crystal violet, (or alamar blue to test for viability as well). Upon washing the plate with ice water several times to clear out stained cells that didn't adhere to the surface, methanol will be added to each well and allowed to sit for 45 minutes. The solution of methanol and stained cells will then be read by a spectrophotometer at 590 nm for the varying absorbances and will be compared to our control of both saline and Candida albicans. This will be beneficial to the future of healthcare as it will allow the number of infections with Candida species to be decreased. Future medical devices coated in Filastatin would be more resistant to Candida biofilm formation and would therefore limit the number of infections and mortality.

Abstract Name: Introduction and Progression of Early Algebra in the Beast Academy Comprehensive Curriculum

As students progress through elementary mathematics curricula, arithmetic is the main point of focus. However, a call for algebra to become a component of the elementary mathematics curriculum has gained momentum because implementing algebra in early elementary curricula increases student understanding of algebraic concepts and eases the transition to deductive algebra later in mathematics. The Beast Academy comprehensive curriculum was developed with a focus on problem solving through monster characters in a graphic novel who demonstrate different ways of mathematical thinking. Beast Academy incorporates problems where students engage with algebraic thinking earlier than suggested in the Common Core State Standards and continues to incorporate problems which emphasize algebraic thinking through practice problems in subsequent levels. This progression introduces students to algebraic language while enhancing their current learning. We are interested in the trajectory of problems which build algebraic thinking as well as problems in which students are doing algebra. We will present our findings on how this curriculum introduces algebra to students, and how current literature suggests this will impact student learning outcomes.

Abstract Name: Duration of Haemophilus ducreyi Viability Following Transmission by Musca domestica

Haemophilus ducreyi is well known as the causative agent of chancroid, a sexually-transmitted disease that causes painful genital ulcers. In recent years, the bacterium has also been identified as the causative agent of non-genital cutaneous ulcers, primarily affecting children of the South Pacific Islands. While much is still unknown about the transmission of H. ducreyi in this setting, H. ducreyi DNA has been detected on flies in an endemic region. This experiment utilizes Musca domestica, the common house fly, as a model system to demonstrate that flies are a potential vector for the transmission of viable H. ducreyi. Utilizing a green fluorescent protein (GFP)-tagged strain of H. ducreyi, this study examines the time period in which H. ducreyi cells are able to survive after transmission by M. domestica. We found that 85.45% ± 28.41% of flies transmitted viable H. ducreyi. Additionally, the duration of H. ducreyi viability was found to be directly related to the bacterial concentration, and the majority of experimental plates had undetectable levels of H. ducreyi within one hour of initial exposure. This study demonstrates for the first time that house flies are capable of mechanically transmitting live H. ducreyi, potentially leading to advanced prevention and treatment methods for skin-ulcerative diseases within the South Pacific Islands.

Abstract Name: Exploring the Knowledge, Attitude, and Practice of Storytelling and Reading on Child Wellbeing Amongst Teen Mothers in Kamuli District, Uganda

Children in Sub-Sahara Africa are faced with a greater risk for various emotional, psychological, and health challenges, contributing to their wellbeing, and because of conditions associated with poverty, children are not meeting their developmental potential. The young population in Sub-Sahara Africa, particularly Uganda, is booming, especially given that the COVID-19 pandemic and two-year school lockdown brought an alarming rise in teen pregnancy. As the young population grows, children's quality of life needs to be prioritized.Stories can be important for child development because they can preserve and transmit culture. The connection between reading or storytelling and child wellbeing has been studied but not as frequently in remote regions such as Uganda. In this study, the author gathered primary data from 30 teen mothers in Kamuli District, Uganda, regarding the knowledge, attitude, and practice of verbal storytelling and childcare. Data is further analyzed using descriptive statistics, including percentage distribution, mean, and frequency counts. Additionally, the author performed a literature review assessing the effect storytelling and reading have on child wellbeing to support their research.Children need to read and listen to stories because stories are ways beliefs and community customs are transferred throughout generations. Stories are a means of communication, generate catharsis, and help enhance verbal proficiency. Thus, resulting in reduced anxiety, higher self-esteem, and the skills to accurately express one's thoughts and feelings.This evidence is relevant to the Kamuli District community to emphasize the importance of sharing stories with their children. Further, this study can act as a resource for other researchers to develop strategies to help the youth of Uganda achieve higher wellbeing through storytelling and reading. With a growing young population in Uganda, there will be greater stress on developing and preserving future children's wellbeing.

Abstract Name: **Search for Antibiotic-Producing Genes in Pseudomonas chlororaphis**

This research is being conducted to try and find new antibiotics. Bacteria mutate constantly and as a result, become resistant to antibiotics, causing a need for new antibiotics. Soil bacteria is a rich source of antibiotics. Many antibiotics that have been isolated from soil bacteria are used as the chemical backbone to produce many different synthetic and semi-synthetic antibiotics. We isolated an antibiotic-producing bacterium from soil in southern Wisconsin. The bacterium was identified as Pseudomonas chlororaphis, which produces a distinctive orange pigment. Our research found a possible link between the orange pigment and antibiotic activity. Other labs have found a link between the orange pigment and phenazine activity. This led us to think that there is a link between phenazines and antibiotic production. We sequenced part of the phenazine pathway genome in order to make primers to knockout out genes within the phenazine pathway. Interestingly, it was found that one of the genes that is in common strains of P. chlororaphis was not found in our specific strain. In order to better understand how phenazines are related to antibiotic production, we plan to target P. chlororaphis genes to be knocked out to determine the source of antibiotic production.

Abstract Name: **Developing a Mice Detector Using Deep Learning Models**

Problem; Background:Micepresent many hazards within buildings. They are known to spread many diseases, through their excrements. Rodents can also cause structural damage to buildings. They can nest by chewing through insulation or they can chew through electrical wires which can cause fire hazards. Due to this, it is critical to inspect the rodent population in a given building to prevent such hazards from being present. However, manual rodent inspections can be difficult and potentially dangerous.Method:A custom object detector implemented in a python program can provide a psolution to this problem. An object detector based on deep learning models such as Faster Region-based Convolutional Neural Network (Faster RCNN) and YOLO framework can be trained to detect miceusing manually annotated images gathered from the open source. The detector can then be evaluated using the intersection-over-union formula, which shows how accurate the detector is. Once it is thoroughly trained and proper accuracy is reached, the detector can be run on a real-time system obtained from a raspberry pi equipped with a camera module. That is, this detects the presence of mice in a real-time model. The detector can then be programmed to send alerts to a user's device, informing them of the presence of rodents. In addition to this, at the time of detection, the program can record the rodent for the user to view and verify that there are indeed rodents present.Goal:The end goal of this project would be to develop an accurate, real-time mice detector, that alerts the user when mice have been detected. This detector can then be placed in a false ceiling environment where mice infestation is suspected, removing the need to investigate the area manually. The mice detector would save time and money while preventing potential accidents from occurring.

Abstract Name: Preventing NicoTEEN Addiction Through Nurse-Led Education on Vaping

The aim of this research project is to develop, present, and evaluate an educational intervention on electronic cigarettes (e-cigarettes) and vaping for non-school staff adults who have influence on adolescents, such as coaches, counselors, and parents. TheU.S.Surgeon Generalreported that the use of e-cigarettes continues to be a public health concern among adolescents. Additionally, according to the Centers for Disease Control, there is evidence that adolescents who use e-cigarettes are more likely to smoke regular cigarettes in the future. While there is a growing body of research on the short and long-term health effects associated with e-cigarettes and vaping, less is known about how we might best prevent adolescents from engaging in use of these products. This project targets adults that spend large amounts of time with adolescents and have the ability to influence them on the dangers of e-cigarettes and vaping. It involves the delivery of an interactive and evidence-informed presentation. The efficacy of the intervention is then studied by comparing pre- and post-test results. Results are forthcoming, but it is predicted that the educational intervention would improve participants' knowledge about vaping and e-cigarettes.

Abstract Name: Improving the Classification Performance on Small-Sized and Imbalanced Datasets

Predicting rare but high-impact events is critical in many medical applications, such as health risk prediction and disease diagnosis. While sensor technology has improved rapidly in the last decade, machine learning (ML) techniques for the prediction of rare events lag behind general prediction models.Most optimization techniques used to train ML models implicitly assume a balanced distribution of events in training data. This research focuses on improving the performance of classifiers on imbalanced and small-sized individual asthma patient datasets using oversampling techniques, as these issues significantly affect medical datasets in healthcare applications.Imbalanced data causes the classifier to be biased toward the class with more data samples (the majority class), reducing its accuracy for minority class data. The class imbalance problem is particularly challenging in the medical domain because the goal is to predict whether a patient is at risk for a particular disease. However, these cases are often in the minority class. Moreover, machine learning-based classifiers require a large amount of data to be adequately trained. Therefore, having a small-sized training dataset is also an obstacle because it hinders the classifier's performance.To improve the performance of prediction models on imbalanced and small-sized asthma patient data, we first investigated existing synthetic minority oversampling technique (SMOTE) variants at the data level. SMOTE variants solve the class imbalance problem by generating synthetic data samples and adding them to the minority class data until the classes are balanced. We proposed three new minority oversampling techniques: Incremental K-Means Clustering (IKC), SMOTEBoost and SMOTEBoost with Control Coefficient (SMOTEBoost and SMOTEBoostCC), and Average Neighbor Vector Oversampling (ANVO). We evaluated the effectiveness of the proposed techniques compared to the existing SMOTE variants. The evaluation results show that the proposed methods are comparable with state-of-the-art oversampling methods.

Abstract Name: **Material Memories: Narratives of the Israeli/Palestinian Conflict**

Since the establishment of the State of Israel and the catastrophe of the Nakba, which entailed the mass displacement of thousands of Palestinians in 1948, the Israeli/Palestinian conflict has dominated global headlines and shaped foreign policy throughout the Middle East and North Africa. The state of constant tension and mutual distrust that has characterized Israel/Palestine since 1948 has also occasionally erupted in violent conflicts. Both Israelis and Palestinians tend to perceive themselves as victims of violence and the other as perpetrators of the conflict, thus mutually enforcing an “us versus them” environment. While the conflict gains significant traction on the world stage during periods of heightened physical violence and war, less attention has been paid to how Israelis and Palestinians experience the conflict on an everyday basis. Likewise, there has been little attention paid to the material memories and realities of the conflict, including how recurring interactions with objects and images allow Israelis and Palestinians to remember narratives of the near and distant past and inspire mutual distrust, structural violence, and resistance to the current state. During five weeks of ethnographic research in Jerusalem, I explored how memory informs the pervasive tension, structural violence, and resistance of ordinary Israelis and Palestinians. My project asked: How do ordinary Israelis and Palestinians narrativize their experiences of the conflict, and how do everyday objects embody these narratives? Drawing on more than thirty interviews and hundreds of hours of participant-observation, I suggest that divergent memories of brutal conflict, structural violence, and dehumanization shape the perceptions of Israelis and Palestinians and fuel everyday tension and mutual distrust. I also argue that individuals in Israel/Palestine utilize objects and images to evoke memories of the near and distant past and resist prevailing violence.

Abstract Name: **Student Shark Research at Millersville University**

The overall purpose of this study is to analyze the historical trends of shark fishing in the Chincoteague Bay area compared to recent data. The research questions we are asking are as follows: what types of sharks were in the area, if they're still in the area/have the number of sharks of any specific species decreased, increased, or remained the same, and finally why or why not? In order to answer these questions, our team must go to coastal cities/states surrounding the Chincoteague Bay area and talk with fishermen, harbor masters, and charter crews to obtain their catch logs and then study the data. Multiple trips throughout the 2022-2023 school year will take place as we travel to Maryland, Delaware, and Virginia.

Abstract Name: **Characterizing YAP Activation in Acoustically-Responsive Scaffolds via Ultrasound-Induced Matrix Stiffening**

Hydrogels serve as an invaluable tool for studying the role of biochemical and biomechanical cues on cell behaviors, includingsubstrate stiffness. However, conventional hydrogels are designed a priori, meaning their characteristics cannot be manipulated once implemented. Our research leverages a novel hydrogel - acoustically-responsive scaffold (ARS) - to control cellular cues in a non-invasive and spatiotemporally-controlled manner using focused ultrasound. An ARS consists of phase-shift emulsions embedded within a hydrogel matrix. Upon exposure to ultrasound, the emulsion is vaporized into gas bubbles in a process known as acoustic droplet vaporization (ADV). Previously, it has been demonstrated that ADV can generate localized matrix compaction and increases in stiffness within ARSs. However, there remains a gap in characterizing the impact of ADV in ARSon the YAP gene, a fundamental regulator of mechanotransduction.Consequently, our in vitro study draws on ARS to demonstrate the nuclear translocation of YAP,a transition correlated with matrix stiffness, when induced by ultrasound. Confocal microscopy andimaging processing arebeing used to study this highly localized matrix compaction. By evaluating stiffness in ARS with the YAP reporter, we can elucidatea better understanding of the hallmarks of focused ultrasound as a novel approach to providing spatiotemporal control over cellular cues. Hence, our research strives to expand the clinical applications of ultrasound and ARS in tissue engineering, including designing more effective drug delivery vehicles and biomaterials.

Abstract Name: **Víðsýni': Exploration of the Influences of Reforestation on Icelandic Landscape Identity**

The consequences of Iceland's deforestation causedby the Viking settlers continue to be apparent with regular soil erosion, flooding, and the challenge of raising livestock. Cover greenery has been vanishing in numerous parts of the land due to volcanic ash, climate change, and human activity. Most of the island lacks tall vegetation. Despite efforts to replant the forests lost to the early settlers, only a handful of projects have yielded noticeable results. During the summer of 2022, I spent eight weeks as an artist in residence at the Akureyri Art Museum in Iceland to create a new series of work inspired by Kjarnaskógur, the local reforestation project that has grown to become the country's most frequently visited woodlands. The paintings resulting from this residency and intense observational research depict the complexities of reforestation and landscape identity through personal, spatial, and cultural perspectives. The mediums used are primarily natural (local) pigments and gouache on found paper, incorporating newspapers and receipts collected during my stay. The stylistic choices and rendering pay tribute to my exposure to Icelandic history and modern architecture, resulting in a bridge between archaic and contemporary narratives. 'Víðsýni', an Icelandic word used both to describe a panoramic view and open-mindedness, is a series highlighting the importance of attentive perception to landscape and it's necessity for the shaping of future sustainable development policies. Approaching this subject from a visual art perspective allows the viewer to experience and reflect on this phenomenon that is otherwise difficult to quantify.

Abstract Name: **Expanding the Accessibility of Undergraduate Student Research**

As a polytechnic university, UW-Stout students are working on projects that range from oral histories and traditional research papers to game design and artwork. Presenters will discuss how the UW-Stout Archives have utilized the open access digital repository Minds@UW to both celebrate and highlight the variety of work undergraduate students are producing. This acquisition of student research project allows UW-Stout and the Archives to raise the profile of undergraduate research and creative inquiry in the arts by making student research widely accessible to researchers outside of UW-Stout. This project also gives the UW-Stout Archivists an opportunity to collect both a variety of research formats as well as topics for longterm preservation. This includes a focus on collecting research and projects from courses, such as Introduction to Queer Studies, that are connected with underrepresented groups and voices on campus. Presenters will walk through their process of working with courses and faculty members to collect student work, making the research accessible for both Stout students as well as external researchers, and preserving the student research in perpetuity.

Abstract Name: **Exploring the Disorder in von Hippel-Lindau Tumor Suppressor Protein by Molecular Dynamics Simulations**

The von Hippel-Lindau tumor suppressor protein is known to cause tumors in multiple vital human organs such as the spinal cord, retina, and varying blood vessels within the brain. It belongs to the class of intrinsically disordered proteins, which lack stable secondary or tertiary structures and their flexibility allows them to engage in a wide variety of interactions with other molecules making them biologically efficient. The folding of these proteins is still a mystery, and the conformational dynamics have remained elusive due to the absence of reliable three-dimensional structure. A simulated study of structural dynamics in the presence and absence of crowders could provide valuable insights of the conformational flexibility of the protein. The structure of the disordered protein was taken from Alphafold database - the database was created by artificial intelligence-aided protein structure solving. Five different protein systems were built: one in only water, one in ethylene glycol, and three more in the presence of varying sized polyethylene glycol (C2nH4n+2On+1) crowders (molecular weights ~ 600, 8k, and 20 k). A 50 ns molecular dynamics simulation was performed, and the data was used for further analysis. The effect of these crowders on the conformational dynamics and energetics was studied in detail using statistical tools. Results obtained in these studies will be presented.

Abstract Name: **The Lack of Awareness of the Long-Term Care Ombudsman Program**

The Texas Long-Term Care Ombudsman Program (LTCOP) is facing a lack of awareness. A lack of awareness can create a shortage of volunteers, thus causing the lack of availability of Ombudsman to advocate for the needs and rights of the residents of long-term care and assisted living facilities. This research is focused on the Texas Long-Term Care Ombudsman Program, which was put in place to protect the rights of residents in assisted living and long-term care facilities. This research is an exploratory study that investigates the lack of awareness of the LTCOP. The student researchers' hypotheses centered on the overall community awareness of the Ombudsman program and the factors that go into recruiting and sustaining the volunteers of the program. The research aims to identify the barriers that prevent the LTCOP from being effective. The student researchers administered 154 mixed methodology surveys to three different subsets: current and past certified volunteers, students on RELLIS campus, and the general public. The survey used included demographic, Likert-Type scale, yes or no, multiple-choice and open-ended questions. The student researchers obtained Institutional Review Board approval and used a non-probability, quota sampling approach. The results indicated a majority of participants were not aware of the LTCOP and its mission to advocate for the rights of residents in long-term care and assisted living facilities. Overall, findings inform the student researchers and allow them to further promote change within the Ombudsman program and improve marketing strategies in the community to increase volunteer numbers.

Abstract Name: **The Effect of Chronic Methamphetamine Administration on Neural Encoding of Value**

In 2020, 1.5 million people in the United States met the criteria for Methamphetamine Use Disorder (MUD; SAMHSA, 2021) and in Appalachian Kentucky, methamphetamine use is on the rise. MUD is characterized by the choice for drug at the expense of other alternatives, making it a decision-making pathology (Koob; Volkow, 2016). Previous studies in our lab have implicated shifts in the relative value between drug and alternatives as a factor in this behavior. To investigate this hypothesis, Intracranial Self Stimulation (ICSS) in the right Ventral Tegmental Area (VTA), a key brain region for the reward system, was used as a direct model of value in order to examine valuation changes before and after chronic methamphetamine injections in a rodent model. Following implantation and customization of stimulation parameters, a frequency threshold program was administered to determine changes in demand for stimulation using a behavioral economic demand analysis. Following threshold training, a Controlled Reinforcement Ratio (CRR) program involving an isomorphic choice between a stable and sweeping range of ICSS frequencies was used to assess value-based decision-making both before and during methamphetamine injections. Once choice data was stable, the animals were given methamphetamine injections (1mg/kg) and placed in locomotor chambers to track sensitization. Following eight days of methamphetamine injections, the frequency threshold was reassessed. Preliminary data analysis indicates that animals did not show methamphetamine-induced locomotor sensitization, but showed an acute increase in locomotion after injection. There was no change in value-based decision-making of the CRR program, but an alternation in the demand for stimulation. Further analysis with the exponentiated demand model and the generalized matching law will allow for a more precise examination of changes in rodent behavior. These results suggest that despite changes in the neural valuation of stimulation to the VTA, the rats showed no impairments in making value-based decisions.

Abstract Name: Fabrication of MEMS Filters for Applications in Rapid Prototyping and Biotechnology

Effective techniques for the separation and spatial manipulation of shaped microscopic particles are vital to applications in fields ranging from biotechnology to manufacturing. For instance, shape-specific separation can be used to isolate microbes and biomolecules. Printers used for rapid prototyping from composite materials could benefit from a device that constrains the orientation of microscale filler materials such as metals, glass or carbon fibers.The separation and alignment of shaped particles is generally challenging, since nonspherical particles can freely rotate and present different faces during motion. In this presentation, we describe the fabrication of lithographically patterned and anisotropically etched microscale pores in a single crystal silicon substrate, that are designed to overcome these difficulties. We present data on the engineering limitations and outcomes of this fabrication process and preliminary results from flow testing. These precision-engineering pathways show promise for both the shape-based separation of non-spherical particles aswell as in controlling their spatial orientations.

Abstract Name: **Polish History and Culture in Texas**

Texas is known for its rich Latin and Spanish influence, but significant pieces of Texas history can be accredited to immigrants from Poland. Polish natives came in waves to Texas and brought with them their work ethic, strength, and vibrant history that would impact the cultural makeup of Texas. I come from a family of Polish descent, and we have not held on to the roots of our history. I figured there was no vast Polish base so far south in America, and I should come to terms with having no ties to my ancestry. However, a dive into the cultural scene of Texas led me to discover an enormous Polish base in the state. The Polish history of Texas can be traced to before the Civil War when Spanish explorers named the San Jacinto River after the Polish saint, Św. Jacek Odrowąż. The impact of the Polish people still influences the state today, bringing a rich layer of cultural diversity to Texas.Texas is home to the nation's oldest Polish settlement, Panna Maria. This city is located south of San Antonio and began the migration of Polish immigrants across the state. Hardship and adversity caused settlers to branch out into nearby towns such as St. Hedwig, Bandera, and New Waverly. Since the original waves of migration, Polish culture has spread through Texas by way of dance, music, religion, and food. The Orleta Dance Ensemble of Dallas brings Slavic routines, clothing, and tradition to the North Texas area. Further south, the Axiom quartet of Houston is reinventing Old World sounds. Houston is a sizeable hub for Polish culture, serving as home to grocery store Polonia and Our Lady of Czestochowa Catholic church. The church hosts two annual Polish cultural festivals in May and September, celebrating two meaningful holidays in Poland.

Abstract Name: **Knowledge Gaps Between Canadian Public Policy and Religious Actors; Another Hurdle for Women in Agunah**

This research seeks to examine the consequences of Canadian public policy and its failure to protect vulnerable populations, especially women in traditional religious communities. Through this examination, light will be shed on greater social issues like gender inequality and cultural alienation, which are pervasive in many Canadian communities. I will use the Jewish divorce phenomenon, known as agunah, the spiritual chaining of spouses, to illustrate the social consequences that arise once public policy overlooks religious affairs. The knowledge gaps in Canadian public policy that enable agunah, worsens human right's abuses, and religious and community alienation as well as weakens Canadian institutions. My research first briefly explains the delay, refusal and extortion of granting a Jewish divorce as get abuse. Get abuse directly contributes to the agunah phenomenon which leaves many severe religious and spiritual consequences in its wake. After an understanding of agunah is established, I deconstruct Section 21.2 of the 1990 Divorce Act and exemplify how a situation of agunah could occur by the manipulation of the provision in order to remove barriers to divorce. Lastly, I employ the 2007 case of "Bruker v. Markovitz" to explore the instances in which existing knowledge gaps weaken Canadian institutions. Though steps have been made by Canadian policy makers and judicial figures to prevent the proliferation of agunah and get abuse cases, there still lacks sufficient precedent or literature available to make meaningful change. This egregious oversight of public policy leaves religious and cultural minorities largely leaves the women to grapple with legal incongruences and spiritual pain. An active effort to grasp religious law and legal nuances by public policy makers must be made in order to mitigate social maladies and protect all populations, including religious and culturally diverse Canadians.

Abstract Name: **Alternative Splicing during Fiber Development in Gossypium hirsutum**

Studying cotton fiber over its development elucidates topics surrounding polyploidy in plants, as well as their evolution. During cotton fiber development, there are key stages: initiation, elongation (primary cell wall synthesis), secondary cell wall thickening, and maturation. Major changes happen within cotton fiber at these stages which may be due to alternative splicing in the genome. Alternative splicing is a mechanism in the genome that can cause different proteins to be produced by the same gene; these differing proteins are called isoforms. We hypothesize that over the course of fiber development, particular isoforms may correspond with known timepoints in cotton plant development. The methodology used for this study includes the growth of Gossypium hirsutum, collection of cotton bolls from 6 to 25 days post anthesis (DPA) with 3 biological replicates, and RNA extraction and Illumina sequencing of each sample. Extracted RNA from samples at 6, 9, 12, 15, and 18 DPA are pooled and sent to be sequenced by Pac-Bio Isoseq. From these sequencing techniques, we will get short reads (Illumina) and long reads (Isoseq). The long reads are more precise with less possible mistakes made during genome assembly - these will act as a map to align short reads together. The short reads ascertained are much smaller fragments of the genome and therefore less accurate unless aligned using a known map (i.e. our long reads). By sequencing short reads at each DPA, the isoforms can be analyzed to determine whether they correspond with a particular day in development. Overall, the results should determine whether there are genes being alternatively spliced at specific timepoints during the development of cotton fiber. Investigation of alternatively spliced genes throughout fiber development in Gossypium hirsutum will aid in the understanding of polyploidy in plants, and the breeding and manufacturing of cotton.

Abstract Name: **Freshwater Mussel Surveys of Southwest Wisconsin**

Freshwater mussels are essential to our ecosystems by enriching the rivers and lakes. Their prevalence throughout Wisconsin has been a scarcely researched topic throughout the years, but the trends of their abundance have begun to emerge. This field however is experiencing renewed scientific interest due to a recent statewide survey conducted by the Wisconsin Department of Natural Resources. These studies have shown the health of northern Wisconsin mussels' communities to be thriving, particularly following rehabilitation efforts in water bodies like the Fox River. Unfortunately, studies in the southeastern part of the state show the opposite results. While there is a myriad of survey results and data from these regions, there is a lack of evidence to show the status of freshwater mussels in Southwest Wisconsin. The previously believed notion was that the populations of the southwestern regions of the state would mirror those of the southeast, particularly given the agricultural activities in the region. However, after extensive surveying of watersheds in the counties of Grant, Iowa, and Lafayette; our evidence shows their presence in select streams of the region, despite being undetected in years prior. Our team explored the factors that were contributing to this inconsistency with our counterparts in the southeast, particularly given that the distribution was patchy. The correlation of factors such as physical, biological, and chemical components was taken into consideration as possible causes of presence or absence. The findings made it apparent that the freshwater mussels were abundant in certain areas of the region but not others. The research we conducted has helped contribute to the baseline knowledgebase of freshwater mussels throughout the state and assisted in providing data for an otherwise largely unstudied region of Wisconsin.

Abstract Name: Molecular Study of Protein-Protein Interactions Associated with Charcot-Marie-Tooth Disease

The progressive neurological disorder associated with disruptions in morphology of the myelin sheath surrounding peripheral nerves is known as Charcot-Marie-Tooth (CMT) disease. This disorder inhibits the motion and control of the peripheral limbs. Amino acid substitutions of Myelin Protein Zero (MPZ), the most prevalent protein found in the myelin sheath, have been identified in patients suffering from this disorder. The effects of these point mutations on the molecular interactions between MPZ proteins are as yet unclear, however, MPZ oligomerization has been hypothesized to impact the structure and integrity of the phospholipid bilayers within which MPZ resides. We undertook a molecular dynamics simulation study to provide further insight into how these mutations perturb the interactions of MPZ molecules within the myelin sheath and disrupt the bilayer structure. We utilized coarse-graining approaches to build multicomponent bilayer membranes containing MPZ and created topologies for mutated forms of the protein. Although there have been over 200 potential point mutation sites identified in CMT patients, preliminary results indicate that an alanine substitution in the extracellular region of MPZ may be responsible for perturbed interactions between MPZ molecules and a disruption of the intraperiod line distance between bilayer membranes. Such a disruption could result in loss of neural signal, thereby impacting motor control downstream.

Abstract Name: Smartphone Use and Well-being

How has Smartphone use impacted the general well-being of people today? The Smartphone usage has certainly increased over the past generation. The use is so prevalent that nearly everyone from 9-99 has one. Questions regarding how this intense Smartphonne use is impacting the overall health and well-being of society has been discussed across many different aspects of research. This research intends to study how Smartphone use impacts the physical, psychological, cognitve and social well-being of individuals across the generations. Previous research tends to focus on one aspect or another of well-being, for exmaple sleep or academic performance (cognitive functioning) or anxiety (psychological functioning). The research is lacking when looking at the global health of an individual and its association with Smartphone use. This study will also examine the specific ways individuals are using the Smartphones as well as how much of their daily life is consumed by the use. A correlational analysis will be completed in the spring semester of 2023 to determine what factors are most impacted by Smartphone use.

Abstract Name: Multicultural Perspectives in Aphasia

Language is the production of our thoughts, cultures, and lives. It converts our minds into a more concrete form that allows people to understand each other. It also associates closely with our habits and mentality. The speech-language-hearing sciences field is one of the whitest fields in the U.S. and most research is biased toward the white-dominant population while some racial and ethnic minorities are more likely to suffer severe strokes and disparities in long term outcomes. Whereas there is almost forty percent of non-white in the United States of America, signaling the existence of diverse mindsets in which the disorders and treatments cannot be concluded only from the existing data.The mental health, the related cultural background, and the customs of different ethnicities may broadly impact the therapy and the results. In the current speech-language-hearing science field, we barely examine clients through the lens of mental health and multiculturalism. This single subject design study is to explore diverse perspectives about aphasia reported by marginalized clients with aphasia. Two participants were interviewed about their views about aphasia. The interview questions were modified from an explanatory model approach proposed by Kleinman and Beeson (2006) to explore the participants' understanding of the meaning of illness. Thematic analysis will be conducted. The results of this study will help further understand and help meet the needs of individuals who belong to an ethnic minority group and are affected by aphasia.

Abstract Name: Fourier Transform Infrared Spectroscopic Imaging for Detection of Biomarkers in Patients with Alcoholic Steatohepatitis

Infrared spectroscopic imaging has been shown to be useful as a diagnostic tool for tissue imaging. IR imaging allows for a label free approach to identifying biomarkers and molecular changes associated with disease progression. Alcoholic steatohepatitis (ASH) is a progressive liver disease caused by prolonged, excessive alcohol consumption. It often leads to liver cirrhosis. ASH is difficult to diagnose because clinically it presents similarly to other liver diseases, like non-alcoholic steatohepatitis. A liver biopsy is the current standard diagnostic method for diagnosing alcoholic steatohepatitis. The current process involves staining and diagnosis by a pathologist, which requires an extended period of time. Early diagnosis is important to prevent further liver damage. IR imaging provides a rapid imaging technique that can be used to identify biomarkers in tissue linked with ASH. In this study, we applied Fourier Transform Infrared (FT-IR) Spectroscopic Imaging to obtain detailed images of liver tissue samples from patients previously diagnosed with ASH. These images contain biochemical information that allows for the determination of biomarkers and biochemical changes associated with alcoholic steatohepatitis.

Abstract Name: Tapering Before NCAA Division I Cross-Country Competition Reduces Plasma HDL-C But Has No Effect on Structural HDL Apolipoproteins

Exercising has shown to increase HDL-C levels in most populations, however it is uncertain if it has an effect in structural apolipoproteins such as apolipoprotein A1(Apo-A1) expression and secretion. Cross-country athletes undergo a period of tapering before competition resulting in reduced physical activity. The purpose of this study was to determine if the changes in physical activity that cross country athletes experience during the season and in preparation for competition affects their HDL-C. We hypothesize that the tapering period will result in reduced HDL-C and its structural apolipoproteins.Twenty seven D-I cross-country athletes, ages 19 to 25 years old, were followed for one season (four months). Blood was collected at the beginning of the season and analyzed for HDL-C levels through enzymatic spectrophotometry using the Alfa Wasserman Ace Axcel® biochemistry analyzer. Apo-A1 and Apo-CIII were measured through Luminex® MAGPIX® multiplex assays. Paired-samples t-test comparing the preseason (pre) vs postseason (post) values was performed using IBM® SPSS Statistics 25.HDL-C levels decreased significantly from pre = 64.2 ± 2.7, vs post = 60.7 ± 2.5 mg/dL p = 0.03. Apo-A1, 92.3 ± 6.5 vs 88.8 ± 6.8, p = 0.23 and Apo-CIII 13.8 ± 0.1 vs 13.3 ± 0.5, p = 0.37 showed no statistical difference from pre vs post. Our study shows that HDL-C levels are decreased by a period of time as short as 4 months. However, we did not observe a change on apolipoproteins A1 or CIII. These findings suggest that although exercise can modulate lipidation of the HDL particle through the process of cholesterol esterification in the reverse cholesterol transportation (RCT), Apo-A1 expression and secretion may be modulated independently of this process as we did not observe any changes in apolipoprotein concentrations.

Abstract Name: Lost Girls: Unmasking Gender's Effects on ADHD Diagnosis

Women and girls are less likely to be diagnosed with ADHD. Although female diagnoses are rising, the disparity lies in females' access to forms of treatment, which they only seem to receive if symptom severity is high. Women and girls are being diagnosed less because symptoms in females often present differently, in a way that isn't as easily diagnosed leaving them lost in the chaos that is ADHD. Males tend to be diagnosed with the ADHD-HI presentation causing them to be more hyperactive and impulsive, while females are diagnosed with the ADHD-I presentation meaning their symptoms appear as inattentiveness, withdrawal, and lack of emotion and mood regulation. Female symptoms can often appear as depression and/or anxiety and typically come with the onset of puberty, which in turn results in an incorrect diagnosis. By internalizing these unrecognized symptoms, a correct diagnosis becomes harder as females tend to "mask" to conform to society's demands as evident throughout history. Society's stereotypes surrounding women have fed into this overall failure of recognition. For instance, when a woman is having trouble remembering something, difficulty concentrating or controlling her emotions she might be referred to as "spacey" "bossy" "crybaby" or "blonde" which are all labels dismissing the real problems women and girls are facing. By not receiving the correct diagnosis they do not receive the help they truly need which can affect their education, and overall growth and development. The gender gap and stereotypes surrounding ADHD and women, which continue to persist need to be addressed so that females get the help they need and deserve.

Abstract Name: **Forensic Evaluators' Considerations of Contextual Information in Adjudicative Competence Cases**

In all instances, the specific collateral and assessment information sources used by forensic psychologists during an evaluation are critical components towards determining a defendant's competence to stand trial (CST). However, a growing body of research suggests forensic psychologists may be influenced by cognitive biases during their evaluations, leading to variability in their decisions, reasoning, and conclusions. Exposure to irrelevant and potentially biasing contextual information during an evaluation has been noted as a contributor to this variance. Nevertheless, the extent to which evaluators use specific information sources and their perceptions of source task-relevance remains largely unknown. The proposed study will address this gap by quantifying evaluators' perceived task-relevance of their most-used information sources across CST referral concern contexts. We will distribute an online survey to licensed forensic mental health evaluators via professional psychology-law listservs (American Psychology-Law Society (AP-LS) and PSY-LAW) and directly contact internship and postdoctoral training directors listed on the Association of Psychology Postdoctoral and Internship Centers directory. Participants will be randomly assigned one of three surveys reflecting clinically plausible referral concern scenarios, each of which will address either a hypothetical defendant's factual understanding of courtroom proceedings, rational understanding of courtroom proceedings, or ability to assist his/her counsel. Analyses will determine potential significant differences and correlations of source usage rankings and task-relevance ratings across referral concern types. Our results will highlight potential inconsistencies between information sources' usage and general perceptions of task-relevance, lay the groundwork for future bias mitigation strategy studies and implementation, and promote the development of standardized CST evaluation methodologies.

Abstract Name: **Alcohol Availability and Crime: Does the relationship vary by the unit of analysis?**

In this study, we analyze the impact of alcohol outlets on crime in Milwaukee, WI estimated at three different levels of aggregation (i.e., block group, tract, neighborhood). We used Esri's ArcPro geocoding tool to map 2020/2021 FY liquor licensed alcohol retailers and separated them by the broad categories of alcohol outlets: on-premises (bars, taverns, etc.) and off-premises (liquor stores, convenience stores, etc.), resulting in 1,293 locations in total across these broad categories. This geocoding tool was also used to map 2020 reported crimes (sex offense crimes are omitted from the geospatial analysis because the spatial location of these incidents is not publicly available), resulting in 34,564 crimes analyzed in this project. Subsequently, these spatial data points (alcohol outlets and crimes) were aggregated across three different units of analysis: census block groups, census tracts, and neighborhoods. In a related project, we estimated socioeconomic characteristics for neighborhoods using the areal interpolation method. Currently, we are analyzing the results of the association between alcohol outlets and crime across these three different units of analysis, when controlling for areal interpolation estimates for the neighborhoods. The analyses will be completed in time for our presentation. This project has important theoretical and methodological implications for criminological and public health literature because it sheds light on whether associations between alcohol outlets and crime exist regardless of the unit of analysis used to estimate the relationships. As such, it contributes to the field by better understanding the nuanced nature of the alcohol/violence association.

Abstract Name: Perceptions of Social Media's Educational Value in Relation to Evidence Based Practice

This project evaluates the educational value of social media platforms including TikTok, Instagram, and Twitter as course-based learning supports in an online graduate-level aphasia course. Components of evidence-based practice (EBP) in each of the three social media platforms are analyzed against student posts. These components include client perspectives, clinical expertise, and internal/external evidence (ASHA, n.d.). Additionally, student perceptions regarding the utilization of social media in course-based assignments are analyzed.Individually, TikTok (Escamilla-Fajardo et al., 2021), Instagram (Carpenter et al., 2020), and Twitter (Hull; Dodd, 2015) indicate a positive response among students and faculty in higher education. Social media in a classroom setting can help co-create knowledge, facilitate different learning styles, promote experiential learning, and enhance collaborative skills (Stathopoulou, 2019). Though each of the platforms are continuously rising in popularity, there is a substantial absence of conducted research studies that evaluate them holistically.A course-based assignment requiring use of each of the three social media platforms was assigned to 24 graduate students in an online aphasia-related course. Six prompts were presented every two weeks, and students used their assigned social media platforms to explore and develop answers to the prompts. Platforms were rotated across all students, so each student used each platform twice.The social media relics submitted by students were categorized based on the three components of the EBP triangle. Frequency counts for the presence of EBP domains within submissions for each platform will be presented. Additionally, student perceptions of each platform, their learning benefits, and their comparative value to the other course assignments will be discussed. Results will be discussed and applied to potential course-based pedagogical applications using social media platforms.

Abstract Name: Smartphones, Attention, and Brain Electrical Responses

Given concerns about how distracting smartphones can be, we are interested in how they affect attention-related brain electrical activity. Previous research suggests that the mere presence of one's smartphone can negatively impact behavioral performance on an attention-related task. The aim of our ongoing study is to investigate whether simply having one's smartphone present and visible (although shut off) influences attention-related EEG (electroencephalographic) activity. We are assessing this in two ways. First, subjects perform an oddball task, which requires attention and responses to occasional target stimuli ("oddballs") among many task-irrelevant stimuli ("standards"). The P3, a late component of the event-related potential (ERP), is typically larger to oddballs (which receive more attention) than standards; we predict an attenuation of this oddball effect in the presence of one's phone versus a control non-phone object (tile). Second, we are looking at EEG power in the beta range (13-30 Hz) as subjects passively view their phone versus the control object. Since beta activity is positively correlated with alertness and attention, we predict greater beta power in the phone condition. Furthermore, we predict a correlation between beta power in response to one's phone and attenuation of the P3 oddball effect by one's phone; that is, the more attention is garnered by one's phone the more we think their phone will distract from a phone-irrelevant attention task.Preliminary data suggest increased beta activity in the presence of the phone and replication of the classic P3 oddball effect, but are unclear about an impact of smartphone presence on P3 amplitude.

Abstract Name: How Development and Experience Affect Perceived Cognitive Load During Distracted Driving

Driving inexperience and inattention increase cognitive load and motor vehicle crash risk. Young age and driving inexperience are strongly associated with crash risk, and a combination may impact cognitive load while driving, particularly when distracted (e.g., cellphones). This project examined age and driving experience on perceived cognitive load during simulated drives under varying distraction conditions. It was hypothesized older age and greater driving experience would be associated with lower perceived cognitive load.One hundred ninety teens (MAge =17.12 years, 53% Female, 53% non-white or Caucasian) were recruited based on age (16 vs. 18) and licensure (Non-licensed [n=109] vs. Licensed within 2 weeks of recruitment[n=81]). Participants completed 3 drives in a high fidelity fully immersive driving simulator. A randomly ordered distraction task (no-task, cellphone call, or texting) was completed for the duration of each drive. During the call and texting tasks, participants communicated with an unfamiliar research assistant who used a semi-scripted list of questions and conversation topics. After each drive participants completed the NASA Task Load Index (TLX), a well-validated self-reported measure of perceived cognitive load incorporating mental, physical, and temporal demands, and perceived performance, effort, and frustration ratings.Repeated measures ANOVA indicated TLX scores from the phone call (M=62.08) and texting conditions (M=71.24) were significantly higher (.001) than those with no distraction (M=47.04). Non-licensed teens reported significantly higher TLX than licensed peers only in no-task conditions, especially for those aged 16. These results suggested that although experience may lower cognitive load for undistracted driving, distractions increase cognitive load regardless of experience.

Abstract Name: Driver Interface Research: Describing Driver Driving Performance

There is an increasing amount of miscommunication and misunderstanding within the transportation industry on the definition and use of different measures and statistics. There is a lack of consistency and existing definitions are often too vague. In 2015, Society of Automotive Engineers J2944, “Operational Definitions of Driving Performance Measures and Statistics”, published a standard for definitions and measures of driving performance. It identified different definitions and outlined proper procedures to follow when applying and measuring different driving performance measures. The purpose of the current project is to create a set of definitions and measures for both on-road and off-road contexts through an extensive literature review. Published data is being compiled for every single measure in the original J2944 standard while also expanding to off-road measures. This expansion to off-road measures is to ease comparisons between on-road data and off-road data and allow the use of the standard in military operations. Since driving has remained practically unchanged since the 1970s, this literature review spans any papers within the last 50 years that focus on driver performance. Once complete, the findings should remove the confusion surrounding confounding definitions in the transportation industry. It will develop a standard for future journal articles, proceedings papers, technical reports, and presentations to follow.

Abstract Name: Race Based Memory Errors in the Cross Race Effect When Remembering a Narrative

Two experiments analyze how a narrative and its protagonist are remembered depending on the participants' race. The cross-race effect (CRE), a phenomenon where individuals have poorer memory for faces outside of ones' race compared to faces within their race, was examined. It was hypothesized that White participants would experience more race-based errors when the protagonist was a Black male in comparison to a White male. Also, White participants would be more likely to confuse the Black protagonist with other Black characters. Black participants (experiment 1 only) and White participants were given a short narrative about a male protagonist, Jackie. Four faces would appear: Jackie and the loiter, who alternated being Black and White, and the cashier and server, who were both White females in experiment 1, but Black or White females in experiment 2. After reading the narrative, the participants responded to a series of questions to test their memory of events and character faces. In both experiments, findings suggest that White participants had a higher rate of race-based memory error when presented with Black Jackie than White Jackie. The results suggest that patterns are used to aid in filling in memory gaps and those patterns can be related to racial expectations. Additionally, White participants, in experiment 1 and 2, misidentified Jackie the most when he and the loiter were both Black. In contrast, Black participants misidentified Jackie the most when both he and the loiter were White. In short, the CRE was supported in both experiments and in Black and White participants. Implications are that race and culture may influence the way we remember and misremember details of an event.

Abstract Name: Fear, framing and fins: Impact of shark media portrayals and Shark Week viewership on US adults? conservation support

From shark attacks on the news to villains in cartoons, mass media often depicts sharks as antagonists. Yet, sharks are keystone species of the oceanic ecosystem and many are critically endangered. Programming like Discovery Channel's Shark Week could spread awareness of the ecological value and vulnerability of sharks, although programs featuring shark aggression may counteract viewers' concerns for their welfare. This study is a 2x2x2 survey experiment with 805 US adults recruited October 2022 from Mechanical Turk. Each participant saw one of eight experimental videos about sharks, which varied with regards to the individual interacting with sharks (celebrity or researcher), the nature of the shark content (educational or aggressive), and the framing of the call for shark conservation (gain or loss-framed). Regular Shark Week viewers reported greater wildlife conservation donation and federal funding support. In the full sample, loss-framed messages inspired greater feelings of hope that we can protect shark species, controlling for conservation support. A three-way interaction indicated greatest hopeful reactions to the loss-framed aggressive video featuring a celebrity. Participants perceived greater social and ecological value of sharks if they saw the celebrity in educational shark content (M = 4.14 out of 5.0) or the researcher in aggressive shark content (M = 4.16; compared to celebrity-aggressive M = 4.07 and researcher-educational M = 4.01). Impact on perceptions of sharks' value was moderated such that only participants who were not regular Shark Week viewers were impacted by experimental factors. Hope was a stronger predictor of intention to donate to shark conservation compared to perceived value of sharks, regardless of Shark Week viewership. Results suggest that scary shark media may not undermine support for shark conservation. Viewers with less exposure to shark content are impacted in more nuanced ways. Findings have practical implications for promoting public support for conservation funding.

Abstract Name: **Comparing Secondary Mathematics Teachers' Technology Use Across Three Countries**

Technology integration in the classroom has been established for years, introducing new teaching styles and execution of pedagogical approaches. Due to remote learning many schools experienced during 2020 and 2021, the technological advancements have intensified, along with the support they provide teachers. Therefore, the field of mathematics education must develop ways to assist teachers in utilizing technology. This study sought to determine the impact the fluctuating environments had on secondary mathematics teachers' ability to teach mathematics within the International Baccalaureate (IB) system, and how these fluctuations affected teachers' ability to promote accessibility, equity, and achievement for students. The presentation reports on qualitative research and thematic analysis conducted with IB secondary mathematics teachers in the United States, United Kingdom, and Australia, and consisted of a questionnaire, interviews, and field observations. The questionnaire encouraged the participants to reflect on their experience during in-person and virtual learning and highlighted two educational frameworks. The interviews presented an opportunity for the participants to expound upon their questionnaire responses and communicate more nuanced expositions regarding their teaching experiences with technology in in-person and virtual classrooms. The field observations created an opportunity to analyze how the use of technology in the classroom impacts the students' abilities to understand the mathematical concepts, and whether the teacher's perspective of their teaching aligns with what actually occurs. Understanding the language used by the participants when they reflect on their teaching and students' learning allowed for comparisons across the three countries. Through the analysis, frequency-based themes were constructed from the questionnaire responses to create an evolution of questions for the interviews. These insights led to the creation of the analytical lens used throughout the field observations. Findings from the questionnaire, interviews and field observations will be shared along with implications for the preparation and development of mathematics teachers regarding technology use.

Abstract Name: **Identifying Cognate RNA Sequences of Non-Structural Protein 9 in SARS-CoV-2**

As an RNA+ virus, SARS-CoV-2 infection (COVID 19) leads to direct translation of viral RNA to produce non-structural proteins (Nsp) responsible for viral replication. For example, Nsp 7 and 8 are thought to act as a helicase, Nsp 9 as a single stranded RNA binding protein and Nsp 12 as the replicase essential to the proliferation of the virus. Studies of homologous, Nsp 9 proteins in HSV, MERS, and SARS-CoV-1 indicate this protein binds both DNA and RNA sequences. In SARS-CoV-2, Nsp 9 contains an unusual OB, greek key motif thought to keep RNA single stranded for efficient replication in other viruses. Together these results suggest, Nsp 9 may function in SARS-CoV-2 to keep the viral RNA linear for replication by Nsp 12; however, little is known about the RNA binding requirements or structural contacts and interactions in this protein-RNA complex. Tryptophan fluorescent studies of Nsp 9 have been developed to identify cognate RNA binding sequences and structures. Initial studies indicate binding of an RNA pseudoknot structure in the 3'-untranslated region of the viral RNA. Further analysis of RNA structural requirements for stable Nsp 9 binding will be important in further deciphering the role of Nsp 9 in SARS-CoV-2 as pseudoknot structures in the 5' and 3'-UTR have served as a switch from viral RNA translation to replication and may serve as a handle for control of this ever infecting and mutating virus.

Abstract Name: **Effects of Microplastics Exposure in the Sea Anemone, Exaiptasia pallida**

Microplastics are one of the most common forms of pollution found in marine environments, and their small size (<5mm) allows them to be easily ingested by marine biota. Exaiptasia pallida is a solitary anemone native to the western Atlantic that harbors symbiotic dinoflagellates like those of reef building corals, and passively feed on prey such as brine shrimp. To assess the influence of microplastics on E. pallida, a series 48-hour laboratory experiments were conducted in which symbiotic and aposymbiotic anemones were exposed to 100 µm polystyrene microplastic beads in the presence and absence of brine shrimp. Ingestion and egestion of microplastics, and photosynthetic parameters were measured at 3, 24, and 48 hours following initial exposure. At 48 h, anemone tentacles were harvested and analyzed for algal symbiont density. Physiological stress in the anemones was investigated via assessment of antioxidant enzymes, superoxide dismutase, catalase, and glutathione peroxidase. E. pallida consumed polystyrene beads in every microplastic treatment, and both presence of brine shrimp and symbiotic state significantly increased microplastic ingestion. Aposymbiotic anemones ingested more microplastics than symbiotic anemones, suggesting that bleached anemone communities may be more susceptible to microplastic pollution.

Abstract Name: **Planning For Water Resources in Iowa**

Water is integral to Iowa's history, geography, and economy. It is the only State with two rivers as its defining borders. Those rivers, the Mississippi and Missouri, were crucial in Iowa's growth and development. Today, Iowa is still reliant on its rivers and waterways for transportation of goods, agriculture, and recreation. Yet, despite their importance, Iowa's water sources are highly susceptible to degradation. Agricultural runoff creates excessive nitrate levels and algae blooms. Soil sedimentation from erosion leaves Iowa water unclean. In addition, Iowa is afflicted with both violent flooding and devasting drought. With all of these issues surrounding water, planning for it becomes a necessity. From rural communities to urban centers, Iowa requires careful and considerate planning for its stormwater runoff and flood mitigation.Many Iowa communities have already established water resources plans, including Des Moines, Ames, Cedar Rapids, and Iowa City. By examining and comparing these plans it is easier to understand Iowa's planning challenges and what solutions are best suited for the State. With this information, one can also extrapolate the actions rural communities can take to protect water quality and generate income while creating recreational services for the community. With advances in agriculture technology, the time is now for rural communities to adopt climate action plans. In doing this, they have the opportunity to both benefit themselves and secure the future ofgenerations to come.

Abstract Name: **Algae Growth in Relation to Biodiversity of Freshwater Systems in Northeastern Wisconsin**

The focus of the study is to determine whether large-scale algae blooms in Wisconsin affect biodiversity in freshwater systems throughout the northeastern part of thestate. We will be focusing on a pond linked to the Fox River system in order to analyze and measure the, overall, biodiversity of the water system. The pond exhibits large algae blooms annually, typically starting to cover <2/3 of the pond surface by June. The study will focus on physical removal of algae using barley straw as a medium of decomposition:One of the products of its decomposition is hydrogen peroxide. Hydrogen peroxide is useful in destroying algae as H2O2 has a weak central bond and will form a hydroxyl radical when its bond breaks. This will target the cell wall of nearby organic compounds, such as the algae, and force the bond to break in order toreform with the radical, essentially killing the algae. The byproducts of this reaction are simply O2 and H2O (oxygen and water). There is no toxic residue left behind in the water. Seeing as the barley straw will be introduced bythe surface of the water, and the reaction will happen relatively quickly, it is unlikely that other organisms will be negatively affected by this process. Any reaction with other organisms such as plants or fish will only damage epithelial cells, however a smaller protist such as algae will be removed quite efficiently. Ostensibly, an increase in the overall health of specific microorganismsshould benefit macro-organismsfurther upthe food chain, as oxygen content increases throughout the freshwater system.

Abstract Name: **Achieving Photomanipulation of Droplets in Porous Microfluidic Systems**

Microfluidics is incredibly useful with boundless applications from chemical biology and information technology to experimental studies on large-scale phenomena. Microfluidic systems are cost-effective, require small amounts of reagent, reduce the time required to output results, and allow for better control of experimental parameters. Unfortunately, operations on the microscale require complex systems including active (pumps, valves, etc.) and passive elements (microchannels, porous media) to control the fluid. Manipulation of droplets with light, based on the photo Marangoni effect, offers a promising solution that could take place of or work with active and passive elements of the system, reducing cost and difficulty, and increasing the efficacy when working at the micro or nanoscale. This technique is based on the unique property of a surfactant called azobenzene trimethylammonium bromide (AzoTAB), which is sensitive to light. The surface tension increases subject to UV light and decreases with blue light. Employing this unique effect, a surface tension gradient can be created at the water-oil surface, leading to an interfacial flow, which can in be used to manipulate an oil droplet. This method does not require any physical contact, or moving parts and thus offers numerous benefits compared to traditional methods such as pumping.I am currently investigating the limits of the manipulation that can be done to microfluidic systems with light and AzoTAB. This project is inspired by the research conducted in Dr. Baigl's Lab in Paris, France, who is a collaborator of my faculty advisor, Dr. Yaofa Li. Currently, I am able to replicate the initial results that the Baigl Lab produced using the AzoTAB provided by Dr. Baigl. We propose to build upon the existing work to: (i) achieve photomanipulation of a droplet in a more complex microfluidic system; (ii) gain a fundamental understanding of the underlying physics by leveraging advanced flow diagnostics.

Abstract Name: **Writing an Original Composition for Clarinet and Piano**

Music has always been a passion of mine. I started learning about music when I was little and it has stayed with me ever since. As I grew older, an area of music that I started to become really interested in was composing. I started by writing short piano pieces, and I eventually made my way to writing two piece for a full wind band. This year, I challenged myself to a new task of writing a piece for solo clarinet accompanied by piano for my senior recital. Writing this piece was a challenge for me because I had to figure out how to make the clarinet part stand out in a way that would resonate with the audience. I went for a more jazzy and bluesy feel when writing the piece because I don't hear that style a lot when listening to clarinet music. I've only heard a few instances of jazzy clarinet, but I really like it and I wanted to add to it. Another challenging aspect of composing the piece was writing a piano part that fit witht the clarinet part. Most of my process when writing the piano part was experimenting with different chord progressions until I found one that fit. The piano doesn't get as many moments to show off as the clarinet does, but I still tried to give the piano part its own moments to shine. Another key feature of the piece is that it shifts character frequently. So some parts may be faster and more upbeat, whereas others may be slower and more moody. All of these made for a valuable learning experience, as I this was the first piece I ever composed for solo clarinet and piano.

Abstract Name: **Biochemical Analysis of Non-Protein Coding RNA LINC00298 and Its Expression in Early Onset Alzhimers.**

Alzheimer's is a terminal-neurodegenerative disease which causes neuronal loss in the brain. This disease affects 5.6 million people a year over the age of 65 and is the most common diagnosis among Dementia patients. Data meta-analysis of Alzheimer's patients has found that specific genes, when expressed, may lead to the development of Alzheimer's. One gene of interest is LINC00298 which is a non-protein coding RNA in the brain that is present in Early-Onset Alzheimer's. Very little is known about the impact of this gene during development. Our research team's focus is to biochemically and biophysically analyze LINC00298. Working in collaboration with the School of Pharmacy at North Dakota State University, using Circular Dichroism and Cell Mobility Shifts, researchers were able to identify that the gene depends on Mg2+ using the electrostatic interactions to undergo significant structural changes upon binding. Additionally, through the use of Mass Spectrometry in coordination with the University of Minnesota Minneapolis, Center of Mass Spectrometry and Proteomics. The LINC00298 gene was biotinylated at the 3' end and bound to streptavidin beads. This testing allowed for an understanding in its interactions with enzyme metabolism as well as protein translation. This new information gives insight on the importance of the gene and will potentially assist in finding solutions for Alzheimer's in the future.

Abstract Name: Cybersecurity in Microgrid Environment

Today's electrical grid infrastructure reflects a trend towards the integration of computer network technology with traditional industrial control systems. This synthesis, often referred to as a "smart grid" would allow for more efficient transmission of electricity, reduced overhead costs for both producers and consumers, reduced peak demand, and more. However, it faces more critical cyber threats since it is the lifeblood of the nation's economy and vital to the health and safety of all residents. In June 2021, Colonial Pipeline paid roughly $5 million in ransom to hackers, and JBS paid $11 million ransom after a similar cyberattack. A report released by the Treasury Department found that around $590 million had been paid by victims of ransomware to their attackers in the first six months of 2021, as such attacks skyrocketed. Given the nature of computer network technology and the increasing prevalence of both state-sponsored cyberattacks and cyberterrorism, there is a clear need to harden such infrastructure to prevent its compromise. Our team in this cybersecurity microgrid testbed project is funded by the WiSys Ignite Grant, where we explore and study the possible cyberattacks against a microgrid. We first survey potential cybersecurity attacks, develop penetration techniques on a scaled-down version of a smart grid, and study the patterns of the successful cyberattacks. Referred to as a "smart microgrid", we attempt to infiltrate and disrupt it in order to better understand its weaknesses and the real-world implications of cyberattacks on critical industrial infrastructure and industrial protocols that are often overlooked.

Abstract Name: Fostering collaboration between parents and speech language pathologists : What impact do motivational interviewing strategies have on parent-child reminiscing intervention?

The literature on parent-child reminiscing conversations from the various disciplines, including developmental psychology and communication sciences and disorders, indicates that these brief and routine conversations about shared, past experiences can have a positive impact on a child's developing language, cognitive, and socio-emotional skills. However, families can reminisce in a variety of styles depending on their culture. Motivational interviewing is a counseling style that aims toguide clients toward developing their own solutions as grounded in their personal values and priorities. With our project we ask the question, "What impact do motivational interviewing strategies have on the collaborations of parents and clinicians of different cultural backgrounds during reminiscing interventions?" To answer this question, we have thus far recruited two families- onemonolingual English speaking family with a preschooler diagnosed with a language delay.; onebilingual family (English and Japanese) with an adolescent boy diagnosed with ASD and TBI. We are video recording our collaborations and parent-child reminiscing. Inductive methods of analysis are employed to identify behaviors that contribute or interfere with effective collaboration between the clinician and parents. Collaboration methods will be refined after initial analysis and additional families recruited for further study. Understanding ways to foster better collaboration with families is essential to creatingindividualized and culturally sensitive interventions.

Abstract Name: **Exploring the Role of Knowledge and Topic Interest in Predicting Mind-Wandering Among College Students in a Night Class**

Purpose: In this study, students self-rated topic interest, familiarity and mind-wandering during and after weekly class sessions. Attention and engagement during class is a crucial aspect of learning (Szpunar et al., 2013). Mind-wandering is a phenomenon that occurs when the mind shifts thoughts from the topic that is being presented to other internal thoughts (Smallwood; Schooler, 2006). Mind-wandering is associated with reduced academic outcomes, including reduced recall of lecture-based content (Risko et al., 2012), and is associated with working memory capacity, intentionality, motivation and increased time on task (Soemer; Schiefele, 2020). Further investigation into the effects of topic interest and topic familiarity may provide additional insights into modifiable factors influencing mind-wandering within the college classroom.Methods: For six consecutive weeks, students in an undergraduate night class were surveyed midway through each class and at the end of each class. At both points in each class session, students were anonymously surveyed regarding their interest level in the course content presented in that class, as well as their familiarity with the topic and the degree of mind-wandering that occurred during class. Mind-wandering was assessed via the five-item Mind-Wandering Questionnaire (MWQ; Mrazek et al., 2013).Relationships will be discussed related to the variables being investigated. Additionally, applications of findings to student self-efficacy, responsibility and metacognitive learning strategies will be discussed as will potential strategies to mitigate mind-wandering during class.

Abstract Name: **What are universities in the upper Midwest doing to prevent sexual violence on campuses?**

A public health priority should be preventing sexual violence on college campuses. According to a 2019 Association of American Universities survey of nearly 182,00 students, 13% of college graduate students reported nonconsensual counter by physical force or an inability to consent. Sexual violence on campuses is persuasive and more prevalent at college compared to other crimes. Colleges have responsibility to prevent sexual violence on their campus through bystander intervention programs, resistance education, and other methods. Available evidence suggests that sexual assault prevention programs can be effective in producing desirable changes in attitudes and behavioral intentions, at least as measured immediately after participation in programs. Many campuses require a program in the beginning of the year as a part of orientation, but do not provide extra support or awareness throughout the remainder of the year. What measures are university's taking to prevent sexual violence among their students. Researchers want to understand the phenomena of sexual violence happening on these college campuses.A survey developed in Qualtrics will be distributed on social media to capture data from a minimum of 100 respondents 18 years of age or older, of any gender who attend a college university in the Mid-West.An exploratory study will be conducted using a non-probability judgment sampling method. A sample size of 100 respondents will be drawn from the population of students 18 years old or older, any gender, and who are attending college in the Mid-West. Data will be analyzed using descriptive statistics, cross tabulation, and triangulation to determine, 1)effective education and training prevention methods in universities, 2) effective support services for students, 3) expectations for personal responsibility in prevention, 4) effective awareness and prevention campaigns to make campuses safer.

Abstract Name: Postmodern Media as a Promotion of Women&#65533;s Mental Health: Classical Literature Juxtaposing Contemporary Mediums

In comparison to classical and canonical literary texts, contemporary pieces of media, such as the television show BoJack Horseman, have a newfound edge by bringing a postmodernist perspective into the representation and destigmatization of mental health and women. BoJack, for instance, contrasts anthropomorphic female animals with human women and identifies what mental wellness means to each. Furthermore, classical literature has laid the groundwork for contemporary mediums of storytelling, which I argue have the ability to be a novel representation of mental health and women by using a postmodernist framing, creating empathy for a neurotypical audience as well as offering solidarity to women who experience complexities of mental health. I examine three different pieces of media having little to no scholarly research on them, but are just as worthy of being viewed and celebrated as canonical literature is on the subject of women's mental health: BoJack Horseman additionally provides a meta-commentary on how industries disingenuously support women's mental health to earn public favor; the intertextual play 4.48 Psychosis is both a poetry collection and a performance piece, allowing for numerous interpretations to be made about how women experience depression; and the video game Milk Inside A Bag Of Milk Inside A Bag Of Milk is able to destigmatize conditions like schizophrenia by immersing the reader in the mind of a young woman who experiences it, allowing them to empathize with her struggle through the utilization of absurdist language and visuals.

Abstract Name: Drivers Of Macroinvertebrate Community Integrity Within Mixed Urban And Agricultural Dominated Mississippi Tributary Watersheds

The “urban stream syndrome” refers to a multitude of impacts caused by urbanization including flashier hydrograph, elevated concentrations of nutrients and contaminants, altered channel morphology and stability, reduced biotic richness, with increased dominance of tolerant species, reduced base flow and increased suspended solids.The drivers of these “symptoms” include impervious surfaces, piping in storm water drainages, habitat and forest loss, water supply and sewer leaking, and direct alterations to channel morphology and flow. The goal of this study was to assess the integrity of the macroinvertebrate community and determine the most significant drivers of such integrity at the catchment, riparian zone, and reach scales. Macroinvertebrates have been used to measure the overall health of the ecosystem and have been shown to be important in overall health in aquatic systems.A higher species diversity of macroinvertebrates increase the health of the stream, a poor FBI for a stream can indicate that an impairment has occurred and further planning, management and restorative processes would be necessary.We used the Family Biotic Index (FBI) to assess the health of our sites. The family biotic index (FBI), a measure of integrity in relation to organic pollution tolerance was calculated. The FBI value is assigned based on the macroinvertebrate tolerance to pollution. The figure below illustrates FBI values and characterizes whether the aquatic system health is poor, fair, good or excellent.

Abstract Name: Campuswide Sustainability: Designing an Early Intervention Training Module to Cultivate a Sustainably Minded Culture

Implementation of sustainable practices are being pursued at universities across the globe. However, getting student buy-in to adopt sustainable habits can be challenging. Over a seven-year period, the University of Wisconsin-Eau Claire has collected data on student behavior as they discard lunchtime waste and conducted audits on the waste found in the compost, recycle, and landfill bins. That data has been used in multiple intervention attempts to educate students on proper waste-sorting when having access to those bins. These interventions have had limited success in generating a statistically significant shift in student behaviors. During the 2022-2023 academic year, we are pursuing a new effort with the goal of preemptively educating students on multiple aspects of sustainability before they arrive on campus. Our university currently requires incoming students to participate in online training modules on topics such as sexual assault awareness (Title IX), equity diversity and inclusion, and information security. We have received approval to add a sustainability-focused online training module for incoming students. We are designing a module that will focus on four sustainability topics: campus-wide sustainability goals, public transportation routes, using the campus's reusable food container program, and proper waste-sorting habits. Each topic will contain microlessons consisting of readings and videos. Each microlesson has questions that must be answered before the student can progress. Our goals are to educate students on effective sustainability practices, encourage them to adopt those practices as incoming students, and for them to see our campus as a place that values sustainability. We will assess the effectiveness of this intervention through future waste audits, observational studies of student behavior and survey responses. Our training module is intended to be used by all incoming students and we expect that our audits and survey results will reflect wider adoption as more and more students complete the training.

Abstract Name: String in Switch ? Usage Analysis and Maintainability

The release of Java 7 in 2011 introduced the capability of using character sequences, hereby referred to as String objects, in switch expressions and their corresponding case statements. This String in Switch language feature allows producing readable and better-performing code when compared to commonly used alternatives like if-else statements, often nested and difficult to modify and maintain. As a consequence, code maintainability can be simplified by incorporating this feature into a project. Our research focuses on the usability analysis of this new language feature, with the goal of observing its usage over time across selected Java-based open source projects. In addition, we perform a comparative analysis between sample statements and equivalent if-else expressions to discuss the maintainability of the code as it relates to the advantages of String in Switch. For analyzing a project, we perform a file expansion that generates revisions for every commit in the project's repository. Subsequently, we build Abstract Syntax Trees (ASTs), allowing us to identify the presence of String in Switch statements present in a target file. With this information, usage-over-time plots are derived, allowing us to observe the occurrence of String objects in switch expressions throughout a project's development history. Of the analyzed projects, our research shows that the String in Switch feature is not widely used, despite its capability of generating cleaner and readable code. We conclude that some of the analyzed projects may be mature, which reduces the need to rewrite functional code into equivalent String in Switch statements. These findings are useful not only for programming language designers in understanding the tendency to utilize new features, but also for instructors in teaching programming languages in a limited amount of time.

Abstract Name: Mountain Glacier Segmentation Method Using Landsat Satellite Imagery and L*a*b* Color Space

Anthropogenic climate change has caused unprecedented warming of the Earth's surface. As temperatures rise, having accurate models for future climate scenarios becomes increasingly urgent. Conveniently, the change of a glacier's size can be used as a physical indicator of the rate of climate change. However, the remote nature of glaciers renders direct measurement impractical. For this reason, researchers have been working to find an accurate remote measurement technique to calculate the area of glaciers. Since there are almost 200,000 glaciers around the world, such a technique also needs to be efficient and ideally automated. Unfortunately, rock debris camouflages many mountain glaciers and further complicates methods to accurately measure glacier area.This project used Landsat satellite images to identify glaciers and segment, or distinguish, them from their surroundings. A color-based image segmentation method was developed to find the area of glaciers from the Landsat images. This semi-automated method was then implemented on images of Gorner Glacier in Switzerland and Franz Josef Glacier in New Zealand. For this method, three satellite color bands were compiled into a false color image and then segmented in the L*a*b* color space. The transformation from the typical RGB colorspace to the L*a*b color space allowed the red "land" pixels to be easily eliminated, leaving behind the blue pixels of the glacier for area calculation. The method was visually successful in segmenting the exposed ice, but it could not differentiate the mountain from the debris-covered ice with high precision.

Abstract Name: Mechanical and Surface Characterization of 3-D Printed PLA-HA Composite

The materials currently used to construct replacement hip and knee joints for humans are stainless steel and titanium. Whilst these materials are strong and fairly biocompatible, they are expensive and can cause adverse long term side effects such as stress shielding. The aim of this project was to construct and evaluate an alternative to these materials, specifically 3-D printed Polylactic Acid and Hydroxyapatite composite (PLA-HA). PLA-HA is a polymer composite of Polylactic Acid (PLA) and Hydroxyapatite (HA). PLA-HA is relatively cheap, very biocompatible, and can be easily adapted for use in a 3-D printer. This vastly simplifies the process of manufacturing unique parts with complex geometries such as a replacement joint. Raw PLA-HA was created in-lab using three different manufacturing methods. These manufacturing methods were Dry Speed Mixing, Wet Speed Mixing, and Magnetic Stirring. The raw PLA-HA was then converted into filament for use in a 3-D printer using a uniaxial filament press. The PLA-HA filament was then to be used to 3-D print three different samples for mechanical testing for each manufacturing method. These samples will be subjected to a variety of tests to characterize their mechanical and surface properties. These tests include destructive tensile tests, micro-indentation, and wear tests. These mechanical and surface properties will then be evaluated to determine if they are sufficient for a joint replacement application. The four different manufacturing methods will also be compared against one another to determine which method produces samples with the desired mechanical properties and distribution of hydroxyapatite throughout its matrix.

Abstract Name: **Search for Antimicrobial Producing Strains in Minnesota Bogs**

Microbes in Minnesota bogs are a largely underrepresented area of study in the search for new antibiotics. New or unstudied species of Minnesota bog bacteria have the potential to combat the current and worsening problem of multi-drug resistant pathogens. The purpose of this study is to identify if lower pH levels are more suitable for different bacterial colonies as opposed to normal pH levels, and determine if these microbes exhibit antimicrobial properties against safe relatives of the ESKAPE pathogens. Methods used reflect the protocols from the Tiny Earth - Studentsourcing Antibiotic Discovery Project. Soils were processed and microorganisms were isolated from the different locations of bogs in Minnesota and grown on various media: 10% Tryptic Soy, Glycerol Yeast Extract, Nutrient Broth, and Actinomyces media at two pH levels (3.8 and 4.8). More acidic pH levels were selected as Minnesota bog soils are more acidic than other soils. Selected colonies were tested on pathogen plates. Microbes found to have antimicrobial properties were further purified on appropriate media and incubated at room temperature. Microbial growth and isolates are compared to ongoing experimentation of soil microbes isolated on “regular” pH media. Characteristics of the pure cultures of the isolates grown on “low pH” media that demonstrate inhibitory activity will be reported. This research will aid in the process of developing new antimicrobial agents that can be used for advancements in the medical field. This study will serve as a baseline for future antimicrobial research in Minnesota bogs.

Abstract Name: **Optimization of Aerial Sensor Suite to Autonomously Detect Wildfires**

Over the past several years, wildfires have become increasingly more extreme, destroying acres of nature and putting people’s lives in danger. Recently, research in this field has turned to aerial robotics and advanced sensor suites as an initiative to identify wildfires sooner. This essay investigates scholarship on the use of unique sensor types and their positioning to enhance the efficiency of rapid fire detection. However, these works have not adequately investigated a higher order of sensor fusion in application with aerial drones. This paper addresses this gap by considering the effectiveness of three types of sensors and multiple combinations of sensors in detecting fires from an aerial perspective. The three sensors that will be tested are RGB cameras, thermal cameras, and LiDAR. Specifically, the project will analyze the strengths and weaknesses of each sensor, then compare sensor suite combinations that create the lowest false-alarm detection rate. The data will primarily be quantitative to reflect individual sensor performance, providing more accurate insight into sensor fusion performance on the final drone. In conclusion, this project will highlight what sensor arrangement suite is more efficient in regards to detecting fires from an aerial drone, and will be useful in determining where future research should go in testing larger, more advanced sensor suites on superior robotics platforms.

Abstract Name: **Deep Learning and Feature Selection for Classification of Kidney Tissue Microarrays**

Renal function is an essential marker in the classification of renal disease and clinical symptoms of renal failure develop when there is 15% renal function. In this study, we used infrared spectroscopic (IR) imaging to investigate biomolecular markers from renal transplant biopsies. These images are used for the classification of regions of fibrosis from biopsies containing renal cell carcinoma (chromophobe and oncocytoma) and the prediction of fibrotic proliferation using biochemical signatures. IR spectroscopy is a diagnostic approach utilizing human tissue to label biochemical signatures. Images are captured in several hundred wavelengths in the infrared region of the electromagnetic giving researchers access to more information than traditional RGB images captured by a microscope. While images captured in several bands are great for disease diagnosis, it poses significant challenges for manual cell review by a pathologist. To address this issue, a fully automated pipeline for image processing is being explored. Preliminary research involves identifying feature importance using various algorithms, each of which returns the significant spectral bands necessary for detecting regions of fibrosis. The outputs are ranked and compared to find the first 150 most important features. After feature selection, a deep learning model called UNet will be applied for the classification and identification of fibrosis. Our results will then be compared to the discriminate analysis of the Bayesian classification used in clinical applications.

Abstract Name: **Human Scent Analysis in Support of Tracking Dogs**

Tracking dogs can follow the scent of a person for more than a mile after they have left the trail. The current scientific hypothesis about how this is possible involves dogs smelling the volatile organic compounds (VOCs) that emanate from dead skin cells shed as a person moves. However, data from tracking dogs is not admissible in a court case as it is not understood how this scientifically occurs. Our data involves swabs of an individual's left and right arms, using the technique of Gas Chromatography Mass Spectrometry (GCMS) to identify and analyze the amounts of compounds that make up a scent. We have found that the data of an individual's left and right arms is more correlated than two random people in the data set, suggesting that each individual has a unique scent profile. Through the comparison of left and right arms from the same individual we have noticed the same compound is not present in both due to the necessity of the GCMS reaching a threshold amount for a compound to be recognized. Using Principal Component Analysis (PCA) we found that 23.1% of the variation in individuals can be explained through the first two principal components. PCA has also determined that heptanal, acetone, and hexanal, which are commonly found in every individual, are the compounds that explain the most variation between scents. Furthermore, PCA shows that there is a difference in clustering between children (under 18 years old) and adults (18+ years old). Our investigation has shown that the age of an individual contributes to the scent profile, an individual is more correlated to oneself than another, and that there are top VOCs that contribute to the variation in individuals scent profiles.

Abstract Name: Scalable Nanomanufacturing of Hierarchical Multicomponent Polymer Assemblies Using Integrated Electrospinning and Microfluidics

Liquid-liquid biphasic complex coacervation occurs when two oppositely charged polymers in salted aqueous solution are mixed and spontaneously separate into one polymer-rich dense phase and one polymer-poor supernatant phase. The use of complex coacervates is widespread in the food and pharmaceutical industries for microencapsulation of molecules and biomolecules. However, the solution process of polymer complex coacervates is slow and limits their industrial application. In this work, we have explored ac-electrospinning to enable rapid and facile manufacturing of polymer coacervate nanofibers for scalable mass production of composite polymer membranes. Distinct from dc-electrospinning, we have found the high tunability of ac-electrospining on the structure of coacervate nanofibers. Specifically, the effects of ac-friend frequency and voltage on the continuous nanofiber formation of two distinct complex coacervates, poly(ethylene oxide) (PEO)-metatungstate coacervate and poly(styrene sulfonate)-branched polyethylenimine (PSS-bPEI) coacervates are investigated to prove the generality of ac-electrospining complex nanofibers. Furthermore, we explore electrospun PSS-bPEI coacervate materials to remove trace organic contaminates for water treatment.

Abstract Name: Exploring The Impact Of Educational Exchange Activities Between UWEC And CIT Project

With the development of educational internationalization, more and more Chinese students choose to study abroad. While ample studies discuss international students, less research examines exchange programs. To better understand the impact of exchange activities on international students and scholars, this case study explored the positive experiences and challenges faced by students and exchange scholars in the University of Wisconsin Eau-Claire (UWEC) and Changshu Institute of Technology (CIT) 1+2+1 program.The research team adopted surveys and interviewers to collect data from exchange students, visiting scholars, and administrative personnel. The results revealed both external and internal factors that accounted for the participants' experience, such as students' perceptions of values in speaking up, sense of fitting in, and the importance/lack of a multilingual classroom environment. The participants shed light on gender, identity, language, culture, education, and communication style. Additionally, results showed that the study abroad experiences influenced students' networking with diverse friends and a better understanding of their own cultural values and prejudices. This project aims to offer implications for future exchange programs between Chinese and American universities, advocate for thoughtful and mutually beneficial cross-cultural communication, as well as offering suggestions for exchange students.What made this research project distinctive and meaningful was that the entire research team consisted of international students and a faculty mentor from China. Both the topic of the project and the background of the researchers represent an effort to promote equity, diversity, and inclusion locally and globally. The research team was able to bring in an authentic, culture-relative, and empathetic lens to examine the gains and challenges experienced by the participants. This project hopes to inspire more international students to engage in faculty-student research experience, enhance their professional and career skills, and amplify their voices.

Abstract Name: Standardizing Documentation of Advanced Care Planning (ACP) Conversations

Advanced care planning (ACP), the process of supporting patients' understanding and sharing their personal values, life goals, and future medical care preferences with the aim of ensuring patients receive the care they desire (Sudore, et al, 2017), is a complex yet necessary part of healthcare. ACP increases healthcare providers' adherence to patients' wishes and desired care (Bernacki et al., 2014) and provides context for future discussions with additional medical providers (Walker et al., 2018). Unfortunately, a community-academic healthcare system did not have a consistent way to document ACP in the healthcare system's electronic health records (EHR) making it hard for the healthcare team to communicate the patient's ACP. Aiming to increase ACP, an outpatient oncology department within a healthcare system implemented a multi-intervention research project with one interventional prong addressing the documentation of ACP. The research team sought to address ease of documenting, determining consistent information to capture, and identifying a consistent location in the EHR to store this information as an additional component to the original educational intervention. In partnership with the healthcare system's Health Information Management Services (HIMS), the team developed a tool within the EHR that enables the healthcare team to easily identify the presence of an ACP document and a Goals of Care (GOC) template. Training, ongoing feedback, and coaching were also provided to support the providers. Data was gathered from randomized patient charts for each provider from August 2021 to August 2022, monitoring GOC discussions, the corresponding documentation, and the location of documentation will be analyzed to demonstrate the impact of the invention. It is hypothesized that the development of the GOC template and search feature will increase the thoroughness of the documentation of ACP.

Abstract Name: Limited Availability of Specialty Medical Care in Puerto Rico

Currently, Puerto Rico stands as a commonwealth of the United States of America, giving it some independence in its internal operations, but functioning ultimately under the federal government of the USA. This has placed Puerto Rico in an economic debt crisis as a result of policy changes made over the past several decades. In this time, Puerto Rico's healthcare infrastructure has been modified to model the system in place in the mainland United States, disregarding the need for regional medical care well-suited for the Puerto Rican population. As a result, the healthcare infrastructure of Puerto Rico is suffering, affecting rural and non-metro areas disproportionately as medical services are concentrated in urban centers. Through privatization upheaval, debt accumulation, and a prevalent pattern of physician migration, Puerto Ricans are unable to receive adequate healthcare on the island. Literature on the subject focuses on the migration of physicians from Puerto Rico to the mainland United States, as well as the aging population of doctors on the island. However, it fails to address the lack of not merely physicians, but rather physicians of concrete specialties. This low specialist availability has been seen to affect those with chronic diseases, such as diabetes and heart disease, most, causing an imbalance as these conditions are those that currently require the most attention. This review aims to address the gap in published literature and pinpoint the specialties in need of physicians through a partnership with the Health Industry Information Platform of Puerto Rico, the largest database of physicians on the island and their practice locations. The resulting data points to which regions of the island lack specialty care most and emphasizes the need for healthcare reform as the system in place is unable to retain its physicians and ensure the medical safety of its people.

Abstract Name: **Optimizing Staining Methods for Arabidopsis Thaliana for Future Studies Understanding Interactions Between Lipopolysaccharide and Glutamate-Like Receptors**

Plant growth has the potential to serve as a model to study the impact of lipopolysaccharide (LPS) on neurophysiology in mammals. Lipopolysaccharide (LPS) is the most common microbial mediator in sepsis and septic shock. More specifically, LPS is an endotoxin from gram-negative bacteria that binds to glutamate receptors (GLR) at the neuromuscular junction. Plants and mammals share highly conserved glutamate-like receptor (GLS), and glutamate serves as a neurotransmitter in animals as well as an essential amino acid in plants and animals. It is believed that LPS binds to glutamate receptors, which block the glutamate response. Understanding the role of LPS on plant root growth can lead to cost-effective avenues to study mechanisms related to septicemia. Previously, the exposure to glutamate prevented primary root growth and promotedlateral root growth in the original root. Glutamate acts as an exogenous signal at the root tip. Because of the similarities, we chose to use theArabidopsis thaliana because of their glutamate- like receptors which are similar to the glutamate receptors in humans. The objective of this project was to optimize growth and visualization methods for Arabidopsis thaliana while using staining techniques traditionally used on bacteria prior to the addition of LPS. Additionally, methods developed within this study have been piloted within a General Chemistry Laboratory that offered a course-based research experience (CURE). Within this study, we propose a staining technique that can be used to visualize root growth during exposure to molecules or toxins, such asglutamate LPS, respectively. Furthermore, we propose a cost-effective staining technique that can be implemented into laboratory classrooms. It appears that glutamate supports root growth after approximatelyone week under ultraviolet light, and the lack of glutamate hindered root growth.

Abstract Name: **Lenition is Scalar Across Spanish Consonant Sets: Implications for Mental Representations of Language**

Lenition—that is, the systematic weakening of consonants—is a thoroughly-studied linguistic process which often acts on consonants in particular grammatical (or, in the fields of phonetics and phonology, prosodic) positions. This process has been documented in a wide variety of languages, including Spanish. Previous papers on Spanish lenition have primarily discussed the acoustic nature of /bdg/ voiced stops, and, to a lesser extent, /ptk/ voiceless stops. The present study thus seeks to broadly measure lenition processes in all consonant sets in the Spanish language, grouped based on manner of articulation (that is, configuration of vocal folds, tongue, lips, etc. in producing a particular sound) as follows: /ptk/ voiceless stops, /bdg/ voiced stops, /n/ nasal, /lr/ liquids, /s/ sibilant, and /fθ/ fricatives. To elicit lenition at varying rates, native speakers of the Northern Peninsular Spanish dialect were recorded reading investigator-constructed sentences aloud in a laboratory environment. Recordings were then analyzed in Praat acoustics software, with particular attention being paid to variation in consonant intensity and duration relative to prosodic environment (in order of low to high: word-medial; word-initial/final; utterance-final; phrase-initial/final; intonation-initial/final). Expected conclusions are that lenition, as defined by a traditional model of phonological features, will be scalar relative to lower prosodic level, that greater lenition will be acoustically indicated by lower-magnitude intensity slopes and thus a shorter duration, and that all consonant classes will exhibit some degree of acoustic lenition processes. Such findings will have implications for the rules that govern our mental representations of language; that is, whether the process of lenition manipulates categorical symbolic representations of sounds (that is, operates along a contrastive model of phonological features) or instead pertains to continuous physical parameters of speech (that is, operates along an acoustic/phonetic model).

Abstract Name: Comparison of Metrics for Activity Differentiation Within Oral-Facial sEMG Datasets

Introduction: Dysphagia is characterized as abnormal swallowing and can result from conditions including dementia, Alzheimer's, and Parkinson's [1]. Rehabilitation can use biofeedback from surface electromyography (sEMG) which captures electrical muscle activation during swallowing. However, sEMG also captures extraneous movements.This case study aimed to identify metrics to differentiate sEMG data of swallowing events from extraneous movements.Materials and Methods: One participant completed 10 movement trials while sEMG data was captured from orofacial and suprahyoid locations. Each trial consisted of four tests for: cough, talking, throat clearing, and head movements. Metrics of sEMG amplitude (difference from baseline) and activity duration (near baseline to near baseline surrounding a peak) were analyzed.Results and Discussion: Swallows had an average amplitude of 106.8 μV (oral) and 75.4 μV (pharyngeal), whereas talking had averages of 85.2 μV and 38.1 μV meaning swallowing required greater muscle recruitment. Head movements had the highest average movement duration with 9.6 seconds (oral) and 7.8 seconds (pharyngeal) compared to 2.1 seconds and 2.34 seconds for swallowing. There were clear differences in the averages, but the high variability between trials prevented identification of clear threshold values.Conclusion: Amplitude and movement duration are two metrics to quantify events in sEMG datasets but were not sufficient to differentiate swallow and non-swallow movements from the conducted trials.Further research is recommended to investigate additional metrics in sEMG datasets for this differentiation or the fusion of metrics to make unique signatures of different event types.

Abstract Name: Exploring Hyperspectral Image Classification using Deep Learning

Classification of hyperspectral images is an important step of image interpretation from high spatial resolution imagery. Different studies demonstrate that spatial features can provide complementary information for increasing the accuracy of hyperspectral image classification. In this study, we propose a method of spectral-spatial classification of hyperspectral images that is based on a hybrid feature selection approach with stacked autoencoders. The resulting high-dimensional vectors of spectral features are classified by several supervised classification algorithms such as support vector machine (SVM), maximum likelihood (ML) and random forest (RF). The experiments are performed on several widely known test hyperspectral images. Preliminary results have demonstrated that the proposed method provides a higher accuracy matrix than existing traditional models.

Abstract Name: Virologic Characteristics of Breast Milk CMV Transmission

Human Cytomegalovirus (CMV) is a member of the ß-herpesvirus subfamily of the Herpesviridae family. CMV is the largest and most complex herpesvirus with a 235,000-dsDNA genome that encodes for about 265 open reading frames. CMV is a frequent cause of congenital infection and the leading cause of non-genetic hearing loss. In addition, CMV exhibits high genetic variability and infection with multiple virus strains has been documented in several populations including babies with congenital infection and children attending daycare. Postnatally acquired CMV infection does not cause disease or adverse outcomes except in very low birth weight infants. However, postnatal transmission of CMV to infants born to seropositive mothers has been shown to be a reliable setting to study the virologic characteristics of CMV transmission to healthy infants. The research examines virologic diversity in breast milk and in infants who acquire CMV via breastfeeding to determine the importance of genetic diversity of CMV strains on transmission. While most CMV seropositive mothers shed the virus in the breast milk, only about half of the breastfed infants will become infected during the first 4-6 months of life. In this study, I examine genotypes of envelope glycoproteins, gB (UL55), gH (UL86), and gN (UL73). In addition, genotyping of US28 will also be performed. I also compared the genotypic diversity of CMV virus populations in breast milk and in infants who acquire CMV via breastfeeding. The objective of the experiments was to compare the genetic diversity and CMV viral load in the breast milk between transmitters and non-transmitters. In addition, the duration of the viral shedding in breast milk was compared between the two groups.

Abstract Name: Yoga As An Approach to Mental Recovery 48 Hours After an Intense Workout

Background: Along with physiological changes, knowledge about yoga and meditation strategies for post workout mental recovery has been investigated. Results show that it improves mental clarity and reduces stress and anxiety levels. Purpose: The purpose of this study is to examine the effects of a 30 min yoga session on mental recovery 48 hours after a high intensity workout. Hypothesis: We hypothesize that if a yoga session is done immediately after an intense workout, it will produce greater mental recovery compared to those who do not participate in the yoga session. Methods: Twenty undergraduate students will complete a 30 minute intense workout. Following the workout, the intervention group will complete a thirty minute yoga/meditation session. The control group will not do anything outside of their usual routine. Conclusion: If our results align with our hypothesis, individuals can incorporate yoga into their exercise routine to benefit overall mental health and recovery.

Abstract Name: Perception of Information and Source Reliability B

The term misinformation is being used so frequently now that it has become an annoying word to represent almost nothing. The perception of whether information is valid seems to be very dependent on who is giving the information. There are many different factors that play a role in deciding whether a source is credible or not. In the US today we are seeing that individuals are siding with news sources that have a similar political ideology when deciding what is fact and what is misinformation. The purpose of this research is to determine what factors correlate with someone's suseptiblity to misleading information. The personal characteristincs being studied include racial/ethnic background of the messenger and receiver, political ideology of the messenger and receiver, news media sourcepreference, expertise level of the messenger and receiver, and percieved trustworthiness of the messenger. The study will use information about controversial topics given by various sources and determine the level of confidence the subjects have about the legitimacy of the information. Demographics regarding the subjects will be collected. A correlational analysis will be made between traits of the message sender and receiver and the rating of the source information. Data analysis will be completed in the spring semester of 2023.

Abstract Name: Radiation dose studies in fruit flies with 350keV electrons

The effects of beta radiation on fruit flies (Drosophila Melanogaster) were studied using the Applied Nuclear Science lab AN400 accelerator modified for electron acceleration and extraction. Dose-dependent effects up to 800 Gy have been observed, with significant effects well below the LD-50 dose for 2-day old larvae. These effects include reduced larvae and aborted development to adulthood. The goal of establishing a population of viable adults in samples showing clear radiation dose effects to study inherent radiation resistance has now been met. The data gathered in the process of this experiment will be used to further calibrate the accelerator for future research.

Abstract Name: Minority Status and Mental Health

Discriminatory behaviors live throughout society today and all generations of the past. How do these behaviors impact groups with minority status? The aim of this study is to research how chronic stress expereinced by people with minortity status impact mental health. There will be multiple angles applied to this study. The first area of interest is how social media either contributes to or gives a community for discriminatory behaviors or does social media allow for an outlet for those with minority status to build support and community. The second area of interest is how does stress related to choronic discrimination exposure contribute to the mental health of individuals with minority status. Previous research has shown disparities in mental health, substance use, and other factors related to mental health among groups with minority status when compared to the same age group of majority status individuals. This study will identify factors associated with positive and negative mental helath development across multiple minority status groups through a survey implemented and analyzed in the spring semester of 2023.

Abstract Name: Expression of Femininity in Animated American Culture: She-Ra

This project examines gender expectations for American women from the 1980s to the 2010s as reflected and reinforced by animated entertainment series, such as She-Ra, which originally aired in 1985, then returned as a reboot in 2018. The series exhibits a leading female character, She-Ra, who changes in both character and appearance from the original 1985 iteration in accordance with shifting ideas of femininity in modern American culture. First, the research investigates ideas of gender inequality for women in American society, then the concept of gender schemas formed by observational learning, and lastly American feminist movements after 1970, each of which guides the study of the social, psychological, and historical contexts of both iterations of She-Ra. Analysis of gendered dialogue from the selected 1985 She-Ra episode reveals the social inequality women experienced in the 1980s, which is similarly continued in the 2010s, as supported by analysis of similarly gendered dialogue excerpts from the chosen 2018 She-Ra episode. Next, an analysis of She-Ra's costume design indicates that, due to constructed gender schemas, ideas of womanhood shifted from a strong feminine appearance in the 1980s to a more androgynous appearance in the 2010s. An analysis of character behavior finds that 1985 She-Ra exemplifies 1980s feminist ideas of reclaiming and redefining womanhood, while 2018 She-Ra exhibits post- and millennial feminist expressions of confidence in womanhood as a personalized and equal gender identity. The research thus concludes that, over time, gender expectations for women have been diverging from binary concepts of gender, a pattern that is demonstrated by animated American series such as She-Ra. Contemporary artists evidently have the power to create media that influences shifting cultural attitudes regarding how women and other gender identities are accepted and integrated into American society.

Abstract Name: Effect of Neurotransmitter Treatments on the Proliferation and Neurogenesis of Adult Hippocampal Progenitor Cells within a Microfluidic Device

Neurotransmitters provide an important role in chemical communication between differentiated neurons and target cells and potentially contribute to neurogenesis. The neurotransmitter dopamine (DA) and its precursor levodopa (L-DOPA) are prevalent throughout the brain and can modulate synaptic plasticity. Additionally, the neurotransmitter serotonin (5-HT) serves a major role in the function of hippocampal neurotransmission. In the present study, we have begun to evaluate the effects of DA, L-DOPA, and 5-HT treatments on the proliferation and neurogenesis of multipotent adult rat hippocampal progenitor cell (AHPC) neurospheres. We developed a microfluidic chip composed of two chambers separated by a set of intentionally misaligned micropillars that serves to mimic the blood-brain barrier (BBB). The chip design allows the diffusion of neurotransmitters from the source chamber to the adjacent chamber containing neurospheres. Cell viability, proliferation, and neuronal differentiation were evaluated on the AHPC neurospheres after exposure to DA, L-DOPA, or 5-HT. After immunocytochemistry was performed on the AHPC neurospheres, fluorescent images were captured and analyzed to determine the percentage of immunoreactive cells. Following DA, L-DOPA, and 5-HT treatments, no negative effects on cell viability were noted. AHPCs showed a statistically significant increase in proliferation and neuronal differentiation following DA treatment compared to the L-DOPA treatment. 5-HT treatment on these cells also showed a statistically significant increase in neurogenesis at the 5 μM condition compared to the control, while proliferation had no significant change. These results begin to provide insight into the role of neurotransmitters in regulating AHPC neurogenesis.

Abstract Name: Multicultural Perspectives in Aphasia

Language is the production of our thoughts, cultures, and lives. It converts our minds into a more concrete form that allows people to understand each other. It also associates closely with our habits and mentality. The speech-language-hearing sciences field is one of the whitest fields in the U.S. and most research is biased toward the white-dominant population while some racial and ethnic minorities are more likely to suffer severe strokes and disparities in long term outcomes. Whereas there is almost forty percent of non-white in the United States of America, signaling the existence of diverse mindsets in which the disorders and treatments cannot be concluded only from the existing data.The mental health, the related cultural background, and the customs of different ethnicities may broadly impact the therapy and the results. In the current speech-language-hearing science field, we barely examine clients through the lens of mental health and multiculturalism. This single subject design study is to explore diverse perspectives about aphasia reported by marginalized clients with aphasia. Two participants were interviewed about their views about aphasia. The interview questions were modified from an explanatory model approach proposed by Kleinman and Beeson (2006) to explore the participants' understanding of the meaning of illness. Thematic analysis will be conducted. The results of this study will help further understand and help meet the needs of individuals who belong to an ethnic minority group and are affected by aphasia.

Abstract Name: Role of Motivation on Academic Success B

The collegiate world is constantly discussing how student motivation is related to student success. How true is this correlation? Does the motivation importance change with the specific course or the format the course is taught in? Can the institution or instructor impact the student motivation level by understanding intrinsic and extrinsic factors that motivate students? The aim of this study is to determine what motivation is and how it impacts the academic success of college students. Factors that will be studied are intrinsic and extrinsic motivation factors, academic performance, familial college experience (1st generation studens vs non 1st generation students), and the role of the institution and faculty. The study will be completed through a survey with a battery of questions addressing all the key areas mentioned above. Demographics will also be collected to compare possible inter-group differences. Correlational analysis will be completed through data collection in the spring semester of 2023.

Abstract Name: It's All In Your Head: Cultural Hegemony In The Stepford Wives; Replicating Behaviors Of Oppressors

The Stepford Wives tells the story of Joanna, a housewife new to the community by the same name. The longer she lives there, the more she grows to believe that the other wives in this community are being turned into robots by their husbands. The novellas author, Ira Levin, thematically depicts a cultural hegemony in the community. Set in the 1960's, Levin depicts the Stepford husbands oppressing and controlling women with behaviors such gaslighting and sexual objectifications. Betty Friedan theorizes about this cultural hegemony from the same era in her work The Feminine Mystique. The Feminine Mystique speaks of a problem without a name, exposing a cultural hegemony controlled by men and oppressive towards women. Because of this hegemonic culture, the women of Stepford have learned to replicate the behavior of their oppressors. The Stepford wives unintentionally replicate this behavior by either sexualizing one another or gaslighting each other. This oppression not only causes women to harm one another, it causes division against them. Feminist Audre Lorde spoke of this division amongst women in her speech, "The Master's Tools Will Never Dismantle The Master's House," when she says: "Without community there is no liberation." In the novella, Bobby takes on the role of a perfect housewife after gaslighting herself into believing she is selfish and isolates herself from her friends as a result. The Stepford Wives exhibit is entirely a façade, which, in fact, teaches women to replicate their oppressors' behaviors. The men in this novel control and oppress women through the aforementioned behaviors. Women's replication of oppressing their own gender causes division amongst themselves. Levin's story is an allegorical representation of the 1960's cultural hegemony and its negative effects on women and on society in general.

Swearingen, Garrett

Abstract Name: **The Effects of the Construction of Masculinity and its Effects on College Age Individuals**

This project analyzed how masculinity is constructed and the effects it has on people who are and aren't considered masculine. Literature in anthropology, for example The Meanings of Macho by Gutman, points out that views of masculinity vary widely within and across cultures. This sparked my initial interest in finding more multicultural views on this topic on my college campus. First, I sent out a survey to a sample of international and domestic students at UW-Stout. The survey asked questions about the individuals' political ideology and a series of questions pertaining to their views on who can and can't be masculine, if they consider themselves masculine, and several questions that gauge the participants opinions on if certain types of masculinity are harmful. Next, I interviewed twelve people from a variety of political ideologies, race and cultural backgrounds, and genders. I will focus on that data for this project. My findings show that there are several reoccurring themes when it comes to the construction of masculinity, which I have coded as "non-generalizable," "social conditioning," and "generalization." Non-generalizable refers to the common view that masculinity comes in many shapes and sizes. Social conditioning is referring to how we treat children assigned male at a young age and how they are taught to act growing up. Generalization refers to how we as a society perpetuate stereotypes and label every individual that identifies or is masculine-presenting with those stereotypes. After discussing the similarities and differences in participant views around masculinity, I will discuss how this demonstrates growth and change in understanding of masculinity.

Sweeney, Jessica

Jessica Sweeney

Abstract Name: **Utilizing Anti-Racist Pedagogy in the Modern U.S. Classroom**

This project examines how educators incorporate current scholarship on Critical Literacy, Post-Colonial Theory, and Anti-Racist Pedagogy and its practices into the modern classroom. Current research from these various scholars identifies the structural racism in U.S. education and provides feedback on how to address it in the classroom. However, most of this research falls within the context of higher education and does not permeate secondary education scholarship. The feedback provided by scholars often does not address the restrictions present within the regulated system that secondary education operates in. This project bridges the gap between theory and real world application by assessing the frameworks and regulations that guide and, in some ways, restrict the classroom today. This research addresses assessment practices within secondary education curriculum per state regulations and frameworks using Anti-Racist pedagogical practices. Given dominant assessment practices that fail marginalized students, it is important to examine ways in which educators can implement assessment practices that are equitable for all learners. Using the Massachusetts ELA Frameworks Reading and Writing standards, this research evaluates the systemic bias within the frameworks and offers solutions and suggestions. These recommendations, informed by current scholarship, tailor suggestions for higher education, and identify how they can be adapted to secondary education. My research conclusion affirms the necessity of the current curriculum with modified dialogue surrounding it's history, while introducing new Anti-Racist approaches and modifications to this curriculum.

Abstract Name: **Perspectives on Teacher Shortage and Retention among K-12 Principals in Rural Areas**

There are currently 567,000 fewer educators in K-12 public schools as compared pre-coronavirus (COVID-19) pandemic, contributing to the high demand for teachers in the United States. School administrators have struggled to hire and retain quality educators. Previous studies emphasized the role of administrative support on teachers' retention. The purpose of the study was to explore the perspectives of school administrators on teacher shortage and retention.A total of 6 principals were recruited by snowball and purposive sampling from several Midwestern rural school districts. Demographics were obtained using Qualtrics. A semi-structured online Zoom interview was conducted inquiring about participants' perspectives on their role, how hiring and teacher retention are going in their school, and their perspectives on the teacher shortage. The interviews were audio-recorded and transcribed. Qualitative analysis methods were used with categorization based on grounded theory. After a team analysis, the researchers came to an agreement on the common themes and drew conclusions from the themes.The three main themes that emerged from the responses to the interview questions were: 1) teacher shortage with decreases in the number of applicants and emergency hiring, 2) COVID-19's impact on schools finding substitute teachers and supporting teachers switching their classes virtually, and 3) supporting new teachers with a mentorship program and mid-to-late career teachers with professional development opportunities.Participants emphasized the importance of listening to their needs and supporting their teachers to do their job. Participants also suggested that teacher education preparation programs could continue to work on developing future educators to become high-quality beginning teachers who are resilient in their profession to combat teacher shortages. Future study is warranted on teachers' perspectives and needs for school administrators' support in their position to narrow the gap between administrators and teachers.

Abstract Name: **The Challenging of Gender Norms in Pride & Prejudice**

Jane Austen wrote Pride and Prejudice in the 19th century when women had no rights. They were to marry for financial stability, take care of their husband and be obedient. (Hughes 2014) However, Austen's novel's main character Elizabeth Bennet challenged gender roles. I am using the novel Pride and Prejudice. As well as multiple peer-reviewed journals to back up my claims. Elizabeth kept her independence throughout the novel. She refused to marry for financial stability and only would marry for love. She never tried to please men. Jane Austen''s Pride and Prejudice was successful in showcasing the challenging of gender norms through the main character Elizabeth Bennet. She was a feminist heroine throughout the whole novel because she never conformed to the proper role women were placed. Austen writing Pride and Prejudice was a big deal because due to Austen writing a novel about gender norms being challenged, she also challenged gender norms in the real world. Austen represented her beliefs through the novel and that impacted her own life.

Abstract Name: **Spectroscopic Investigation of the Lowest Triplet State of Alpha-Pyrone**

Molecular triplet states are chemical species that have two unpaired electrons. Triplet states are formed through the process of electronic excitation, in which energy from light or other sources promotes an electron from one molecular orbital to a higher one. The unpairing of spins via triplet excitation imparts significant chemical reactivity to triplet states, because these species behave as diradicals.In this project, we are using laser spectroscopy to investigate the lowest-lying triplet state of the alpha-pyrone molecule. Pyrone isomers, having formula C4H4O2, are conjugated carbonyl compounds containinga six-membered ring, with an ether linkage inside the ring. In alpha-pyrone, the ether oxygen is in position 2 of the ring with respect to the carbonyl group. Previously, we studied gamma-pyrone, in which the ether oxygen is in position 4. We learned how the vibrational frequencies in the lowest triplet state of gamma-pyrone differ from the frequencies in the ground state.In our current work on alpha-pyrone, we use a tunable dye laser that produces light in the 375-400 nm range to promote a carbonyl lone-pair electron into the lowest π^* molecular orbital.This process creates the lowest triplet state, denoted T1(n,π^*). By using the cavity ringdown (CRD) spectroscopic technique,we can detect laser absorptions that excite various modes of vibrational motion in the T1(n,π^*) state. Theinformation we obtain using CRD spectroscopy is analogous to that availablefrom aninfrared spectrum of the ground state.Thetriplet-state vibrational frequencies measuredin this projectare allowing us to understand how the conjugation and ring strain in the alpha isomer differ from these properties in the gamma isomer. This information will help researchers in the field of synthetic photochemistry better understand reactivity of the pyrones.

Abstract Name: **The Teaching of Menstrual Health in 20th Century America**

This essay is about the transition of teaching menstrual health in America over the course of the 20th century. While originally menstrual health was a private matter saved for mother-daughter discussion, the subject was pulled into the public sphere after the Second World War. Young menstruators found themselves underprepared for menarche; sanitation and cleanliness became an American ideal, and the capitalistic nature of our nation brought upon us new menstrual products and puberty guides. Kotex and the Kimberly-Clark Corporation had big roles in these factors. Once the demand for equipping girls for menstruation was understood as a necessity with every new generation, these companies dedicated their time to fix this issue while also earning themselves a lot of money and becoming prominent household names. They sold new products and guides, as well as the importance of hygiene, by telling menstruators how often they should change (and buy) pads and the importance of keeping clean while menstruating.This essay uses popular puberty guides Very Personally Yours and “You’re a Young Lady Now” from 1948 and 1952, respectively, as primary source material of how young menstruators were learning about their bodies, as well as what was being taught. Secondary sources were pulled from a variety of books and articles, including works from Joan Jacobs Brumberg and Lara Freidenfelds, both well-respected women’s and medical historians. As this essay explores Brumberg and Freidenfelds takes on the transition of menstrual education and consumer behavior, a contrast in feminist opinion appears and is examined.

Abstract Name: Identifying Wild Bees Using DNA Barcoding

The purpose of this DNA barcoding project was to identify bees for the Tucson Bee Collaborative (TBC) to get an understanding of biodiversity of bee species in Arizona. This is important because Arizona is one of the largest bee biodiverse areasin the world. The TBC is a partnership between Pima Community College, the Arizona-Sonora Desert Museum and the University of Arizona. The mission of the TBC is to build a thorough database of allbees that are native to the Sonoran Desert Region, in order to ensure future conservation as the climate changes.In order to extract DNA, the leg of our bee was crushed and combined with proteinase K. The mixture was placed in a heated bath and vortexed, giving us the beeDNA. To make many copies of theDNA, we used a polymerase chain reaction (PCR). A cycler heated and cooled the DNA intermittently,resulting in more copies of DNA, specifically the CO1 gene, the "barcoding" gene. We used gel electrophoresis to verify that PCR was successful.After we obtained a quality strand of DNA, we sent the sample to a laboratory to be analyzed. We took both directions of the sequence and inputted them into DNA Subway.We could then compare and identifyour bee's DNA to sequences in DNA databases from Genbank and The Barcode of Life Database (BOLD).We successfully identified our bee to the species level. The bee was identifiedas a Lasioglossum microlepoides. Our results were published in BOLD. The information we generated will help future researchers better understand and conserve this species.

Abstract Name: Greening a Grignard

In our lab curriculum, we use a modified version of the diastereoselective synthesis of (+/−)-1,2-diphenyl-1,2-propanediol first reported by Ciaccio et. al.to offer a useful experiential companion to thinking about conformational isomers, Newman projections, and steric constraints typically covered early in an Organic Chemistry I course. However, introducing this diastereoselective reaction designed for second-semester students early in the semester challenges nascent student lab skills.Methyl iodide is a strong alkylating agent, and among the more dangerous reagents used in our lab. Although we initially sought to replace the methyl iodide with ethyl chloride, we found the Grignard preparation difficult with this weaker alkylating reagent. Instead, we began using a commercially available ethyl magnesium chloride solution.which has allowed us to avoid using the alkylating agent on site and limited our demand for the preparation of a more hazardous material elsewhere. This also improved flow-through times for the lab. We were able to achieve similar selectivity to the original research as observed by comparing melting point of our (+/−)-1,2-diphenyl-1,2-butanediol 115 °C to literature values of 115-116°C for the product expected by addition to the less hindered face and 105-106 °C for the diastereomer.We hoped to further adapt this reaction to use the analogous furoin molecule as a starting material instead of benzoin. The resulting (+/−)-1,2-difuryl-1,2-butanediol, unreported in the literature, decomposes from a reddish solid into a black tar from 54-59 °C, unfortunately making it unsuitable for our lab.

Abstract Name: **Sex-Related Differences in PACAP Expression in the PVT of Rats**

The paraventricular nucleus of the thalamus (PVT) and the neuropeptide, pituitary adenylate cyclase activating polypeptide (PACAP),are associated with motivated and affective behaviors, including alcohol drinking and binge eating, but while PACAP has been found to be densely expressed in the PVT of male rodents, this remains to be characterized in females. Prior research in male rats found that the peptide isoform PACAP-27 was more highly expressed than PACAP-38, and that PACAP-27 expressionwas heavier in the posterior than anterior subregion of the PVT. The purpose ofthis research was to determine if there are sex-relateddifferences in the expression and distribution of the PACAP isoforms in the PVT. We performed fluorescent immunohistochemistry for PACAP-27 and PACAP-38 on tissue containing the PVT from adult, male and female Sprague-Dawley rats (n= 5/sex), followed by confocal microscopy and ImageJ analysis. The percentage of DAPI cells that co-labeled with PACAP-27 was greater in females than in males (52% vs. 44%) and, as in males, increased from anterior to posterior PVT, displaying a significant main effect of sex [F(1, 8) = 13.867,p= 0.006] and subregion [F(1.23, 9.84) = 7.758,p= 0.016]. The percentage of DAPI cells co-labeling with PACAP-38 was also greater in females than in males (17% vs. 11%), displaying a significant main effect of sex [F(1, 8) = 19.866,p= 0.002], but there was no significant effect of subregion [F(2, 16) = 2.465,ns], consistent with prior findings. These results indicate that both PACAP isoforms are more highly expressed in the PVT of female rats and that PACAP-27 and PACAP-38 show similar distributions across the PVT in females and males. Together, these findings suggest that PACAP may underlie some established sex-related differences in motivated and affective behavior.

Abstract Name: **False Memories: the Fear Factor**

Purpose: How does mood affect susceptibility to false memories? People are less likely to form false memories when sad, ostensibly because sadness encourages memory encoding of item-level information, while neutral moods encourage holistic processing, in favor of the gist (Storbeck, 2013). Though the protective benefit of sadness in avoiding false memories has been demonstrated, we investigate how both sadness and fear–another important negative emotion– affect susceptibility to false memories. This is significant to investigate because when a negative event is experienced, people often remember vivid and specific details of the incident. In these traumatic scenarios, fear is likely the strongest emotion. From our work, we will be able to demonstrate whether fear, like sadness, protects against false memories.ProcedureParticipants view movie clips validated to reliably elicit the desired emotions: neutral, sadness, fear (Gross; Levenson, 1995; Hewig et al., 2005) and rate their mood using the positive and negative affective schedule (PANAS). False memory susceptibility is evaluated with the Deese–Roediger–McDermott (DRM) paradigm in which participants study lists of words that are each related to a critical, unpresented lure, then take memory tests on the words. If a participant misremembers a critical lure as being presented, a false memory has occurred (Roediger; McDermott, 1995). The mean number of falsely recognized critical lures across the three mood conditions will be analyzed using ANOVA. This project has received IRB approval and data collection has begun.Expected Results and ImplicationsIf fear, like sadness, confers a protective benefit against forming false memories as we hypothesize, participants in neutral moods will have significantly more false memories than sad or fearful participants. Of theoretical significance, we will determine if fear, like sadness, encourages detail over gist processing. Of applied significance, this study may add to our understanding of memory formation in traumatic situations.

Abstract Name: **Soil Organic Carbon Inventory in Regenerative versus Conventional Agriculture**

We calculated carbon inventory between contrasting agricultural practices. We selected sampling sites with the same soil type and landscape position to contrast regenerative and conventional agricultural practices. We measured bulk density and soul organic carbon on soil cores up to 79 cm.We analyzed soil organic carbon by dry combustion using an elemental analyzer. We observed that soils under regenerative practices of 5+ years have more carbon inventory. Soils under 5 years of regenerative practices may not have more carbon inventory than conventional soils. Regenerative agricultural practices can increase soil carbon storage but it can take multiple consecutive years of regenerative practices to see an increase in soil organic carbon.

Abstract Name: **Hot-Spot Management in Microelectronics through Atomic Modeling**

Transistors are the foundation of the modern economy. Increasing the density of transistors on a chip is the continuous goal of chip designers because this increases the processing power of the device. Because the heat generated by chips is increased when more transistors are on the chip, heat management is a critical issue. It is essential to develop a predictive model, especially for high-heat flux regions in a nano transistor, to design and develop highly reliable transistors for modern electronics. The channel regions of the state-of-the-art nanosheet field-effect transistors (FET) are prone to high local heating due to confinement at the nanoscale. The localized nature of heating is particularly challenging to mitigate using conventional cooling approaches. We develop a first-principles model that predicts the temperature map of the channel region of a nanosheet FET. We use atomistic molecular dynamics simulations to model the channel region under applied thermal gradients. The thermal gradients simulate operational conditions, so functionality can be assessed and improved upon. This allows us to simulate the local temperatures and heat flux without needing to fabricate a physical assembly. I build the configurations of atoms in a perfect lattice which are then run through an equilibration process to create a structure that resembles a real-world structure. Finally, a simulated heat gradient is applied to the structure to find the heat flux generated under operational conditions. Furthermore, we aim to adapt the model to model materials for power electronics. Heat dissipation in these devices since poor heat dissipation is the main factor that limits their performance. While saving time and money, our approach predicts the thermal properties of the intrinsic region of transistors. We anticipate this will make chip development easier and be the basis for future models that predict heat in other parts of the chip.

Abstract Name: **Examining Length of Stay (LOS) and Hospital Readmission of Pneumonia Patients in the U.S between 2010-2014.**

The healthcare industry has generated large amounts of data over the last decades. Digitization and effective combination of that information brings significant benefits such as detecting diseases in early stages, predicting certain developments or outcomes, and identifying patients at risk for health complications. Given these emerging trends, this study has two overarching goals. The macro level goals are: 1) to expose students to healthcare management related issues, 2) to enable students to research the dynamics of healthcare management systems, and 3) to analyze and understand the role of the Big Data concept in decision-making processes in the healthcare industry. The micro level goals are: 1) to analyze the readmission and length of stay (LOS) trends of pneumonia patients between 2010 through 2014 at a national scale using the Nationwide Readmissions Database (NRD) provided by the Healthcare Cost and Utilization Project (HCUP) in the U.S., 2) to examine the impact of LOS on the likelihood of hospital readmission, with an emphasis on discharge disposition and patients underlying conditions, and 3) to illustrate various readmission trends depicted by patients under different payers, medical comorbidity, and discharge disposition. It illustrates various readmission trends depicted by patients under different payers, medical comorbidity, and discharge disposition. The study implemented multiple linear regression model and revealed that LOS significantly impacted the readmission of pneumonia patients. It also showed that readmission and LOS of pneumonia patients varied by age, gender, medical comorbidities, insure type, discharge position, discharge month, socio-economic status, day of admissions, ownership of hospital, severity of condition, hospital bed size, elective/non-elective cases, teaching status of hospitals, and total charges between 2010 and 2014 in NRD.

Abstract Name: **Student Attitudes Toward Vending Machine Options On UWEC Campus**

The food environment in which college students live can play a significant role in the transition into adulthood. Many students establish habits in college that may follow them for years. The options in Vending Machines (VMs) are frequently Energy-Dense, Nutrient-Poor (EDNP) foods. These EDNP foods are typically high-calorie, high-fat, and high-sugar. Providing students access to vending machines that only offer EDNP snacks is cause for concern, as students will likely carry these snacking habits with them into adulthood.Such snacking habits may place them at risk for chronic diseases such as type two diabetes, hypertension, and dyslipidemia. Those who suffer from obesity may also be at risk for comorbidities such as depression, anxiety, and other psychological disorders.This study aims to uncover the pattern of snack consumption of students at the University of Wisconsin -Eau Claire Campus, and student attitudes toward healthy vending options by utilizing a questionnaire about vending options. The questionnaireassesses the attitudes and trends of VM use, consumption of certain foods from VM, and other opinions towards VM on the UWEC campus.Findings from this study will be used to influence the University to select more nutritious options for vending machines in campus buildings.

Abstract Name: **Comparing Trajectories Toward Activism Amongst Asian American and Latinx Young Adults**

Following the murder of George Floyd, the Black Lives Matter movement inspired an increased awareness of social injustices and racism in America. In this research, we examine how the anti-racism movement that followed this historical event impacted Latinx and Asian American young adults and their social activism. We conducted in-depth interviews with Asian American (n=12) and Latinx (n=12) emerging adults who identified as activists. Utilizing Interpretive Phenomenological Analysis we examined recurring themes in participants' life stories that explained their involvement in activism. We found that both Asian and Latinx participants were motivated to join political-cultural heritage organizations to bridge and integrate their American and ethnic cultural identities. Prejudice against the Latinx community motivated Latinx participants to become involved in cultural-political organizations in comparison to Asian American involvement in organizations alike, which led to an increased awareness of anti-Asian racism. The rise of the Black Lives Matter movement motivated Asian American activists to advocate against Asian discrimination. In contrast, the Latinx participants were more motivated towards coalitional activism for people of color, specifically Black and Brown. This research illuminates the similarities and differences in trajectories toward activism for Latinx and Asian American young adults.

Abstract Name: **Glutaraldehyde Substitution Reaction with Surface Tethered Cysteamine**

Glutaraldehyde is commonly used to link proteins to a surface; however, the reaction kinetics and mechanism are not well studied. We have investigated the kinetics of the reaction between solution phase glutaraldehyde and surface bound cysteamine using surface-enhanced Raman spectroscopy (SERS). Pseudo-first order rate constants were found to be slower in the surface than in solution.

Abstract Name: Individual Granulin Domains Cause Differing Effects on Cathepsin D Activity

Frontotemporal dementia (FTD) is a leading cause of early-onset dementia and is pathologically characterized by degeneration of the frontal and temporal lobes of the brain. While many cases of FTD are sporadic, several genetic causes have been identified as well. One genetic cause of FTD is loss of function mutations that affect a protein called progranulin, a secretory protein that functions primarily within the lysosome. It is composed of 7.5 unique granulin domains into which it is cleaved in the lysosome. Despite these granulins acting as the functional units of progranulin, they have been not been studied extensively with their individual functions remaining unknown.The goal of this project is to determine if any individual granulin is sufficient to recapitulate progranulin's effects on lysosomal or cellular function. Progranulin has been found to influence the activity of neurons in a variety of ways. One well-characterized effect of progranulin overexpression in rat neurons is a decrease in the activity of cathepsin D when measured in lysates. We found that the granulins had differing effects on cathepsin D; some granulins upregulated cathepsin Dactivity while others mirrored progranulin's effects and decreased its activity. Multi-granulin fragments, however, consistently caused a downward trend of cathepsin D activity. In the future, we hope to determine the role of the individual granulins in other progranulin-mediated cellular processes, including resistance to excitotoxicity and modulation of autophagy. Understanding the role of the granulins in neuronal function will broaden our understanding of how progranulin deficiency causes FTD.

Abstract Name: Estimating The Path of COVID-19 Using Phylogenetic Techniques

Genetic data provide a wealth of information about the evolution of organisms and their unique features. When it comes to viruses, genetic data is crucial for surveillance and vaccine development efforts. The COVID-19 pandemic led to the collection of large amounts of genetic data on the coronavirus. With such data, the evolution of COVID-19 has been documented since the onset using phylogenetic trees. Strains that are sampled and sequenced can be placed as leaf nodes in these trees. These strains contain spatio-temporal data about where and when the strain was discovered. Internal nodes connecting each branch represent a relationship between the sample and its ancestor. Unlike leaf nodes, the location of internal nodes can never be known exactly. The goal of this research is to estimate the locations of internal nodes using ancestral character state reconstruction and find the full evolutionary path of COVID-19. We obtained genetic data through GISAID which is a large database focused on collecting and sequencing samples from viruses related to influenza and COVID-19. Our sample size is over 8 million, containing spatiotemporal data and other metadata. GPS coordinate data were extracted by processing the location names. To estimate internal node locations, we used ACCTRAN, a form of ancestral character state reconstruction algorithm that annotates internal nodes using characters from leaf nodes and the tree paths. The results provide a novel estimation of the locations of internal nodes and the full spatial path of the phylogenetic tree which will shed light into generating accurate phylogenetic trees from limited sample data.

Abstract Name: **Resilience in Chinese America: Tensions of Immigration, Economic Development, and Cultural Change in the Formation of Community**

Younger Chinese Americans are less aware of the spatial and historic relevance of how, why, and by what means their ancestors survived in this country. What is the role and interplay of immigration, economic development, and cultural change as tensions in Chinese American history of place-making and community building? How are spaces of community formed when analyzing Chinatown as a site that is deeply interconnected with the social imagination of a community (Anderson 1987)? How is the construction of a place related to the interpersonal connections that materialize beyond the physical? These questions are highlighted by examining urban Chinese American sites within San Francisco and Los Angeles. This project draws on two case studies to examine how Chinatowns have confronted and resisted a history of violence, discrimination, and development. This historical analysis reveals how Chinese Americans have historically been able to and continue to form community despite xenophobia and exclusion. It also uncovers factors that both encourage and complicate the existence of a continuous unity amongst these Chinese American sites informed by Kay Anderson's interpretation of community as both a site as well as a social imagination.

Abstract Name: **THE USE OF FOOD PANTRIES AT FOUR YEARS COLLEGES**

Studies have indicated that students attending universities are experiencing food insecurity. However, the participation rate in campus-based food pantries among students is very low at campus-based food pantries because of its physical location and fear of sigma among students. The objective of this mixed method study is to examine the awareness and use of campus-based food pantries to gain a better understanding of the barriers associated with utilizing campus-based food pantries. Current students at Northeastern Illinois University and individuals working as volunteers in the campus-based food pantry during the fall semester of 2022 were surveyed. The results from the study will identify the issues contributing to low participation rate and provide recommendations to help increase participation at university food pantry. Mixed research methods through surveying and interviewing were utilizing, allowing for thorough exploration of students' participation in the food pantry. Surveys were made available to students across campus through flyers with a QR code. The survey collected demographic information about the students including income, ethnicity, and marital status. The survey also asked individuals to indicate their food security status, food pantry knowledge and participation, and identify reasons their level of food pantry use. These results were analyzed using means, standard deviation, and correlation. Findings from this study revealed that many low-income and first-generation college students suffer significant from food insecurity. Due to various challenges and barriers, these students do not participate in food pantry to alleviate their food insecurity. Common reasons for students to not use the food pantry were lack of basic information, fear of being judge by others, and the potential embarrassment of being seen in the food pantry. It is important that the university community help promote the food pantry and awareness to increase participation and decrease food security experiences by college students.

Abstract Name: **How Art Interpretation Preserves Memory: The Significance of Historic Responses to A Sunday Afternoon on the Island of La Grande Jatte (1884)**

This paper discusses how art interpretation preserves memory by reflecting upon several different interpretations of A Sunday Afternoon on the Island of La Grande Jatte (1884) by George Seurat. Throughout history, audiences have interpreted La Grande Jatte's message and preserved its significance in their own way. Still, each memory has centered around and brought forth a feeling of harmony. This paper argues that the timeless, compelling nature and legacy of Seurat's masterpiece demonstrates a powerful characteristic of our memories—their ability to simultaneously shift, change, and even contrast while still holding the innate emotion and significance embedded in our remembrances. These memories, as mentioned, are rooted in an unique interpretation of the art work. Art interpretation plays an essential role in the legacy of artworks, but it is commonly seen as a nuanced subject. Nevertheless, the practice of hypothetical intentionalism—combining authorial intention with meaningful, educated interpretations to draw legitimate and lasting conclusions about a work—can simplify our understanding of the purpose and merit of art interpretation. As the practice of hypothetical intentionalism unifies interpreters through common themes, liberates interpreters through creativity, and allows all reasonable interpretations to be heard, everyone is given a seat at the intellectual table—making artwork more compelling, engaging, and influential. The visual, technical, and memorial workings of La Grande Jatte shows its potential as a tool for analysis.

Abstract Name: **Sentiment Analysis of Plastic Ban on Social Media**

Plastic waste has destructive environmental and health consequences, and it primarily affects marine life due to the single-use plastic waste seeping into the ocean. Moreover, in 2019 a total of 73 million metric tons of plastic waste was recorded in the U.S. alone, translating to 221 kilograms of plastic waste per inhabitant. Intending to reduce the amount of plastic waste generated in the U.S., many states have enforced the single-use Plastic ban regulations, and as of May 4, 2022, New Jersey has become one of them. Similar to any actions taken by authorities, enforcing those regulations aroused a response from different communities. The purpose of this study is to analyze the reaction of the population affected by the implemented regulations over time. This study based itself on comments gathered from Reddit. Web scraping was conducted tocollect data from Reddit from 2017/01/01 to 2022/06/30 based on a combination of the keywords regarding plastic ban. The results consisted of a dataset of 46,562 comments, then submitted to a series of text preprocessing and cleaning using NLP techniques. Finally, we use the NRC lexicon to analyze and categorize each comment per NRC lexicon emotion standards which include anger, fear, anticipation, trust, surprise, sadness, joy, and disgust. We found a higher frequency of emotions, such as scared, angry, surprised, and happy, regarding the ban on single-use plastic. Rearranging the NRC lexicon emotion ratio into two sentiments: negative and positive, we conclude that more people are negative toward the ban on single plastic use. This study could go further by comparing the emotion ratio between different states. Conducting this study on comments gathered on a monthly basis instead of a span of five years would produce a mor eaccurate result on how the population in the U.S. feel about the plastic ban.

Abstract Name: **Developing Economical Snowplow Navigation System for Whiteout Conditions.**

Whiteout conditions during winters in Iowa create hazardous conditions for all drivers, especially snowplow drivers. We set out to assist the Department of Transportation of Iowa in adding modifications to snowplowing trucks to assist drivers in navigating extreme road conditions. To accomplish this, we sought suitable sensors that can operate efficiently under extreme conditions. We plan to run tests this winter to determine which sensor best suits our goal. The sensors we currently plan on using are GPS-IMU, radar, and possibly lidar. Our goal is to collect data from multiple sensors, analyze the data, and finally output an intuitive yet non-distracting GUI to assist the driver. Current tests show that the GPS-IMU sensor can assist the driver the best, as the sensor we picked, the Swift Duro, provided us with GPS data within 1 cm of accuracy. The radar we chose is the Delphi ESR for its high sensitivity and accuracy. We will be conducting tests under whiteout conditions this winter to understand its capabilities for our application. We collected the data using ROS running on a Ubuntu Server and used Python to process the collected data.Currently, the primary computing hardware used is the Nuvo-7002E, which costs north of $1000. My focus is on testing different low-cost hardware to perform the tasks, i.e., collecting, analyzing, and outputting data. I've been using the Raspberry Pi, which costs less than $50, to collect data from sensors, and so far, it appears capable of handling most tasks. One possible issue is that the Pi might be unable to handle CPU power-intensive operations like map generation. Hence this winter's test would be crucial in understanding its full capabilities.

Abstract Name: **Codes from Fiber Products of Curves**

When we are storing many data across multiple devices, it is possible to lose some data. We explore a way that generates and stores the data effectively and efficiently; in other words, if we lose some data, we can use our other data to recover the lost information. We are using curves with many points over finite fields by using the fiber products of curves and evaluation codes to achieve this goal. To obtain an explicit multi-dimensional recovery structure, we use fiber products of curves with many points. The data we are encoding is that of polynomials of limited degrees, which are encoded using the evaluation at the points on the curve. We compute the minimum distance, length, and dimension of these codes to get a measure on their usefulness and practicality.

Abstract Name: **Food Insecurity and Sustainability in Wisconsin: Understanding the Influence of Technological Advancements and Labor Mobility**

This work is a development project for my undergraduate research next year. Food insecurity is one of the most serious problems while number of farms and farmworkers are decreasing. I conducted a literature review through Google Scholar and the school library, and data collection through USDA Database and Census Agriculture. From the data collection, I collected the data of the population of farmworkers, food insecurity, and precision agriculture adoption rate in the United States, Wisconsin, and surrounding Midwest states roughly between 1995 to 2020. The result of my research shows that there seems to be a negative relationship between the population of farmworkers and precision agriculture adoption rate. There seems to be no relationships between other combinations of variables. From this result, it would be encouraged to make sure the people, who are supposed to or want to move between industries, are supported through educational and training opportunities through scholarships. Regarding the information I obtained, I have three future visions for the related research. The first vision is to conduct a US county-level analysis of the same variable with more rigorous analysis method. The second vision is to conduct global/macro-level analysis of the same variables with more rigorous analysis method. The last vision is to find out the method of calculating the efficiency provided by precision agriculture, which is highly ambitious and need more education for myself. As I obtain ideas for other variables or other ways to holdresearch, I am going to add those ideas for the future ideas.

Abstract Name: **Analysis tool for Mapping and characterization of Climate, Chemistry, and Clouds of Exoplanets (including promising Terrestrial planets) using MIRI (Mid-Infrared Instrument) Phase Curve Program of James Webb Space Telescope(JWST).**

In this project we are utilizing data gathered by the JWST(James Webb Space Telescope) to understand the atmosphere of transiting exoplanets. The purpose of this project is creating a framework to analyze atmosphere of exoplanets by using datasets derived from the observations of exoplanets'from recently launched JWST. I will also present findings based on the investigations of the star spots of transiting exoplanets with the ground based telescopes. I will be using simulated data to attain the necessary skills and techniques over the course of an academic year . These techniques are utilizing (AY 2022-23) data from JWST. Data is in the process of being more and more available.MIRI (Mid Infrared Instrument) onboard JWST helps to study very high redshifted entities for example galaxies in the distant universe. MIRI can pierce through dust to study and take images to study chemistry of the planet formation regions and take images of planets' atmosphere including our own Earth. In addition, on a grand scheme of scientific-applications, it is important to study the high redshifted objects, because the signature of metals in the the universe moves to the wavelength of the Infrared which MIRI will be able to study. MIRI is operating over a wavelength range of 5 to 28 microns. JWST has a camera as well as a mid-infrared spectrograph. A spectrograph is an instrument for dispersing radiation (electromagnetic radiation or sound waves) into a spectrum and recording the detected light into a multichannel detector (credit:The International Society of Optics&Photonics). Research project's goal is to showcase scientific findings by proposing process and findings of an open source software framework which will leverage interdisciplinary segments of astrophysics that consist of physics of optics, data analysis, instrumentation (MIRI) onboard JWST, infrared spectrography, planetary atmosphere of a transiting exoplanet, and software development.

Abstract Name: Political and Social Biases in Reasoning

Our research investigates the phenomenon of people consuming information that confirms their preexisting beliefs, a significant contributor to political polarization and a problem that is widely considered to be a threat to democracy and governance efficiency. We hope this study could make us more aware of the partisan news we consume and how that carries biases in our beliefs. We provide participants with ten tweets from U.S. senators, half of which are liberal and half of which are conservative. Then, we ask them to choose at least four items to read. We compile their responses and assign scores such that negative scores indicate more conservative choices and positive scores indicate more liberal choices. Then, we discovered, as numerous prior studies have shown, that participants select articles shared by those who share the same political affiliation as them (i.e. Dems choosing dems, GOPs choosing GOPs.). After one week, we inquire about the participants' memories of reading these articles. We ask if they remember reading each tweet individually and compare their answers to our own records. Based on a pilot study, we found that participants tend to exaggerate the quantity of articles they have read. We also discovered that whether or not a person recalls reading an article has little association with their political views (i.e. a Democrat will remember reading an article posted by a Republican Senator as much as remembering reading an article posted by a Democratic Senator). Our findings show that people are more willing to consume political knowledge that aligns with their formed political beliefs. However, counter-intuitively, people are nearly equally as good at memorizing political information from both sides. We are working to refine the procedure and collect more data through surveying more participants from Prolific, an online platform.

Abstract Name: Gait Impairment in a Rat Model of Brachial Plexus Birth Injury

Brachial plexus birth injury (BPBI), a neuromuscular injury occurring during a difficult birth when the neck is excessively stretched, damages the brachial plexus nerve bundle and leads to shoulder and elbow impairment. Resulting musculoskeletal deformity occurs around the glenohumeral joint, which facilitates functional shoulder range of motion and gait movement. While previous studies assessed specific impairments including gait impairments caused by BPBI, they only examined one time point post-injury. Our objective is to create a timeline over which these impairments develop and their impact on shoulder growth and function. Sprague Dawley rats were divided into 4 surgical groups (postganglionic neurectomy, preganglionic neurectomy, forelimb disarticulation, or sham surgery) and received surgery on one forelimb at postnatal days 3-6, followed by sacrifice at either 3, 4, 8, or 16 weeks after surgery. Videos of walking (5m/min) and running (10m/min) gait were recorded for each group at 3-, 4-, 6-, 8-, 12-, and 16-weeks post-surgery(n=9-60 per timepoint). Metrics including stride length, stride time, stance time, and duty factor were compared across groups with ANOVA (α=0.05) and Tukey posthoc tests. Preliminary results indicate that both neurectomy and disarticulation groups had smaller injured-limb stance times relative to the sham group for both walking and running at 4 weeks. Walking duty factor was lower for the neurectomy groups at 4 weeks relative to sham; disarticulation groups had lower walking and running duty factors at weeks 3 and 4 relative to sham. Additionally, injured limb stance time for walking and running was greater for preganglionic neurectomy than postganglionic neurectomy over time. These results suggest a temporal change in functional shoulder movement across time and better functional limb recovery following preganglionic BPBI. limbs. Understanding when functional shoulder movements are altered following BPBI is critical for developing more targeted and timelier treatment strategies.

Abstract Name: Gene Kranz: An Exceptional Leader

Gene Kranz, a NASA flight director from the onset of the space race through the end of the Apollo era, consistently demonstrated his steady perseverance and capable leadership during the entire span of his tenure. As early as high school, Kranz encountered situations that required making difficult decisions. Despite the pressure, Kranz controlled his emotions and carefully considered options before making what he deemed the right choice. As he progressed into his career, Kranz learned to heed others' advice. Because he accepted guidance from multiple mentors during flight training and his early career, he was later able to apply his wisdom in even the most challenging conditions presented by the infant space program. Even when failure seemed inevitable, Kranz refused to accept defeat. Instead of relying on his own knowledge, he listened to every member of his team to reach a solution. Kranz's approach to teamwork and how it accentuated his skills as a leader will be examined in depth. Furthermore, his unalterable perseverance will be highlighted because it is one of the primary features that truly defined him as a leader. Because his steadfast perseverance, strong emphasis on teamwork, and incredibly high standards were prevalent throughout his tenure, Gene Kranz proved to be an exceptional leader.

Abstract Name: ?Designing a Safe Sensory Home For a Client Who Has Retinitis Pigmentosa?

Making the home safe for the visually impaired client but still functional and aesthetically pleasing. The client of this specific project is a husband and wife who both work from home. The husband has Retinitis Pigmentosa. Retinitis Pigmentosa is a disease that affects the retina of the eye. As time goes on the person's eye site diminishes more and more until the only site the person has is a pin site. Material selections are very important from colors to slip resistance. Using high contrast between baseboards and walls makes it easier to navigate space. Using textural cues are important too, using carpet for bedrooms and hard flooring in common spaces shows where the client is in home.Giving the client textural cues makes it easier for them to navigate around the house safely. Being able to step into a room and feel the ground is different gives them a quick view of where they are in the home rather than having to seek something familiar. In this home, the design includes light-colored walls with black crown molding, baseboards, doors, door framing, light switches, and electrical plugs. Making sure that the flooring material is slip resistant to avoid accidents, using fixtures that have high contrast compared to the wall they sit on, and lots of light for the user. Throughout the space task lighting is also a key element in the space. Adding under cabinet lighting, lighting next to chairs or desks, and bedside lighting helps when the client needs to perform a task. All these aspects put together create a functional and safe home for all the users involved.

Abstract Name: **Efficacy of Student Mobile Health Application: The Case of SUNY Brockport**

The importance of universities to provide mobile applications for students and faculty is becoming a growing trend since business operations, as well as academic activities, are affected using technology. Research published in 2021 says that the number of health-related applications in the Apple and Google Play stores has exceeded 97,000 with approximately 100 new applications being added per month. This indicates the potential for growth in the mobile health application market. For these reasons, it is important that the SUNY Brockport Health Center investigates the importance of designing a mobile application that can benefit students and the Brockport community at large. This study aims to determine the effectiveness of a health center application that students and faculty can use. With the changes in day-to-day life since the COVID-19 era, there has been an increasing need for mobile health applications. Designing a mobile application (MyHazen App) for the Brockport community could potentially provide students easier access to the services that the online portal provides, with a more user-centered design approach and improved capabilities. This study comprises four main phases: (1) Gathering user requirements through an institutional approvement, (2) Designing a high-fidelity prototype using Figma, (3) Developing a student-based mobile health (mHealth) applicationtool using Swift and XCode, and (4) Determining if students will adopt to the MyHazen application by conducting a usability testing for student user feedback through an iterated design approach.

Abstract Name: **Enslaved Baptisms: How African Slaves Joined The Christian Faith and Made It Their Own**

American slavery is often understood in terms of understanding the inhumane conditions forced upon African slaves by white settlers and United States citizens, and seldom examines the lives of the slaves themselves. As a result, this conceptualization fails to take into account the unique cultural practices and daily lives of enslaved people. In my paper, Enslaved Baptisms: How African Slaves Joined The Christian Faith and Made It Their Own, I seek to answer both how enslaved men, women, and children eventually joined the Christian body despite the strong opposition from slaveholders, and how these same enslaved people created a unique Christian doctrine that gave them spiritual freedom and purpose. I will also look at how Christianity was used in different capacities for enslaved people and slaveholders, and how the religion was used as a protest religion and a religion of oppression, respectively. Through the use of primary sources such as newspapers, diary entries, memoirs, multiple monographs, as well as countless journal articles this paper will illustrate the connection between Anglican missionary work and the strong Christian faith that developed amongst African American slaves through the mid-seventeenth to mid-nineteenth centuries.

Abstract Name: **The Future of Plastic Waste: A Multi-Disciplinary Approach**

Approximately 300 million tons of plastic waste is produced every year worldwide; only ~7-9% is recycled.The result is harmful plastic waste accumulation that negatively impacts ecosystems and communities around the world. Polyethylene terephthalate(PET) is one of the most abundant plastics due to its transparency and chemical strength. While naturally occurring PET-degrading bacterial enzymes have been identified (i.e., PETase and MHETase), their physiological requirements make them ill-suited for industrial use. We attempted to address this problem by bioengineering a chimeric PETase::MHETase protein for enhanced PET degradation. Review of recent literature revealed a collection of PETase and MHETase-optimizing mutations shown to enhance temperature and pH tolerance. Building from this work, our approach was to combine these nucleic acid changes into a single modified open reading frame (ORF) to support even greater PET degradation capabilities. The synthetic plasmid DNA construct was transformed into E. coli and expressed to produce a novel chimeric protein. The biomanufactured product was purified by nickel column chromatography and quality-tested using standard assays. Finally, functional assays allowed us to measure PET plastic degradation. Recognizing that typical practices in life science laboratories are part of the plastic waste problem, our team explored and implemented ways to make our laboratory—and others like it—more sustainable. Additional methodologies from the field of STS (Science, Technology and Society) were used to consider, imagine, and develop greater understanding of the implications of plastic waste and how a bioremediation-based solution might be implemented in the future.

Abstract Name: **The Beloved Community: Creating a collaborative experience to explore Ethical Decision Making and Perspective taking using historical references**

The goal behind creating this experienceis to allow participants to engage with the decisions, actions, and perspectives of the governmental officials, college administrators, and student demonstrators during the 1960s student sit-ins for Civil Rights in Montgomery, Alabama. This project allows participants to see themselves in each of the moral leader comparators lived experiences as told by them, as well as engage with the original documents and newspaper coverage of the events. The events selected for this pilot spawned two landmark legal cases—the Dixon v. Alabama State Board of Education (1961) and the Sullivan v. NY Times (1964). This poster presentation outlines the metamorphosis of historical content into a collaborative, playable experience. Using content that was analyzed by previous teams, our goal was: to create archetypes of the people involved in the actual events; segment events into specific questions; and organize information access to individual players based on character perspective. Students then meet synchronously to debate the “Event Questions” from the perspective of their assigned archetype. At the end of the timed discussion, all participants propose and present to the group, a course of action based on their research and the impact of the discussion. This continues for four rounds. At the end of the experience, suggestions for actions are compared to the historical documentation of the events. Based on the game mechanics used in “The Situation Room Experience,” students move from exploring contemporary events, back in time, where information is received through newspapers, flyers, radio and word of mouth, to better understand the context of decisions that still affect us today.In addition to understanding history, this experience can be used to promote the higher order skill development needed by college students - empathy, perspective taking, intercultural agility, and ethical decision-making.

Abstract Name: **State-Sponsored Gambling: A Pragmatist Perspective**

Through an application of John Dewey's pragmatist philosophy, this research evaluates the morality and efficacy of using state lottery revenue to help fund K-12 education in the United States. While previous scholars have used rigid utilitarian or Kantian ethics to evaluate lotteries, pragmatism provides a unique, adaptive perspective to the dilemma. Using many of Dewey's essays and his monograph, Ethics (1908), this study first establishes the tenets of his philosophy which apply to the dilemma: the value of individualism, educational reform, and governmental responsibility. Then, an evaluation of state lottery commissions from 1980 – 2020 reveals the most common ethical issues to be regressivity, low efficacy, and a lack of government transparency. To assess these practices, Dewey's model of describing morality via value judgements was applied to each ethical issue. The results suggest that the current system is neither ethical under pragmatism nor effective at what it claims to achieve. This challenges the continuation of the state lottery system as-is with possible solutions including: the utilization of progressive revenue collection, ensuring a higher quality education for all citizens, and privatization of lotteries. In time, these solutions would likely render the current lottery system cyclically self-defeating. Further research could include a comparative analysis of the funding of public education between states, with and without state lotteries, to provide more quantitative evidence demonstrative of state lottery efficacy.

Abstract Name: **Queer Mortuary Practices: The Performance of Death and Dying in AIDS Epidemic New York City**

How was the right to be remembered and cared for reflected in the burial practices of queer people during the AIDS epidemic? This paper explores the connection between the material culture of Hart Island, a public burial ground off the coast of the Bronx, and the performance of death and dying during the AIDS epidemic in New York City. Centered on a bioarchaeological approach to the embodiment of inequality, I also draw from performance theory, queer archival theory, the development of ballroom aesthetics and alternative kinship structures, and the body as a form of protest to situate the disaccord between government-directed mortuary practices and community-based care. Since many queer relationships lacked the legal recognition required to claim the remains of a decedent, individuals who died of AIDS-related complications were relegated to unmarked graves. The rebranding of Hart Island as an AIDS-quarantined burial ground is an example of the state's creation of material culture, yet the painted rocks left along the island by bereaved loved ones also contribute to the island's archaeological record. Given that queer people were denied the practice of traditional funerary rites, extravagant performances of death and dying (as a form of protest) developed in response to the aforementioned axis of structural violence. These included die-ins, publicly visible parody-like funerals, and the public spreading of ashes. With the recent rise of queer bioarchaeological and Black feminist archaeological theories, there emerges a new framework for understanding the search for autonomy and continued acts of resistance embodied in these queer mortuary practices.Keywords:AIDS epidemic, mortuary archaeology, 1980s-90s New York City, Hart Island, queer kinship

Abstract Name: Prenatal Development of the 13-Lined Ground Squirrel

The 13-lined ground squirrel (Ictidomys tridecemlineatus; 13LGS) has excellent daytime vision based on numerous cone photoreceptors in their retinas; a human-like lens and eye structure; and a markedly larger portion of occipital cortex devoted to visual inputs. Therefore, the 13LGS has been identified by the National Eye Institute as a valuable alternative rodent model for studying treatments of human visual disease. In addition, the 13LGS is an invaluable model for exploring possible translation of its hypometabolic hibernation physiology to various aspects of human medicine, including blood banking, emergency brain and cardiac care, and manned spaceflight. Despite all these advantages of the 13LGS for multiple fields of biomedical research, the species' embryonic and fetal development over ~27 days' gestation remains undescribed. This project tested the hypothesis that the Theiler Staging criteria established for laboratory mice can be applied to the 13LGS. All animal procedures were pre-approved by the UW Oshkosh Institutional Animal Care and Use Committee and were carried out in a USDA- and AAALAC-accredited facility.Multiple pre-implantation embryos (collected 1-4 days post-copulation), 16 fetuses, and 1 neonate were collected from UW Oshkosh Squirrel Colony specimens over several years and preserved. Using a dissecting microscope, their crown-rump measurements and gross anatomical features corresponding to Theiler Stating were documented. The available pre-implantation embryos were found to span TS1-4, whereas the available fetuses spanned TS16-26. The neonatal specimen constituted TS27. The species' characteristic stripe/spot pattern was visible in the skin by embryonic day 21, corresponding to TS24. To capture TS5-15, additional 13LGS specimens must be collected in future breeding seasons, but the images reported here represent about two-thirds of this useful model species' prenatal development. Supported by the UW Oshkosh Squirrel Colony, NIH U24EKY029891-04 and the UW Oshkosh McNair Scholars Program.

Abstract Name: Evaluation of an Online Citizen Science Game as a Remote Course-based Undergraduate Research Experience (CURE)

The COVID-19 pandemic highlighted a critical need for rapidly connecting students to remote research experiences during times of unexpected constraint when college campuses are closed. To address this gap, a new remote course-based undergraduate research experience (CURE) was developed around the citizen science game Foldit. In recent years, citizen science games have grown in popularity and many of them have reported participants making genuine discoveries for complex research problems. Foldit crowdsources human creativity and spatial reasoning skills to solve computationally challenging problems in de novo protein design. Because it is free, available online, and designed to be accessible to non-scientist audiences, Foldit can be broadly and efficiently adopted across institutions both as a CURE or as an apprenticeship-based traditional undergraduate research experience. The Foldit CURE was designed for novice researchers with no prerequisite courses. The first iteration of the course consisted of 20 students ranging from freshmen- to senior-level with diverse demographics and academic majors. This study aims to address the following research questions: (1) How can the online game Foldit be implemented as a remote or hybrid CURE? (2) What impact does the Foldit CURE have on students' content knowledge and competency in research thinking? (3) What impact does the Foldit CURE have on students' attitudes towards themselves and the STEM field? (4) What were the successes and challenges of this remote CURE from the perspective of the faculty and students? Analysis of learning assessment and course evaluation surveys revealed that students showed gains in content knowledge, competency in research thinking, scientific identity, self-efficacy, and interest in STEM. Altogether, results from this study suggestthat remote CUREs can yield positive student outcomes and can be used to guide the development of future CUREs involving citizen science games.

Abstract Name: **Food As Medicine Program Analysis**

The relationship one has with food is directly correlated with one's health. Our current health system has a severe issue with individuals with chronic illnesses who face issues of affordability and accessibility to food. This has led food pantries across the country to develop food as medicine programs which can consist of medically tailored meals, medically tailored packages, and nutritious food referrals. Ultimately, the goal of these food intervention programs is to help create a better lifestyle and improve the health of individuals with food insecurity and chronic illnesses. This presentation will focus on an analysis of the Food as Medicine program at the Food Pantries for the Capital District. Our hypothesis is that Food as Medicine intervention programs improve the health of individuals with chronic illnesses which is evident through the changes in their A1C levels, BMI, number of hospitalizations, and blood pressure.

Abstract Name: **Designing An Undergraduate Forensic Chemistry Experiment on the Levels of Amphetamine in Urine Using Two Different Methods.**

Amphetamine is used to stimulate the central nervous system in patients with ADD/ADHD (Attention Deficit Disorder/Attention Deficit Hyperactivity Disorder). This drug benefits those who need it, but according to FHE Health, it is widely abused by 11.1% of all college students.The aim of this procedure was to design a teaching lab on determining amphetamine in urine samples. For the first part of the experiment amphetamine was evaluated in synthetic urine samples through an Enzyme-Linked Immunosorbent Assay (ELISA kit) that commercially available and is widely used in drug labs to qualitatively analyze whether amphetamine is present in a sample. This experiment determined whether the ELISA kit would be able to be used to find accurate quantitative results. The ELISA kit operates based on competition between the drug in the urine sample and the drug enzyme conjugate for antibody binding sites on the 96-well plate. The absorbance values were obtained with a microplate spectrophotometer. Once the values were obtained from the spectrophotometer, the data was analyzed to find the concentration of the drug in an unknown sample. Samples containing between 30.0 ng/mL and 300. ng/mL of amphetamine were analyzed using this method. The percent error for the calculated concentrations was 90.2% for the lowest concentration values, and around 13.9% for the high concentration, showing that the kit is unreliable at lower concentrations. The second part of the experiment involved the use of Gas Chromatography/Mass Spectrometry to compare the two methods and for better quantification of the concentrations of amphetamine that are detectable in methanol. Amphetamine is extracted from urine and then evaluated using the GC/MS. Both of these experiments were designed to be used as lab classes for the forensic concentration program. The experimental procedures and results obtained using the two methods will be discussed in this poster.

Abstract Name: The Rise of QAnon: From a Chatroom Board to an International Movement

This project will investigate how online indoctrination of the conspiracy theory QAnon has led to the formation of groups and movements in an international context through time. This is important because the belief in the QAnon conspiracy has led to violence, both in the United States and internationally. Such events include the January 6th, 2021 and the “Freedom Convoy” in Canada. Regardless of the origin, the ideas rooted in QAnon conspiracies have grown worldwide; if you have access to a computer, you are able to interact with QAnon content. What is concerning is how QAnon has co-opted legitimate movements to push their narratives, such as with #savethechildren. Moreover, QAnon has given rise and fueled similar conspiracies both in the United States and worldwide. This project will also investigate the differences between American and International ideals of tolerance by comparing international and American free speech law. This will give insight into how different countries react to far-right conspiracy movements. We will be utilizing the Twitter API and the coding language python to create a machine learning model to track the spread of QAnon through time. Once we get key data points, we will cross-reference them with what was in the news at the time. This project is done in the hopes of contributing into the new research of extremism online.

Abstract Name: Examining and Defending the Constitutionality of Equity, Diversity, and Inclusion Trainings within Higher Education.

Equity, diversity, and inclusion training in higher education has been used to educate students and open them to worldviews that they have not traditionally been exposed to. Although these trainings often bring a positive new perspective for students, they recently have found themselves in opposition to free speech advocates. Historically, students attending public universities have benefitted from the broad speech protections afforded to them under the 1st Amendment. One relevant protection included under the 1st Amendment is the right against compelled speech. The Supreme Court has ruled on this matter in West Virginia State Board of Education v. Barnette (1943) and Wooley v. Maynard (1977). Unfortunately, some universities’ training procedures have overlooked the compelled speech doctrine. Through exploration of 1st Amendment case law and data pulled from the Foundation for Individual Rights and Expression (FIRE) network, an in-depth analysis has determined various patterns and themes that lead diversity trainings to cross over from education to coercion. This research culminates in a comprehensive guide on how to adjust diversity trainings to avoid constitutional conflict, while keeping the goal and efficacy intact. If steps are not taken to remedy possible constitutional violations, this issue has the potential for litigation. If it were to go to court, its ability to meet the strict scrutiny standard would need to be proven, which is demonstrated through this research with case law and scholarly constitutional interpretations. This study provides a significant framework for evaluating the constitutionality of diversitytrainings, which will hopefully be broadly implemented in the future.

Abstract Name: **The Effects of Aspartame Exposure on Survival and Behavioral Profiles of Fathead Minnows**

Since the mid-1900s, artificial sweeteners such as aspartame have become one of the most widespread sugar substitutes in the world. Increased levels of aspartame metabolites (phenylalanine, aspartic acid, and methanol) can lead to impaired metabolic function in the brain leading to pre-mature brain tissue degeneration which can increase the likelihood for developing neurodegenerative diseases. The purpose of this study was to measure behavioral abnormalities and survival of fathead minnows exposed to aspartame. Fathead minnows were exposed to 0 mg/L, 10 mg/L, 100 mg/L, or 1,000 mg/L aspartame for 4 weeks with survival measured daily. Following the exposure period, a novel tank diving test (NTD) and a light/dark preference test (LDP) were used to identify any behavioral abnormalities. ANOVA indicated a significant (0.05) impact on survival at the highest tested concentration. Both behavioral assays showed no significant differences (0.05), indicating no clear effect on behavioral profiles at any level of aspartame exposure. Other published research has shown that aspartame has neurodegenerative properties based on behavioral testing and variations in neurotransmitter homeostasis in the brain in zebrafish. Our results suggest that behavioral effects due to aspartame exposure may be species-specific. Research on other fish species will be necessary to determine the scope of neurodegenerative properties of aspartame on aquatic vertebrates.

Abstract Name: **Examining Trends of Online Incivility as Tweeted by US Congress**

Social media continues to engrain itself as a medium for communication in contemporary politics. Social media cuts the middleman out as candidates are now able to speak freely and directly to their constituents as opposed to traditional news sources (Petkevic and Nai, 2022).With politicians now utilizing social networking sites as a form of broadcasting to their public audiences, incivility amongst them festers. Incivility is defined as language that uses an unnecessary disrespectful tone towards the participant (Coe et al., 2014). Incivility online encompasses direct insults, attacks on character, sarcasm, as well as extreme and/or dramatic language. These characteristics were coded for incivility from a sample of two thousand tweets, taken from official US congressional accounts between 2016 and 2020. The following research questions are addressed:
From this dataset, were direct insults and/or character attacks used more commonly than any other form of incivility.
What direct insults and/or character attacks such as, liar, shame, failure, corrupt, dumb, and idiot were commonly used towards others?
These research questions provide the opportunity to further understand trends of incivility.

Abstract Name: **Analysis of Environmental Education in Higher Education Programs: Opportunities for Professional Development**

Higher education programs across the continent address environmental education (EE), but how these programs incorporate EE is highly dependent on what resources they rely on. While some educators align their coursework with themes from the North American Association for Enviornmental Education (NAAEE) Guidelines for the Professional Development of Environmental Educators, there is an existing need for support to improve environmental education integration. Our research compiled responses from surveys and interviews of higher education members. The survey assessed the integration of EE in higher education programs, exploring topics, strategies, priorities, and networks. A database of faculty members who've integrated EE into their classes were contacted to take the survey. This study explored which strategies faculty members are currently using to teach their students such as inquiry-based learning activities, inclusivity approaches, modeling environmental education activities, and teaching outdoors. This includes some of the supports they draw on to do so and the overall design of university programs themselves. Survey results were then compiled and reviewed for descriptive analysis which included coding for themes. Survey respondents ranked sharing, standardizing, and improving EE professional development as a top benefit for statewide networks of higher education professionals. Respondents also indicated example assignments and opportunities to talk with other professors would help improve the delivery of EE in their contexts. Active statewide networks create opportunities for faculty to share resources such as syllabi, curriculum ideas, and to provide connecting points with other EE supporters. This study provides insights for the creation of these networks and creating professional development experiences for faculty members.

Abstract Name: **Bacterial Surfactant Production using Hydrocarbons as Nutrient Source**

Biosurfactants are secreted by bacteria and consist of a polar head and nonpolar tail. Current knowledge of biosurfactants stems from model bacterial isolates in laboratory settings, whereas knowledge is lacking in the understanding of environmental isolates' biosurfactant production. A multidisciplinary project explores the role of biosurfactants in the life cycle of Psychrobacter sp. PL19, a bacterium isolated from a brackish Antarctic Pond. Data presented herein focus on the role of biosurfactants in the bioavailability and biodegradation of hydrocarbons using respirometry. Three questions are being addressed: (i) Can Psychrobacter sp. PL19 grow on hydrocarbons? (ii) Does stimulating biosurfactant production enhance the growth of Psychrobacter sp. PL19 on hydrocarbons? (iii) Do biosurfactants released by Psychrobacter sp. PL19 promote the growth on hydrocarbons of non-biosurfactant producing bacterial strains? Psychrobacter sp. PL19 was able to grow on either hexadecane, naphthalene, or benzene at 4°C. CO2 production rates were similar for all three substrates and ranged between 0.18-0.20 fg CO2 cell−1 day-1 on average. Fundamental understanding of the role of biosurfactants in the environment can lead to improved bioremediation strategies in cold temperature environments.

Abstract Name: **Fascicle and Aponeurosis Detection from Ultrasound Images**

The amount of torque produced by a human muscle is found to be highly correlated to the angle between fascicles and aponeurosis. Ultrasound technique can be used to capture an image stream of the muscle fibers from a human subject during functional actions and can be useful in non-invasively measuring skeletal muscle architecture, which contains human intent information. The manual process that has been used in the past to deduce the anatomical characteristics of muscles from US pictures is arduous, time-consuming, and subject to variation between researchers. In this research project, we intially invited a human expert to label the two target muscle fibers as our reference, i.e., the ground truth, then we proposed to develop an efficient machine learning-based detection method utilizing Microsoft CUDA, Azure and Python OpenCV library enabling parallel computing that can mimic a well-trained human expert in identifying fascicle and aponeurosis, and hence therefore, computed the pennation angle (PA) with decreased time complexity and to an acceptable accuracy. The architecture assumes muscle fibers have tubular/linear characteristics; thus, we may hypothesize that the Hough transform can enhance the feature. It should also be robust for low-frequency image streams. We contrasted the suggested algorithm with two established benchmark methods: Alex and Vgg. The performance of the proposed approach showed higher accuracy in our dataset, with readings similar to thehuman expert. The calculation of human muscle torque performed using the proposed method shows promising potential in automatic muscle fascicle orientation detection to facilitate implementations in biomechanics modeling, rehabilitation robot design, human robotics, degenerative muscle disease tracking, physical therapy, and neuromuscular disease diagnosis with low-frequency data stream. Additionally, we also observed that thedecrease in program run time might have thepotential for real-time computing for these applications in clinical settings.

Abstract Name: **Genetic Contributions of APOE & TOMM40 to Mitochondrial Morphology & Alzheimer's Disease**

The strongest genetic risk factor of late on-set Alzheimer's disease, LOAD, is the apolipoprotein allele APOE ε4. APOE is an apolipoprotein that transports cholesterol and amyloid-beta proteins between cells and across the blood-brain barrier. Previous research suggested APOE ε4's relation to LOAD is tied to inefficient cholesterol; lipid transportation. Thus causing amyloid-beta protein accumulation and plaque formation in the brain. New research suggests that APOE ε4 affects other cellular functions, such as cellular glucose metabolism. TOMM40 rs2075650, a translocase of the outer mitochondrial membrane, is another single nucleotide polymorphism tied to Alzheimer's disease. Interestingly, genes APOE and TOMM40 are in proximity on chromosome 19 and share linkage disequilibrium. In order to study their effects on cellular level, HEK293 cell lines carrying combinations of these alleles will be created using Piggy-bac homology-directed repair method facilitated by CRISPR Cas9 technique. The Piggy-bac plasmid vector contains GFP, Puromycin resistance and hsvTK genes for cell selection. Once the cells are verified through sequencing, we will evaluate the effect of APOE ε4 on the distribution and transportation of cholesterol inside and outside HEK293 cells, glucose metabolism through mitochondria, and also to study its interaction with TOMM40 rs2075650.

Abstract Name: **CRY-based Optogenetic Tools for Drug Discovery**

The circadian clock is composed of input signals, an oscillator, and output functions that regulate circadian rhythms. Within the mammalian circadian clock, the suprachiasmatic nucleus is driven by transcription translation feedback loops (TTFL), which has activator proteins, CLOCK and BMAL1, and repressor proteins, period (PER) and cryptochrome (CRY). Disturbed clock proteins can cause sleep disorders, immune disorders, and mood disorders. To study CRY's role in the mammalian circadian system, we developed an optogenetic tool to examine interactions between CRY and nuclear receptors (NRs).We used a mammalian two-hybrid assay to examine the interactions between mouse cryptochrome (mCRY1 and mCRY2) and NRs: androgen receptor (AR), glucocorticoid receptor (GR), and pregnane receptor (PXR). If CRY interacts with the NRs, luciferase is transcribed and the cells glow in the plate reader. Since our optogenetic tool showed high luciferase expression when mCRY1/mCRY2 interacted with NRs and this interaction has already been confirmed, our optogenetic tool proves to be an accurate indicator for interaction between clock components and receptors.With a successful optogenetic tool, we have a high throughput assay to test interactions between other clock components, NRs, and small-molecule modulators in transfected mammalian cells. Small-molecule modulators adjust the circadian clock's period by targeting input pathways or specific pockets on clock proteins. KL001 is one small molecule that has been identified to affect both mCRY1 and mCRY2's binding ability with other proteins. Other small molecules work as selective drugs, binding only to mCRY1 or mCRY2, or have therapeutic properties for diabetes (GR), testosterone/androgenic hormone disorders (AR), and steroid hormone receptor PXR.Ultimately, our optogenetic tool allows us to investigate CRY's role in the regulation of mammalian development and metabolism. Understanding the effects of drugs on the interaction between the cryptochromes and the receptors will help in developing drugs to regulate these hormonal processes.

Abstract Name: **INOS inhibitor, or 1400W, mitigates pathological morphology of microglia in nerve agent (soman)-induced rat model of epilepsy**

Epileptic seizures are known to induce neuroinflammation milieu in the brain involving the activation of resident immune cells and microglia. Microglia undergo aberrant morphological changes following brain insults, producing an excessive amount of induced nitric oxide synthase (iNOS). Therefore, in this study, we investigated the effects of the iNOS inhibitor, 1400W, on abnormal microglial morphology in a nerve agent (soman)-induced rat model of epilepsy. Morphometric analysis was performed to assess the number of branches, their lengths, endpoints, and cell body area for individual microglial cells. In the soman-treated group (epileptic), the vast majority of microglia showed a reduced number of branches, endpoints, shorter branches, and larger cell bodies as opposed to numerous, lengthy branches/endpoints and relatively small cell bodies in the control group. In contrast, in 1400W- treated soman exposed animals, these aberrant phenotypes of microglia were restored in which microglia show a greater number of branches, endpoints, longer branches, and smaller cell bodies relative to the soman vehicle treated group. Overall, these findings highlight the important roles of iNOS in mediating microglia-driven neuroinflammation, and its inhibition is neuroprotective against epilepsy-induced neuroinflammation. Therefore, strategies intervening with iNOS inhibitors could mitigate seizures and their associated pathologies in epilepsy.

Abstract Name: Updated Annotation of Platyhelminth G-Protein Coupled Receptors

Parasitic schistosome flatworms (Schistosoma haematobium, Schistosoma mansoni, and the zoonotic parasite Schistosoma japonicum) are responsible for the disease schistosomiasis which affects >200 million people. There is a need to identify new druggable targets in these parasites, given that there is no human vaccine and the current reliance on praziquantel monotherapy raises the potential for the emergence of drug-resistance. G-protein coupled receptors (GPCRs) are a logical starting point, since they control important aspects of schistosome biology such as neuromuscular function and reproduction. These targets are also highly druggable; over 1/3rd of FDA approved therapeutics act through these receptors. Updated genomes for several important species of flatworms have recently become available, providing significant improvements over previous drafts. There are likely additional GPCRs in these improved genomes that were not annotated in previous versions. Here, we have bioinformatically predicted the GPCRs present in these updated flatworm genomes using tools such as HMMER3 and BLAST, and used tree-building approaches to classify these additional receptors. These new annotations will assist drug discovery efforts by expanding our knowledge of parasite druggable targets, as well as enable improved analysis of omics datasets to better understand the mechanisms of existing therapeutics.

Abstract Name: Impact of Communication Channel on Voter Behavior: An Exploration of the Intersection of Political Communication and Campaign Theory

A founding principle of American democracy is the right to vote. Inevitably, the communication styles of politicians and their teams have changed over time. While early voters relied heavily on word-of-mouth and newspaper circulation to raise awareness of candidate platforms and turn out voters, today's voters are inundated every campaign cycle by candidate advertisements. These advertisements can be in the form of yard signs, but have also crept into online streaming services like Hulu and YouTube TV, and music platforms like Spotify. In the last 10 years social media, smart phones, and the ubiquity of data have allowed for more targeted and precise campaign communication as campaigns seek to target core demographics to increase voter turnout. Currently, political communication comes in the form of billboards, celebrity endorsements, rallies with politicians, text messages, media advertisements, direct mailers, emails, phone calls, and door-to- door canvassing. This study examines five of these political communication channels (endorsements, billboards/signs, texts, TV advertisements, and rallies; Green;amp; Gerber, 2015), and the impact of these communication channels on voter intention. Using a quasi-experimental design (n = 182), we identified association(s) between political communication channels and intention to vote amongst participants aged 18-22 at a small, midwestern Liberal Arts college. This study provides an important addition to the literature by examining if social media channels (advertisements, online advertisements, etc.) which have exploded in popularity over the past ten years, impact actual intention to vote amongst GenZers.

Abstract Name: **Investigation of the Effect of Nozzle Temperature on Tensile Strength of Reinforced and Nonreinforced Polypropylene in Fused Filament Fabrication Process**

Fused filament fabrication (FFF), a popular 3D printing method, is increasingly being used to create parts for service rather than simply for form prototypes. A primary advantage of FFF is the short lead time from design to realization of a part; this allows third-party users to quickly make parts for repairs. Commercially available filaments are made of a range of materials, including unreinforced or “neat” polypropylene, bead-reinforced polypropylene, and fiber-reinforced polypropylene. While manufacturers of filament rolls typically provide preferred printer settings (including nozzle temperature) it is valuable to understand the effect of nozzle temperature variation on part strength as well as the tradeoffs incurred with the usage of different polypropylene variants. Furthermore, the most readily available strength data refers to material that has not undergone the FFF process. Having specific information on the tensile strength of polypropylene variants subject to a range of manufacturing conditions will provide valuable design information for those who intend to create service parts from polypropylene via the FFF process.

Abstract Name: **Changes in Chemical Oxygen Demand of Surface Waters in Dunn County**

Chemical oxygen demand (COD) is an indicator of the amount of oxygen required to oxidize organic and inorganic substances in water. COD testing is commonly done on samples of water contaminated with domestic and industrial waste. Discharge of wastewater by industries introduces organic materials that deplete dissolved oxygen available for aquatic life. In Dunn County, this wastewater disposal coupled with runoff from farms and residential areas can negatively impact aquatic ecosystems. COD analysis is an efficient way to determine the aquatic health of water sources, where increasing levels indicate an increase in substances susceptible to oxidation.To assess the susceptibility to oxidation, water samples were collected following a general timeline of herbicide, pesticide, and fertilizer application in the area. Samples were collected from three locations in Lake Menomin, two locations in Tainter Lake, and two locations in Red Cedar River.One set of samples was collected mid-July, a second set was collected at the end of September. COD analyses were conducted using the Open Reflux Method; samples were refluxed in a strongly acidified solution with excess standard K2Cr2O7 to oxidize any organic and inorganic components present, followed by titration with standard ferrous ammonium sulfate with ferroin indicator to determine the unreacted dichromate.Results of the analysis showed decrease in COD (ppm O2) of samples from one location in Tainter Lake (107.60±50.06 to 36.20±11.26), and two locations in Lake Menomin (97.53±44.01 to 41.80±8.09 and 249.27±31.40 to 83.80±6.94). An increase in COD was detected in an area by the Red Cedar River (20.73±9.45 to 36.07±4.69). These findings may indicate that pesticides, herbicides, and fertilizers from farm run-off, discharges from boats, and algae growth affect the COD levels in these surface water.

Abstract Name: **Domestic Intercultural Experiential Learning: A Case Study Working with the Afghan Refugee Population**

Abstract: This case study examines the reflections and civic engagement of twenty-five students in a domestic immersion program with Afghan refugees, identifies if students thought or felt differently about civic participation, and connect the circumstances that caused change to occur. Student reflection and changes in civic engagement were measured by recording responses to questions before, during, and after the immersion. Pre-immersion responses centered about a desire to learn about the Afghan refugee population, and during the immersion focused on an increased global awareness and personal social responsibility specific toglobal citizenship. Post-immersion themes included increased civic engagement and the aptitude to apply knowledge and skills, including career planning, volunteering, and educating others. Results of this study suggest a strong connection to civic engagement and global awareness, as well as the reevaluation of social hierarchies and broadening of perspectives. Keywords:community engagement, Global responsibility, Action learning.

Abstract Name: **Neurodiversity, Personality, and Mental Health Challenges**

Prominent variations of neurodiversity include autism spectrum disorder (ASD), attention deficit hyperactivity disorder (ADHD), and dyslexia. Institutions of higher education should foster an inclusive environment for these individuals, which includes understanding common behavioral attributes, limitations, predictors, prevalence, and desirable adaptations. Participants in our pilot study were 23 females and 8 males (31 total), drawn from convenience and student sources. The primary goal in this first foray into investigation of neurodiversity in higher education was to focus on personality and related associations with common attributes of these three forms of neurodiversity. Follow-up with larger samples is planned to investigate their prevalence and effects / limitations in the college environment. Results found that openness to experience correlated negatively with typical ASD symptoms such as difficulty with social norms (r = -.52, .01). Neuroticism correlated positively with ASD symptoms (r = .46, .05), and individuals higher on neuroticism were more likely to suffer burnout (r = .74, .00001). Participants endorsing ADHD symptoms also reported higher burnout (r = .50, .01), and participants not reporting ADHD symptoms reported higher levels of self-care activities (r = -.46, .01).Although this pilot study focused on associations and not causality, our results nonetheless identify several correlates of neurodiverse symptoms and provide direction for follow-up research. The potential benefits of enhanced understanding of neurodiversity in higher education include targeted resources, classroom adaptations, and counseling resources. In short, continued research offers great potential to afford neurodiverse students the same opportunity to succeed as neuro-normal students.

Abstract Name: **Finding Better Solutions for Available MRI Contrast Agents - Fe(II) Complexes Exhibitng Temperature Dependent Spin Transition**

Studies have shown that existing contrast agents containing Gd that are used in Magnetic Resonance Imaging (MRI) are neuro- and nephrotoxic and can accumulate in the brain for many patients, especially those with renal complications. Our goal is to find a replacement for Gd contrast agents by designing an agent based on Fe(II) complexes that is dynamic, activatable, and targeted for thermal tumor ablation therapies. A key property of Fe(II) complexes is that they can undergo thermally induced spin-state crossover (SCO). However, finding an appropriate temperature range in which a SCO would occur for these therapies is critical for future applications.The behavior of numerous SCO complexes, particularly octahedral Fe(II) complexes, has been well described. Key to meeting the goals of this project is identification or chemical manipulation of currently known structures that undergo temperature-induced SCO without degradation at temperatures between 60 – 80 °C. Prior SCO complexes have been found to undergo spin transitions at much lower temperatures due to difficulties in stabilizing low spin states at room temperature. In the case of terpyridal Fe(II) complexes, the high stabilization of the low spin states results in SCO temperatures that are too high.Thus, to find iron complexes that meet the temperature SCO requirements for a contrast agent, we have synthesized a new type of tridentate ligand that contains a bipyridal unit along with a pyrazole, triazole, or an imidazole group. We will use these new ligands to explore their structural characteristics and feasibility towards MRI contrast agents and biological applications. The synthesis and characterization of all Fe(II) compounds, along with their magnetic susceptibility at various temperatures to determine their potential effectiveness as contrast agents, will be presented.

Abstract Name: **Synthesis and Characterization of Novel Boron Oxide Materials**

Boron-based compounds are a subject of interest for materials chemists, especially when it comes to nanomaterials and catalysts. A major selling point of these materials are their high stability and activity as catalysts. A particular material of interest is tetrahydroxydiboron, which has some unique characteristics when subjected to heat treatment. There is very little literature on the results of this heat treatment, other than the understanding that a distinctive B2O2 phase is formed via dehydration. An optimal synthesis method was developed using multiple Design of Experiments (DoE) programs. The mechanism for the synthesis was upheld via TGA analysis. Thisphase, after characterization via powder XRD, XPS, TEM, and solid-state NMR, was concluded to have a distinct structure from other common boron oxide compounds. While mostly amorphous, there is still a distinct crystal structure forming during the synthesis process, leaving room for further crystallinity improvement and determination of crystal structure.

Abstract Name: Compressed Earth Block Production and Characterization

Compressed Earth Blocks (CEB) are an alternate building material made of soil, sand, water, and cement. Compared to traditional masonry units, these CEB are cost effective, sustainable, and can be made on site. The big distinction between traditial masonry units and CEB stems from the fact that CEB is unfired. The performance of the CEB is heavily dependent on the soil type and mix design (ratio of soil to water to cement). The use for these bricks can be seen in the NAE Grand Challenge of restoring and improving urban infrastructure. However, in order for CEB to be used in construction, engineers must have a better understanding of how the mix design will affect the final material performance in order to make sure that projects are up to code. This poster presents the research done to evaluate how mix design affects the final compressive strength of CEB, as well as looking at how consistent the compressive strength values are. CEB was tested at both 7 day and 28 days to see how the final compressive strength varies at partial and full strength. In addition, the poster seeks to show future use of this block in developing countries, through the use of a program that would allow workers to do field tests on soil and input it so that they could determine what the soil type they were working with was, and how that would affect their final mix design and block performance.

Abstract Name: Determining if the M1 and M2 muscarinic acetylcholine receptors underlie the neuroprotective ERK 1/2 cascade in the telencephalon of zebrafish

Zebrafish have gained popularity as a model organism for the study of neurodegenerative diseases. However, shortcomings exist in current knowledge regarding the function of muscarinic acetylcholine receptors (mAChRs), a class of G-protein-coupled receptor, in zebrafish brain. Five types of mAChRs (M1 – M5) exist in the brains of mammals and zebrafish that contribute to cognitive processes. Extracellular signal-regulated kinase (ERK) is a protein required for learning and memory, and ERK activity is stimulated by phosphorylation downstream of mAChR activation. ERK dysfunction provides a potential link between mAChRs and disease pathogenesis. Previously, we've shown that stimulation of mAChRs using the non-specific mAChR agonist oxo-m induces ERK phosphorylation in the zebrafish brain. The objective of the current study is to investigate the roles of the M1 and M2 mAChRS in ERK phosphorylation in the telencephalon, a structure required for learning and memory, in zebrafish. To this end, a combination of mAChR subtype-specific compounds targeting the M1 and M2 mAChRs will be used. Zebrafish brains will be extracted before treatment ex-vivo in oxygenated artificial cerebrospinal fluid (acsf) containing the agonist oxo-m and pirenzepine, an M1 selective inhibitor, methoctramine, an M2 selective inhibitor, or benzyl quinolone carboxylic acid(BQCA), an M1 potentiator. Following treatment, Western blots will be performed to determine the amount of phospho-ERK present in the telencephalon. The findings from this study will contribute to understanding M1 and M2 mAChR function in zebrafish.

Abstract Name: Minority Status and Mental Health

Discriminatory behaviors live throughout society today and all generations of the past. How do these behaviors impact groups with minority status? The aim of this study is to research how chronic stress expereinced by people with minortity status impact mental health. There will be multiple angles applied to this study. The first area of interest is how social media either contributes to or gives a community for discriminatory behaviors or does social media allow for an outlet for those with minority status to build support and community. The second area of interest is how does stress related to choronic discrimination exposure contribute to the mental health of individuals with minority status. Previous research has shown disparities in mental health, substance use, and other factors related to mental health among groups with minority status when compared to the same age group of majority status individuals. This study will identify factors associated with positive and negative mental helath development across multiple minority status groups through a survey implemented and analyzed in the spring semester of 2023.

Abstract Name: Is The Damsel in Distress: Physiological differences between sexes in a sexually plastic species

In animals, most organisms have separate sexes and some species have sexes combined in one individual. Sex is different in plants, where most individuals are both male and female and only some species have separate sexes, known as dioecy. Separate sexes in dioecious plants allows individuals to specialize to better carry out their reproductive roles. This is because plants must make trade offs when spending energy between reproduction and other life history traits such as growth and defense. Often, females allocate more resources to reproduction compared to males which can result in lower vegetative growth rates. However, females often exhibit higher photosynthetic rates to offset their costs of reproduction. A better understanding of the sex-based differences in physiology, due to specialization, is necessary to better understand tradeoffs in life history theory. We investigated how the cost of reproduction varies by sex in Striped Maple trees by measuring photosynthetic rate, branch extension, and fluorescence(a measure of stress) on known females, males, bisexuals, and nonreproductive trees in the spring and summer. We found that sex is a significant predictor of branch extension, with females growing less in a year compared to males and nonreproductive trees. Both females and bisexual trees showed significantly lower rates of photosynthesis compared to males and nonreproductive trees, with all trees having lower rates of photosynthesis in the summer. Bisexual trees showed no significant difference compared to any other sex, suggesting that bisexual trees are not more male or female-like. Interestingly, tree stress, as visible in fluorescence, was affected only by season, not sex expression. Finally, a lower growth rates for females indicates a sex-specific cost of reproduction which may be associated with lower rates of photosynthesis in female-flowering trees. Because of the changing climate, these findings are especially relevant in understanding and managing ecological communities.

Abstract Name: **Using Machine Learning Models to Predict the Prices of Vehicles**

In more recent times, eCommerce has become increasingly common in several economic sectors including the automotive industry. In fact, the Union Bank of Switzerland has estimated that 50% of vehicle sales will be completed online by 2030. With the world becoming increasingly digitized, there is a need to improve the ease with which one can legitimately sell a car online. In this work, machine learning models were designed to predict the selling prices of cars based on their images. The dataset used for this project contained approximately 64,500 images of cars with their make, model, year, manufacturer suggested retail price (MSRP), front wheel size, horsepower, displacement, engine type, width, height, length, gas mileage, drivetrain, passenger capacity, number of passenger doors, and body style. The subset of data used for this work contained 500 random images from the abovementioned dataset. For this work two convolutional neural networks were used, one for cleaning the data and another for predicting the prices of the vehicles. The clean subset of data contained 242 images. The data was split into training, validation and testing sets which contained 70%, 10% and 20% of the data respectively. The algorithms produced have the potential to be used by websites that sell cars to inform individuals or businesses that are selling cars how much a vehicle would sell for by analyzing a provided image.

Abstract Name: **A comparison of high- and low-powered pulsed electromagnetic field therapy (PEMF) equipment on mechanical nociceptive thresholds and behavior in horses**

Evaluating components of stress or discomfort is an important step when working with new modalities of therapy equipment involving animals, in this instance horses. This ongoing study will be using behavioral and factors involving mechanical nociception to evaluate and compare both pulsed Electromagnetic Fields Therapy (PEMF) and Bio-Electro-Magnetic Energy Regulation (BEMER) therapeutic modalities. Eight horses over a period of eight weeks will be used in the University of Wisconsin River Falls equine herd that have never been exposed to either stimulus before. Intensity of stimulus will be dependent on each horse's individual needs. Prior to the initiation of treatments, a baseline mechanical nociceptive threshold (MNT) will be taken along 8 locations of the dorsal aspect of the thoracolumbar region. Pressure will be applied using an algometer until an avoidance response is observed, this could include moving away from the applied pressure, skin twitching, or localized muscle fasciculations. Horses will be randomly assigned to a treatment order. Magna wave will be applied every other day for 30-minute sessions on the front, middle, and hind region of the horse for 10-minutes in each section. BEMER will be applied twice daily for 3 consecutive days. On the first day the application will last 5-minutes for both sessions, the second day both applications will last 10-minutes, and on the final day applications will last for 15-minutes. During each treatment session, behaviors will be documented including licking and chewing, sighing, yawning, lowering of the head, decrease in locomotion, and a decrease in pawing. Following the last treatment session a post MNT will be taken using the procedure described above. After data has been collected for the first 4 weeks, horses will be switched to the opposite treatment. All data will be analyzed via a crossover study where statistics will be run at 0.05.

Abstract Name: **Conditioned Place Avoidance and the Potential Effects of Endocannabinoids in Hirudo verbana, the Medicinal Leech**

Chronic pain is a significant problem worldwide, yet efficacious treatments remain frustratingly out of reach. Both a sensory and emotional component to the pain experience exist, which complicates successful treatment. Comparative behavior and physiology studies may provide important insight into conserved aspects of pain and nociception. While there have been considerable studies on the sensory component of nociception in invertebrates, little research has been done into potential aspects of motivational or affective responses to noxious stimuli. Here, the medicinal leech, Hirudo verbana, serves as a model to examine motivational behaviors in the presence of noxious stimuli or potentially pain-relieving endocannabinoids. Two sets of experiments were designed, conditioned place aversion (CPA) and conditioned place preference (CPP). In the CPA experiments, animals were exposed to a noxious 0.5% acetic acid solution in one of two substrates, the plastic surface of the dish (smooth) or the dish lined with small gravel (gravel). When acetic acid was paired with a gravel substrate, an aversion to gravel was observed at 24hrs and 96hrs after training, while this change was not seen in controls. In the CPP experiments, animals were injured and anandamide, (AEA), an endocannabinoid and potential pain-reliever, was paired, with one of two substrates. When paired with a smooth substrate, unexpectedly, an aversion to the smooth substrate was observed, suggesting that AEA actually enhanced nociception. These results suggest some aspects of affective responses to pain are present in Hirudo verbana and beg further exploration of the pro- and anti-nociceptive effects of endocannabinoids. Further experiments are underway to assess changes in locomotion under the effect of endocannabinoids, as well as conditioned place avoidance and operant conditioning experiments using mechanical, rather than chemical, noxious stimuli.

Abstract Name: **Broken Social structures: the carcinogens of Andre Giroux's le gouffre a toujours soif**

In the face of an industrializing and urbanizing province, Québec's provincial government under premier Maurice Duplessis (1936-39 and 1944-59) turned towards the past. To maintain their statuses, the government and the Catholic Church embraced an ideology of clerico-nationalism, which presented a nostalgic and romanticized portrait of Québécois life, one that was rural, pious, and insulated from anglophone influence. However, the urban Québécois had very different lives, often struggling to support themselves by working for the economically dominant anglophone elite, who conspired with Duplessis to crush francophone unions. Beginning in 1940, a wave of authors responded to the Duplessis administration by transforming Québec's literary landscape from idyllic countrysides to harsh urban realities facing Québécois. As Jane Moss has demonstrated, novels of this eraso frequently featured gravely ill characters that literary historians refer to these novels as "morbid literature,"in which being ill and being Québécois were synonymous. Despite the numerous texts associated with the movement these works have received little critical attention, with some works being almost entirely overlooked. Such is the case for Andre Giroux's Le Gouffre a toujours soif. My paper will examine how illness in Giroux's novel served as a metaphor for the social ills harming urban francophones, notably those associated with clerico-nationalism and the power structures associated with this ideology. Particular attention will be paid to the role of the spirit-body connection in the novel: the role of personal and interpersonal expressions of religion in affecting the sickness.

Abstract Name: The Dream Machine as Confluence: Hallucination, Neuro-Diversity, and the Creative Industries.

Our research project focusses on how a social media campaign was designed and implemented to explore how people engaged with the ideas of dreams and hallucinations. Specifically, the class project involved working collectively, and in four dedicated groups, to build a dream machine* and research the idea of neuro-diversity and perception-diversity. The four groups were: designers, who constructed the dream machine; social media recorders, who developed a multi-platform media campaign for the project from inception to implementation, including documenting how the other groups worked and researched their areas; music composers who designed a soundtrack to accompany the machine; and multi-media poster designers, who researched the history and culture of the original dream machine to create a series of poster images. Each group required specific research focus as well as an interdisciplinary exchange across all the groups. In many ways we see this as 'confluence in action', breaking down disciplinary barriers to explore new ways of thinking about complex issues and ideas. Our presentation will articulate three key aspects of the project: how by working across multiple disciplines (notably, creativity studies, arts and humanities, cognitive sciences, communications) we came to understand better the confluence of ideas in practice; how various elements of social media can be utilized to explore wider philosophical and aesthetic issues; and how our University's program in Creative and Cultural Industries provided ways to connect across a wide and diverse audience to engage in the interdisciplinary nature of knowledge. In addition to the presentation, we would like to bring the dream machine to the conference so others might experience its hallucinatory effects and better appreciate the relationship between research and practice.*The dream machine was originally designed by the artist Brion Gysin and has been used in research to explore the idea of neuro-diversity and perception-diversity.

Abstract Name: Community Engaged Partnerships With Southeast Asian Community Health Liaisons, Leaders, and Health Care Professionals: A Pilot Project on Opiate Awareness, Overdose and Psychoeducation

Opiate addiction and overdose is a major public health concern that disproportionately affects minority communities, yet little is known about the impact in Southeast Asian communities.1) Pilot a sustainable program of opiate awareness, pharmaceutical awareness, and education in Southeast Asian (SEA) communities. 2) Assess community needs around opiate education, prevention, and medical care for opiate addiction, and 3) Engage professionals (stakeholders) on SE Asian community needs. A three-part model included: 1) A train-the-trainer psychoeducational program delivered by community health liaisons (CHLs), 2) Stakeholder engagement around SEA opiate prevention, overdose prevention/reversal, and care (medical, mental health, pharmacy, and Narcan distribution professionals) and 3) Guided conversations with community leaders. Training sessions were delivered virtually, whereas community sessions varied in their delivery methods (verbally in a community's native language). Three community health liaison training sessions involved a train-the-trainer psychoeducational model on the nature of opiates, drug effects, pharmacist-patient communication, stigma, and community comfort in discussing opiates. A pharmacy professor delivered five two-hour training sessions for the CHLs. We held stakeholder conversations with pharmacy students, physicians, addiction counselors, and clinic supervisors. Common barriers identified were funding and availability of translators, stigma, transportation, and community awareness of resources available. Significant needs exist in SEA communities. First, we observed a lack of knowledge and awareness around opiates across communities. Program materials delivered in a narrative format were useful (per leader feedback). Several leaders and community members expressed concern about the community proliferation of online purchases of drugs marketed as painkillers. Third, community members may lack awareness of risks around opiates and addictive potential. Cultural factors and stigma prevent community members from seeking information and treatment, and there is a need for Narcan education and linguistically and culturally competent providers.

Abstract Name: **Biocatalytic Synthesis of Substituted Muconic Acids**

Catechol dioxygenases are non-heme iron ring-cleaving dioxygenases (RCDs) that are useful in producing highly conjugated products via ring cleavage of catechol substrates. These enzymes are often characterized for their ability to oxidatively break down phenolic waste products, enabling the bioremediation of benzene-derived pollutants and contributing to green chemistry initiatives. However, few studies have been pursued which seek to use these enzymes for synthetic purposes. For example, Type I RCDs generate muconic diacids, which have broad potential as synthetic building blocks to valuable molecules, such as adipic acid. Yet, most studies of Type I RCDs feature limited substrate scope exploration, low substrate concentrations, and almost no examples of preparative scale biocatalytic reactions. In this study, we sought to evaluate the potential of the Type I RCD chlorocatechol 1,2-dioxygenase (ClcA) for preparative scale synthesis. Previous studies of ClcA were focused on improving observed kinetic parameters by truncation of 13 C-terminal residues, generating the isoform ClcA_Δ13. However, there is little published information on the reactivity of ClcA_Δ13 with a broad variety of catechol substrates at high substrate concentrations. Our initial studies have focused on reactions of ClcA_Δ13 with simple catechol substrates at synthetically relevant concentrations to assess reaction yields. Our studies seek to optimize these reactions by evaluating other factors, such as temperature, pH and buffer composition. Using this information, we will perform milligram scale reactions to isolate and characterize the products of these reactions, demonstrating the synthetic potential of ClcA_Δ13 and related Type I RCDs.

Abstract Name: **Assessing Functional Limb Use in a Rat Model of Brachial Plexus Birth Injury**

Brachial plexus birth injury (BPBI) is a common perinatal condition affecting the cervical and first thoracic nerve roots. Children with persistent symptoms of BPBI experience upper-limb motor dysfunction and muscle paralysis, impairing their ability to perform daily tasks. Previous studies in rat models of BPBI have assessed function extrinsically via range of motion and grip strength but have not assessed spontaneous functional limb usage, an important indicator of functional deficits following injury. Our goal is to quantify paw usage preference to determine post-BPBI changes in forelimb function. We hypothesize BPBI, particularly with shoulder muscle contracture, will result in forelimb usage deficits. Three groups of Sprague Dawley rats underwent surgical neurectomy of C5-C6 nerve roots on postnatal days 3-6. Postganglionic and preganglionic neurectomy groups resulted in nerve damage with and without muscle contracture, respectively. A control sham neurectomy group experienced no nerve damage. The cylinder test was performed before sacrifice at 3, 4, 6, 8, 12, and 16 weeks post-surgery (n=2-24 per group per timepoint) to assess paw preference. Videos were recorded of rats exploring in a clear, vertical cylinder and analyzed for forepaw usage by counting how many times the rat pushed off the table, rested against the cylinder wall, and landed on the table with each and both forepaws. Total forepaw usage will be compared between groups and across timepoints via ANOVA with Tukey's correction.Preliminary data suggest that 1) rats with preganglionic injury tended to use their injured limb more than rats with postganglionic injury until week 8, and 2) in both injury groups, use of the injured limb was preferred least for vertical reach and rest against the wall compared to pushing off and landing. Spontaneous limb usage may provide predictions about the capacity to perform specific tasks and inform therapies in BPBI patients.

Abstract Name: **The Relationship Between Sex Hormones, Cognitive Function, and Mental Well-being Across the Menstrual Cycle**

Research shows women typically take longer to recover from concussions than men; however, there is little understanding of why. One of the most significant differences in males and females is their fluctuations in sex hormones. The goal of this study was to examine the relationship between estradiol and progesterone level fluctuations, neurocognitive performance, and concussion and mental well-being measures across a menstrual cycle. In a sample of 12 female identified participants, progesterone and estradiol levels were measured across the span of a month at week zero, two, and four, from both blood and saliva samples. At the time of each sample collection, the participants completed the Four-Dimensional Symptom Questionnaire (4DSQ; distress, depression, anxiety, and somatization scales), King-Devick (oculomotor assessment), and Immediate Post-concussion Assessment and Cognitive Testing (ImPACT; neurocognitive testing and concussion symptom scale). On the weeks not in the lab, the participants completed a survey asking about concussion symptoms (ImPACT) and their overall mental well-being (The Warwick-Edinburgh Mental Well-being Scale). In this survey, participants were also asked about the typical length of their period and the date of their last menstrual cycle. Using this information, the phase of the menstrual cycle at which each of the samples were collected was estimated and the change in each of the measures, including hormone levels, between the luteal and follicular phase was calculated. The data shows that as the change in estradiol levels increases, the verbal memory score on ImPACT decreases (r=-.801, 0.05) and anxiety and depression measure scores on the 4DSQ also decreases (r=-.828, 0.05; r=-.739, 0.05). No other significant correlations were found. The implications of this research is to add to the current literature and provide opportunity for education on the relationship between sex hormones, cognitive function, and mental well-being.

Abstract Name: **Microgrid Communications Cybersecurity Comparisons**

The smart microgrid is a part of the general smart grid, which is defined as an electricity grid that enables intelligent operations via data communication. The smart microgrid can make intelligent decisions to produce significant savings by lowering energy costs and by managing onsite energy usage to avoid peak energy prices while supporting grid stability and improving return on investment. However, when utility companies extend their proprietary substation OT network to the Internet to cover the microgrids, they open the doors for cyberattacks. OT cyber securities are mostly focused on three main areas including the end device security, network access security, and infrastructure security. Cyberattacks on microgrids attack all areas and affect data integrity, data confidentiality, and data availability. The attacks can be implemented through remote access or plug-in media to compromise the data before or during transmission. Currently, in the power industry, most of the cybersecurity research is conducted on substation networks, while there is a few on microgrids. However, due to its distributed nature and remote access requirements, the microgrids communication network has a relatively loose protective environment, more complex platform, and is less professionally monitored. These factors make the microgrid an easier target for cyberattacks, hence requiring more specific cybersecurity research and defense measurements. In this paper, we focused on the cybersecurity issue in the microgrid. First, we explain the distinctive characteristics of the microgrid network and compare it with the substation network. Next, we discuss the main data acquisition protocols (Modbus, DNP3, GOOSE 61850, and SMV) and the time synchronization protocols (NTP, SNTP and PTP) and their cybersecurity options. Finally, we conclude with the guidelines on cybersecurity measurement in microgrids.

Abstract Name: **Designing DICE-X: A Course-based Undergraduate Research Experience Investigating Impact of Chemical Exposure on Neurodevelopment in Xenopus laevis**

Inequitable access to science education and opportunities is well-documented across all educational levels. One glaring disparity is in undergraduate research opportunities. The leading solution for these inequities is to implement course-based undergraduate research experiences (CUREs). Though the number of CUREs and the field of neuroscience are growing, few published CUREs exist within neuroscience. Additionally, while the impact of CUREs on women and people of color in STEM is relatively well-known, very little literature exists on first-generation and low-income (FGLI) students. To address these gaps, we designed a developmental neurobiology CURE, called DICE-X: Developmental Impacts of Chemical Exposure on Xenopus, and pre- and post-assessment tools that measure outcomes for underrepresented (particularly FGLI) students.To design DICE-X, we identified an overlap between relevant research in developmental neuroscience, desired learning outcomes, and feasible protocols given facility constraints. Chemical exposure during development is situated at the intersection of these categories, and it is fairly inexpensive to manipulate, making it an ideal experimental variable for undergraduates. We chose Xenopus as a model organism due to ease of husbandry and embryonic manipulation alongside access to an existing colony. The assessments were written after existing models with modifications specifically to determine FGLI outcomes.In the multi-week CURE, students explored primary literature in neurodevelopment and created proposals for novel research investigating developmental exposure to student-selected chemicals. Students then created spinal explant cultures to assess neurite outgrowth and student-selected behavioral assays to determine any behavioral deficiencies caused by chemical exposure. Students ultimately created posters summarizing their research projects and presented them to peers and faculty at Hamline University. Preliminary results from the assessment indicate gains in areas around self-efficacy and scientific identity. We hope that the dissemination of DICE-X and assessment data leads to an expansion of CUREs in neuroscience that will benefit all, including FGLI, students.

Abstract Name: **Producing Datasets: Creating Mock Crime Scene Footwear Impressions Dataset**

One of the fundamental problems in forensic science is a lack of data. Creating datasets representative of casework is a challenge, because it can be difficult to obtain large quantities of images collected under the same protocol and with the same shoes. Though, the data collected in this way can be of significant use for researchers and training within forensic science disciplines. This project's main objective is to create an open-source database containing a sizeable number of high-quality images of shoe impressions. The team at the Center for Statistics and Applications in Forensic Evidence (CSAFE) worked to collect images that could be representative of those found at crime scenes and made publicly available to the broader forensic and research communities. With mixed impression types, flooring, lift techniques, and digital file types, the complete dataset will include nearly 800 shoeprint images contained in more than 1,700 digital files.Our presentation will focus on the best practices for developing a data collection process, writing protocols and publishing open-source datasets, with the intention of reproducibility and details on how/why the project is important, as well as the process we went through while working on it. Attendees will walk away (pun intended) knowing: The significance of larger data sets for researchers and training; Actionable solutions to various obstacles associated with large dataset collection; Essential considerations for writing data collection protocols; and The importance of open-source data.

Abstract Name: **Machine Learning Recommender Systems**

Machine Learning has allowed evolution and versatility in data mining,manipulation, and pattern inference for informed decisions. Traditionally, recommender systems did not utilize machine learning and were only based on hard-coded instructions. This could not meet the ever-changing user behavior. The ML Recommender Systems project investigates theuse of Machine Learning in building recommender systems for multiple use cases. Examples of such use cases include recommender systems for movies to watch, music recommenders, and an adaptive controller for smart home technologies. A movie recommender system was built using the Python programming language and Google's open-source TensorFlow and TensorFlow Recommenders platforms. Through Google Colab, a TensorFlow dataset, MovieLens, was prepared for training, evaluation, and testing. A user interface was built with Anvil Works and pure HTML5, PHP, and Javascriptfor demonstration purposes only. Currently, the model for music recommendations is being trained using the same technologies.The adaptive controller for IoT intelligent homes is also currently being tested. This model accepts user data through how they interact with a low-cost Raspberry Pi-based smart home and uses that data for energy-saving recommendations. After testing this model with a locally built smart home system, I anticipate seeing improved energy usage in low-cost smart homes. Also, there is a plan to build different recommender systems for all possible datasets, such as images, numbers, andwords fore-commerce products, entertainment, text prediction, and search engines. Upon completion, the built models should be integrated into the business, entertainment, and utility tools to allow practical recommendations that users find helpful. However, this should not come at the expense of their security and privacy. As such, the built models should run locally within the systems so that inference and processing will not be remote.

Abstract Name: **3D Printing to Improve Patient Outcomes for Mini-Thoracotomy Aortic Valve Replacements and Mini-Mitral Valve Repairs**

Aortic valve replacement (AVR) was established in the 1960's and has become a routine therapy to treat patients with severe aortic valve dysfunction. AVR is usually performed using a full sternotomy and cardiopulmonary bypass support. Since the late 1990's, minimally invasive procedures have been developed for aortic valve surgeries, such as the mini-thoracotomy AVR. These less invasive procedures claim reduced postoperative complications, shorter lengths of stays in the hospital, and lower mortality. However, the minimally invasive nature may provide challenges in the viewing of patient anatomy during the procedure. This project will provide the 3D printing capabilities needed to investigate if using 3D printed anatomical models for pre-operative planning and/or patient education will result in better patient outcomes for mini-thoracotomy AVR surgery, particularly in those with thoracic abnormalities. For selected patient cases, the Mayo Clinic Luther Campus will provide UWEC researchers with DICOM files for segmentation and 3D printing. The UWEC research team will perform the segmentation and provide the physical 3D anatomical model with initial feedback on accuracy from Mayo physicians. Ultimately, the Mayo Clinic collaborators will evaluate the effectiveness of using the 3D models in patient outcomes as well as patient education on the procedure.

Abstract Name: **TRENDS AND VARIATIONS OF NO2 POLLUTION (2005-2019) OVER TEXAS: VIEW FROM THE GROUND AND SATELLITE**

Nitrogen oxide (NOx = NO + NO2) is a widely occurring air pollutant that impacts atmospheric chemistry and human health. NOx is formed from various sources, such as lightning, vehicle emissions, and various geological activities. In this study, we present the NO2 variations and trends from 2005 to 2019 over Texas using measurements from an Ozone Measuring Instrument (OMI) abroad, the NASA Aura satellite, and compare with in situ surface NO2 measurements from US Environmental Protection Agency (EPA) Air Quality System (AQS) network. Both OMI and AQS datasets display distinct emission reduction rates from 2005-to 2020, including the COVID-19 lockdown.

Abstract Name: **The Exhibition of the Chinese Lady: Racialization through the Representation of Afong Moy**

I will examine how the Chinese woman emerged as a category in exhibitions in the 19th century. My research analyzes the exhibition of Afong Moy, the first known Chinese woman in America. I question both, what it meant for exhibitors to represent her, as well how she was represented. Rather than assuming the representation of a Chinese body, I analyze the way in which Chinese as an ethnic category is produced through her. Unlike travel logs and newspapers, the exhibition obscures the divide between the audience and what is being represented. In other words, the exhibitions' display is taken as the real object. However, the exhibitors' claim to represent a real Chinese woman is contradictory as they simultaneously construct Moy as a character for exhibition. Her career begins as she is brought on a trading ship from Guangzhou to the United States where she is renamed, staged, directed, and constructed as an object to be observed and understood. As her exhibition is established, the characteristics of difference are outlined by the way in which she is decorated. Specifically, the bound foot becomes the fixation by which she is defined as ornamental and outside of time. Afong Moy then is a character that has been produced by those who depict her, and comes to represent the concept of a Chinese woman to her audiences. The Chinese woman as a concept then, is not a preexisting, immutable category, but is constructed by those in the privileged position to represent it.

Abstract Name: Speech-Language Pathologist Confidence and Preparedness When Working With Bilingual Children

Accredited graduate programs in speech-language pathology are required to provide evidence that students attain competence in assessing and serving clients from diverse cultural and linguistic backgrounds. The American Speech Language Hearing Association (ASHA) recently developed and implemented courses and continuing education for professionals on how to work with bilingual populations. While these resources are useful, they do not clarify the levels of confidence and preparedness experienced by the professionals using them. Recent work evaluated SLP confidence, but did not report on students in SLP graduate programs, an additional group that is preparing to work with bilingual children. Given the evolution of the sociocultural climate, paired with changes in demographics and certification requirements, our work aims to identify more current levels of confidence and preparedness of SLPs, as well as future SLPs in Wisconsin when providing services to school-age bilingual children. Self-perception of confidence and preparedness may have clinical and academic implications with respect to effectiveness in providing services to school-age bilingual children, as well as parents' involvement in their child's therapy and maintenance of the native language. Information about practitioner and student confidence may inform SLP training programs on how to improve or modify graduate experiences and continuing education to support professionals in the field in serving school-age bilingual children. It is expected that previous experience working with bilingual children will lead to higher confidence and preparedness in current and future SLPs. It is also predicted that SLPs and future SLPs who are bilingual will report feeling more confident and prepared when working with bilingual children. Due to complex variables, current perceptions of confidence and preparedness are unknown.

Abstract Name: Period Poverty within the Twin Ports and Beyond

Period poverty, the lack of access to menstruation supplies and facilities, creates inequality within everyday life. Previous research looks at urban areas to assess the inequality faced within menstruation (Sector-Turner et al., 2020). A deeper understanding of availability of educational resources related to menstruation and the challenges faced by those who menstruate is needed. This study looks specifically at states within the Midwest. Assessing areas such as Duluth and Superior, a metropolitan rural area, allows for a better understanding of the overall effect of menstruation inequalities. Often those facing period poverty miss important events such as school or work due to lack of supplies. We collected data from a range of students, many being undergraduates from a variety of socioeconomic backgrounds. A survey was distributed electronically, and participants were encouraged to share this link with peers. A qualitative and quantitative survey was provided to the public for a two-week period. These survey results brought forth the inequalities faced by those who menstruate. Menstruation inequality was experienced by groups above and below the poverty line. Discovering the challenges faced by those who menstruate provides a deeper understanding to the limitations faced within daily routines.

Abstract Name: **Resistance to Opioid Induced Respiratory Depression in Xenopus laevis**

Opioid induced respiratory depression (OIRD) is a major cause of opioid related death. In mammals, OIRD is, in part, caused by a hyperpolarization of respiratory neurons in the brainstem due to opioids binding to mu-opioid receptors. However, preliminary results obtained from the African clawed frog (Xenopus laevis) suggested that their respiratory system may be less susceptible to opioids compared to mammals. Here, we hypothesized that the respiratory system of X. laevisis resistant to opioids. IsolatedXenopusbrains generate respiratory activity that can be readily recorded via the laryngeal nerve over 12 hours. Taking advantage of this preparation, we examined the breathing activity of the ex vivo frog brains in the presence of variable concentrations of a mu-opioid receptor agonist (DAMGO) to test this hypothesis. The results reveal that the respiratory system of X. laevisis indeed tolerant to opioids compared to mammals; in neonatal mice, the Pre-Bötzinger complex (which is responsible for respiratory inspiration in mammals) stops its activity in the presence of 100nM of DAMGO whereas the application of 500nM of DAMGO did not block the respiratory activity ofXenopus. The results of this research sets the stage to explore the neural mechanisms ofXenopusopioid resistance.

Abstract Name: **The Gun Control Debate: A Polarized Narrative**

The debate around gun control in America is a shining example of our severely polarized political system, and how issues quickly become partisan. The narrative has been split into two sides, divided by party, to the point where the debate is no longer productive. Each narrative views the gun-control debate through a terministic screen that prevents the issue from being viewed as a whole picture. Each side, however, does not include key pieces of information and therefore loses credibility. It is also harmful to divide the argument into two narratives, because it prevents a single solution that works for everyone from being found. In order to satisfy one side of the debate, one must betray the other side. In reality, there is actually a significant amount of common ground between Americans. Most Americans are in agreement that there needs to be restrictions in place for the purchase of guns, as well as restrictions on what type of guns can be put into public circulation. Politicians primarily ignore this common-ground in order to keep the issue partisan, however. By promoting division between Americans, they can continue to use the issue as a way to gain votes in elections. Breaking away from the partisan perspective, placing restrictions on who can purchase guns, and extensive background checks prior to purchasing should all be implemented. Placing caps and restrictions on campaign donations by outside sources is another step that needs to be taken to ensure political figures are not being financially influenced to avoid taking action. An issue that causes so much destruction and death yearly cannot be maintained as a partisan issue or a ploy for politicians to use to their advantage. By working with what is already agreed on, a significant amount of action can be taken to prevent unnecessary gun violence.

Abstract Name: **Length Variation at a Microsatellite in the Human Relaxin (RLN2) Promoter Affects Transcription Levels in Vitro**

Complications with preterm birth are the leading cause of infant mortality and morbidity worldwide. Several factors contribute to susceptibility, but previous studies identified an association with the promoter region of the relaxin gene (RLN2) and levels of relaxin during pregnancy. RLN2 codes for human relaxin hormone, which is involved in preparation of membranes and cervical tissue at the onset of labor. We hypothesize that different compositions of a $(CT)_n(GT)_m$ microsatellite within the relaxin promoter will produce different levels of relaxin. To test our hypothesis, we amplified the ~1kb upstream promoter region from four different previously genotyped human DNA samples, ligated the products into a pNL1.1 luciferase reporter vector, and transfected into a human placental cell line to quantify transcription in vitro using a luciferase assay. DNA sequencing confirmed these promoter alleles contained 23, 28, 33, and 38 microsatellite repeat units. Differences in transcription levels among alleles were evaluated with a one-way ANOVA test. These results will be discussed in light of human genetic variation at RLN2 and susceptibility to preterm birth.

Abstract Name: **Exploring Underrepresented Aviation Students' Mental Health and Success in Higher Education: A Phenomenological Study**

In recent years, college students' mental health has significantly declined, especially within minority student populations. Within the aviation industry, unattended mental health concerns in pilots have led to various fatal accidents. With devastating mental health-related incidents in the aviation industry, educational institutions must take the necessary steps to set their students up for long-term success in every aspect of life. Furthermore, due to the ongoing pilot shortage crisis across the United States, the aviation and aerospace industry has launched diversity, equity, and inclusion (DEI) campaigns designed to attract future employees from underrepresented groups. This project aimed to study the student experience regarding mental health in underrepresented minorities in aviation and aerospace degree programs. To do so, the researchers deemed it crucial to understand the aviation and aerospace students' psychological symptoms through the use of a feasible and reliable instrument such as the Counseling Center Assessment of Psychological Symptoms (CCAPS-34). The resulting data was used to provide the initial step in determining the acceptability, feasibility, and potential of the CCAPS-34 as a measure of distress in help-seeking aviation and aerospace students. Additionally, qualitative focus groups were conducted across two aviation-focused higher education campuses to understand the needs and wants for mental health. Our results showed an ongoing need for widespread, comprehensive reform through social support, promotion of psychological well-being, and activities with minimal psychological distress.

Abstract Name: **Mental Health and Undergraduate Social Work Education: Identifying the Gaps**

Social work is one of the leading careers in mental health treatment and research. Many resources are available to graduate/clinical social work students as they learn to assess, diagnose, and treat mental health disorders. Unfortunately, the same is not true regarding resources for undergraduate/generalist-level social work students. A brief review of undergraduate social work programs in the South Atlantic region of the United States showed that most undergraduate social work curriculums do not include courses specific to mental health. Because generalist social work practitioners engage with a diverse clientele, many of whom experience mental illness, undergraduate social work students must receive structured and focused instruction to increase their mental health literacy. Therefore, this research explores how undergraduate social work professors incorporate mental health content into their courses. I do this by conducting a thorough literature review and engaging in IRB-approved research to survey how social work professors provide mental health education in undergraduate social work classes. My proposal aims to call attention to the significant gap in mental health education at the undergraduate level. By advocating for undergraduate mental health education, I believe society will benefit tremendously, as holistic education will allow generalist social workers to provide more inclusive and competent services to their clients. By providing a significant focus on mental health education, we will not only honor diversity among our clients but will also increase our inclusion and competency in treatment, intervention, and support.

Abstract Name: **Social Media and Self-esteem**

Social media, what did we do before it existed? Were we better off before or are we now? The debates around social media use are endless. There are strong viewpoints on both sides. Some believe it is literally the demise of human society, contributing to the delinquency of minors and providing negativeinformation that molds the minds of the young. Others believe it is entertainment and provides no harm to society and has no impact to the changing world we live in. Still others are cautiously in the middle. While social media has been around for some time now, we still know very little about the potential long-term impact. The population most influenced is the young. This research study explores the association between age of beginning use of soical media and the impact on various aspects of development.The key areas of interest are mental health, self-esteem, sexualization, achievement and addiction. Correlational analysis will be completed in the spring semester of 2023.

Abstract Name: **Early Cortisol Exposure Alters Morphology of Zebrafish Embryos**

Stress hormones such as cortisol are essential for development and play a particularly important role in human fetal development of the brain, lungs, and kidneys. Excess exposure to cortisol from stressed mothers is known to negatively affect fetal neurodevelopment. However, the specific changes and mechanisms involved in altered development are not well characterized. We investigated how exposure to increased cortisol affects early embryonic development in zebrafish. Embryos were exposed to different concentrations of cortisol (10-254uM) at 3 hours post fertilization (hpf). Zebrafish were then observed and imaged at 96 hpf via brightfield microscopy and subsequently screened for abnormal phenotypes. Nine phenotypes were screened for: survival, body axis curvature, yolk sac shape or size, craniofacial development, muscle development, body length, pericardial edema, yolk sac edema, and blood pooling in the head/yolk sac. Fish were then categorized based on the number of phenotypes they displayed as none, mild, or severe. Initial results suggest dose-dependent changes in morphological development of zebrafish embryos exposed to cortisol with the most common abnormalities being pericardial edema and abnormal yolk-sac size/shape. In addition, there was no change in survival rate between zebrafish exposed to different concentrations of cortisol. Results from these experiments can help define morphological and functional alterations at cortisol concentrations relevant to understanding fetal development under maternal stress in humans.

Abstract Name: **The effect of variation in Cerium in Aluminum-Cerium Alloys on microstructure and hardness**

Traditional aluminum alloys are lightweight and cost-efficient but lose their mechanical strength at elevated temperatures. Combining aluminum with cerium creates easy-to-cast Al-Ce alloys that exhibitdramatically improved high-temperature performance. A set of aluminum-cerium alloys at nine compositions ranging from 2% cerium to 18% cerium (weight percentages-wt.%) were cast, and the effect of composition on the microstructure and hardness was studied. Micrographs revealed two major phases in all the cast alloys, including primaryα-Al and intermetallic Al11Ce3 phases. The volume % of intermetallic phase, hardness, and density increased with cerium content and are reported along with the average sizes of each phase. Until 14wt% Cerium, the microstructure showed primary-α aluminum and eutectic (lamellar structure of primary-α aluminum and intermetallic). Above the eutectic compositions of 14wt% Cerium, the microstructure showed primary Al11Ce3 particles and the eutectic phase. The current work helps understand the effect of the variations in composition on microstructure and selected properties. This understanding can improve the widespread adoption of Al-Ce alloys.

Abstract Name: **Yearly Survival and Growth Rates of Propagated Fatmuckets (Lampsilis siliquoidea) in Central Wisconsin**

Freshwater mussels are key members of riverine ecosystems and are crucial for improving water quality. Mussels serve as valuable indicator species and suffer from many environmental disturbances, but despite their importance, large gaps remain in knowledge of freshwater mussels in Wisconsin. We measured the survival and growth of mussels exposed to ambient conditions in two streams in Central Wisconsin. Both selected streams included those that support diverse mussel assemblies. On October 29th, 2021, we received 120 Fat Muckets (Lampsilis siliquoidea) from the Genoa Fish Hatchery, measured, then released them into suitable areas on the Mill Creek; the Plover River Near Stevens Point, WI. Before release, mussels at the Mill Creek site averaged 1.853 cm in length, 1.03 cm in width, and 0.52 cm in thickness. At the Plover River site, mussels averaged 1.859 cm in length, 1.068 cm in width, and 0.546 cm in thickness. We utilized silos to encompass the 1.5-year-old mussels. Each site has 1 silo, containing 15 individuals per silo. Our objective is to determine seasonal survivorship and growth rates throughout our year-long study. Experimentation at these sites will provide an indication to determine which areas are suitable for future reintroductions. We expect 1) Mussel growth and survival will be significantly reduced in the winter months, compared to the summer months. 2) Mussel growth and survival will be significantly different between the two sites. These sites were measured monthly beginning April 21st and lastly October 21st, 2022. This is part of an ongoing study through the University of Wisconsin – Stevens Point's student chapter of The Wildlife Society.

Abstract Name: **A Natural Language Processing Analysis of Reddit as a Social Media Platform for Discussions on Mental Health**

Following a substantial destigmatization effort this past decade, mental health has emerged as an area of intense interest to the general populace, with discussions on the subject cropping up seemingly everywhere. This is particularly true online, where more and more spaces are being set up specifically for users to offer any relevant thoughts, opinions, advice, or even first-hand experience with the subject. For the purposes of this study, post data related to mental health from over a 4-year period was sourced from a set of targeted communities on one the web's largest and most active social platforms, Reddit.com, and anatomized in terms of both a sentiment analysis and topic model using a Python-based toolset and Natural Language Processing (NLP) techniques. This work was undertaken in an attempt to uncover how mental health is most often approached and viewed by the site's contributing userbase, along with precisely what topics typically lie at the forefront of mental health discussion on the site. On the sentiment analysis side, results indicated that a majority of the posts from the collected dataset could be categorized as negative in tone, whereas the highest charting pinpointed emotions identified were found to be sadness, fear, trust, and anticipation. Then, on the topic modeling end, "time", "life", "people", "friend", and "anxiety" were found to be the top five most frequently used significant terms amongst post content, while "Question", "Need Support", and "Venting" were identified as the most common tags used to typify the different kinds of posts made about mental health on the site. Additional work is planned to extend the topic modeling results through the application of more sophisticated machine learning techniques, as well as the inclusion of comment data as a vector for analysis.

Abstract Name: **Correctional Compassion: Examining Age and Empathy Among Correctional Officers Working in Restricted Housing Units**

Currently, little research considers empathy among those working in restricted housing units (RHUs/solitary confinement). The present research explores empathy and other characteristics among correctional officers (COs) working in RHUs. Data for the present research comes from 89 semi-structured interviews with COs working in six male prisons and one female prison between 2017 and 2019. Interviews were coded using ATLAS.ti, a qualitative data management software, and were coded using a semi-grounded technique, which allowed for themes to emerge organically, while also allowing researchers to code for themes such as age, perceptions of positive or negative characteristics, interpersonal relationships, and the definitions and perceptions of empathy. During analysis, COs were grouped into the following age groups: young adults (20 to 39 years old), middle adults (40 to 59 years old), and older adults (60 to 80 years old). Within their respective age groups, individuals were placed in subgroups pertaining to their perceived empathy and positive or negative characteristics. The three subgroups were, “displayed empathy and positive characteristics”, “not enough information”, and “lacking a display of empathy and/or displayed negative characteristics”. Preliminary analysis suggests that COs in the “Older Adults” group consistently report the most negative characteristics and reported lacking empathy compared to the other age groups. Preliminary findings suggest that older COs display low levels of empathy, which is insightful in considering whether there should be an age cap for working in RHUs.Further, theoretical implications include expanding current literature about COs working in RHUs and suggests that age may be important when considering empathy and job performance.

Abstract Name: **Sex and age estimation using CT images in Forensic Anthropology**

Forensic anthropologists reconstruct the biological profile (e.g., ancestry, sex, and age) of skeletal remains for victim identification at a crime scene. However, the preservation state of the skeletal remains may be compromised due to taphonomic factors, which requires alternative methods for assessing morphological features present on the bones. Bone mineral density (BMD) is known to be affected by sex and age of individuals. In this regard, sexual differences in BMD and its relationship with age have been studied. Recently, three-dimensional (3D) imaging technology such as computed tomography (CT) has been popularly used for forensic anthropological examination. The purpose of this study is to generate new methods for sex and age estimation from the Korean skeletal remains using CT data and related software. In this study, a new concept, digital bone loss (DBL), will be introduced. Whole body CT scan data from 240 Koreans (119 males, 121 females) were studied. Mean ages of the samples are 55.1 years and 53.6 years for males and females, respectively. Three open-source software (3D Slicer, Meshmixer, and CloudCompare) were used to calculate DBL. In this study, DBL is defined as the ratio of loss in the number of faces between two 3D models which are reconstructed using different thresholds in the Threshold tool of the Segment Editor module of 3D Slicer. Logistic regression models and linear regression models were generated for sex and age estimation, respectively. This study suggests that DBL can be possibly used as a proxy for BMD and thus, can serve as an indicator for sex and age estimation in forensic anthropology.

Abstract Name: **Drones as a supplement to medical transportation in densely populated urban areas.**

As major cities have their infrastructure struggle to keep up with the density of urban life and the influx of people moving into city cores, the movement of supplies within a city core will become a tangible issue. The delivery drone enables the use of open skies to move critical medical supplies between suppliers and demand points. This will allow healthcare operations to operate smoother while increasing the availability of niche treatment options. This procedure will enable savings in the healthcare industry, as it is easier to move an antivenom to a patient versus moving the patient to a Tier 1 trauma center that carries the antivenom. Diverse mathematical models have been proposed to address this problem. In this study, we use an existing model in the literature and analyze the computational stability using a real test case. Further, we investigate a new model capable of determining optimal distribution center locations and their corresponding service locations by introducing two objective functions.

Abstract Name: **Novel insights on the genetic identification of giant knotweed species in Wisconsin (genus Reynoutria, Polygonaceae), using the nuclear LEAFY gene**

Knotweed plants in the genus Reynoutria are native to eastern Asia, but they have become troublesome invasive weeds in other parts of the world. Two species grow in North America: the Japanese Knotweed (R. japonica) and Giant Knotweed (R. sachalinensis), as well as a hybrid known as Bohemian Knotweed (R. × bohemica). The separate species may have different ecological tolerances, competitive strengths, or susceptibilities to herbicides or biocontrol agents, and therefore it is important to identify them correctly. Because of the close relationships among invasive knotweeds and their propensity to hybridize, identification using molecular methods is particularly useful. Previous studies have used the nuclear LEAFY gene to identify parent species and hybrids in the native and invasive range, but the current data consists only of the second intron of the LEAFY gene. Almost nothing is known about the protein-coding portion of the gene, and knowing more about protein differences between R. japonica and R. sachalinensis might have some bearing on the biological function of these invasive plants. In this project, we set out to sequence a larger portion of the LEAFY gene in Reynoutria species, to enable a comparison of protein sequences and potentially to discover new diagnostic regions of the sequence. Identifying the rest of the sequence will offer us more tools for easily identifying hybrids. We designed new PCR primers by comparing previously published LEAFY gene sequences from related species in the plant family Polygonaceae, and we used these to sequence new portions of the gene for Reynoutria species. We were able to sequence the entire second exon for both parent species and hybrids, as well as the first intron which had not been sequenced before. We are working to develop specific PCR primers that can identify species and hybrids more economically.

Abstract Name: **Electrode Sharpness, Spark Gap, and Spark Prevention**

Ben Franklin's experiments with lightning in the 1700's showed that sharp-tipped metal rods reduce the chances of a strike near the rod itself. This has been confirmed as recently as the early 2000's e.g. by C.B. Moore et al, 2000, 2002, in research with actual thunderclouds. Similarly, sharp-tipped "needle" electrodes are commonly observed to prevent fully-developed sparks from laboratory electrostatic charge generators. In this case, (1) just how sharp must the electrodes be for spark prevention? And (2) by what process does a sharp electrode prevent emphatic sparks? We seek to answer these questions experimentally, by (1) using a Van de Graaf charge generator with spherical-tipped "receiving" electrodes of varying sizes, and (2) by investigating the phenomenon of "corona" as the discharging mechanism: What is corona? How does it differ from an emphatic spark? We compare our small-scale findings to the present view of how lightning rods reduce the chances of nearby strikes.

Abstract Name: **Comparing Trajectories Toward Activism Amongst Asian American and Latinx Young Adults**

Following the murder of George Floyd, the Black Lives Matter movement inspired an increased awareness of social injustices and racism in America. In this research, we examine how the anti-racism movement that followed this historical event impacted Latinx and Asian American young adults and their social activism. We conducted in-depth interviews with Asian American (n=12) and Latinx (n=12) emerging adults who identified as activists. Utilizing Interpretive Phenomenological Analysis we examined recurring themes in participants' life stories that explained their involvement in activism. We found that both Asian and Latinx participants were motivated to join political-cultural heritage organizations to bridge and integrate their American and ethnic cultural identities. Prejudice against the Latinx community motivated Latinx participants to become involved in cultural-political organizations in comparison to Asian American involvement in organizations alike, which led to an increased awareness of anti-Asian racism. The rise of the Black Lives Matter movement motivated Asian American activists to advocate against Asian discrimination. In contrast, the Latinx participants were more motivated towards coalitional activism for people of color, specifically Black and Brown. This research illuminates the similarities and differences in trajectories toward activism for Latinx and Asian American young adults.

Torres, Maylyn

Abstract Name: Gateway to Merced: Queer Experience

Merced has been commonly known as the “Gateway to Yosemite” for decades. A small town that is just a stop on the way to other areas. As a result, there is a collaborative effort to gather information from underrepresented groups in Merced County to showcase the value of Merced. This effort also aims to produce open-ended discussions and embrace all aspects of the community. The purpose of my project is to gather the history and experiences of the LGBTQIA+ community in Merced County since there is near to none recorded. We have interviewed individuals who have experienced or viewed the changes in how the LGBTQIA+ community is treated and included in the community. These interviews are conducted and recorded through video and audio. They are then transcribed and preserved as oral histories. The results will likely exhibit discrimination and negative actions against the community prior to the 2000s. The results will also examine how the existence of the University of California, Merced has had an impact in pushing the Merced community to be more forthcoming with its support of the LGBTQIA+ community. The Merced area has multiple communities that have been overlooked due to the lack of sharing experiences with the mass public. There are many unique and interesting narratives that deserve to be preserved and publicized to frame the true value of the area. In collecting this information for Merced County, there is hope that this may inspire others to do the same for their communities.

Abstract Name: Systematic Review and Meta-Analysis of how Heat and Antipyretics Affect the Course of Viral Upper Respiratory Infections in Adults

Viral upper respiratory infections (URIs) are common (i.e. the common cold) and have caused pandemics in 1918 and 2020. URIs are frequently treated with fever-blocking medications (antipyretics, like acetaminophen or ibuprofen), because they reduce symptoms. However, feveris an evolutionarily-conserved response to infection that mechanistically enhances various immune processes and experimentally improves survival in animals. Human studies exploring the effects of antipyretics on the course or outcome of viral URIs are inconsistent. We performed a systematic review to see how body temperature modulation affects the course of viral URIs in adults. Our primary outcome was time to symptom resolution. We used predefined search criteria of peer-reviewed articles on Embase, CINAHL, PubMed, and Cochrane databases. Inclusion criteria included observational studies and randomized controlled trials of viral URIs (e.g. no antibiotics) in adults that compared antipyretics or heat-based therapies (e.g. sauna or exercise) to a control group. Each article was reviewed by two independent reviewers with discrepancies resolved by a third party. We reviewed the abstract and title of 8886 articles and 140 full texts. Thirty-one studies met inclusion criteria for data extraction, of which 27 studies tested antipyretics and 3 tested heat-based therapies. There was significant heterogeneity among studies and only five studies reported the primary outcome. Meta-analysis of randomized controlled trials found no significant effect of antipyretic use on the average number of days it took to resolve an URI: -0.2 days (95% CI: -1.3 to 1.0) comparing antipyretic group versus control. In conclusion, we did not find evidence that antipyretics significantly prolong URIs overall. However, there may be other costs of blocking fever in URIs (e.g. complications like pneumonia) or antipyretics may prolong illness in specific types of infections or patients. Our inconclusive findings underscore the importance of further research into this common clinical scenario.

Abstract Name: Pressurized Device For Mitigating Atrophy in Soleus During Long-Duration Spaceflight

Astronauts experience many microgravity-induced neuromuscular issues during spaceflight, including the decline in skeletal muscle mass and neuromuscular activation. The removal of support withdrawal contributes to space-induced muscle atrophy by disrupting sensorimotor connections at the muscle and neuronal levels. Rapid degradation of muscle mass and tone, particularly in anti-gravity postural muscles, compromise the ability to walk and stand after long-duration spaceflight. The objective of this project was to design and fabricate a specialized boot with an insole that applies oscillating pneumatic pressure, therapy reactivating soleus mechanoreceptors. The boot included two airbags,exerting 40 kPa of pressure each,placed directly on the sole of the foot located at the calcaneus and the metatarsals. Adjustable straps accommodated were added to help stabilize the ankle and provide security. The airbags were programmed to inflate and deflate every 3 seconds over a 20-min period every hour for 6 hours. To test the efficacy of the boot, surface electromyography (sEMG) was used to detect neuromuscular activity in the soleus. Following the Surface Electromyography for the Non-Invasive Assessment of Muscles guidelines, one pair of electrodes was placed at ⅔ of the line between the medial condyle of the femur to the medial malleolus for the soleus muscle, and a second pair of electrodes was placed at ⅓of the line between the head of the fibula and the heel to read activation of the gastrocnemius. The system was grounded at the tibial tuberosity. When the airbags inflated, the soleus produced an increased amplitude and frequency with the ankle in a neutral position.These results indicate that there was neuromuscular activity created by the boot,which indicates that the device will help in attenuating the negative neuromuscular adaptations in the soleus via afferent signaling.

Abstract Name: Men Managing Body Image and Appearance through Clothing

The current study follows previous research conducted in 2004 that examined men managing body image and appearance using clothing. Clothing is a tool that can be used to assist a positive body image and can also be used to cover up negatively viewed aspects of one's body. A review of the literature reveals appearance management, body image, practicality, and cultural ideals are reoccurring themes in the literature on men's clothing presentation. There is an existing belief that men lack body image issues. However, this is a rejected notion as many men have a drive for muscularity and a yearning to prove their body's worth, yet would not admit to caring about their appearance or body image. This study will survey men who attend Millersville University during the Spring 2023 semester to determine how clothing is used to communicate body image and a desirable appearance. Four primary questions will be asked to gather data based on several factors, including body image feelings and hiding or emphasizing aspects of one's body. The data will be coded using 4 themes, which consist of cultural ideals, practicality, body image, and appearance management. The researcher may also code for new themes as they emerge from the data. Using these themes, the researcher plans to investigate similarities and differences between groups based on the information gathered from demographic questions. This study hopes to add to the limited existing knowledge on men's body image and appearance management techniques. As of now the researcher is unsurewhat her data will reveal, however, if it follows previous researcher's datait may conclude that men value practicality, men believe they should not care about how they look, clothes are used to conceal or reveal, and clothes fit a cultural ideal.

Abstract Name: **An Examination of the Feminine Perspective of Death: Classical Greece**

In studying ancient Greek history, just like in other periods, the roles and activities of women, not to mention their thoughts and opinions, were mostly overlooked until recent decades. This project explores the women's perspectives of death during the Classical Greek period, roughly the 5th and 4th centuries BCE. This project brings women's involvement and understanding to the forefront in examining death, an experience universal to all cultures. While some scholars have analyzed various literary texts regarding death and dying, my study combines written evidence and archaeological remains, such as funerary stelae and painted pottery. The various archaeological remains are examined in their funerary context and decorations. Certain written evidence will also be examined. Women could not have official public roles, and they do not usually appear in written histories and documents. However, female characters are often depicted in Greek plays, making them a source of literary evidence. Furthermore, women were responsible for preparing the deceased's body and were the primary mourners at Greek funerals. Because these were private ceremonies, we can search for their perspectives on the objects and artworks associated with funerals. The main goal of my project is to understand what Greek women at this time thought about the process of dying, death itself, and the acts of mourning.

Abstract Name: **Equity & Access: a Case Study on Educational Attainment of Vietnamese American Graduates**

This project addresses the wrongful stereotypes and assumptions of the Model Minority Myth (MMM) and unravels claims on inherent racial and ethnic qualities determining educational outcomes through mixed methods research: quantitative survey responses and qualitative interviews. This project is inspired by the framework of Participatory Action Research (PAR), making this research project less of an excavation but more of a means of understanding community needs through acknowledging lived experiences. Participants are from the researcher's alma mater, La Quinta High School (Westminster, CA) which neighbors a "Little Saigon" community and graduates large populations of Vietnamese American students. The focus on Vietnamese Americans' sense of identity and belonging, general well-being, and educational journey helps to disaggregate data within the Asian American community to explore the experiences of an often "invisible" group among Southeast Asians. Of the survey's 26 respondents that provided contact information, 10 signed up for and completed semi-structured interviews (N = 10). The interview questions were split up into four chronological sections: (1) Basic demographic information regarding identity (2) Family history and background on household number and dynamics, (im)migration history, jobs, education (3) Individual education experiences and tracking from elementary school, middle school, high school, college and, if applicable, graduate school (4) Reflection on identity, MMM, and other racialized educational experiences. Grounded in Pierre Bourdieu's asset-based theories of social, cultural, and economic capital, the interviews reveal barriers for educational attainment for Vietnamese Americans. Themes of requests for support emerge in the forms of culturally-responsive curriculum, language and cultural accessibility within educational institutions, and college preparatory to handle the "hidden curriculum."Keywords: College prepatory, Asian Americans, educational equity, social and cultural capital

Abstract Name: **Creating a Cost-Benefit Analysis Guideline from Ecological Economics: How Can This Be Applied to Landfill Mining?**

With an aim to examine the profitability of landfill mining, a cost-benefit analysis model was developed using ecological economics principles. The research combines the traditional business analytics cost-benefit analysis (CBA) with the policymaking CBA process from Harvard Business School Online and the Harvard School of Public Health respectively. This study also incorporates Paul Hawken's ecological commerce concepts to create a new cost-benefit analysis model for private business applications. The new CBA process consists of six major steps, focusing mainly on step two (identifying the cost and benefits), and step three (assigning the common currency value to each cost and benefit). By using landfill mining as an example, ecological principles are showcased in a practical application. Besides suggesting an alternate use of landfills, the new guideline for an ecological cost-benefit analysis provides a deeper understanding of the true value of waste. This research can set an example for how businesses could utilize waste and potentially adopt a "no waste" mindset.

Tran, Kristine

Institution: ***VA - Virginia Commonwealth University***

Abstract Name: **Normalization of the Infantilized Woman and Sexual Girl**

Although beauty and attraction are subjective, the beauty industry calls upon women and young girls to "enhance their features" via cosmetic products, plastic surgery, harsh diets and intense exercise regimens to be considered attractive. Victoria's Secret, one of America's most popular lingerie companies, was founded by a man despite the store's goal to market lingerie for women. If the male gaze is responsible for the general definition of the ideal woman, then the impact of the portrayal of and language used towards women in American popular media between the 1950s and 1970s must be examined, because acknowledgment of American societal expectations for feminine beauty is necessary to understand deeper, gender-related issues, such as the infantilization of adult women and sexualization of young girls. To understand the effect of thesesocietal expectations, three women who played a key part in changing societal norms for women were compared: Marilyn Monroe, Lucille Ball, and Julie Newmar. By cross-referencing key examples of these adult women being infantilized on television, in addition to their advancements in the television industry, there is a connection between them that stems from societal norms that call for women to be sexual and beautiful, but also innocent and pure. This contradiction opens the gateway to the sexualization of young girls, and therefore, enables predatory behaviors toward women.From a social and feminist perspective, this analysis emphasizes the need for modern-day American society to acknowledge the contradictory, societal expectations for women that may be related to the predatory and violent behaviors exhibited by men towards women.

Abstract Name: **Creation of electro-magnetic assisted "Star-like" formation from cancer cells using laser trapping technology**

Cancer is the second leading cause of death among humans worldwide. Although radiation therapy is the most effective course of treatment for patients, it still causes harmful and long-lasting damage to their bodies, ruining their quality of life. The initial purpose of this study was to minimize radiation damage caused by cancer treatment using laser-trapping (LT) technology. However, amidst experimentation, two scientific phenomena were discovered: "Dark-space" and "Star-like" formations. Both discoveries were observed to have power absorption and conservation abilities, which can be utilized in the world's constant technological advancements. Thus, the purpose of this study was expanded into 3 phases: Single-cell ionization, "Dark-space" formation, and "Star-like" formation. Phase 1 used an infrared laser trap to find the minimal radiation required to ionize a BT20 cancer cell. A 3:1 mixture solution of BT20 cancer cells and micron-size magnetic beads was instilled onto a depression slide and used to conduct measurements for over four years. Further, on to Phase 2, a "Dark-space" forms when the magnetic beads and cells interact with the laser trap that acts as an energy storage capacitor and rapidly expands as more and more radiation is absorbed. This expansion causes all surrounding matter to accelerate towards the dark region, yet it can never penetrate the space. Upon explosion, the energy of the "Dark-space" causes the surrounding matter to form into a plasma. Leading into Phase 3, a "Star-like" illumination forms once the plasma interacts with the laser trap. This interaction causes an emission of intense blackbody radiation that grows and becomes more robust as more energy is absorbed. Overall, applications of this study may provide improvements in cancer treatment, microchip technology, and solar energy harvesting.

Abstract Name: **Evaluation of transportation inequality in rural Nebraska**

This paper is to address one of the important issues related to transportation inequity in rural areas in the state of Nebraska. Transit equity implies that there will be a link between affordable public transportation and employment opportunities. Residents in rural communities face broader transit and transportation inequities that are more difficult to address than residents living in urban communities. Data collected and analyzed from the US Census Annual Estimates in 2020 indicated that out of 500 cities in Nebraska, only 17 have appropriate access to public transportation, whereas 483 cities received less or non. To better serve those under-resourced communities, this paper offers needed shifts for addressing these issues, including potential solutions that make transportation mobility and network more equitable distribution to rural areas. A multi-method research strategy consisting of a qualitative research approach, a case study, and data from the National Household Travel Survey is used to explore transportation behaviors among disabled adults in rural and urban areas and four regions across the state of Nebraska. These findings emphasize the relative importance of various modes of transportation for participating in activities and the continued reliance on personal vehicles, either as a driver or a passenger, particularly among rural disabled residents. It is anticipated that the results from the research will be helpful in reducing the transportation inequity gap between rural and urban areas and providing suggestions to public agencies for decision-making in the development of sustainable transportation infrastructure initiatives across the state of Nebraska.

Abstract Name: Stabilizing the Dimer of Non-Structural Protein 9 in SARS-CoV-2

SARS-CoV-2 is an RNA+ virus that is directly translated by the host cell to produce non-structural proteins (Nsp 1-16) essential to the replication of viral RNA. One interesting non-structural protein, Nsp 9, contains an unusual OB-greek key motif known in other viruses to bind single stranded RNA working with the helicase to allow efficient replication.Additionally, this protein is thought to dimerize for efficient RNA binding; however, the specific mechanism of dimerization and the interaction between this dimer protein and a cognate RNA sequence are currently unknown. To better understand the requirements for dimer Nsp 9-RNA binding, we have made a cysteine mutant to covalently stabilize this dimer. Tryptophan fluorescent studies have been developed to determine differences in binding affinities of both RNA and DNA sequences to help identify requirements of complex formation between Nsp 9 and, an as of yet, unidentified cognate RNA. Initial studies indicate binding of an RNA pseudoknot structure could aid in sequestering Nsp 9 to untranslated regions of the viral RNA.

Abstract Name: A Hijacker's Demise: An Account of the D.B. Cooper Mystery

D.B. Cooper's 1971 commercial plane hijacking is a significant unsolved case in American history. This project provides answers to the research question: What happened to D.B Cooper, the unidentified plane hijacker of November 24, 1971? To answer this question, this paper reviews the literature written on D.B. Cooper and analyzes the available primary sources written about his disappearance. The sources gathered consist of publications by the Federal Bureau of Investigation (FBI) and other newspaper articles reporting on the incident. There are only two possible answers to the research question; D.B. Cooper died or D.B Cooper is still alive. The analysis of the primary source material throughout this paper leads to the conclusion that D.B. Cooper did not successfully escape the plane hijacking, ultimately causing his demise.

Abstract Name: Enhancing Healthcare with Real-Time Body Gesture Recognition: The DroneX Solution

Due to the increasing popularity of drones in mainstream entertainment and business sectors and the limitation of controllers, we realized the need for hands-free control and expansion of user-defined commands that hardwired controllers cannot support for drones. This project uses the DJI Tello drone to recognize different commands through body gestures. The DroneX should distinguish between a series of body gestures and return the desired commands to the Drone. We have implemented the MediaPipe tool by using its APIs to currently recognize eight gestures; stop, take/up, land, forward, backward, left, right, and flip. We also used OpenCV and its APIs to display the image on a separate device. The DJI Tello drone is used as the environment for deploying the DroneX software. The Tello is connected to a separate device via Wi-Fi limited to 100 meters. It has a camera that is 5 megapixels (2592 x 1936), has an 82.6-degree field of view, and is HD 720 p. We are aware that DJI RyzeTM has a drone called the DJI Spark that uses hand gestures to issue commands. We are using body gestures to have a better range than hand recognition. Social media platform Snapchat also had a drone called Pixy that would take a selfie of the user, but Snapchat discontinued the efforts to develop it in August 2022. Pixy would just take a picture and return it to the user's hand. Currently, the DroneX project has some limitations, such as working in low-light flight conditions, harsh environment flight, and in an area of multiple detected objects. In future work, we plan to overcome the mentioned limitations, detect gestures at big distances, and include larger body gestures in our dataset.

Abstract Name: Screening Type III CRISPR Complexes for Enhanced Signal Amplification

Type-III CRISPR-Cas systems are programable RNA-guided detection systems that recognize RNA targets by complementary base pairing. Target RNA recognition activates a polymerase domain that selectively polymerizes adenosine triphosphate (ATP) into cyclic oligomers of adenosine (cOA). In bacteria, target detection-dependent polymerization of ATP amplifies the cOA alarm signal during an infection, and we recently repurposed these systems for sequence-specific detection of SARS-CoV-2. However, the sensitivity of these new CRISPR-based diagnostics is still insufficient for clinical applications. To improve sensitivity, we are screening type III complexes from Thermus thermophilus, Streptococcus thermophilus, and Enterococcus italicus to determine the rate of cOA synthesis (kcat). Complexes that synthesize cOAs more rapidly will be incorporated into the diagnostic to increase overall sensitivity.

Abstract Name: Preparing Communication Disorders and Sciences Students to Collaborate with Interpreters: The Power of Interdisciplinary Experiences

Nearly 25% of children in the United States currently speak a language other than English at home (Ann Casey Foundation, 2022). Despite the clear and compelling need for competent and linguistically responsive assessment and intervention practices, practicing speech language pathologists (SLPs) frequently report feeling underprepared to accurately work with interpreters when serving dual language learners (DLLs) (Guiberson; Atkins, 2012; Santhanam; Parveen, 2018). However, collaborative training experiences can provide SLPs and interpreters with the opportunity to converse about their roles, discuss ethical problems with interpretation, and merge their shared thoughts to ensure best practices for clients (Zhang, 2020). The purpose of this research project was to understand the ways in which an interdisciplinary simulated training experience and interdisciplinary immersion screening experience compare and contrast in relation to communication sciences and disorders (CSD) and interpreter students' feelings of preparedness for working collaboratively within their future professions. Researchers gathered data through reading, analyzing, and then qualitatively coding CSD and interpreter student summaries written post- simulated experience and post-screening. Student reflections included overall perceptions of the experience as well as perceptions regarding the ways in which the experiences influenced their feelings of preparedness. Student reflections and interviews were analyzed using inductive coding procedures as described by Merriam and Tisdell (2016). Codes, categories, and subcategories were revised and operationally defined during the coding process, until a final set of codes, categories, and subcategories was developed. Findings highlight the similarities and differences in CSD and interpreter perceptions, as well as the similarities and differences in student perceptions of an interdisciplinary simulated experience as compared to an interdisciplinary immersion screening experience. Findings will inform future pre professional and professional training experiences designed to increase SLP confidence and competence for working with interpreters and to increase the quality of interpreter and SLP practices for DLLs.

Abstract Name: Minority Status and Mental Health

Discriminatory behaviors live throughout society today and all generations of the past. How do these behaviors impact groups with minority status? The aim of this study is to research how chronic stress expereinced by people with minortity status impact mental health. There will be multiple angles applied to this study. The first area of interest is how social media either contributes to or gives a community for discriminatory behaviors or does social media allow for an outlet for those with minority status to build support and community. The second area of interest is how does stress related to choronic discrimination exposure contribute to the mental health of individuals with minority status. Previous research has shown disparities in mental health, substance use, and other factors related to mental health among groups with minority status when compared to the same age group of majority status individuals. This study will identify factors associated with positive and negative mental helath development across multiple minority status groups through a survey implemented and analyzed in the spring semester of 2023.

Abstract Name: **Yearly Survival and Growth Rates of Propagated Fatmuckets (Lampsilis siliquoidea) in Central Wisconsin**

Freshwater mussels are key members of riverine ecosystems and are crucial for improving water quality. Mussels serve as valuable indicator species and suffer from many environmental disturbances, but despite their importance, large gaps remain in knowledge of freshwater mussels in Wisconsin. We measured the survival and growth of mussels exposed to ambient conditions in two streams in Central Wisconsin. Both selected streams included those that support diverse mussel assemblies. On October 29th, 2021, we received 120 Fat Muckets (Lampsilis siliquoidea) from the Genoa Fish Hatchery, measured, then released them into suitable areas on the Mill Creek; the Plover River Near Stevens Point, WI. Before release, mussels at the Mill Creek site averaged 1.853 cm in length, 1.03 cm in width, and 0.52 cm in thickness. At the Plover River site, mussels averaged 1.859 cm in length, 1.068 cm in width, and 0.546 cm in thickness. We utilized silos to encompass the 1.5-year-old mussels. Each site has 1 silo, containing 15 individuals per silo. Our objective is to determine seasonal survivorship and growth rates throughout our year-long study. Experimentation at these sites will provide an indication to determine which areas are suitable for future reintroductions. We expect 1) Mussel growth and survival will be significantly reduced in the winter months, compared to the summer months. 2) Mussel growth and survival will be significantly different between the two sites. These sites were measured monthly beginning April 21st and lastly October 21st, 2022. This is part of an ongoing study through the University of Wisconsin – Stevens Point's student chapter of The Wildlife Society.

Abstract Name: **Fabrication of MEMS Filters for Applications in Rapid Prototyping and Biotechnology**

Effective techniques for the separation and spatial manipulation of shaped microscopic particles are vital to applications in fields ranging from biotechnology to manufacturing. For instance, shape-specific separation can be used to isolate microbes and biomolecules. Printers used for rapid prototyping from composite materials could benefit from a device that constrains the orientation of microscale filler materials such as metals, glass or carbon fibers.The separation and alignment of shaped particles is generally challenging, since nonspherical particles can freely rotate and present different faces during motion. In this presentation, we describe the fabrication of lithographically patterned and anisotropically etched microscale pores in a single crystal silicon substrate, that are designed to overcome these difficulties. We present data on the engineering limitations and outcomes of this fabrication process and preliminary results from flow testing. These precision-engineering pathways show promise for both the shape-based separation of non-spherical particles aswell as in controlling their spatial orientations.

Abstract Name: **Simulation of the Shear Flow Dynamics of Suspended Microscale Particles**

Understanding the shear flow dynamics and wall interactions of non-spherical particles suspended in fluid media is important in a number of fields, from large scale phenomena like coastal erosion to mesoscopic and microscale applications such as additive manufacturing with fiber-reinforced composite filaments and shape-based separation of particles and biologicals.In particular,focusing on the geometric orientations of high-aspect ratio fiber-like particles suspended in low- and high-viscosity fluids transported through precision engineered pores with radially asymmetric geometries. This includes using a combination of analytical methods and numerical simulations with computational fluid dynamics solvers ANSYS Fluent and STAR CCM+ to evaluate the ability of customized microscale pores with tapered sidewalls to orient and align fibers suspended in fluid media. We believe these results to also provide valuable insights into nanoscale applications such as the wafer-scale printing of aligned carbon nanotubes for microelectronic circuits.

Abstract Name: **Disparity in Neonatal Abstinence Syndrome by Race/Ethnicity, Socioeconomic Status, and Geography**

Recent updates to the HCUP-KID database offers an opportunity to examine the relationship between key sociodemographic-factors and U.S. national disparities in neonatal abstinence syndrome (NAS). We used 2016 and 2019 cycles of cross-sectional data from HCUP-KID national all-payer pediatric inpatient-care database to estimate NAS prevalence (ICD-10 code P96.1) in newborns ≥35 weeks gestational-age, excluding iatrogenic-cases (ICD-10 code P96.2). Multivariable generalized-linear-models with predictive-margins were used to produce race/ethnicity-specific stratified-estimates for select sociodemographic-factors, reported as risk-differences (RD) with 95% confidence-intervals (CI). Final models were adjusted for sex, payer-type, ecologic income-level, and hospital size, type, and region. The overall weighted-sample prevalence of NAS was 1.14% (n=7721/677721) and did not differ over cycles. In fully-specified models, NAS prevalence among Whites was 1.67% (95% CI: 1.54, 1.80) higher than Blacks and 1.72% (95% CI: 1.59, 1.86) higher than Hispanics; and NAS among Blacks was 0.14% higher than Hispanics (95%CI: 0.04, 0.25). NAS prevalence was highest among Whites on Medicaid (RD: 4.2%; 95% CI: 3.97, 4.48) compared to Whites on private-insurance (RD: 0.4%; 95% CI: 0.34, 0.46), and Blacks (RD: 0.82%; 95% CI: 0.71, 0.92; RD: 0.14%; 95% CI: 0.08, 0.421), or Hispanics, with either payer-type (RD: 0.66%; 95% CI: 0.57, 0.75; RD: 0.10%; 95% CI: 0.04, 0.17) respectively. NAS prevalence was higher among Whites in the lowest income-quartile (RD: 2.6%; 95% CI: 2.36, 2.88) compared with Blacks (RD: 0.55%; 95% CI: 0.45, 0.65) and Hispanics (RD: 0.48%; 95% CI: 0.37, 0.59) in the same quartile, and all subgroups in other quartiles. NAS prevalence was higher among Whites in the Northeast (RD: 2.47%; 95% CI: 2.14, 2.79) compared to Blacks (RD: 0.57%; 95% CI: 0.35, 0.78) and Hispanics (RD: 0.33%; 95% CI: 0.19, 0.48). Compared with Blacks and Hispanics, Whites on Medicaid, in the lowest income-quartile, and the Northeast U.S. have the highest NAS prevalence.

Abstract Name: **Functional Characterization of Genes in the Plant Fatty Acid Elongation Pathway using Synthetic Biology Approaches in Yeast**

The plant cuticle is a hydrophobic barrier that is the first line of defense between aerial organs and the external environment.The cuticular waxes protect against both biological and non-biological stressors and are composed of fatty acids and their derivatives. The very long chain fatty acyl-CoAs that are precursors for cuticular wax biosynthesis are synthesized by the fatty acid elongation pathway in maize. The maize Ketoacyl-CoA Synthetase (Kcs) and Glossy2 (Gl2) gene families are two of many enzyme families that are necessary for the elongation of the VLCFA precursors. Based on previous research, specific genes within these two families may interact either directly or indirectly to affect the elongation of fatty acids: Kcs5 and/or Kcs6 with Glossy2 and/or Glossy2-like. Moreover, the function of the Glossy2 gene family in maize is still not defined. To study the relationship between the Kcs and Glossy2 gene families, we took a heterologous systems approach by expressing and characterizing different combinations of these maize genes within yeast. VLCFAs were profiled from the different Kcs-Gl2 engineered strains grown to stationary phase and gene function inferred from VLCFA accumulation patterns.These results will be presented and discussed.

Abstract Name: **Is the Student Loan Forgiveness Plan Fair?**

Recently, President Joe Biden signed an executive order forgiving student loan debt for millions of eligible students. People are eligible for between $10,000 and $20,000 based on the types of federal loans they took. This executive order has created significant debate among the population and the major news networks on the topic of fairness. This survey had the goal of discovering the publics opinion of fairness on this executive order. My hypothesis was that Democrats would support the bill more than Republicans and independents. To test my hypothesis, I wrote a survey on Survey Monkey with the data being collected through Amazon Mturk. My survey consisted of 197 completes from Americans aged 18 and older. The results revealed that for the question of fairness for students who have paid off their debt, Republicans and Independents disagree more with fairness than Democrats. Republicans disagreed 12.2% and Independents disagreed 24.2% compared to Democrats disagreeing with 0.9%. This is statistically significant at the one percent level. Since the executive order is stuck in the courts, this is valuable to all lawmakers because it shows which Americans are more likely to support this executive order and other similar orders.

Abstract Name: Perceived Benefits of an Aphasia Creative Arts Installation Using a Project-Based Intervention Framework

This study explores the value, as perceived by individuals with aphasia and their care partners, of an aphasia creative arts installation at a local coffee shop. Members of a local aphasia group, utilizing a project-based intervention framework, developed individual creative arts pieces that were displayed publicly during a two-month art installation at a local coffee shop. Additionally, narrative descriptions were provided by each individual and linked via QR code next to each art piece displayed. Nominal group technique (NGT) was used to explore the perceived value of the creative arts project using project-based intervention to support ongoing community participation and aphasia awareness. Following NGT procedures, multiple iterations of semi-structured interviews were completed with both individuals with aphasia and care partners. Interviews were framed around four primary domains: successes, barriers, impacts on the community, and impact on self/partner with aphasia.People with aphasia identified primary themes of success, which included aphasia awareness, team effort, and location, while a success identified by care partners was honoring their partner with aphasia publicly. The primary barrier was perceived to be uncertainty according to both people with aphasia and care partners. People with aphasia reported the primary impact on the community to be the outreach to the public and friends, while care partners reported aphasia awareness to be the primary impact on the community. The project-based intervention framework utilized in this aphasia group collaboration resulted in identity enhancement, aphasia awareness, and meaningful participation in a collaborative fashion. The utility of the project-based intervention framework and applications of themes derived from interviews will be discussed relative to future individual and group aphasia projects.

Abstract Name: Detecting Bias in Intelligent Autonomous Hiring Systems

This project analyzed if artificial intelligence (AI) hiring systems demonstrate prestige bias, and how that bias may be mitigated. We chose to look at prestige bias since the quality of a candidate's education will naturally be reflected in their skills and experience; a school's reputation should not additionally be factored into a hiring decision. Of note, this project analyzed prestige bias against Historically Black Colleges and Universities (HBCUs). The majority of students attending HBCUs are people of color who are already marginalized members of society. We examined how hiring site Indeed utilizes AI to list candidate resumes by relevance and measured the relationship between a candidate's resume ranking and the university they attended. We expect to find a negative association between HBCU status and ranking, which is stronger than the association between ranking and other confounding variables such as experience type, degree level, field of study, etc. Subsequently, we will develop our own AI system, utilizing hiring decision data that we collected from Indeed, to observe if it will present a similar bias. If so, then we will apply debiasing techniques to our model to create a new AI hiring system that is not biased against HBCU applicants. With businesses considering AI as a tool for hiring, companies must understand that AI hiring systems can perpetuate the same biases found in human hiring on a larger scale.

Abstract Name: Generating Novel Chiplet Designs Utilizing the Wave-Function Collapse Algorithm in Python

Computer algorithms can be used to autonomously generate novel computer chiplet designs. Chiplet designs are very popular in common computers and include designs such as x86 and x32. The uses for these chips range from smart thermostats to super-computers. The goal of this research is to use the Wave-Function Collapse Algorithm—an algorithm that analyzes a provided image then produces a similar output image—to produce a new chiplet design by autonomously placing chip features, such as an Arithmetic Logic Unit, and Control Unit, on a two-dimensional die. After providing the program a sample image, loosely based on current designs, it will produce a new image with features from the original sample. These new images are then assessed by various metrics like distance between units, and physical size of the units, to determine the usability of a chiplet if it were fabricated according to the output design. Further planned research includes employing machine learning to optimize chiplets for performance and more efficient chiplet synthesis for processes like extreme ultraviolet lithography, and wet etching.

Abstract Name: Mechanical Properties of Organic-Inorganic Composite Films: Comparing the Impacts of Flexible vs. Rigid Organic Components

A series of organic-inorganic composite films composed of alkanethiol-capped gold nanoparticles and dithiol crosslinking molecules were assembled upon the air-water interface within a Langmuir trough. The mechanical properties of films containing conformationally flexible alkanedithiols were compared to those containing rigid bi- and terphenyl dithiols via measurement of minimum collapse pressures. The results of this study address the specific role of nanoscale materials components,further enabling the rational design of nanoarchitectures with specific chemical, physical, and mechanical properties.

Abstract Name: Spectroscopic Investigation of the Lowest Triplet State of Alpha-Pyrone

Molecular triplet states are chemical species that have two unpaired electrons. Triplet states are formed through the process of electronic excitation, in which energy from light or other sources promotes an electron from one molecular orbital to a higher one. The unpairing of spins via triplet excitation imparts significant chemical reactivity to triplet states, because these species behave as diradicals.In this project, we are using laser spectroscopy to investigate the lowest-lying triplet state of the alpha-pyrone molecule. Pyrone isomers, having formula C4H4O2, are conjugated carbonyl compounds containinga six-membered ring, with an ether linkage inside the ring. In alpha-pyrone, the ether oxygen is in position 2 of the ring with respect to the carbonyl group. Previously, we studied gamma-pyrone, in which the ether oxygen is in position 4. We learned how the vibrational frequencies in the lowest triplet state of gamma-pyrone differ from the frequencies in the ground state.In our current work on alpha-pyrone, we use a tunable dye laser that produces light in the 375-400 nm range to promote a carbonyl lone-pair electron into the lowest π^* molecular orbital.This process creates the lowest triplet state, denoted T1(n,π^*). By using the cavity ringdown (CRD) spectroscopic technique,we can detect laser absorptions that excite various modes of vibrational motion in the T1(n,π^*) state. Theinformation we obtain using CRD spectroscopy is analogous to that availablefrom aninfrared spectrum of the ground state.Thetriplet-state vibrational frequencies measuredin this projectare allowing us to understand how the conjugation and ring strain in the alpha isomer differ from these properties in the gamma isomer. This information will help researchers in the field of synthetic photochemistry better understand reactivity of the pyrones.

Abstract Name: Disparities Affecting the Knowledge of Female Pelvic Floor Disorders

Pelvic floor dysfunctions (PFDs) are the most common problems faced by women post-partum, however, only a few have access to and awareness of physical therapy (PT). Due to its prevalence, PFD is now considered a public health issue, including urinary incontinence, fecal bowel incontinence, pain during intercourse, and pelvic organ prolapse. White women and women of color had no significant difference in experiencing PFDs, and yet women of color had statistically less knowledge of PFD conditions. African Americans and other women of color are also less likely than white women to recognize childbirth as a risk factor for urinary incontinence and pelvic organ prolapse. Research demonstrates that women with a higher level of education have greater proficiency of PFDs compared to those with a lower level of education. Socioeconomic factors play a major role in the knowledge of PFDs because a higher annual income can provide better access to education and medical care. The aim of this study is to assess women's knowledge of PFDs and raise awareness about the importance of pelvic PT and its benefits for women after childbirth in order to prevent PFDs. Given that there is a lack of research in this area, we aim to bridge the existing gaps regarding the roles that age, racial, and socioeconomic disparities play in the need for education about PFDs, as we believe that this knowledge will help lower PFD cases with the help of pelvic physical therapy. The subjects will be 30 females between the ages of 20 and 40, recruited from college campuses, community centers, and healthcare providers. Data will be collected via a survey consisting of open- and close-ended questions to ascertain women's knowledge and awareness of post-partum PFDs and available therapy options. The survey will be developed in consultation with two licensed pelvic physical therapists.

Abstract Name: **Potential Anti-Cancer Effects of Chromene Thiazole Thioether Derivatives**

Previous studies have shown that chromene-based compounds exhibit anti-cancer properties as a result of their ability to function as microtubule destabilizing agents. Thiazole and thioether also function as notable pharmacophores with anti-cancer properties. Using a library of in-house synthesized chromene thiazole thioether compounds, we hypothesize that these compounds will have enhanced anti-cancer abilities compared to the individual components and will function by affecting microtubule stability. The derivatives vary by a heterocyclic ring structure, and we aim to examine how different structures affect reactivity with tubulin. Primary molecular docking studies completed with AutoDock Vina demonstrated promising binding affinities between the synthesized compounds and the colchicine binding site of tubulin. The destabilizing agent, nocodazole, has a binding affinity of -.6.4 kcal/mol whilst the synthesized benzimidazole derivative has a greater binding affinity of -8.4 kcal/mol. All compounds achieved a binding affinity between -7.0 and -8.4 kcal/mol indicating promising reactivity with tubulin. To analyze the effect of the compounds on microtubule dynamics, we are now conducting in-vitro tubulin polymerization assays to observe their impact on the rates of polymerization relative to paclitaxel (a stabilizing agent) and nocodazole (a destabilizing agent). We will also be testing the compounds on a human cancer cell line (A375) to examine their anti-mitotic effects.

Abstract Name: **Suicide Prevention Among Oklahoma?s Student Veterans**

In 2020, the Governor of Oklahoma issued a statewide challenge to reduce and eliminate suicide among Oklahoma's service members, Veterans, and their families. As a result of this challenge, in 2022 a survey concerning suicidal ideation among Oklahoma's student Veterans was conducted. Multiple agencies were involved in the development of the survey, including the University of Central Oklahoma, and the Oklahoma Department of Veterans Affairs. The survey contained items concerning demographics, social support, military affiliation, and academic status. Additionally, to measure depression severity, the ten items from the PHQ-9 survey (Kroenke, Spitzer,; Williams, 2001) were included. To prepare for distribution, campus Veterans offices were contacted regarding their current outreach practices. The survey was then distributed through Veterans offices at campuses across Oklahoma, including career-tech centers, community colleges, primarily undergraduate institutions, public research universities, and private institutions. In all, 105 student Veterans responded. Chi-square tests and t-tests were performed to identify factors related to suicidal ideation and major depression. Following this, a multiple regression model for predicting the overall PHQ-9 score was developed. These results will be disseminated to Oklahoma higher education institutions to assist with their outreach efforts and to bring awareness to deficiencies in their current practices.

Abstract Name: Social Media and Self-esteem

Social media, what did we do before it existed? Were we better off before or are we now? The debates around social media use are endless. There are strong viewpoints on both sides. Some believe it is literally the demise of human society, contributing to the delinquency of minors and providing negativeinformation that molds the minds of the young. Others believe it is entertainment and provides no harm to society and has no impact to the changing world we live in. Still others are cautiously in the middle. While social media has been around for some time now, we still know very little about the potential long-term impact. The population most influenced is the young. This research study explores the association between age of beginning use of soical media and the impact on various aspects of development.The key areas of interest are mental health, self-esteem, sexualization, achievement and addiction. Correlational analysis will be completed in the spring semester of 2023.

Abstract Name: Secondary Metabolites from Moroccan Lavandula Mairei

Lavandula maireiis a wild plant native to the southern mountainous region of Morocco. Morocco regularly harvests native and wild plants for their medicinal properties, but this leaves the native plants at risk of being over-harvesting and leading to the plant's extinction. Early research has shown that essential oils from L. maireiexhibit antibacterial activity against some Gram-positive and Gram-negative pathogens as well as multi-drug resistant pathogens which affect those that work and are treated in the hospital. In addition, research done on L. mairei essential oils showed high levels of carvacrol which is known to be antibacterial and can be used as a food preservative. Other than the research on L. mairei essential oil, no other work has been done with the plant. After receivingL. maireiextract (which was extracted with alcohol), HPLC analysis was performed to separate out potentially active compounds from the extract. This was performed to separate the constituents and to investigate which constituent(s) has/have biological activity. Five compounds were isolated and their structure elucidation using spectroscopic data (NMR and Mass) will be reported.

Abstract Name: **Characterization of Structure-Property Relationships of Stimuli-responsive Copolymers**

This research focuses on the characterization of structure-property relationships of stimuli-responsive copolymers for applications as dispersants in architectural coatings such as paints, primers, and stains. Stimuli-responsive polymers can dramatically change their physical properties in response to small changes in their environment. An important change in properties can be seen at the cloud point, the temperature where the polymer becomes insoluble in aqueous solution and indicates self-assembly or aggregation of the polymers. Copolymers with varying compositions were synthesized using Activator Regenerated by Electron Transfer Atom Transfer Radical Polymerization (ARGET ATRP), a synthesis technique that allows for narrow control of the molecular weight of the copolymers. Nuclear Magnetic Resonance Spectroscopy (NMR) and Gel Permeation Chromatography (GPC) were used to confirm the polymer structure and molecular weight dispersity. Polymer solubility and self-assembly were measured using Ultraviolet-Visible Spectroscopy (UV-Vis) and Dynamic Light Scattering (DLS) as a function of temperature, pH, ionic strength, polymer composition, and polymer concentration. These copolymers dramatically change solubility as a function of temperature and pH because of the tertiary amine. At low pH and low temperature, hydrogen bonding with water dominates behavior, so the polymers are water soluble. As pH or temperature is increased, the intramolecular forces control behavior, so the polymers become insoluble in water. The copolymer composition will shift at what specific temperature the solubility changes. Understanding structure-property relationships of these stimuli-responsive copolymers allows for optimization in applications. Stimuli-responsive polymers with these unique properties could be used as dispersing agents as a novel alternative to current commercial agents.

Abstract Name: **Zwitterionic Bergman-Triggered Cascade Polymerization: An Usual Multistep Plateau Cascade Leading to Transition Metal-Graphene Nanoribbon (TM-GNR) Hybrid Semiconductors Using Boron-Metal Couple**

With a accelerated growth in artificial intelligence (AI), designing high-speed and low power semiconducting material is of utmost importance. The present study provides a theoretical basis to access novel transition metal-graphene nanoribbon (TM-GNR) hybrid semiconductors whose DFT-computed band gaps were much narrower than the commonly used pentacene. A systematic investigation into the bandgaps and the methods to access these novel materials will be discussed. Additionally, the role of unusual hydrogen bonds and plateau reactions in successful cascade polymerization will be discussed.

Abstract Name: The Relationship Between Self-Monitoring, LGBTQ+ Identity, and Social Media Use

This study analyzed the relationship between self-monitoring, LGBTQ+ identity, and social media use patterns. Self-monitoring has been shown to influence friendship formation and activity patterns in face-to-face interactions. This research extends previous work by analyzing the interaction between self-monitoring characteristics and social media use in an inclusive way. The purpose of the present study was to explore the ways self-monitoring and LGBTQ+ identity predict social media use on different platforms. A total of 100 participants (66 cisgender heterosexuals, 34 belonging to the LGBTQ+ community) completed surveys assessing self-monitoring, frequency of social media use (both active and passive), number of platforms being used, and emotional states after using social media. Results indicate that high self-monitors are more likely to follow a larger number of people on TikTok and Instagram and people who identify as LGBTQ+ are more likely to follow a larger number of people on TikTok. Also, compared to cisgender heterosexual participants, LGBTQ+ participants post information about a greater number of topics on social media and report a greater number of emotions after using social media. Specifically, women who identify as LGBTQ+ report more positive feelings after using social media than men do. Moreover, self-monitoring total score and component scores as well as LGBTQ+ identity significantly predict the total number of accounts participants have on social media, so that high self-monitors and people who identify as LGBTQ+ have more social media accounts. These findings support the value of exploring self-monitoring and social media use with a focus on gender/sexual diversity.

Abstract Name: When the Right to Access (Life) Becomes a Burden: Accessibility to Public Health for Disabled People in Virginia during the COVID-19 Pandemic

This study examines two key accessibility issues for disabled people in Virginia during the COVID-19 pandemic: the accessibility of information about COVID-19, and access to vaccinations. Has disabled peoples' legal right to health care services and information been upheld in the time of the COVID-19 pandemic in Virginia?This study evaluates the accessibility of five web pages created by the Virginia Department of Health, and five web pages created by health districts in Virginia about COVID-19 guidelines and services. The accessibility of websites was determined under the standards of Section 508, a federal law "that requires agencies to provide individuals with disabilities equal access to electronic information and data comparable to those who do not have disabilities, unless an undue burden would be imposed on the agency." The level of compliance to these guidelines was measured by metrics provided by the Trusted Tester Program housed in the Department of Homeland Security. This study used both an accessibility testing tool and manual testing to determine the level of accessibility for each website.The findings are as follows: (1) Levels of compliance were low (2) Disabled people were overlooked when planning Covid-19 responses (3) They were denied equal access to information necessary for proper care and survival. 4.) Because Section 508 describes responsibility for accessibility as a "burden on agencies" rather than as "a human right," access is not prioritized in times of crisis. This case, I argue, reaffirms the importance of a disability justice framework, because it goes beyond mere compliance.

Abstract Name: WRAPping Our Heads Around the Impact of Advertisements Near Schools

The aim of this research project is to generate evidence surrounding the type and amount of advertisements displayed by alcohol/tobacco retailerswithin a one-mile radius of nine high schools in Eau Claire County. This project specifically centers on surveying the advertisements of alcohol, nicotine-containing products, and processed foods on the property exteriors(including gas pumps, bollards, entry doors, exterior facing windows, etc.). Studies showthat adolescents are exposed to alcohol advertisements on a daily basis which impacts consumption and drinking habits, as well as the vulnerable developing brain. The U.S. Surgeon General reported that the use of e-cigarettes is on the rise among adolescents and continues to be a public health concern. For this population, close proximity between schools and retailers who sell and advertise junk foods is largely associated with higher consumption rates of these same foods. Based on concerns from Eau Claire County high school students and administrators, amodified survey from the Wisconsin Retail Assessment Project (WRAP) will be utilized to identify the content and quantity of advertisements near local schools. The project outcome involves the creation and dissemination of an original, interactive, and evidence-informed presentation created to inform public health and city officials who then have the opportunity to use the data to affect signage. The results have yet to be determined, but it is predicted that a majority of retailers near Eau Claire County high schools advertise alcohol,processed foods, and nicotine-containing products. This in turn increases accessibility, affordability, and acceptance of further product usage in adolescents.

Abstract Name: Feeling left out and angry: The impact of social exclusion, impulsivity, social distress, and pain on anger

Social exclusion (when an individual is ostracized or ignored by others) can increase social distress and social pain in addition to anger and aggression. Furthermore, impulsivity (a predisposition to unplanned reactions to internal or external stimuli without regard to the negative consequences) has also been linked to negative affective and behavioral outcomes. The current study is the first to assess if social distress and social pain mediate the relationship between impulsivity and state anger in the context of social exclusion. Participants (n = 105) engaged in an online social media task with a group of 6 fictitious participants and wrote a self-description that was ignored by all the other group members (viz. induction of social exclusion). Measures of social distress, social pain, and state anger were then collected. A serial mediation analysis revealed that social distress and social pain mediated the relationship between impulsivity and state anger, b = + 0.1589, 95% CI: [+0.0301, +0.3565]. Specifically, increased levels of impulsivity were associated with increased social distress (b = +0.8696, p = .0194) which led to increased social pain (b = +0.8846, .001) and this in turn was associated with increased state anger (b = +0.2065, p = .0014). Implications for the impact of social exclusion and impulsivity on social distress, social pain, and state anger in addition to other negative outcomes such as violence will be discussed.

Abstract Name: **How can ponderosa pine seedlings be propagated to improve drought resistance in the field?**

Ponderosa pine, a widespread species in the western US, is a valuable species economically and environmentally. The preservation of this species is important for the ecological health of many forests due to increased temperatures, drought, and frequency of forest fires. Reforestation efforts following fire and timber removal often fail because seedlings propagated in greenhouses are not resilient to stressful field conditions. To increase seedling field survivorship, drought resistance, and to decrease mortality rates, we implemented a number of treatments in the greenhouse during the initial propagation. The treatments were a manipulation of water supply and different types of fertilizer, tested with seeds collected from varied elevations. After threemonths of growth in the greenhouse under these treatments, we measured height and both shoot and root biomass of the seedlings. We also measured days to mortality on a subset of the seedlings. Seedlings subjected to drought treatment and amino fertilizer grew shorter but survived longer. These seedlings allocated more biomass below ground, which likely contributed to their longer survivorship in the days to mortality test. However, despite the potential benefits these treatments conferred to seedlings in the greenhouse, all seedlings experienced nearly 99% mortality after they were outplanted to a nearby field site. We suspect that most of this mortality was due to frost-heaving, a process whereby seedlings can be pushed out of the ground during frost-thaw cycles that occur in soils in the winter, and is exacerbated by the creation of bare patches of soil around the seedling during planting.

Abstract Name: **Lead Telluride Nanoparticle based Radiation Detectors**

In the Advanced Nuclear Technology Lab, we focus on creating high resolution, ionizing radiation detectors using lead-telluride (PbTe) nanoparticles. These nanoparticle based detectors can be superior to current single-crystalline detectors because they facilitate low-cost solution-based manufacturing and, from a physics perspective, enable size-dependent control of the band-gap and suppression of thermal-loss processes. Whether nanostructured or homogeneous, semiconductors convert neutrally charged particles into electrons and thereby into a useful signal to identify the type of interacting radiation. This approach offers a fast and cheap alternative to traditional methods which typically are characterized by very low yields and small detector volumes. Nanoparticles can have unique properties due to their high surface-area-to-volume ratio causing them to be highly reactive and able to exhibit unusual properties. We are developing the chemical process needed to create these semiconductors; however, as stated above, nanoparticles are highly reactive so slight deviations in the production of the semiconductor results in massive changes in viability as a radiation sensor. We are running numerous trials to see what factors are best for the semiconductor formation such as pH, functional ligand type, cleaning procedures and particle sizes. In terms of the ligand that functionalizes the nanoparticle, we are testing both thioglycolic acid (TGA) and mercaptosuccinic acid (MSA) as our bonding ligand with a hypothesis that the TGA will be a better bonding agent since it is much smaller and should allow for better loading on the surface of the semiconductor. While going through a vacuum filtration, the pH and nanoparticle sizes affect how it loads on the surface of an ANF. We have created PbTe-polymeric detectors from both PbTe-TGA and PbTe-MSA, but the PbTe-TGA devices exhibit higher loading and better detection performance while PbTe-MSA exhibits less nanoparticle-to-nanoparticle bonding and therefore more uniformity in the solid.

Abstract Name: **Conformity and Friendship Satisfaction Among University Students**

The rhetoric around one's role in a friendship or relationship is largely shaping up to promote a lack of conformity. Adolescents and young adults are now regularly told to "stand out" and perhaps that fitting in isn't always the best option. This, however, prompts the question of what role conformity plays in impacting friendship satisfaction. This paper explores whether there's a correlation between an individual's level of conformity and their level of friendship satisfaction. Gender and relationship status are explored as potential mediators in this relationship. The participants' level of conformity was measured using the Elevator experiment, where participants enter an elevator and find 4 other people facing the rear end of the elevator. Participants accordingly make one of three decisions, they either turn and face the rear end (conformity), continue standing the same way (non-conformity), or hesitate (mid-level conformity). Participants then completed a questionnaire that assesses their level of platonic friendship satisfaction across three scales. This process was completed 75 times by participants, with 25 students conforming, 25 not conforming, and 25 mid. Results of the Anova show that there is no significant correlation between conformity and friendship satisfaction; however, there was a significant correlation between gender and friendship satisfaction, which indicated that girls are overall more content with their friendships. This opens lots of areas for future research, as it can be worthwhile to explore some of the other factors that result in girls being more satisfied with their friendships at this specific age.

Abstract Name: **Different Light Intensities Significantly Affect the Growth and Fucoxanthin Concentration of the Oleaginous Diatom Fistulifera solaris**

Biofuel production using algae is believed to have tremendous positive impacts on the environment and it seems a promising solution for global warming. However, growing algae on a large scale takes many resources and mass production of biofuels is not yet economically viable. In this study, an oleaginous diatom, Fistulifera solaris, was cultured in autotrophic conditions under four different light intensities for 14days to determine which conditions allowed for higher biomass and higher fucoxanthin concentration, a valuable photosynthetic pigment that is expensive and can make the process of biofuel production affordable. As a measure of abundance, absorbance values of diatoms in 750 nm wavelength (OD750) were obtained ondays 0, 7, and 14. Onday14, biomass and fucoxanthin concentration were measured. Statistical analyses revealed a significant change in growth of diatoms under the four treatments which can be explained by varying rates of reproduction of the diatoms grown under different light intensities. Specifically, the highest OD750 and biomass was found in medium-high light intensity while the highest fucoxanthin concentration was found in low light intensity. It is suggested that diatoms grown in low light intensity are ideal for increased fucoxanthin concentration due to the downregulation of a gene, which is responsible for encoding a fucoxanthin precursor, in exposure to high light intensities. Considering this data and findings from similar studies, it is suggested that mixotrophic conditions, which involve both autotrophic and heterotrophic conditions, may be better for growing F. solaris for biofuel production.

Abstract Name: **Judging Books By Their Covers: Diet Culture Rhetoric Within College Student Communities**

This research takes a qualitative and mixed methods approach to exploring diet culture rhetoric through a rhetorical analysis and a food medicalization lens. A rhetorical analysis of the front and back covers of twelve diet books was used to create a coding scheme to categorize the rhetoric. This was applied to ten semi-structured interviews of students on the University of Wisconsin-La Crosse campus. The rhetoric from these were compared to the rhetoric of the diet books to determine if there were similarities or differences, and furthermore, if a relationship existed between them. The research has shown that while a clear causation between the diet book rhetoric and the rhetoric of the students wasn't supported, they indicated connections to the larger world of diet rhetoric which included social media, television, and other media. They also indicated a connection to the rhetoric of food medicalization, which is used to frame food as treatment or a form of medication to solve problems in the body that may or may not be legitimate.

Abstract Name: **Evaluation of Signaling Events by Activated Protein C Cleavage of Protease Activated Receptor 1 on Human Platelets.**

Activated Protein C (APC) regulates blood coagulation by cleaving cofactors in the coagulation cascade. Recent studies have shown that APC can cleave the Protease Activated Receptor(PAR1)on endothelial cells at a different site than thrombin does; this elicits cytoprotective effects and protection from endothelial dysfunction. While PAR1 is also expressed in human platelets, studies have shown that human platelets are not activated by APC. Here, we investigate differencesin APC/PAR1 mediated signaling in human platelets. A tethered peptide TR47 based on the cleavage site of PAR1 by APC has been designed and shown to cause similar effects as APC on endothelial cells. We investigated whether the tethered peptide causes platelet activation and triggers signaling events in human platelets. Platelet activation was traced through Born Aggregometry, and precipitated proteins were analyzed by Western blotting. SFLLRN, another tethered peptide mimicking the action of Thrombin on PAR1, was used asa control agonist, which caused human platelet aggregation, ADP secretion, and downstream signaling events such as ERK phosphorylation. We found that TR47 did not cause any platelet activation, nor wasERK phosphorylation observed. These preliminary results suggestthat other factors or pathways in endothelial cells might contribute to cytoprotective signaling events and mitigation of dysfunction. We anticipate finding evidence that TR47 might be working on other proteins to cause signaling events and protection from endothelial dysfunction.

Abstract Name: **Systematic Review: Canine Hip Dysplasia**

Canine hip dysplasia is an abnormality of the hip joints that occurs in most dog breeds. Hip joint abnormalities are anything from shaped deformity of the femoral head of the hip, undersized or oversized femoral head with the acetabulum, and any diseases that affect the hip decreasing the mobility of the dog. According to data gathered, the main factor that causes hip dysplasia in dogs is genetics. However, external factors like exercise, nutrition, dog breed, and growth rate also influence the susceptibility and rate of intensity in hip dysplasia of dogs. The systematic review was implemented to gather information about different dog breeds in relation to canine hip dysplasia. The data was gathered from scholarly databases using the search terms hip dysplasia in dogs; canine, and the word dog was interchanged with the name of the dog breed being researched. Based on previous literature review the top dog breeds most susceptible to hip dysplasia are English Bulldogs (55%), German Shepherd (50-55%), and Rottweilers (41%). The external causes for hip dysplasia in these dog breeds were weight, nutrition, and excessive breeding. Dogs that are least susceptible to having hip dysplasia are Borzois, Siberian Husky, and Doberman with a prevalence of 1.9%, 5.3%, and 6.1%, respectively. Data still needs to be gathered on why these dog breeds have a low chance of getting hip dysplasia compared to other breeds. This research is important because genetics plays a factor in hip dysplasia susceptibility but there are other factors that may increase or decrease the chance of getting hip dysplasia. If more dog owners knew more about their dog breed they would be able to put their dogs on a proper diet to lower the chances of getting hip dysplasia.
Keywords: Hip dysplasia, genetics, dog breeds, femoral head, acetabulum, systematic review

Abstract Name: **Dignify Dwellings: Habitat Structure for Displaced Communities**

Refugees are not a temporary state; many live their lives or grow in an environment that they do not call home. The immediate need for survival during a crisis uses light-deployable shelters that are not meant for long term conditions. Displaced communities are driven to live in camps where they experience an overwhelming and overcrowded environment. Their need for safety, privacy and dignity is imperative. For that reason, this research focuses on providing a dwelling taking into account three components; what makes a dwelling a home? How can we as designers empower a community? And through which tectonics can we provide feasible dwellings for refugees?As a precedent, Shigeru Ban's shelters use paper tubes, a flexible material that can be found anywhere using adaptable joinery. Using this concept of adaptability, this research aims to develop a flexible system using principles of scaffolding. Scaffolding is accessible, deployable and easy to transport. It can also be applied to different materials such as bamboo, metal, or wood. The aim is to design a module/ system with a mechanism that refugees can assemble without any prior training. The module would consist of a lightweight frame, an enclosing membrane, the earthwork, and the hearth.Besides the tectonics, this research seeks to elevate shelters into a home. The feeling of home is subjective based on people's culture, feelings, tastes, etc. Nonetheless they all share one thing; free-will. Yona Friedman's theory "La Ville Spatiale" empowers the inhabitants to decide by themselves. This approach allows refugees to have authority of their own lives by being able to choose and embrace their homes. My research aims to design a module/system with variations, by exploring joinery and kit-of-parts building techniques. The design strategy is to assemble these modules to become a home and then a community.

Abstract Name: Efficacy of Social and Physical Support for Cancer Patients

Cancer is the second leading cause of death in the United States. In addition, cancer treatments provoke harsh side effects that demand extra strength from the patient. Cancer causes lifestyle modifications that can be detrimental on the patients' health; however, healthy habits can potentially increase the chances of a positive prognosis. Additionally, physical, and social support has proven to help patients in their fight against cancer. Since the lack of physical and social activity in patients with cancer has been shown to correlate with mental and cognitive decline, ultimately reducing quality of life, the purpose of this study is to examine the relationship between physical activity and quality of life in patients with cancer And increase their overall quality of life. This project included eight female participants that are currently struggling with cancer, or the cancer is in remission. The program consisted of group discussions, fine motor movements, and various physical activities twice a week for three weeks. Using pre/post intervention questionnaires and a dependent t-test, the significance of social and physical activities amongst the participants were analyzed. The dependent t-test showed a significant difference (t=-3.729, p=0.007) in the overall quality of life between pre and post program. These preliminary results imply that implementing a support group such as Healthy Habits that includes the use of physical and social activity, improves the overall quality of life of patients with cancer. In conclusion, the program created an additional outlet for individuals with cancer to find a relatable support group that can aid with daily struggles. Further analyses in a larger sample and with longer duration will provide stronger evidence about the relationship between physical activity and quality of life in patients with cancer.

Abstract Name: Education System Vs. Undocumented Students

The American education system is made to provide students access to a bright future; however, for undocumented students that is not the case. The research below will show that the system has limited their ability to experience a system that those who are documented have access to. Due to this, undocumented students face issues related to their mental health, emotional well-being, lack of access to resources, racial injustice, and effects on household. The lack of solutions has led to an unequal education system; however, there is nothing being done to come up with solutions. Although there are holes in education, teachers and those of higher power are not taking the time to understand all that these students face. Undocumented students are left to face these struggles on their own, ultimately setting them up for failure. While some students have the help of DACA,Deferred Action for Childhood Arrivals,they are still limited when receiving an education. Limitations should not exist when it comes to an education that will be their door to an unlimited future.Their fear of getting deported leads to unattended emotional and mental issues (Lad, 2013). Their fear of an incomplete household leads to an unfocused school career (Rangel, 2022). Their lack of resources leads to unreachable goals (Terriquez, 2015). The struggles of others' stereotypes lead to an unfair pathway to success (Lopez,2018). While many think there is only one pathway of education, that pathway comes with many obstacles for undocumented students. The education system has given undocumented students opposition, which is why we decided to bring light to this issue.

Abstract Name: Algae Growth in Relation to Biodiversity of Freshwater Systems in Northeastern Wisconsin

The focus of the study is to determine whether large-scale algae blooms in Wisconsin affect biodiversity in freshwater systems throughout the northeastern part of thestate. We will be focusing on a pond linked to the Fox River system in order to analyze and measure the, overall, biodiversity of the water system. The pond exhibits large algae blooms annually, typically starting to cover 2/3 of the pond surface by June. The study will focus on physical removal of algae using barley straw as a medium of decomposition:One of the products of its decomposition is hydrogen peroxide. Hydrogen peroxide is useful in destroying algae as H2O2 has a weak central bond and will form a hydroxyl radical when its bond breaks. This will target the cell wall of nearby organic compounds, such as the algae, and force the bond to break in order toreform with the radical, essentially killing the algae. The byproducts of this reaction are simply O2 and H2O (oxygen and water). There is no toxic residue left behind in the water. Seeing as the barley straw will be introduced bythe surface of the water, and the reaction will happen relatively quickly, it is unlikely that other organisms will be negatively affected by this process. Any reaction with other organisms such as plants or fish will only damage epithelial cells, however a smaller protist such as algae will be removed quite efficiently. Ostensibly, an increase in the overall health of specific microorganismsshould benefit macro-organismsfurther upthe food chain, as oxygen content increases throughout the freshwater system.

Abstract Name: Religious Counselors and Cultural Competence: When Beliefs Collide

Individuals with a fundamentalist religious orientation respond defensively to challenges against their religious beliefs(Abeyta; Blake, 2020). Individuals who are intrinsically religiously oriented are internally focused and help others based on their own values, whereas quest-oriented religious individuals are altruistic and act based on the values of those they help, (Batson 1976, Batson et al., 1989). Researchers aim to understand the relationship between orientations of religiosity and counselors' perceived multicultural competence with clients. In this exploratory mixed-methods study, 35 counseling students and alumni from a small midwestern religiously affiliated college completed a survey with open-ended questions and scales. The short answer questions ask about faith, experiences in clinical training, and counseling practice. Participants completed the 12 Item Quest Scale (Batson; Schoenrade, 1991), Revised Religious Orientation Scale (Gorsuch; McPherson, 1989), Multidimensional Cultural Humility Scale (Gonzalez et al., 2021), Lesbian, Gay, Bisexual, and Transgender Development of Clinical Skills Scale (Bidell, 2017), and Fundamentalism Scale (McFarland, 1989). Researchers discovered participants who score themselves as fundamentally oriented and see religion intrinsically, score highly in self-awareness. Participants who score highly in quest orientation score highly in competence to work with LGBTQ+ clients. The results were: significant positive correlations between intrinsic and fundamentalist (N=29, r= 0.646, 0.000), fundamentalist and self-awareness (N=29, r= 0.416, 0.25), quest and LGBT DOCSL (N=35, r= 0.384, 0.04), as well as significant negative correlations between fundamentalist and quest orientations (N=29, r= -0.595, 0.001). Qualitative responses indicated that counselors who wrestle with their religious beliefs are more willing to engage clients' values. Conversely, religiously certain counselors displayed more internal conflict and less confidence when helping clients with differing beliefs. These initial results support Abeyta and Blake's (2020) findings that those who are more fundamentalist and intrinsically oriented help others according to personal values.

Abstract Name: Community College "CUREs" Engagement Deficits in Biology

Madison Area Technical College (Madison College) is a public technical and community college serving Madison, WI, and the twelve surrounding counties. Total enrollments exceeded 24,000 students in the 2021-22 academic year, with 42.2% of entering full-time students in Fall of 2020 continuing the following Fall. The Liberal Arts transfer program offers seven tailored pre-majors designed for transfer and satisfaction of the first two years of general studies at some institutions, with the University of Wisconsin-Madison serving as our largest transfer partner. A federally funded initiative to improve transfer student success through the establishment of Course-Embedded Undergraduate Research Experiences (CUREs) was established in majors' biology courses beginning in Fall 2018. This project has resulted in over 500 students participating in skills-focused CUREsin biology courses, and is expanding beyond the target courses to include related courses and programs. Prior to our CUREs implementation, only 18% of students completed abiology majors course series within two semesters. After CUREs implementation, 32% of students complete abiology majors course series within two semesters.Our panel will discuss this, and other outcomes of implementing CUREs in our biology courses, as well as the challenges and opportunities associated with implementing CUREs at a community college. Details about two of our collaborative CUREs initiatives, including ourwork implementing Tiny Earth and Sea Phages across three different biology courses will be highlighted.

Abstract Name: How using TikTok around the clock is associated with symptoms of depression and loneliness among college aged students

Social media has become a huge part of daily life for adolescents all over the world. Previous studies have investigated social media platforms, such as Facebook and Instagram, and the effects they have on college aged students. However, there is a lack of research pertaining to the new social media platform, TikTok. This study will examine the influence of TikTok on college aged students, specifically examining depressive symptoms, levels of loneliness and differences of these associations among genders. This study will consist of two surveys, the CES-D scaleto evaluate depressive symptoms and the UCLA Loneliness Scale (Version 3) to evaluate levels of loneliness. Participants will also be asked to complete a demographic questionnaire. We anticipate that we will find a positive correlation between depressive symptoms and the usage of TikTok, and a positive association between the usage of TikTok and levels of loneliness. We anticipate that there will be different associations depending on gender; females and nonbinary individualsbeing more positively associated to depressive symptoms and levels of loneliness than males.Findings will be prevalent to increaseawareness of the negative effects social media can have on mental health, and to provide universities and college students with updated resources surrounding these issues.

Abstract Name: **Phages are Friends: Viruses Helping to Reduce the Prevalence of Pathogens in Waterways**

Pathogenic bacteria can be found in almost all waterways. Contamination of urban waterway environments by these bacteria could serve as a potential reservoir for infection. Antibiotic resistance is becoming increasingly common among various species of known human pathogens, such as Klebsiella oxytoca and Providencia alcalifaciens, both of which are readily found in streams. This resistance limits the ability of medicine to effectively treat infections caused by these bacteria. One way in which antibiotic-resistant bacteria could be countered is through the use of bacteriophages. Bacteriophages tend to be extremely selective towards potential host cells. Human pathogens such as K. oxytoca and P. alcalifaciens, which can be found in local streams in the south suburbs of Chicago, could potentially be controlled by bacteriophage. Characterizing these bacteriophages will document the ways in which phages impact bacterial populations in local waterways with an emphasis on the prevalence of these two pathogenic bacteria. These effects will be researched in controlled freshwater environments. The host range of the bacteriophages will be evaluated by testing a specific bacteriophage against multiple species of gammaproteobacteria. Metagenomic analysis will be used to establish a connection between the presence of these bacteriophages and the overall microbial community in a given waterway. Bacteriophage could control the populations of pathogenic bacteria, both in the body through phage therapy and as a method of environmental cleanup through phage water treatment.

Abstract Name: **A Naturalistic Conception of Necessity**

This paper explores the issue of philosophical necessity, which sits at the root of modal logic and is a concept of interest for scholars from nearly every field of philosophy. The precise nature of necessity and the correct manner of application, however, are subject to debate. This research offers a new way of considering necessity from a more naturalistic perspective. I suggest a mapping of some of the traditional elements of necessity (composition, number, identity, etc.) to perceptual structures that correspond to demonstrated neuroscientific principles. Further development and verification of this perspective could offer meaningful insight into a number of puzzling questions in different fields of philosophy, mathematics, and more – including the Continuum Hypothesis and the problem of hypertolerance, among others.

Abstract Name: **How Gender Influences Gym Comfort Level in UCO Students, Staff and Faculty**

Background. Physical activity and its positive effect on overall health has been studied for decades. The goal of this research is to understand if there are observable differences in gym comfort level between self-identified genders. Methodology. Researchers curated an online questionnaire to measure one's comfort level in the gym. Data collection spanned over 6 weeks during the summer of 2022. The participants (N = 290) were 24.83% cis men, 65.52% cis women, and 9.66% transgender/gender-non-conforming (GNC). Results included students, staff and faculty with several cross-tabulations functions performed through SPSS 28.0 to examine differences between self-identified genders. Results. Notable results indicated that on a scale of 1-10 (lower scores indicating less comfort) the average result for cis men being 7.90, cis women at 5.21, and GNC individuals at 6.14. Percentages listed indicate a "yes" to if participants are comfortable in certain settings. 83.33% of cis men were comfortable participating in weight training activities in contrast to 35.79% of cis women and 53.57% for GNC individuals. When asked about cardiovascular training, 100.00% of cis men were comfortable as opposed to 76.32% cis women and 75.00% of GNC individuals. Those who were comfortable in the gym in terms of social setting were: 80.56% cis men, 37.37% cis women and 46.43% GNC. Discussion. Through data collected, researchers have been able to support the hypothesis that there are differences in gym comfort levels between gender identities. One limitation was confronting how to protect transgender or non-cis individuals because the response was very low. To do this, all non-cis people were grouped into one category (though researchers acknowledge that there are differences between trans/gender fluid/non-binary individuals). Possible outcomes to this result could be future improvement on making public and private gyms feel more open and comfortable to all genders.

Abstract Name: **Foredune Change on the Duluth-Superior Barrier System: A GPR Analysis**

The Duluth-Superior Barrier System (DSBS) in Duluth, MN and Superior, WI is one of the largest freshwater barrier systems in the world. The DSBS is home to fragile dune and wildlife ecosystems as well as Park Point neighborhood, a small, beach-facing community on DSBS. Wind erosion, increased lake levels, and human modification and activity have threatened the stability and future of the DSBS. Formed by wind, foredunes are ridges located parallel to the shore, anchored by vegetation. Foredunes help stabilize the shore and restrict the amount of sediment transported by wind and wave erosion. Without foredunes the risk of beach degradation and property loss on the DSBS significantly increases. Ground penetrating radar (GPR), a non-invasive method which creates near-surface cross section profiles of the ground below, making it an ideal method for examining the fragile dune features of the DSBS. GPR profiles were taken at various sites along Park Point to image the subsurface. These profiles provide information as to the processes that are impacting and changing the structure of the DSBS. Topographic data was collected with the Topcon RL-H4C laser level and GPR lines with the Sensors and Software pulse EKKO Pro 100 system at frequencies of 500MHz and 100MHz. The profiles were then processed and interpreted using EKKO_Project5 software. GPR lines taken at the northern end (8th St.) of the DSBS compared to lines collected near the middle (27th St.) of the DSBS show sediment loss on the northern end and sediment gain and dune growth at the middle location. The internal layering shown in the profiles and topographic data indicate possible degradation of the beach and foredunes at the northern site and progradation at the middle site. These changes are cause for concern because of the negative impact on residents and ecosystems.

Abstract Name: EFFECTS OF ATYPICAL ANTIPSYCHOTICS IN RATS TRAINED TO DISCRIMINATE BETWEEN 22 AND 2 HOURS FOOD DEPRIVATION

In humans, weight gain is a side effect of atypical antipsychotics. In rats, clozapine increases eating, but reduces food-related, operant behaviors. Ziprasidone has smaller or no effects on eating in rats. Given the short half-life of clozapine in rats, we tested the effects of acutely administered clozapine and ziprasidone on the discriminative stimulus effects of food deprivation. Male, Sprague-Dawley rats were trained to discriminate between 22 and 2 hrs(hours) of food deprivation in a two-lever operant task. Under 22 hrs deprivation, left lever presses were reinforced by a 45 mg food pellet. Right lever presses were punished with 8 seconds of darkness. Under 2 hrs deprivation conditions, the contingencies were reversed. Training sessions lasted until 10 reinforcers were earned or 15 minutes elapsed. Training continued until rats emitted 80% or greater condition appropriate responding before the first reinforcer was earned for 8 out of 10 sessions. After acquiring the discrimination (M = 71, SEM = 6 sessions), subjects were food deprived for 2 or 22 hrs and injected subcutaneously with either clozapine (1.0-5.6 mg/kg), ziprasidone (0.32-1.0 mg/kg) or vehicle (1.0 ml/kg). For the 5 minute or 5 reinforcer test sessions, responses toward either lever were reinforced under the FR 15. Test trials were conducted every 15 min for 2 hrs. After test session, food intake was recorded for 1 hour. Clozapine and ziprasidone did not induce hunger-like responses under 2 hrs deprivation. After 22 hrs food deprivation, clozapine (1.0-5.6 mg/kg) significantly reduced hunger-like stimuli induced by 22 hr deprivation, whereas ziprasidone had no effect. Under both deprivation conditions, clozapine decreased food intake, but ziprasidone did not. These data indicate clozapine decreases feeding-related behaviors in rats. Atypical antipsychotic medications have different effects on food-related behaviors in rats and humans.

Abstract Name: Systematic Review and Meta-Analysis of how Heat and Antipyretics Affect the Course of Viral Upper Respiratory Infections in Adults

Viral upper respiratory infections (URIs) are common (i.e. the common cold) and have caused pandemics in 1918 and 2020. URIs are frequently treated with fever-blocking medications (antipyretics, like acetaminophen or ibuprofen), because they reduce symptoms. However, feveris an evolutionarily-conserved response to infection that mechanistically enhances various immune processes and experimentally improves survival in animals.Human studies exploring the effects of antipyretics on the course or outcome of viral URIs are inconsistent. We performed a systematic review to see how body temperature modulation affects the course of viral URIs in adults. Our primary outcome was time to symptom resolution. We used predefined search criteria of peer-reviewed articles on Embase, CINAHL, PubMed, and Cochrane databases. Inclusion criteria included observational studies and randomized controlled trials of viral URIs (e.g. no antibiotics) in adults that compared antipyretics or heat-based therapies (e.g. sauna or exercise) to a control group. Each article was reviewed by two independent reviewers with discrepancies resolved by a third party. We reviewed the abstract and title of 8886 articles and 140 full texts. Thirty-one studies met inclusion criteria for data extraction, of which 27 studies tested antipyretics and 3 tested heat-based therapies. There was significant heterogeneity among studies and only five studies reported the primary outcome. Meta-analysis of randomized controlled trials found no significant effect of antipyretic use on the average number of days it took to resolve an URI: -0.2 days (95% CI: -1.3 to 1.0) comparing antipyretic group versus control. In conclusion, we did not find evidence that antipyretics significantly prolong URIs overall. However, there may be other costs of blocking fever in URIs (e.g. complications like pneumonia) or antipyretics may prolong illness in specific types of infections or patients. Our inconclusive findings underscore the importance of further research into this common clinical scenario.

Abstract Name: **Examining the St. Olaf First Year Experience**

In the fall of the 2022-2023 school year, St. Olaf College implemented a new First Year Experience (FYE) program. This new program consists of a revamped New Student Orientation (NSO), biweekly St. Olaf Orientation to Academics and Resources (SOAR) programs, and a seminar and writing course requirement, in an attempt to improve first year student satisfaction and success. In order to measure satisfaction and success, we compared data from NSO surveys, SOAR feedback surveys, the St. Olaf Learning Goals Questionnaire (LGQ), and the National Survey of Student Engagement (NSSE), in addition to general retention and student grade information, from this academic year, to similar data collected in previous years. We conducted exploratory data analyses which indicated clear correlations between student satisfaction and the timing of various portions of the FYE program. We then compared summary statistics and ran statistical tests to quantify and validate the trends in our data. These tests and observations indicated significant improvements in satisfaction and success that may be attributed to the new FYE program, such as improved performance on the LGQ in areas corresponding to required seminar content, and increased senses of belonging and connection among students following the week of Student Orientation. However, our work also highlights some aspects of the program with little to no impact on satisfaction or success, such as a majority of required biweekly SOAR sessions. Based on our results, recommendations will be made to St. Olaf College in order to revise and alter the FYE program for future incoming students.

Abstract Name: **Mental Health In Athletes**

Athletes who are in higher education, collegiate athletes, are individuals who can struggle with addressing concerns related to their own mental health. Athletes can develop these ailments due to their environment: self-esteem stigmatization, sport-related injuries like concussions, influences from coaches, their view on social status, and even overtraining. This research examines the effectiveness in outreach programs and the outcomes from having a mental illness as well as correlational factor of stress. In an attempt to analyze athletes and their stressors, a survey was directed to those who participated in sports. The search for a correlation between coaches and causes of stress, questions were asked in a survey related to athlete stress and relationship with the coaching staff. The participants responded with 'probably yes' and 'probably not'. This showed that athletes were prone to facing stress at an average and above-average level. Stressors and rehabilitation in athletes are reported to have been extremely difficult. Results reported back that athletes definitely struggle to reach out to others. The group also searched for solution rates regarding outreach encouragement with peers and coaches. The report shows a vast majority responded that they weren't encouraged by others. The results showed that mental illness is potentially still a hidden topic across the sports world. This study aims to help support the research that collegiate athletes do experience mental ailments and that these ailments are caused by many factors: the responsibilities of training and overcoming challenges, the consequences of injuries, and advice from coaches or peers.

Abstract Name: Borodin String Quartet No. 2

Borodin's Second String Quartet in D Major is a piece that requires advanced ensemble techniques, fine intonation work, and balanced melodies. It is an essential quartet piece within the string repertoire, and one which our group has grown from immensely while preparing.
The passing of melodies from cello to first violin and viola to second violin requires eye contact, breathing, and togetherness as a group. Borodin includes immediate tempo changes marked at the two animatos, as well as poco a poco dim. e rit at the end of the piece.
Beginning in the deceptively easy key of D Major, intonation inaccuracies are not easily hidden in this piece. Several moments require the performers to play in unison or octaves, and every chord must be carefully tuned. Compounding this, the piece changes keys several times during its development. The F#s in these keys are naturally dissonant and difficult to tune, especially in a group setting. Our quartet has spent hours together refining our intonation.
Throughout the piece, the first violin and cello converse with each other by trading the main melody. Later in the development section, the melody is passed around to the rest of the quartet. At the recapitulation, the cello hands the melody to the viola, requiring a strong sense of balance among the group. Because of this, our quartet has been working on balancing the melody and the accompaniment. The passing melodies require each member to use the same bow techniques and distribution, keeping everything uniform and beautifully phrased.
An influential work for any group, Borodin's second string quartet blends beautiful melodies and textures with flawless technique to create a timeless masterpiece.

Abstract Name: Investigating the use of crayfish as environmental water quality sentinels for metal pollution in Indiana creeks

Ephemeral creeks and streams can be difficult to monitor and assess for water quality. Unfortunately, these same water systems can play a significant role in the input of metals and other pollutants into major waterways. Metals are often the result of nonpoint source or historic point source pollution that is no longer active, making assessment and exposure prevention difficult. An economical and reliable approach to determine water quality in these areas would be the use of reliable sentinel species that are endemic, easily identified, and respond in a quantifiably way to metals in the environment. Macroinvertebrate assemblages have been historically used to create comprehensive biotic indexes, but these indices can be complicated, seasonal, and difficult to assess without identification bias. For this project, crayfish samples, water samples, and sediment samples were collected in several creeks in Indiana representing a variety of environmental exposures. We hypothesized that because are omnivores and biotic engineers, their environmental interactions place them in a unique niche making them a reliable sentinel species. By testing and comparing the bioaccumulation of metals in crayfish tissue, water, and sediments to dominant species, average crayfish size, and population density, we can reliably predict creek health for metals. Our results determined thatFaxonius rusticus(rusty crayfish) were found in creeks with higher environmental metals. Also, crayfish cephalothorax measurements were smaller in higher metal environments. This data, along with metal bioaccumulation and biomagnification make crayfish an excellent sentinel for water quality in creeks.

Abstract Name: Role of Motivation on Academic Success

The collegiate world is constantly discussing how student motivation is related to student success. How true is this correlation? Does the motivation importance change with the specific course or the format the course is taught in? Can the institution or instructor impact the student motivation level by understanding intrinsic and extrinsic factors that motivate students? The aim of this study is to determine what motivation in education is and how it impacts the academic success of college students. Factors that will be studied include intrinsic and extrinsic motivation factors, academic performance, familial college experience (1st generation students vs non 1st generation students), and the role of the institution and faculty. The study will be completed through a survey with a battery of questions adressing all the key areas mentioned above. Demographics will also be collected to compare possible inter-group differences. Correlational analysis will be completed through data collection in the spring semester of 2023.

Abstract Name: The role of response format in assessing the impact of increased video playback speed on comprehension

Background: The use of asynchronous video lectures as a means of content delivery has become a common feature of college courses. This is obviously true of online courses; however, the steady growth of asynchronous learning approaches in face-to-face classes has accelerated rapidly in response to the COVID-19 pandemic (Lee, 2020). This requires students to play a more active role in self-regulating their learning; however, this also allows students greater flexibility in choosing how they engage with lecture content. Consequently, students often watch online content at accelerated speeds. To date, research findings have been mixed as to whether this negatively impacts comprehension (Lang et al., 2020; Murphy et al., 2021). Performance discrepancies among studies may be partly explained by differences in the response formats used to assess comprehension (Collins et al., 2020). The current study aims to describe the role of response format (i.e., open-ended vs. multiple choice questions) in evaluating the impacts of increased media playback speed on comprehension.Methods: Thirty-five college-aged students watched three 15-minute researcher-created video lectures relating to cognitive psychology, each presented at a different playback speed (i.e., 1x, 1.5x, 2x). After watching each lecture, participants answered ten multiple-choice and ten open-ended questions to assess comprehension. Each question set had two versions with identical question stems but different response formats. Videos and question sets were counterbalanced across participants to reduce ordering effects. Analyses have not yet been completed. We expect higher scores on multiple-choice questions and slower playback speeds. We also expect the open-ended questions at 2x speed to be disproportionately harder than other conditions. The application of findings to pedagogy and student study strategies will be discussed.

Abstract Name: Potential Anti-Cancer Effects of Chromene Thiazole Thioether Derivatives

Previous studies have shown that chromene-based compounds exhibit anti-cancer properties as a result of their ability to function as microtubule destabilizing agents. Thiazole and thioether also function as notable pharmacophores with anti-cancer properties. Using a library of in-house synthesized chromene thiazole thioether compounds, we hypothesize that these compounds will have enhanced anti-cancer abilities compared to the individual components and will function by affecting microtubule stability. The derivatives vary by a heterocyclic ring structure, and we aim to examine how different structures affect reactivity with tubulin. Primary molecular docking studies completed with AutoDock Vina demonstrated promising binding affinities between the synthesized compounds and the colchicine binding site of tubulin. The destabilizing agent, nocodazole, has a binding affinity of -.6.4 kcal/mol whilst the synthesized benzimidazole derivative has a greater binding affinity of -8.4 kcal/mol. All compounds achieved a binding affinity between -7.0 and -8.4 kcal/mol indicating promising reactivity with tubulin. To analyze the effect of the compounds on microtubule dynamics, we are now conducting in-vitro tubulin polymerization assays to observe their impact on the rates of polymerization relative to paclitaxel (a stabilizing agent) and nocodazole (a destabilizing agent). We will also be testing the compounds on a human cancer cell line (A375) to examine their anti-mitotic effects.

Abstract Name: Potential Molecular Probes from Derivatives of Diphenylpyraline for Cannabinoid Receptor

Brain complexity regarding reward mechanisms has been studied for decades to uncover individual behavior related to motivation. Cannabinoid 1 receptors (CB1R) are located in the part of the psychoactive region of the brain and play a role in the reward system of psychostimulants. It has been shown that diphenylpyraline (DPP) and its analogs bind to CB1R. Hence, developing a CB1R selective probe could help provide more insights into brain reward mechanisms. To accomplish this, molecular modeling using Schrodinger software, synthesis, and biological testing using an iterative approach is being used to uncover the best compounds. Fortunately, the synthesis of most molecules is accomplished in under five steps depending on the method and optimization procedures are reported herein. The modeling leverages the protein data bank structure of CB1R. Molecular docking experiments performed on the CB1R structure (pdb 5TGZ) generated a five-point pharmacophore model for the binding of halogenated DPP analogs within the cannabinoid receptor. Calculated binding energies for the halogenated piperidyl analogs docked to CB1 agree with in vitro data, with fluorinated compounds having greater affinity than chlorinated compounds. This initial modeling informs a synthetic strategy where combinations of hydrophobicity and halogen additions on the phenyl rings may afford access to greater specificity and affinity for the respective protein targets. Optimization of these compounds using a pharmacophore approach could lead to greater specificity and affinity for the CB1 receptor. This rational approach to small molecule development has the potential to produce DPP analogs for use as novel molecular probes. In addition, toxicity studies conducted inform if the compound is suitable for animal models. Results from this iterative approach are reported herein.

Abstract Name: **Influence of Magnetic Fields Generated by Atmospheric Cold Plasma on Superoxide Dismutase Activity**

Cold plasma (CP) is a novel nonthermal processing technology that has recently shown great potential for use in the food industry to decontaminate foods and food contact surfaces. Generation of CP produces ionized gases with excited and reactive species, suggested to inactivate microbes due to irreparable membrane and/or genetic damage. Understanding of mechanisms of microbial inactivation by CP has proven complex, dependent on surface/microorganism type, gases present, and system setup. Specific CP systems, such as dielectric barrier discharge (DBD) generate atmospheric CP (ACP) at atmospheric pressure. Treatment using DBD ACP requires induction of a strong electromagnetic field. Previous research suggests that at certain magnitudes of magnetic field strength, superoxide dismutase (SOD) activity increases significantly within bacterial cells. The proposed mechanism of this increase in activity is thought to be enhancement of co-factor binding (e.g., Mn2+) to SOD. Considering DBD ACP (a) generates a magnetic field and (b) produces free radicals, reactive oxygen, and nitrogen species, the objective of this study is to characterize the influence of magnetic fields generated by ACP treatment on SOD activity and bacterial cell viability.Preliminary results indicate an increase in magnetic field strength decreases cell viability with a concomitant release of 260-nm absorbing material. However, differences in cell membrane leakage between magnetic field strength treatments were insignificant, even as cell viability decreased with increase in magnetic field strength.Further studies will characterize the relationship between magnetic field strength and cell viability at different ACP voltages. The activity ofSOD will also be measured in conjunction with increased magnetic field strengths to support cell viability results. The final results may indicate a simultaneous increase in SOD activity and cell viabilityat a specific magnitude of magnetic field strength.

Abstract Name: **Using Enzyme-Linked Immunosorbent Assays (ELISA) to Understand Insulin-Degrading Enzyme (IDE)-Phosphatidylinositol Phosphate (PIP) Lipid Interactions**

Insulin-degrading enzyme (IDE) has been linked to Alzheimer's Disease and Type II Diabetes due to its function in degrading insulin and the amyloid-beta peptide. IDE is, therefore, a potential therapeutic target for these diseases. This research aims to identify how IDE produced in the cell cytosol accesses its substrates, which are likely cleaved within the cellular endosomal system. It is hypothesized that some IDE localizes to endosomes by initially binding to phosphatidylinositol phosphate (PIP) lipids located in the endosome membranes. Computational docking studies suggested a site on IDE that might mediate an interaction with PIP lipid head groups. An enzyme-linked immunosorbent assay (ELISA) was used to evaluate whether mutations in this putative binding site disrupt interactions with artificial liposome membranes doped with PIP lipids. Results show that the mutations do affect PIP binding, with the variants IDER824A,H885A,R892A and IDEQ813A,N821A,H885A having reduced or no detectable interaction with liposomes bearing phosphatidylinositol 4,5-bisphosphate (PI(4,5)P2). This loss or reduction of PIP interaction supports the hypothesis that IDE interacts specifically with PIP head groups and that this interaction is mediated by the proposed binding site. Improved understanding of this mechanism could someday enable the development of therapeutics for AD and/or diabetes mellitus and explain why these diseases are frequent comorbidities. While studying IDE-PIP interactions it was also observed that PIP lipids can bind in the inner chamber of the clamshell-like IDE molecule. The lab previously obtained a crystal structure detailing this binding interaction. Future work will investigate the possibility of IDE having a second function as a lipid transfer protein, which the lab is beginning to explore using a liposome-based lipid transfer assay.

Abstract Name: **The effects of chronic mild stress on traumatic brain injury recovery**

Traumatic brain injury (TBI) is a debilitating condition which results from a concussive blow to the head and can produce epilepsy, mental health issues, and cognitive and behavioral impairments. The long-term impacts of TBI include brain edema, hypoxia, as well as damage to neural processes, the effects of which may compromise blood-brain barrier function and promote inflammatory responses. It is not clear if prolonged exposure to stress exacerbates symptoms associated with TBI thus the current experiment addresses the impact of chronic mild stress (CMS) on anxiety-like and depressive-like behaviors in a mouse model of TBI. The current study also assesses the combined effect of CMS and TBI on gliosis, the process through which glial cells respond to central nervous system damage. Using S100β staining, we quantified the extent of gliosis in the cortex and hippocampus of mice exposed to CMS, TBI or a combined treatment of both CMS and TBI.

Abstract Name: **Engage Students in a Lab class with a Research Collaborator**

Here we present a model of engaging undergraduate students in a laboratory course-based biomedical research experience. Students learn mammalian culturing skills and how to monitor cell behavior using assays that can also generate preliminary research data. Most of the research has involved testing chemicals or extracts that might have therapeutic purposes. The students finish the class with skills they can use to get an entry-level or part-time position in a biological research facility, or they may consider changing their career plans. Numerous students continued to seek out research opportunities having learned that undergraduates can indeed conduct research. Because the research is course-based, most of the material costs for the researcher are related to the variable being tested, such as chemicals purchased for this unique experience. Our experience with this model has been encouraging, however there are challenges including buy-in from collaborators, difficulty in quickly producing results, the time required to manage the model, and collecting publishable data. This model could be effectively employed to test the behavior of genetically-altered cells.

Abstract Name: Improving the Strength of 3D Printed Material by Inducing Low Frequency Vibrations

3D printing is a cost-effective option compared to other manufacturing methods but the printed parts from conventional materials (PLA+,PETG,ABS) often do not exhibit great tensile strength. The limitations come from the amount of the material and the fill factors used. Traditional methods to increase tensile strength include applying greater infill factors and thicker sample features but these methods may result in greater printing times/cost. To overcome this limitation, work at San Jose State university is inducing low frequency (5-10Hz) vibrations during the printing. For this purpose, a vibration motor (ERM/MTR/9000RPM-1.3V) was directly attached to the nozzle of the printer (Tronxy/X5SA). A special holder was used to hold the motor to attach it to the printer head to induce vibrations during the printing. For the overall dimensions of the specimen, ASTM-D638-Type-1 standard was adopted that gave the printed samples a thickness of about 7 mm. Different printing conditions included the variation of the fill factor (20%,60%,100%) with and without vibration. The printed samples were examined against the porosity and a fluid displacement method was adopted. Experiments show that induced vibrations were able to lower the porosity by 10 to 15% for identical fill factors. Initially samples were sent to Applied Technical Services (Gorgia) and the tensile strength for all printed samples (100% fill factor) with and without induced vibration was measured. The testing results indicate that for our 3D samples, induced vibrations did increase the tensile strength from 26.2 to 30.7MPa (~17% increase) for the corresponding applied loads of 4.1kN to 5.15kN respectively. The corresponding increase in the maximum stress was about 15.7% for 60% fill factor printed parts. New results from an inhouse testing machine at SJSU are being collected and analyzed. Final presentation will include full discussion on the impact of induced vibrations for various sample materials.

Abstract Name: Education System Vs. Undocumented Students

The American education system is made to provide students access to a bright future; however, for undocumented students that is not the case. The research below will show that the system has limited their ability to experience a system that those who are documented have access to. Due to this, undocumented students face issues related to their mental health, emotional well-being, lack of access to resources, racial injustice, and effects on household. The lack of solutions has led to an unequal education system; however, there is nothing being done to come up with solutions. Although there are holes in education, teachers and those of higher power are not taking the time to understand all that these students face. Undocumented students are left to face these struggles on their own, ultimately setting them up for failure. While some students have the help of DACA,Deferred Action for Childhood Arrivals,they are still limited when receiving an education. Limitations should not exist when it comes to an education that will be their door to an unlimited future.Their fear of getting deported leads to unattended emotional and mental issues (Lad, 2013). Their fear of an incomplete household leads to an unfocused school career (Rangel, 2022). Their lack of resources leads to unreachable goals (Terriquez, 2015). The struggles of others' stereotypes lead to an unfair pathway to success (Lopez,2018). While many think there is only one pathway of education, that pathway comes with many obstacles for undocumented students. The education system has given undocumented students opposition, which is why we decided to bring light to this issue.

Abstract Name: 3D Solid State Lithium-ion Battery Simulation

Currently, one of the most popular technologies for the development of a new generation of batteries is solid-state lithium batteries. One of the challenges with researching these batteries is that it is expensive and time-consuming to conduct research with physical materials. For this reason, computer simulations are employed to carry out these studies, but many of the current simulations are limited to models in one dimension (1D) and two-dimensions (2D). In this research, we utilized AutoCAD design software and battery design module to creating a simulation of a 3D solid-state lithium-ion battery on COMSOL Multiphysics. COMSOL is a modular software which is utilized to be able to perform diverse types of simulations.We use the Introduction to Battery Design Module model representation from COMSOL as a guide that contains the instructions for reproducing a 2D lithium-ion battery model, and were able to develop a representation with the same dimensions in AutoCAD but with added three-dimensionality (3D). Once the 3D model of the battery was designed, and assuming a single ion conducting interface, we combined the AutoCAD import module and implemented the 3D structure on COMSOL. The single-ion conducting interface is employed to theoretically simulate a solid electrolyte, which makes our electrolyte behave similarly to such system. Since COMSOL incorporates a library with several materials, one can easily simulate across various compositions. Such simulation can be used to investigate a diverse list of materials when implemented in the solid-state battery and thus be able to develop improved physical experiments with the materials that can produce optimum results.

Abstract Name: Modern Medicine Vs. Traditional Medicine: Systematic review a Covid-19 analysis

SARS-CoV-2 (Covid-19) is a respiratory virus that fluctuates in severity depending on the physical state of a patient. Symptoms that may arise due to Covid may range from a mild cough, light fever, to organ failure. Modern medicine is separated from traditional medicine in the sense that the use of evidence, research, and testing is used consistently for the development of treatments for different illnesses and in this case Covid. Traditional medicine is a form of ancient medicine that has been passed down for centuries with the focus of mentality, physicality, and spirit always being the front runner. The purpose of this research is to compare the efficiency of both modern and traditional practices and how they compare in treating Covid. A systematic review was performed by extracting information from numerous articles comparing the different forms of medicine used to treat or reduce symptoms of Covid. Using modern medicine alone to treat covid showed to be effective however based on the data from clinical trials recovery rate and improvement rate of symptoms took longer when treated with modern medicine alone.Modern medicine is used to treat the virus itself while the side effects are still potent in patients who go the modern route for treatment. In traditional medicine the body as a whole is the main focus in treatment meaning the symptoms are what's targeted with traditional medicines. Based on the literature review it is concluded that the use of both traditional and modern medicine is the most effective for treating Covid as whole (the virus and the symptoms). Since the coronavirus is known for mutating at a fast rate, the information from these clinical trials is useful in demonstrating how the use of modern and traditional medicine is necessary to treat a virus like Covid.

Abstract Name: **Behind the Scenes of Dark Triad Traits: A Study of Neurocognition and Emotional Processing**

The Dark Triad consists of personality traits of Machiavellianism, narcissism, andpsychopathy. These traits have been found to be negatively correlated with empathy.Machiavellianism and psychopathy traits have also been demonstrated to be associated withpoorer self-control, whereas narcissism and psychopathy traits have been linked to impulsivity. However, still little is known about the relationships between Dark Triad traits and other aspectsof neurocognitive processes. This ongoing study examines a broad scope of neurocognitive processes (i.e., self-control, inhibition, impulsivity) and emotional processing (i.e., emotionalawareness, and empathy) to determine specific predictors of Machiavellianism, narcissism, andpsychopathy traits in university students Data are currently available on 53 university students. Participants' personality traitswere assessed using the Short Dark Triad questionnaire. Neurocognitive functioning wasmeasured using the Tangney Self-Control Scale, Stop-It Inhibition Test, and The BalloonAnalogue Risk Task (BART). In addition, participants' emotional awareness was assessed usingthe Toronto Alexithymia Scale, whereas empathy was measured using the Empathy Quotient. For the interim analyses, traits of Machiavellianism were regressed on the five neurocognitive predictors (self-control, inhibition, impulsivity, emotional awareness, andempathy), using a simultaneous multiple regression procedure. The regression analyses revealedthat among the predictors, response inhibition (Beta = -0.001; t = -1.975, p = .05), emotional awareness (Beta = -0.011; t = -2.113, p = .040), and empathy (Beta = -0.026; t= -4.603, p = .0001) were significant determinants of Machiavellianism traits, whereas only empathy (Beta = -0.025; t = -2.785, p = .008) was the strongest determinant of psychopathy traits. However, none of the neurocognitive processes were significant predictors of traits of narcissism. Preliminary findings from this study could potentially expand our understandingthe specific roles of neurocognitive functioning in individuals with the Dark Triad traits.

Abstract Name: **Analysis of the Effect of Temperature on Red Light Responses in Arabidopsis thaliana**

Plant responses to red (R) and far-red (FR) light are mediated by the phytochrome (phy) pathway. Many details of this pathway are unknown, including how it interacts with other environmental signals. Work by our lab and others has shown that two genes called Light-Response BTB 1 and 2 (LRB1 and LRB2) regulate the phy pathway in the plant Arabidopsis thaliana by encoding proteins that induce phy degradation. Plants containing mutations within both genes (lrb1/lrb2 mutants) display hypersensitivity to R because of increased phy levels. Our lab has conducted genetic screens to identify lines ("enhancer mutants") with mutations that increase the lrb1 lrb2 R hypersensitivity. The enhancer mutations in the lines thus far characterized are located in the phyB gene, which encodes the phy that is the primary mediator of R responses in Arabidopsis. Recent work by other groups has shown that phys also act as temperature sensors, as temperature affects the rate at which the phys convert between their inactive and R-promoted active forms. Given their role in modulating phy levels, the LRB genes may also mediate temperature responses. Furthermore, our phyB mutations might alter temperature sensing. We are investigating this by comparing the effects of different temperatures on R responses in lrb1 lrb2, enhancer mutant, and wild-type plants. The lines have been grown under red light at 26°C (warm) and 22°C (room) temperatures under "short-day" conditions (8 hours of light and 16 hours of darkness). Hypocotyl length in seedlings was measured and compared, as this length is a sensitive and quantitative measure of light response. These experiments are ongoing and our results will be presented.

Abstract Name: **Determining the Community Dynamics of Siderophore-producing Bacterial Cultures from Carlsbad Caverns National Park (CCNP) Caves, Carlsbad, New Mexico**

Siderophores are produced by microorganisms to acquire essential ferric iron. Siderophores are crucial for microbial survival, but the function of siderophores for subsurface cave microorganisms have not been extensively studied. Due to the essential function of siderophores, microbial siderophore-producers have been suggested as helpers in a microbial community that have unculturable bacterial members. We are interested in understanding the community dynamics of mixed cave cultures (more than one type of bacteria per culture) that previously showed siderophore-strong and -weak production. We hypothesize that mixed cave cultures contain a siderophore-producer helper that aids the growth of an otherwise unculturable culture. Cave cultures were isolated from ferromanganese depositslocated in Spider Caveand Lechuguilla Cavefrom Carlsbad Caverns National Park (CCNP). Siderophore-producing cultures were grown at 20°C on three types of sterile agar plates and used to determine the colony morphologies, gram status, and to complete 16S rRNA gene sequencing. The majority of both groups, siderophore-strong and -weak cave cultures showed that the morphologies had a cream, translucent, and smooth appearance, with only one culture named 1-3, that had a yellow morphology. Using Gram stain, 60% of the siderophore-strong and -weak cave cultures demonstrated that they were mixed with at least two different bacteria and 40% had one bacterium. 16S rRNA gene sequencing showed that three of five siderophore-strong cultures were mixed with two or three different phyla. Three of five siderophore-weak cultures were shown to be mixed with two different phyla. Interestingly, two common phyla member pairs,Bacteroidetes/Beta-ProteobacteriaandBacteroidetes-/Alpha-proteobacteriawere shown in both siderophore-strong and -weak, with at least one of the members to be an uncultured bacterium clone. Overall, the siderophore-producing cave cultures revealed microbial-pairs of phyla that may provide insights to how cave microorganisms survive in an oligotrophic environment.

Abstract Name: **An Analysis of Youth in an Upward Bound Program**

This research project focused on a strength-based assessment for youth entering the Upward Bound program. The Upward Bound program is a program at UW-Eau Claire that is federally funded and dedicated to the preparation for, admission to, and successful completion of a college degree. This program applies to first-generation and/or low-income high school students. The research collection focused on identifying assets in the students' lives and the strengths they possess, rather than analyzing the hardships they face and skills they may lack. The reason for this positive approach is that it has been found in past Upward Bound programs to better cultivate concrete change. This prompts students to first acknowledge and celebrate the networks they already have built around them. In order to further understand their environments a mixed-method approach was used. The qualitative data was collected through interviews, in which the questions focused on the participant's school experience, neighborhoods, and what their typical day at home would look like. In addition, the participants created ecomaps, timelines of important life events, and genograms. This process allowed for a connection to be built between the researcher and the participant. As for the quantitative data, the participants were given a Strengths and Difficulties Questionnaire (SDQ) that focused on their emotional well-being. Through this research, it was shown that COVID-19 has negatively impacted youth and their environments. The SDQ total of 2022 has shown an increase in conduct problems, peer problems, hyperactivity, and prosocial skills in comparison to 2019. As for the qualitative analysis, key themes were safety issues (drug use/ fighting) at school as well as racism/inclusivity.

Abstract Name: **Understanding Anatomy & Physiology students' knowledge and perceptions of learning sexual health**

The purpose of this research is to understand Anatomy; Physiology (AP) student's knowledge and perceptions of learning about sexual health and sexual pleasure. Investigating the understanding of this will entail analyzing surveys on students' knowledge of sexual health and their perceptions of learning about sexual health in both class settings and out of class settings. The surveys will also allow us to compare student growth in the subject from the start of the semester to the end of the semester of their AP classes. The overall purpose of this project is to include sexual pleasure in AP context. By adding this context in AP it will cause science to be significantly more inclusive. Especially when using sexual pleasure and the associated anatomy and physiology to represent a true variation of people, not just androcentric and heteronormative people but also LGBTQ+ communities, experiences, and bodies. It is important to realize that by including a truer variation, science communities will gain valuable perspectives, acceptance, and it will provoke new thinking. Additionally, as a result of adding sexual pleasure in A&P context, it will prepare healthcare professionals when having conversations or treating sexual health matters. For having sexual pleasure education in AP context can empower individuals in their own bodies. For this reason, it is important to consider the knowledge and perceptions of students in order to incorporate sexual health and pleasure into undergraduate curricula.

Abstract Name: **CIBERSORTx: Deconvolution of Glioblastoma Transcriptomics to Quantify Tumor Heterogeneity**

Glioblastoma (GBM) is the most aggressive primary brain tumor characterized by biological heterogeneity within and between patients. Deconvolution methods have shown recent promise in their ability to characterize tumor heterogeneity by enumerating cell state abundances and their gene expression levels from cheap bulk RNA-Seq datasets using a single cell RNA-Seq reference. However the accuracy, reliability and reproducibility of these methods remains challenging to assess particularly when most require these reference datasets to be downsampled. To assess these metrics we selected CIBERSORTx, a machine learning deconvolution framework to predict cell state composition and cell-specific gene expression levels. Moreover, we conducted univariate and multivariate Cox proportional hazard models to test whether these cell state abundances are prognostic. We have applied CIBERSORTx to two separate cohorts of bulk RNA Seq: image-localized biopsies from Mayo Clinic and Barrow Neurological Institute (157 samples, 44 patients), and TCGA (173 samples, 166 patients) along with a single nucleus RNA-seq reference cohort (32980 cells, 22 samples, 7 patients) that has 18 cell states, which cover a variety of tumor, immune and normal cells. First pass analysis shows similar cell state abundances and cell-state correlations between cohorts. We found 6 prognostic cell states for overall survival in univariate analyses. Our work not only provides more biological insight for treatment stratification, but uses this approach to connect omics and imaging to gain a deeper insight into GBM heterogeneity non-invasively.

Abstract Name: **Quantifying the Relationship Between Arbuscular Mycorrhizal Fungi and a Native and Invasive Thistle**

Our research explored the relationship between arbuscular mycorrhizal (AM) fungi and two prairie plants – the native Pasture Thistle (Cirsium discolor) and the invasive Canada Thistle (Cirsium arvense). AM fungi associate with the majority of plants and assist in mineral nutrient uptake. In return, they receive photosynthetically fixed carbon from host plants. Their relationship with plants can be quantified by assessing dependence upon and responsiveness to AM fungi. Dependence is defined as the plant's inability to grow without AM fungi while responsiveness is the growth difference between inoculated and non-inoculated plants. We hypothesized that Pasture Thistle would have a stronger responsiveness and dependence on AM fungi than Canada Thistle because of the degraded mutualism hypothesis, which states that invasive species do not associate with local mutualists as closely as native plants. To test this hypothesis, we grew plants with and without AM fungi at ten different soil phosphorus levels, with twelve replicates per treatment. We measured the longest leaf length and height weekly, and after 10 weeks of growth, determined overall root and shoot biomass. We found that Pasture Thistle and Canada Thistle could both grow without AM fungi. Pasture Thistle was more responsive to AM fungi, growing 37% better when inoculated than when not inoculated, while Canada Thistle, showed a negative responsiveness. These results support our hypothesis that the invasive species would have a degraded mutualism with AM fungi. It is likely Canada Thistle lacks a strong relationship with AM fungi because it grows in disturbed areas where there is a low AM fungal presence.We also found that Pasture Thistle was most responsive at a soil phosphorus level similar to that in its native range, suggesting that it likely has a shared evolutionary history with AM fungi.

Abstract Name: **Randomly Generating the Unknot**

The definition of a knot in knot theory is an embedding of a circle in 3-dimensional space. Two knots are called isotopic if they can be deformed to each otherwithout cutting or passing a strand through another. Knot theory was first introduced in the 1960s by chemists Frish-Wasserman, and biologists Delbruck-Fuller. We study a new perspective on the theory of random knots based on the universal knot diagrams introduced in a recent paper by Even-Zohar--Hass--Linial--Nowik. We ask what the probability of a randomly generated potholder knot is unknotted. A potholer knotconsists of a family of knots starting with an n-by-n square grid. As the parameter n goes to infinity every knot admits such a diagram. By studying small potholder diagrams, we present some numerical evidence toward the conclusion that the probability of a randomly generated potholder knot being unknotted should be zero. We present explicit computations of theexpansion of these potholder diagrams in one direction. By studying the process of randomly generating a potholder knot in terms of a Markov chain, we present forward progress towards proving this result. These preliminary results represent a work in progress.

Abstract Name: **Computational Discovery of an Inhibitor to APOBEC3B as Treatment for Cancers**

APOBEC3B is a naturally occurring protein in humans which has the purpose of fighting off certain ailments, such as HIV, by changing certain nucleic acids in our DNA. For immunity purposes, it is typically beneficial to have such a protein in our bodies. However, fitting with the textbook definition of cancer, the problem occurs when there is an overexpression of APOBEC3B in our bodies. At that point, APOBEC3B begins to convert too many nucleic acids, and this helps create more mutations in our cells which in turn creates tumorous bodies as the cells begin to replicate rapidly. The goal of this research would be to help find an inhibitor for the APOBEC3B protein from a database of unresearched ligands to keep the protein from binding to our DNA and creating hazardous cell growth. The primary source of these potential inhibitors isthe ZINC12 database from which we have already sorted through six million different candidates to find the top 200.From the six million candidates, the top 30 have been selected based on how easily they might bind to APOBEC3B. Now, similarities havebeen found between those top candidates and then improved upon using chemical intuition and drug design techniques to create the best drug possible. However, we have also used a novel technique,de novo ligand design, which uses software to assemble entirely new candidates based on those same top 30 candidates. We have now simulated those de novocandidates in the same manner as the previous candidates, and this analysis has produced a promising inhibitorof APOBEC3B, and keptthe drugbound to the protein in increasingly more realistic situations.

Abstract Name: **Interventionism and American Foreign Policy: Tracking Public Opinion on U.S Foreign Policy and Recent International Events**

On August 26, 2021, 13 U.S. service members were killed during the final departure of U.S. Forces from Afghanistan after 20 years of war. This incident has brought U.S. foreign policy decisions into the spotlight. As soldiers and Gold-Star families begin to process the disaster in Afghanistan, more and more Americans grow concerned with American foreign policy. The results of this work will assist in our understanding of how young citizens are being affected by the current political climate, and how their identity might present a bias in their opinions on foreign policy.In order to link certain demographic qualities to feelings on U.S. foreign policy, we conducted a survey consisting of open and closed-end questions regarding demographics and exclusive questions relating to foreign policy. A total of 121 students from Eastern Connecticut State University participated in this research to give us an interpretation of the feelings of students toward this topic. Overall, the findings displayed throughout this research established a relationship between the variables we cared to examine. For example, one of the biggest findings was that democratsare 15.02 times more likely to believe that the United States should play a role in hosting refugees as it relates to foreign policy. This generation has seen unprecedented global instability and the ultimate goal is to understand the impact of recent events and how one's social/political identity has impacted this. Hopefully, these findings will motivate others to audit their own beliefs and see the other side of the fence in terms of policy.

Abstract Name: **Increased Intake of Alpha-Linolenic Acid is Associated with Higher Exam Scores**

Roughly 60% of the human brain is fat. Essential fatty acids (EFAs) Linoleic and alpha-linolenic acids are critical for building the brain's structure, synthesis of neurotransmitters, and developing the visual cortex, among other important functions.This study investigates how EFAs intake may affect brain function, and if these effects are reflected in student exam performance. We hypothesize that increased consumption EFAs will be associated with higher test scores.An analysis of cognitive function based on exam scores was conducted on 602 student participants attending Weber State University. Two-day diet records were collected. Grams as well as percentages of recommendation consumed based on required calories of linoleic and alpha-linolenic EFAs were calculated from the diet record using Diet and Wellness Plus software. The data analysis was completed using RStudio. Models were created using linear regression and variables were removed based on p-value using backward elimination. The best model created included the following variables: LinoleicCal% (the fraction of the total calories required provided by linoleic fatty acid), α-LinolenicCal% (the fraction of the total calories required provided by alpha-linolenic fatty acid), and the interaction between the previous two variables. Exam scores increased by 5.43 times, for each additional α-LinolenicCal% percentage increase ($p = 0.01$). For each percentage increase on both LinoleicCal% and α-LinolenicCal%, exam scores decreased by 0.27 times ($p = 0.02$).Our results show that it is not only the amount but also the ratio in which these two fatty acids are consumed that influences exam score performance. This is in accordance with previous studies showing that intake of omega-3 polyunsaturated fatty acids are inversely related with risk of impaired memory and flexibility in middle aged adults.

Abstract Name: **Welcoming The Dear Neighbor: The Catholic Interracial Council Twin Cities**

Conversations surrounding racism both on individual and systemic levels continue to be at the forefront of American society. Our research aims to understand the tensions between individual and systemic solutions to racial change in the context of the Twin Cities during the 1950s and 60s. Though implications of racist thought have permeated the country for centuries, the 2020 murder of George Floyd and subsequent recent racial unrest in Minnesota has increased conversations concerning systemic change. To understand how systemic change will look in the future, we must first understand the efforts of the past. Our research centers on one national organization striving for change during the mid 20th century, the Catholic Interracial Council, also known as the CIC. The Twin Cities chapter of the CIC (CICTC) made great headway with community action and education during the beginning of the civil rights movement, but fell short of lasting systemic change. Though many efforts were made within the community, no legislature was passed to further their mission of racial equity. To understand CICTC contributions in conversations surrounding discrimination, inequality and needed change, we conducted an oral history interview with CICTC founding member, Patricia Caponi. Following the interview, we examined some of her personal documents from her time in the CICTC which included newsletters, correspondence, and informational pamphlets. Through analyzing these sources, we were able to see the challenges in working to alleviate systemic racism, such as the lack of supportive legislature and community push-back to anti-racist policy. Analyzing the CICTC's work demonstrates the possibilities and limits of individual efforts in anti-racist efforts and the importance of systemic change.

Abstract Name: Learning Hispanic Community Health Needs Through Oral History Interview in Rural Western Wisconsin

At the onset of the COVID-19 pandemic, UWEC's Public History Program and McIntyre Library joined with the Chippewa Valley Museum to launch the Western Wisconsin COVID-19 Archive (WWCA), a rapid-response project archiving oral histories and artifacts related to COVID-19 and its impacts in Western Wisconsin. One of the imperatives of the archive is to preserve a diverse picture of the pandemic's effects across our communities. With this goal in mind, a team of UWEC History, Spanish, Latin American; Latinx Studies, and Nursing faculty and students launchedVoces del Campo/ Rural Voices, which has worked to preserve oral histories with the immigrant Hispanic and Latinx farmworkers who have become the essential—but often silenced—backbone of Wisconsin's dairy industry. Documenting immigrant experiences is essential for present and future students, educators, policymakers, public health providers, and community members to understand and provide health and community infrastructure for the diverse rural communities of western Wisconsin. This presentation will present the methods used and lessoned learned by students conducting and analyzing oral history interviews with rural, multilingual communities. In particular, the presentation will demonstrate trends in health and community concerns and beliefs revealed through the analysis of Spanish-language interviews conducted with farmworkers during COVID-19 vaccine clinics using the qualitative data analysis software NVivo. Following the discussion of methods, challenges, and trends, the presentation will offer practical advice for how to utilize interviews and their analysis to improve public health initiatives, along with ideas for how students and faculty across a variety of academic disciplines can incorporate oral history interviews and analysis into their own research agendas.

Abstract Name: University of Wisconsin-Superior Writing Center: Collaboratively Creating an Equity, Diversity, and Inclusion Statement

In this presentation, we will be discussing the content and process of creating an Equity, Diversity, and Inclusion (EDI) statement. We specifically worked on an EDI statement for the University of Wisconsin-Superior Writing Center. We, as Writing Center staff, felt it was important to have our own EDI statement in addition to our University's general statement. We wanted to make it specific to what we do: meet students where they are in their writing journey and give them the tools to expand their writing skills. With our EDI statement, we wanted to emphasize that the Writing Center is a place of learning for everyone regardless of their race, ethnicity, sexuality, cognitive ability, etc. In addition, we wanted to emphasize that we, as writing consultants, are committed to having a growth mindset. After the idea was pitched in a staff meeting, we analyzed Inclusivity/Anti-Racism statements from four organizations outside the University. We then identified ideas we felt were important before combining them into three themes relevant to the Writing Center: linguistic freedom, anti-racism and inclusivity, and safe spaces. With these themes in mind, we drafted a statement and got feedback from other campus organizations. After several revisions, the final EDI statement was published on the UW-Superior website. One major benefit of collaboratively creating our EDI Statement is that it helps us to reflect and prioritize our shared goals and values—plus, it communicates our values and priorities to the entire campus. Our EDI Statement encourages diverse voices and welcomes people of all identities, including those based on neurodiversity, which echoes our mission statement.

Abstract Name: **Neural and Behavioral Correlates of Sensation Seeking**

We sought to clarify both behavioral and neural characteristics of sensation seeking. In particular, wewere interested in two components of event-related brain potentials (ERPs) elicited during a response inhibition task: the P3a, which is elicited by novel, unexpected, stimuli, and the P3b, which is elicited by targets. Participants completed self-report questionnaires to measure their sensation seeking. During the task, participants were presented with three types of visual stimuli in randomized order at a rate of approximately one every 1.25 s. The stimuli were (1) non-targets, to which they should make a response, (2) targets, to which they should withhold a response, and (3) novel stimuli, to which they should withhold a response. The targets and non-targets were relativelybenign,but required sustained attention to tell them apart. The novel stimuli were photographs depicting arousing situations (e.g., skydiving). Based on previous research, we predicted that (1) the P3a would be positively correlated with sensation seeking, (2) the P3b wouldbe negatively correlated with sensation seeking, and (3) response accuracy to novel stimuli would be inversely correlated with sensation seeking. P3a and total sensation seeking were positively correlated, but the relationship was small and not statistically significant. In contrast to our prediction, P3b was moderately positively correlated with total sensation seeking. Finally, response accuracy was not correlated with total sensation seeking. Although none of our hypotheses were supported for total sensation seeking scores, we did find relationships between the ERP components and total sensation seeking, boredom susceptibility, and disinhibition.

Abstract Name: **Equilibrium Quartet presents Keen by Roshanne Etezady**

Equilibrium is a saxophone quartet at the University of Wisconsin-Eau Claire. The quartet was formed in Sepember of 2021 and is composed of undergraduates students, all with different majors: music education, applied instrumental music, integrated strategic communication-advertising, and biology. In our time as a quartet, we have performed in masterclassses, auditioned for competitions, and prepared multiple recitals. As an ensemble, we are interested in exploring timbre, balance, and color within the constraints of saxophone quartet. The saxophone is an incredibly flecible instrument capable of producing a wider range of wounds and colors. Roshanne Etezady's piece,Keenutilizes the saxophone quartet's unique ability to blend into one homogenous sound by leaning on droning characteristics to drive the piece. Etezady also highlights the individual instrument's timbral qualities in solo passages. We chose this piece because it explores a wide range of colors and challenges musicians to maintain consistent blend and balance in the extreme registers and dynamics of the saxophone. We are excited to share the music of Roshanne Etezady, a contemporary classical composer who uses timbre and balance to capture intense emotions in the pieceKeen. To keen means to express grief with a loud and sustained cry of sorrow. Etezady uses the concept of keening to stucture the piece and model the emotional affect of the title. However she goes beyond imitating this human response to grief. The unison drones are contrasted by shifting melodic lines andintense dissonances that further evoke a distressing affect. In our performance, we hope to convey this intense feeling of sorrow and highlight the work of composer, Roshanne Etezady.

Abstract Name: **Evaluation of various short read genome assemblers on sea slug genomic data**

Each living organism, such as a human to a fish possess a genome, which is the complete set of genetic material. After sequencing a genome, the process of genome assembly takes fragments of nucleotide (DNA) sequences and places them in the correct order. There are different kinds of programs that allow us to take a great number of these sequences and place them in an order that corresponds to the original sequence. Scientists use the genome assembly to find out information such as the evolution of a species and compare genomes with other species. In this project, we are working with DNA sequences from the sea slug Elysia crispata. Interestingly, this sea slug is photosynthetic. We sequenced the genome of this sea slug and we used 13 different genome assembly programs to attempt to assemble this genome. We wanted to determine which of these programs (MEGAHIT, SPAdes, ABySS, MaSuRCA, Clover, Platanus allee, Mini SR, Wengan, IDBA, SOAPdenovo, Geneious, GATB-Minia and Discovar denovo) produced the best genome assembly. Our results showed that the top 2 genome assembly programs were MaSuRCA and MEGAHIT. MaSuRCA reference assisted, MaSuRCA and MEGAHIT produced the assemblies with the highest percent of complete and partial core genes with the sea slug data. However, they are still highly fragmented given the high total number of sequences in the final assemblies.

Abstract Name: **Theoretical Predictions of WISE Photometry for Dwarf Galaxy AGN**

All large galaxies, like the Milky Way, host supermassive black holes (SMBHs) with masses greater than 1,000,000 solar masses at their centers. While stellar mass black holes (10-100 solar masses) are also common, intermediate mass black holes (IMBHs) between the two extreme mass regimes remain surprisingly rare. SMBHs may have evolved in different ways, but at one stage of their evolution they must have been IMBHs. Therefore, finding IMBHs can shed light on the evolution process of SMBHs. A premier way of identifying black holes is to look for active galactic nuclei (AGN), a combination of a black hole and an accretion disk that sits in the center of a galaxy, because they can produce more radiation than the entire rest of the galaxy. Dwarf galaxies show promise for finding IMBHs because they resemble galaxies of the early universe when SMBHs formed, but there is a lack of data on dwarf galaxies with active galactic nuclei (AGN). Previous papers have identified AGN using infrared photometry, the summation of the light output over a range of energies. The Wide-field Infrared Survey Explorer (WISE) has gathered photometric values on 3/4ths of a billion astronomical objects. Our preliminary results from simulated dwarf AGN suggest that WISE photometry primarily identifies dwarf AGN as star forming galaxies because of their low ionization and the low percentage of the total light output coming from the AGN. However, observations show that some dwarf galaxies are actually identified as AGN using WISE photometry. In these cases, our simulations can provide unique constraints on the physical conditions within those galaxies, which represents progress in understanding the hosts of IMBHs.

Abstract Name: **Remote Sensing Analysis of the Relationship Between Sand Dune Topography and Vegetation Response to Varying Precipitation in the Central Great Plains**

The Central Great Plains is a premier site of potentially mobile loess (wind-blown dust deposits) and sand dune landscapes. As climate quickly changes, these features are vulnerable to destabilization and movement as the likelihood of extreme weather increases. To predict sand dune response to changing climates in the future, it's important to understand how sand dune landscapes have historically responded to changing climate. The objective of the study is to determine how vegetation on sand dunes have reacted during previous years with high and low precipitation. Vegetation is a potential factor in susceptibility to erosion and thus landscape stability. Using various remote sensing data, the study aims to determine how vegetation responds to unusually dry and wet years in different parts of sand dunes, such as the crests and interdunes. Understanding the relationship between sand dune topography and vegetation growth is key to predicting sand dune activation and movement, both of which are processes that can significantly affect landscape morphology in the Central Great Plains.

Abstract Name: **A Comparison of Actigraph Accelerometers Worn on Non-Domninant and Dominant Wrists in Free-Living Conditions**

Background: Physical activity (PA) levels act as indicators of overall health status to the public as well as healthcare providers. Accurately quantifying PA levels is a key component for creating and analyzing public health initiatives to increase PA among the general population (Buchan et al., 2020). As technology has advanced, wearable activity trackers have become one of the most popular means of measuring daily PA (de Man et at., 2016).Purpose:The purpose of this study is to examine the degree of agreement between PA data collected from accelerometers worn on the dominant and non-dominant wrists, which will help us verify the conventional use of the non-dominant wrist as a device placement in PA studies. Methods: This project will be conducted over the spring of 2023, and 15 college students will be recruited from the University of Minnesota Duluth. Participants will wear an Actigraph Centrepoint Insight Watch (Pensacola, FL, USA) on both their dominant and non-dominant wrists for seven consecutive days during waking hours. PA as a variable will be identified using the following measures: step counts, time spent for each PA intensity (e.g., sedentary time, light, moderate, and vigorous PA) as well as raw vector magnitude. Frequency and intraclass correlation analyses will be performed to compare the PA data collected from non-dominant and dominant wrists, as well as weekday and weekend days.Expected results:It is unclear whether the results of this study will show significant discrepancy between data collected on the two different device placements, which is why the findings of the proposed study are valuable.Conclusion:As it becomes more prevalent for PA to be tracked using a wrist-worn device, the findings of this study would help healthcare professionals, as well as the general public, better understand how to accurately measure and interpret their PA information.

Abstract Name: Nondimensional Wind Shear Over West Texas Terrain

Nondimensional wind shear was computed using high frequency wind measurements obtained on a 30 meter tower located near Big Spring, TX. The three components of the wind, along with temperature, were sampled at 32 Hz using sonic anemometers positioned at five height levels on the tower. Coordinate rotations were performed to produce longitudinal, transverse and vertical components of the winds and turbulence statistics were generated for the different measurement heights. These statistics allowed inter alia for the determination of u_star velocity scales, nondimensional wind shears, and Monin-Obukhov stability parameters. Because of limitations due to a significant roughness sublayer and finite fetch, two middle height levels were used in the analysis. Parameterizations found from previous studies are compared to results from this analysis.

Abstract Name: Identifying Beta-lactam antibiotic resistant E.coli using immunofluorescence with antibodies specific to beta-lactamase.

Bacterial antibiotic resistance is a global phenomenon with significant implications for human health. Pathogen resistance has been proposed to result from horizontal gene transfer from non-pathogenic resistant organisms. Resistance genes are common in natural microbiomes, however, their distribution in nature is not well-characterized. The goal of this project was to develop a sensitive immunofluorescence assay to detect bacterial resistance to beta-lactam antibiotics. Escherichia coli cells were transformed using a plasmid containing a gene for beta-lactamase. Resistant and non-resistant E. coli were fixed, adhered to coverslips, and exposed to antibodies specific for the enzyme TEM-beta lactamase. A secondary antibody with a fluorophore was incubated with the E. coli cells. Cells were also stained with DAPI to visualize DNA to obtain a total count of bacteria in the sample. Fluorescence microscopy was used to detect the presence of cells containing beta-lactamase. Our results showed that immunofluorescence was useful in detecting beta-lactamase expressing E. coli cells. Non-transformed E. coli cells showed no immunofluorescence. Transformed E. coli cells exposed to secondary antibody alone did not show fluorescence, indicating that there was no non-specific binding of the secondary antibody. Our results indicate that immunofluorescence is a promising technique for detecting bacterial resistance to antibiotics such as penicillin or ampicillin.

Abstract Name: The Associations between Belongingness, Trust, and the Willingness to Donate to One?s Alma Mater

Donations are a vital part of keeping universities up and running across the globe. Thus, it makes sense that universities have a vested interest in fostering relationships with students that will generate future donations. This study examines the degree to which feelings of belongingness, trust, and engagement in campus activities affect an individual's willingness to donate to their alma mater. The 72 participants in this study represent a diverse group of students at the University of Wisconsin-Eau Claire. The findings indicate that feelings of belongingness with the university and the belief that one can trust the university are more strongly associated with a willingness to donate. Engagement in campus activities was not significantly associated with a willingness to donate. Thus, we learned that while it is important for a university to provide opportunities for students to engage in campus life, the university should spend equal time fostering a sense of belongingness and trust with their students.

Abstract Name: Michigan Sports Tourism Strategy Project: Inventory Phase

Communities nationwide are pursuing the sports tourism industry to generate economic and social benefits. As such, local and state governments are striving to incentivize the public and private promotion of sports tourism events and the construction of venues. Because the study of the relationship between public investments and sports tourism benefits is emerging, there is a gap in research and data to guide these endeavors. Moreover, as competition grows between prospective host municipalities, coordination at the regional and state levels will be crucial in preventing inefficiencies. In Michigan, there is an aspiring, grassroots push to create a state-level sports tourism strategy to foster coordination and reduce inefficiencies. Among the first steps in any state-level movement is the development of a database of sport tourism events and venues. In this project, we examine the role of event and venue inventories as a critical baseline for strategy formulation, asking questions about how inventories should be designed, assessing database management options, and identifying challenges around data collection from public and private sources. Specifically, we utilize a mixed-methods approach to create a state-wide database of sports tourism events and venues in the State of Michigan from 2010 to 2022. First, we collect and report on quantitative data for events and venues like size, type, capacity, location, sport, and community details. Next, we augment these event and venue data with qualitative data from interviews with key stakeholders, including public officials, industry professionals, and regional sports commissions. From these findings, we make recommendations about the creation of a state-wide sports tourism strategy for Michigan and, by extension, developing a model for other states in the US. By focusing on state-level strategies, this research fosters efficient investments into the industry and, ultimately, increases the capture of economic and social benefits from the sport tourism sector.

Abstract Name: **Socioeconomic Vulnerability and Environmental Inequalities: a Case Study of Climate Change Impacts in Egypt's Delta Agricultural Sector**

Egypt's Nile Delta has historically had a significant impact and drawn a sizable population because of its abundant resources and trading opportunities. The Nile Delta faces a significant risk of being severely damaged due to flooding brought on by extreme climate change. Temperature increases, unpredictable rainfall patterns, and increasing sea levels are some of the effects of climate change on these cities. When we start to look deeper at the impacts of climate change on different groups of people, a question begins to pose itself. How are the effects of climate change distributed, and is it proportional to the level of contribution to emissions? The objectives of this research are to identify the detrimental effects and threats of climate change on farmers in Egypt's delta agricultural sector and the vulnerability of farmers. A hybrid methodology and system mapping were used to accomplish these objectives. Farmers and other internal and external stakeholders, including professionals, government officials, and NGO representatives, were also interviewed. The results of this study show and prove that farmers in Egypt's delta region are highly vulnerable due to ineffective practices and weak and inadequate government communication. The study also demonstrates that households with lower incomes and less access to natural resources are more vulnerable to the risk of flooding and sea level rise. Income disparities and asset distribution at the community level tend to be greater at higher risk exposure levels, suggesting that households with higher individual vulnerability also have higher collective vulnerability.

Abstract Name: **Learning and Memory in Harvester Ants**

Ants are an effective animal model for associative learning, and the purpose of these experiments was to produce a novel paradigm for studying associative learning in harvester ants and to measure the retention of learned associations. In Experiment 1, ants were maintained in nests consisting of a gel food source containing sucrose (“US only” condition), with some animals that were also exposed to a plant stimulus in their nests (“CSUS” condition). Ants were later individually tested using a stimulus discrimination task that measured ants’ engagement with familiar and unfamiliar stimuli. Ants did not show a preference for the paired (familiar) stimulus; however, animals in the paired condition spent more time overall engaging with the stimuli than ants in the US only condition. In Experiment 2, we examined associated learning using a modified paradigm in which ants were maintained on a sucrose-restricted diet and later exposed to a novel gel food source containing sucrose (“US only” condition), with some animals exposed to the gel treated with a plant stimulus (“CSUS” condition). Like Experiment 1, ants were later individually tested using a stimulus discrimination task that occurred either 1 hour, 24 hours, or 48 hours following the end of exposure to the gel. Ants showed a preference for cilantro when paired with the gel after 24 hours (0.03), but not after 1 hour or 48 hours (p’s 0.05). Ants in the CSUS condition spent more time exploring the plant stimuli than ants in the US only condition after 24 hours, but not after 1 or 48 hours. These findings suggest that associative learning using these paradigms is retained at 24 hours.

Abstract Name: **Ethyl Cinnamate Nanobead Sunscreen Characterization Using Mouse Skin NIH/3T3 Fibroblast Cells**

Exposure to the sun with no skin protection can result in damage to skin cells and the DNA within. Many commercially available sunscreens use nanoparticles as physical blockers to reflect or absorb the ultraviolet B radiations (UVB). Nanobeads, on the other hand, can absorb UVB while safely encapsulated—preventing the formation of dangerous radicals. In this project, ethyl cinnamate embedded nanobead sunscreen was synthesized from a commercial ester, ethyl cinnamate, and characterized for effectiveness in preventing DNA damage from harmful UVB rays using mouse skin fibroblasts, specifically a NIH/3T3 cell line. The ethyl cinnamate nanobead sunscreen was synthesized by embedding ethyl 4-methoxycinnamate in a polymer “shell” of Pluronic, a 3-block copolymer that has a hydrophobic middle and two hydrophilic ends. Synthesis of nanobeads was performed by previously optimized technique called Flash NanoPrecipitation. Briefly, the technique involved combining one stream of organic solvent (containing the Pluronic and ethyl 4-methoxycinnamate) with two streams of deionized water in a custom-made flash precipitation apparatus. Thin layer chromatography (TLC) and UV/Visible spectrophotometry with a lambda-maxof 288 nm confirmed the purity of the product. The effectiveness of nanobead sunscreen was determined by concentration-based trials on 3T3 mouse fibroblasts using the Neutral Red Dye cytotoxicity test. Samples were exposed to UVB light and a decrease in cell death was measured for various dilutions of the nanobeads. DNA damage in the form of Thymine-Thymine (T-T) dimer formation was quantitated using an Enzyme Linked Immunosorbent (ELISA) assay to measure the formation of 6-4 photoproducts and then compared to a no sunscreen nanobead control. A thin layer of nanobeads was 99.02% effective at preventing T-T dimer formation from UVB.Keywords: Sunscreen, Nanobeads, Fibroblasts, 6-4 photoproducts, Thymine dimer

Abstract Name: **What?s all that noise about?: Alarm-calling in California ground squirrels**

Many socially-living diurnal animals have evolved vocalizations known as alarm calls as a mechanism for reducing predation. California ground squirrels are a major prey species for coyotes, rattlesnakes, and birds of prey, but must also cope with human foot traffic and anthropogenic noise. This project characterizes the acoustic structure, duration, ecological context, and timing of these calls produced by ground squirrels. Combining naturalistic and automated acoustic monitoring, we describe the extent to which humans and dogs versus natural predators trigger naturally-occuring alarm calls in California ground squirrels across the 24-hour cycle. First, from naturalistic observations as part of my Long-term Behavioral Ecology Project on California ground squirrels at Briones Regional Park, we document that calls are associated with natural predators but not humans visitors. We also describe the contexts in which squirrels produce either a short, non-repetitive vocalization or a longer repetitive bout of alarm calls. Second, we present data from acoustic monitoring devices and camera traps that confirm ground squirrels mainly call during daylight hours, a time of day before coyotes emerge at the site. Our data confirm the alarm-calling “schedule” for these animals and offer new insights into not only what triggers them to call but also the temporal patterning of fear responses over time.

Abstract Name: **Student Self-Reflection as a Tool for Tracking & Assessing The Undergraduate Research Experience: What advice would you give to yourself before your first research experience**

This presentation focuses on scholars who have participated in undergraduate research and reports on findings from a survey that investigated student perceptions of the advice they would give themselves prior to their first research experience. Students who participated in the survey presented their research at a multidisciplinary poster symposium. Students voluntarily filled out anonymous surveys on paper postcards (n=69). Data included the scholars' responses to the survey question, the students' major, and class standing. Thematic analysis of survey questions revealed encouraging sentiments and constructive advice, such as lack of data being a part of the process, self-confidence, and fruitful experiences. Preliminary themes included: active participation, dynamic learning, and self-belief. This presentation provides insight into the self-reported lessons learned through practical research experience. The main goals of the survey were: to offer symposium presenters an opportunity for self-reflection on their research experiences and to remove the intimidating perception of an exclusive environment, associated with high-impact research experiences. By offering a visual representation of multifaceted advice from accomplished peer researchers, new student researchers could feel encouraged to participate and stay in research experiences. These findings offer insight into avenues for enhancing the student experience during intake by naming the challenges and encouraging them to be bold in their approach while also helping coaches see where scholars can be encouraged to be bold in their approach. Promising applications for tracking and assessment include: assessing progress midway through a lens of developmental milestones, proactively and cooperatively deploying inclusive interventions to barriers, inviting the student into the problem-solving process, and offering tools that promote self-efficacy and a sense of well-being throughout the research process for student success.

Abstract Name: **Automated Cosmic Ray Shield**

A Cosmic ray is defined as a highly energetic atom or other particle traveling through space near the speed of light. These particles which also include light are harmful to humans and electronics devices that are unshielded from them. Current Cosmic ray shielding consists of Steel-Aluminum alloy plates with a small gap between them to block particles through sheer mass and attenuation which is not effective enough for long term use. A more effective means of shielding from cosmic rays will need to be implemented to make space travel more viable.This project will logically simulate the sensor input output to control a gas that will be ionized, most likely hydrogen to create the cosmic ray shield that will react to various degrees of radiation dynamically. Due to the hazardous environment that is space the system will need to carefully control voltage and temperature of the plasma used as a shield. The operation is as follows: sensor detects cosmic rays then system energizes gas to absorb / deflects rays with a variable voltage control. The system finds an equilibrium point between electrical current applied to the ionized gas and the absorption/deflection and detection of incoming cosmic rays. A voltage potential is applied to the gas which ionizes it changing its state to plasma which allows the hydrogen to absorb more energy. The plasma will deflect the most cosmic rays while a current is running through it providing structure to the plasma. And creating the electrostatic and magnetic field which will assist in particle deflection. The system will settle into an equilibrium position where the least amount of current necessary to absorb and deflect particles is supplied to the plasma. While retaining the potential to increase current flow depending on ray intensity.

Abstract Name: **University of Wisconsin-Superior Writing Center: Collaboratively Creating an Equity, Diversity, and Inclusion Statement**

In this presentation, we will be discussing the content and process of creating an Equity, Diversity, and Inclusion (EDI) statement. We specifically worked on an EDI statement for the University of Wisconsin-Superior Writing Center. We, as Writing Center staff, felt it was important to have our own EDI statement in addition to our University's general statement. We wanted to make it specific to what we do: meet students where they are in their writing journey and give them the tools to expand their writing skills. With our EDI statement, we wanted to emphasize that the Writing Center is a place of learning for everyone regardless of their race, ethnicity, sexuality, cognitive ability, etc. In addition, we wanted to emphasize that we, as writing consultants, are committed to having a growth mindset. After the idea was pitched in a staff meeting, we analyzed Inclusivity/Anti-Racism statements from four organizations outside the University. We then identified ideas we felt were important before combining them into three themes relevant to the Writing Center: linguistic freedom, anti-racism and inclusivity, and safe spaces. With these themes in mind, we drafted a statement and got feedback from other campus organizations. After several revisions, the final EDI statement was published on the UW-Superior website. One major benefit of collaboratively creating our EDI Statement is that it helps us to reflect and prioritize our shared goals and values—plus, it communicates our values and priorities to the entire campus. Our EDI Statement encourages diverse voices and welcomes people of all identities, including those based on neurodiversity, which echoes our mission statement.

Abstract Name: **Resilience in LGBTQ+ Catholic Young Adults**

Religiosity and spirituality correlate significantly with well-being, self-esteem, and optimism (Koenig, 2012). However, there is a scarcity of research on this relationship pertaining to lesbian, gay, bisexual, transgender, and queer/questioning (LGBTQ+) individuals and the perceived impact of religion and spirituality on their lives. The circumstances LGBTQ+ individuals face are complex, as identity conflict may occur when integrating religious and sexual identities (Gibbs and Goldbach, 2021). Studies have been conducted on resilience in LGBTQ+ young adults and on LGBTQ+ identity formation within Catholicism, but the relationship and interactions among these factors, including implications for practicing faith, have yet to be analyzed. This study endeavors to analyze these topics through a resilience-based lens to understand the co-existence of Catholic and LGBTQ+ identities within young adults. Resilience and sexual identity formation models will be utilized to (1) assess the resilience of LGBTQ+ Catholics, and (2) compare assets and resources present in LGBTQ+ young adults who choose to continue or discontinue practicing Catholicism. Through this research, we hope to shed light on factors involved in LGBTQ+ young adults' choice to continue or discontinue faith practices and to inform family and religious communities in their understanding of the unique faith-based considerations LGBTQ+ individuals face.

Abstract Name: **The Impact of Malnourishment and Oxidative Stress on the Reactivation of the Epstein-Barr Virus in Burkitt lymphoma cells**

The Epstein-Barr virus (EBV) is a herpesvirus, which are known for the ability to switch from a latent to lytic infection in host cells. EBV is estimated to have infected up to 90% of the human population, with many never showing symptoms of infection. After years of latent infection, EBV can reactivate its lytic cycle, which can play a role in some diseases, especially among immunocompromised individuals. The mechanism behind EBV lytic reactivation is not fully understood; however, there are some chemicals known to cause this reactivation. A common reactivator used in experimentation is the compound butyrate, a lipid metabolic regulator produced by gut microflora. This study seeks to determine the extent that chemicals produced during malnutrition and oxidative stress impact EBV reactivation. The compounds sodium 3-hydroxybutyrate and lithium acetoacetate were introduced to infected Burkitt lymphoma cells to see their impact on lytic activation. These compounds are ketone bodies produced during lipid metabolism; done when cells are lacking energy from traditional metabolism of glucose. In addition to providing information on the impact of insufficient nutrition, these compounds are similar in structure to butyrate, so the importance of chemical structure was simultaneously studied. The other cellular stress investigated was oxidative stress. Reactive oxygen species (ROS) were investigated because there is evidence that introduction of these compounds can cause EBV reactivation, so the impact of ROS on EBV reactivation produced by the cells themselves was of interest. EBV reactivation was determined using reverse transcriptase quantitative Polymerase Chain Reaction (RT-qPCR) to measure changes in expression of BZLF1, an early reactivation transcription regulation gene. Oxidative stress was quantified through changes in glutathione proliferator gene expression measured via RT-qPCR.Gaining insight on causes of EBV reactivations supplies targets for EBV reactivation related disease treatments.

Abstract Name: **Black Robes: God?s Patriots that Prepared America**

The various causes of the American Revolution have been studied by scholars for centuries. The Revolution of 1776 can trace its roots back different sources; however, the role of colonial American pastors, while once studied regularly, has not received the same level of academic attention in recent years. Many pastors in general, and a few in particular, are noted for the direct impact they had on preparing colonial Americans for the American Revolution. The Rev. John Wise, in the late 17th and early 18th centuries, preached sermons against oppressive and usurping royal governance on topics such as taxation without representation is tyranny. These sermon on issues of politics would find renewed interest by the colonists decades later. One of the more famous pastors of colonial America who is well known today is George Whitefield. This pastor traveled the colonies during the First Great Awakening preaching to the colonists on the importance unification, in regard to belief in God, with his Father Abraham sermons. This unification of faith would later extend into the political realm through the creation of a uniquely American identity. A third major figure was the Rev. Jonathan Mayhew, who preached a famous sermon, among many other sermons throughout his life, on submission to government. His sermon on Unlimited Submission paved the way for a colonial population, who were regular church attendees, to have a Biblical basis for their rebellion against the British Crown. These ministers built the foundation for a colonial population to be prepared for a political and military revolution.

Abstract Name: **Vicon sensed Post-stroke rehabilitation exercise assessment using Attention-based CNN**

Cardiovascular diseases are one of the concerning problems in the United States. According to CDC, approximately 805,000 people suffer heart-related problems every year, out of which 605,000 are the first time. Physicians suggest rehabilitation exercises to the surviving patients as these exercises will help the patients in bringing back their physical function and mobility before the injury. Due to recent technology amelioration, many are using Motion Capture Systems to perform the suggested movements. To improve the performance of these sensors, we develop a model that concentrates only on dominant parameters skipping the rest. With the help of optimization techniques and algorithms, built models will identify the critical parameters from the inputted data. We introduce an Attention-based CNN model on 117-dimensional Vicon sensor angle data to enhance the sensor's performance in identifying the performed exercise. Convolutional layers in the network will help extract the input data's in-depth features, and LSTM layers mine the long-time series features. We have used the UI-PRMD - Vicon ten movements data for building the proposed model. Our attention model has outperformed many complex architectures with an overall average of 0.007881 MAD and 0.012343 RMSE for ten movements.

Abstract Name: **Investigation of the Effect of Nozzle Temperature on Tensile Strength of Reinforced and Nonreinforced Polypropylene in Fused Filament Fabrication Process**

Fused filament fabrication (FFF), a popular 3D printing method, is increasingly being used to create parts for service rather than simply for form prototypes. A primary advantage of FFF is the short lead time from design to realization of a part; this allows third-party users to quickly make parts for repairs. Commercially available filaments are made of a range of materials, including unreinforced or “neat” polypropylene, bead-reinforced polypropylene, and fiber-reinforced polypropylene. While manufacturers of filament rolls typically provide preferred printer settings (including nozzle temperature) it is valuable to understand the effect of nozzle temperature variation on part strength as well as the tradeoffs incurred with the usage of different polypropylene variants. Furthermore, the most readily available strength data refers to material that has not undergone the FFF process. Having specific information on the tensile strength of polypropylene variants subject to a range of manufacturing conditions will provide valuable design information for those who intend to create service parts from polypropylene via the FFF process.

Abstract Name: **How Organizational Readiness Can Support Practice Change**

Low-income individuals often experience higher rates of mental health disorders due to various social determinants of health, such as high cost of care, low-quality care, and being uninsured or underinsured. One way to improve mental health outcomes among these populations is to integrate behavioral health services into primary care and public health settings to meet the holistic needs of patients. The Holistic Opportunity Program for Everyone (H.O.P.E.) Initiative is a behavioral health integration initiative launched in 2020 at four Mecklenburg County Public Health clinics. This program aims to more holistically identify and address the physical, nutritional, and behavioral health needs of patients. Integrated care initiatives are not without implementation challenges. Assessing organizational readiness throughout the lifespan of the initiative can be a useful tool to create responsive practice change. To measure readiness for the H.O.P.E. Initiative, the Readiness for Integrated Care Questionnaire (RICQ) was administered 3 years in a row through Qualtrics to assess change in readiness overtime. Program Champion, a readiness subcomponent, is defined within the RICQ as individuals who put organizational weight behind an innovation. Results indicated that the number of self-identified program champions increased from 44% to 89% between 2020 and 2022. In each year, at least one fifth of self-identified program champions were in a leadership role while other roles consistently had staff who did not identify as a program champion. The RICQ can provide useful information across the lifespan of an initiative to drive practice change such as inviting program champions to leadership meetings and the development of a H.O.P.E. Bulletin. By completing the assessment annually, program leadership is able to monitor factors that are facilitating and hindering program success and coordinate efforts to build implementation readiness for the H.O.P.E. Initiative.

Abstract Name: **Panel discussion: Creating a developmental curriculum to build research skills**

In this panel discussion, moderated by Abby Hemmerich, four panel members will share examples of undergraduate research embedded across the curriculum and within individual courses. These examples will highlight principles of research woven through progressive courses in chemistry, psychology, kinesiology, and natural sciences, helping students build skills developmentally from their first year to graduation. David Durkin (co-author, Darion Isom) will discuss a series of integrated labs to grow research skills throughout the middle years of the chemistry major, culminating in an independent, problem-based learning project. Details about the final “Special Project” will be presented; this project requires students to utilize all of their skills to independently design the experiment, request materials, perform of the experiment, and write the research report. Nicole Depowski will present a case study of a psychology program with research introduced at the introductory level, integrated practice across the curriculum, and a capstone senior thesis project. Early exposure to scholarship focuses on locating and reading research, while students gain skills in research ethics and design at the next level. The third year requires use of primary sources, with synthesis and analysis, culminating in a senior thesis project in which students produce their own research. Brian Wallace will discuss the process for building evidence-based practice and research principles into the kinesiology curriculum to prepare students for graduate school or health and fitness professions. Changes to student engagement in research and outcomes related to faculty-mentored research will be discussed.Chimdimnma Esimai (co-author,George Ude) will present a series of course-based research experiences that engage a whole class of students in a research question or problem. Although individual projects are restricted to a single course, students experience multiple opportunities for these projects across the curriculum, providing complementary content and developmental progression in skills.

Abstract Name: **Letting the Narrative Unfold: Black Female Storytellers of the 21st Century.**

In the world of television and film, Black women have not had the chance to be the true visionaries behind the camera and be the star in front of the camera. The purpose of this project is to highlight and analyze the dynamic representations of Black women through the eyes of Black female storytellers, and the impact their storytelling has on women in the Black community. This project focuses on three Black female storytellers, Ava DuVernay, Shonda Rhimes, and Issa Rae, and the work they have created with Black women at the center of those narratives. Some examples of their television work are DuVernay's Queen Sugar (2016-Present), Rhimes' Scandal (2012-2018), and Rae's Insecure (2016-2021). I watched episodes and a film from these creators while taking extensive notes on the plot, character archetypes, dialogue, and cinematography. Furthermore, I read about the role Black female writers and directors have in television and film, representations of Black women, and the culture and identities that shape the way society views Black women. I conducted an auteur analysis and analyzed specific themes and cinematic conventions from the works of each storyteller. So far, I discovered how important it is for Black women to tell their own stories to create a more accurate and well-rounded portrayal of themselves. Many people of color do not see authentic representations of themselves on screen. This project emphasizes the need for all people of color to break more boundaries in controlling all aspects of the narrative to create purposeful and meaningful stories others can relate to and enjoy. I plan to continue my research in the spring of 2023 to further analyze the themes and connections between all three auteurs and their works, and display the unique, compelling, and relatable stories that Black women have to share.

Abstract Name: **Categorizing Genetic Disorders via Machine Learning**

Genetic disorders are a prominent concern in society, as they can cause serious health problems. Being able to quickly identify the type of genetic disorder a person has may allow early treatment to minimize the impact of genetic disorders on people's lives. The goal of this project is to develop a model that can predict the type of hereditary disorder a person has using data about their current health indicators and their family's genetic history. I used the statistical programming language R to analyze a simulated data set from Kaggle using machine learning methods such as k-nearest neighbors. I will present results on the accuracy of different multivariable machine learning methods and visualizations that can be used to understand the association between genetic disorders and single-variable predictors.

Abstract Name: **Evaluating Plasma Vitamin A and E Concentrations in a Mature Horse Herd Housed in a Dry Lot or Pasture**

Vitamin A and E are adequately supplied to horses when they consume fresh pasture. However, horses in the Upper Midwest often become deficient during the winter months which can be detrimental to horse health. Considering the prevalence of deficiency has not been widely documented, this study aims to evaluate plasma vitamin A and E concentrations in the UWRF horse herd related to pasture versus dry lot housing conditions. Twenty-seven mature adult horses were used in the study. Thirteen horses were housed in a dry lot with hay-only access while fourteen horses had pasture access during the summer. All horses had access to a free-choice mineral and vitamin mix. Blood samples were taken in February (winter), May (spring), August (summer), and November (fall) and sent to Michigan State Veterinary Diagnostic Laboratory for analysis. Data were analyzed using PROC MIXED in SAS with significance set at P≤0.05. Adequate vitamin E was classified as 2.0 to 4.0 µg/ml and adequate vitamin A was classified as 175 to 300 ng/ml. In the winter and spring, 70 to 74% of horses were deficient in vitamin E with an average concentration of 1.83 µg/ml. Plasma vitamin E concentrations remained inadequate in dry lot horses in the summer at 1.43 µg/ml (P>0.05) while concentrations rose in pastured horses to 2.4 µg/ml (0.05). When evaluating vitamin A, 81% to 85% were deficient in the winter and spring, respectively, with an average concentration of 145 ng/ml. While pastured horses exhibited an increase in plasma vitamin A in the summer compared to dry lot horses (0.05), 64% of pastured horses remained deficient. These results demonstrate the prevalence of vitamin A and E deficiency in an Upper Midwest horse herd on a hay-only diet.

Abstract Name: **Equilibrium Quartet presents Keen by Roshanne Etezady**

Equilibrium is a saxophone quartet at the University of Wisconsin-Eau Claire. The quartet was formed in Sepember of 2021 and is composed of undergraduates students, all with different majors: music education, applied instrumental music, integrated strategic communication-advertising, and biology. In our time as a quartet, we have performed in masterclassses, auditioned for competitions, and prepared multiple recitals. As an ensemble, we are interested in exploring timbre, balance, and color within the constraints of saxophone quartet. The saxophone is an incredibly flecible instrument capable of producing a wider range of wounds and colors. Roshanne Etezady's piece,Keenutilizes the saxophone quartet's unique ability to blend into one homogenous sound by leaning on droning characteristics to drive the piece. Etezady also highlights the individual instrument's timbral qualities in solo passages. We chose this piece because it explores a wide range of colors and challenges musicians to maintain consistent blend and balance in the extreme registers and dynamics of the saxophone.We are excited to share the music of Roshanne Etezady, a contemporary classical composer who uses timbre and balance to capture intense emotions in the pieceKeen. To keen means to express grief with a loud and sustained cry of sorrow. Etezady uses the concept of keening to stucture the piece and model the emotional affect of the title. However she goes beyond imitating this human response to grief. The unison drones are contrasted by shifting melodic lines andintense dissonances that further evoke a distressing affect. In our performance, we hope to convey this intense feeling of sorrow and highlight the work of composer,Roshanne Etezady.

Abstract Name: **Exploring College Students' Reports of Help-Seeking Attitudes and Levels of Self-Reliance and Self-Compassion**

Mental health concerns among college students are on the rise, with up to 40% of students reporting mental health conditions such as anxiety and depression. The majority of these students do not seek help, possibly due to barriers (e.g., costs, appointment availability), negative attitudes towards help-seeking, and self-reliance (i.e., dependence on oneself to solve one's problems).Another factor that may be associated with help-seeking is self-compassion. Self-compassion is extending compassion to one's self when experiencing difficulty or inadequacy. While this factor has not been examined within the context of mental health help-seeking, it has been studied within the context of academic coping strategies, specifically one's ability to cope with perceived academic failure. Neff et al. (2005) found that college students who reported higher levels of self-compassion also reported more adaptive strategies for coping with academic failures. Given that help seeking is often an adaptive coping strategy for mental health issues, it is possible that self-compassion is related to mental health help-seeking.The purpose of this study is to explore the relationships among self-reliance, self-compassion, and help-seeking attitudes within mental health and academic contexts. The three research questions are: 1) What are the relationships among college students' reported levels of self-compassion, self-reliance, and help-seeking attitudes? 2) Are these relationships consistent across both academic and mental health help-seeking contexts? And 3) Are there group differences (e.g., sex, ethnicity, class level) in college students' reported levels of self-compassion, self-reliance, and help-seeking attitudes?This study will contribute to our understanding of the factors associated with students' decisions and attitudes surrounding help-seeking.

Abstract Name: **The Toxicological Effects of Duloxetine as a Polymeric Nanoparticle Drug Delivery System in Rats**

Duloxetine (Cymbalta), a serotonin-norepinephrine reuptake inhibitor (SNRI) is an antidepressant which has previously shown relatively low negative toxicological effects and promising depressive symptom management. However, Duloxetine (DLX) encounters an issue in its drug delivery performance due to its high metabolic dissolution rate which can influence both potency and efficacy. Nanoparticles, in particular, Solid Lipid Nanoparticles (SLNs) can be used as an effective drug carrier system for DLX. If DLX is paired with a SLN (SLN-DLX) for depression treatment, it could provide a relatively low toxicity effect while increasing the concentration of the drug's potency in particular to the brainstem and 5-HT terminal areas. While using nano-template engineering techniques, SLN-DLX solutions were fabricated to be further analyzed for toxicological analysis in a rodent model. Equal numbers of 3-month-old male and female Long-Evans Rats received daily 10 mL/kg intraperitoneal (IP) injections of either 5 mg/kg DLX, 5 mg/kg SLN-DLX, SLN, or saline vehicle on four consecutive days. General physical appearance and daily weights were recorded during treatment. Rats were euthanized and brains collected and post-fixed in paraformaldehyde on the fifth experimental day for further histological analysis. We hypothesized that rats with SLN injections and SLN-DLX injections will exhibit no toxicological differences when compared to the saline group. There was no significant effect on weight in any treatment group, p > .05. Histological analyses are forthcoming, but we hypothesize that there will be no significant toxicological difference between treatment groups. For future directions, we hope to conduct a study looking into behavioral differences in chronic stress induced rodent models from the same administration of treatments.

Abstract Name: **Policies at the Tudor Court: The Change and Development in policy under Henry VII and Henry VIII from 1500-1540**

Policy in England during the Tudor era, especially during the reigns of Henry VII and Henry VIII were shifting constantly and based on the Government structure, Marriages, Friends executed, and councilmembers abusing power, there were always changes to the policies of the country. This will also focus on nobles and their impact, or their presence at court and their home region creating a situation where England was able to be forced to alter their stance permanently from the status quo of the past. Henry VII and the establishment of most policies and setting the base for change. In the earlier years, Cardinal Wolsey and Charles Brandon were influencing Henry VIII. Once Wolsey had fallen out of favor Thomas More is next followed by Thomas Cromwell both focusing on religion In their own way based off their own views. When focusing on policies of religion, I will contrast the churches stances against Henry and those who in the country were for and against the policy. I will also be able to show who pushed and made the changes happen over the full reign of Henry VIII and those who moved to stop the shift from the government and gentry. I will then move to the people who were able to squeeze their way into the inner circle and support or not support policies to help determine what would play out. Overall, the project will provide an insight into the greater aspects of how domestic policy changed over the reigns of Henry VII and Henry VIII through both religious conflicts and power struggles by those who wished to usurp the throne, and how the stage was set for his on and daughters when they came to the throne.

Abstract Name: **Mimicking Permanent Phosphorylation of HP1a in Drosophila melanogaster Causes Sterility**

The Heterochromatin protein 1 (HP1) family are non-histone chromosomal proteins that are key factors in the formation of heterochromatin and in transcriptional regulation. HP1 proteins are found in many eukaryotic organisms including plants, animals, and fungi. HP1a fromD. melanogaster was the first HP1 protein discovered, and it has been intensively studies for more than three decades. HP1a can act both as a repressor and an activator of transcription. Like many other proteins, HP1a undergoes post-translational modifications such as phosphorylation. However, little is known about the functions of HP1 post-translational modification, including phosphorylation. To advance our understanding of HP1a's post-translational modifications, we produced two HP1a mutants that either mimic or block phosphorylation. Specifically, we replaced serines (S) 88/89/91 (S88/89/91) either with glutamic acid (E) to mimic permanent phosphorylation or with alanine (A) block phosphorylation. Using these mutant strains, we investigated how phosphorylation of HP1a impacts its known functions. Western blot analysis demonstrated that the phospho-mimic HP1a protein is stable and accumulates to similar levels as wildtype HP1a. Polytene chromosome analysis indicated that the phospho-mimic HP1a protein continues to localize to heterochromatic regions of the genome, including the centromeres and telomeres. On the organismal level, we found that homozygous phospho-mimic HP1a mutants have a significant reduction in fertility for both males and females compared to heterozygous and wildtype animals. We observed a significant decrease in ovary size for the homozygous phospho-mimic HP1a mutant females when compared to heterozygous and wildtype animals. Parallel experiments with the HP1a phospho-block mutant strain are ongoing. Overall, our results show a significant fertility decrease, possibly due to the decreased ovary size in homozygous mutants, but no disturbance of HP1a localization on polytene chromosomes. These results suggest that phosphorylation of HP1a proteins at the site we modified (S88/89/91) might have specific functions in the Drosophila germline.

Abstract Name: **Ligand effects in molybdenum catalyzed oxidation of benzylic alcohols**

Conventional reagents used in alcohol oxidation reactions pose severe economic and environmental consequences. Nevertheless, such reagents are heavily relied upon due to the fundamental role of alcohol oxidations in the chemical processes used by various industries, such as the pharmaceutical and biofuel industries. With sustainability in mind, this project intends to evaluate alternative methods of alcohol oxidation using novel dioxomolybdenum catalysts. Due to a lack of literature surrounding molybdenum catalyzed alcohol oxidations, the role of each component will be thoroughly investigated through the evaluation of a diverse range of alcohols including primary and secondary benzylic as well as aliphatic alcohols in oxidation reactions. A comprehensive understanding of ligand effects in the context of these oxidations will also be developed. Under our optimized conditions, the oxidations can be achieved over a 24-hour reaction time at 120°C using 2 mol% molybdenum catalyst in dimethyl sulfoxide, which acts as both the solvent and the oxidizing agent. As a result, the conversions and yields in these catalytic alcohol oxidation reactions vary from 20% to 99% based on the alcohol substrate used, and there is an evident efficiency linked with the use of the novel catalysts. The reaction is chemoselective and yields aldehyde as the sole oxidation product from primary alcohol substrates. A competing dehydration pathway has been observed with certain electron-rich benzylic alcohols, resulting in the formation of corresponding olefins. With further optimization, these catalysts can be assessed for large-scale industry applications with the goal of pushing industrial processes to become more environmentally friendly.

Abstract Name: Case Studies for Constructivism Learning Theory-Based Academic Research Education

Academic research experience has been widely acknowledged as an effective active learning method to enhance student learning outcomes. Most research universities provide research opportunities for advancing the professional and personal development of their undergraduate students. Some programs even require undergraduate research as part of the bachelor's degree. However, there is a lack of theoretical framework guiding academic research education due to its open-ended context, and its requirement for creativity, exploration skills, and domain knowledge. To address this knowledge gap, in this study, we proposed a pedagogical framework for academic research education based on constructivism learning theory. The framework includes 3-round pre-session evaluations and 12 one-on-one advisory sessions. Each student is working on an individual research project that is designed to best suit their interests. Students are the lead of the projects, while the role of their research mentors are facilitators and coach. We applied the proposed research education methodologies to 90 students, including 78 high school students ranging from Grade 9-12 and 12 undergraduate and graduate students. The project completion rate is 92.3% for high school students, and 83.3% for undergraduate students. All the students have reflected that the research experience has efficiently advanced their critical thinking, problem solving, systematic exploration, and academic communication skills. With the holistic development brought by the research training, 80% of the high school students have successfully got into Top 30 institutions in college application. These results indicate the effectiveness of the proposed methodology, and in future work, the authors plan to further propagate the method to more students.

Abstract Name: Low-Carbon Footprint Concrete for 3D Printed Buildings

3D printing concrete has recently emerged as a revolutionary technology. Over the past two decades, developments in the technology have allowed a wide variety of applications, e.g., the fabrication of buildings. Cement manufacturing accounts for approximately 5% of anthropogenic CO2 emissions worldwide. The carbon footprint created from concrete is unsustainable for the environment. New forms of concrete containing alternative materials such as waste products and bio-aggregates are being implemented to reduce the overall carbon footprint. In our research, we are testing various mixes of concrete containing shredded wind turbine fibers, recycled glass powder, corn stover, and biochar. These materials were chosen as they provided a balance of strength, workability with the 3D concrete printer, and lower carbon emissions. To test our mixtures, we developed the following workflow: mix, cure, test, and evaluate. Each concrete mixture contained varying mix ratios of cement, sand, water, and one of the alternative materials. To ensure proper test results, we made 4 test mixtures containing 3 specimens for each material. This resulted in a total of 12 specimens for each material. Each specimen was cured for 28 days under water. After curing, we tested the compressive strength of each specimen on a hydraulic press machine and analyzed measurements of the load and stress. We then calculated the carbon footprint of the concrete mix with each alternative material. This data allowed us to analyze the mixtures and determine the most suitable candidate for 3D concrete printing. The new concrete mixes showed a varying level of compressive strength and showed a noticeable reduction in carbon footprint compared to the standard concrete mix. The technology of 3D concrete printing in combination with eco-friendly concrete will lay the foundation for a more sustainable future for housing.

Abstract Name: **Automated Cryptocurrency Trading Strategies Based on Market Signal and Deep Learning Approach**

Digital cryptocurrency first emerged in 2009 and is a currently thriving open-source community and payment network. Its ecosystem is gaining lots of attention from business, consumers and investors. In this paper, we replicated the trading strategies that have been developed for the stock market and back testedthese strategies on five different cryptocurrencies' (Bitcoin, ETH, USDT, USDC and BNB)historicaltrading data. We also developed an automatic effective trading strategy based on the short-term price prediction using the Deep Learning approach to maximize the total return.In the end, we concluded with the annualized performance return, sensitivity and reliability of the proposed trading strategies.

Abstract Name: **Evaluation of Marine Layer Characteristics at a Lake Michigan Shoreline Impacted by High Ozone**

The Wisconsin's Dynamic Influence of Shoreline Circulation on Ozone (WiscoDISCO) campaign involved obtaining atmospheric measurements to create a model of atmospheric layering of a shoreline environment impacted by high concentrations of ozone. The 2022 field campaign ran from June 19 - 24, 2022. The Uncrewed Arial Systems (UAS) utilized in this campaign were two DJI M300 multirotor copters each equipped with a Personal Ozone Monitor (POM) and an iMET sensor. UAS were flown at a Lake Michigan shoreline in southeastern Wisconsin to obtain simultaneous overwater and overland measurements of air temperature, relative humidity, ozone concentration, and wind speed and direction. Measurements from WiscoDISCO-2022 were used to characterize the marine layer during lake breeze circulation using identifiers of atmospheric inversion. The field campaign captured atmospheric measurements during a total of 52 flights, 34 over land and 18 over water consisting of a vertical ascent from a fixed location. All overwater flights correspond to simultaneous overland flight. The presence of an over land internal boundary layer underneath an inverted marine layer was observed during most lake breeze events, where over water inversion extended to the near-lake surface. Calibrations on the ozone monitor were done on every other flight each day using a transfer standard and all ozone readings of the POM were adjusted to these calibration results. Observed differences in simultaneous observations of marine layer dimensions and ozone will be discussed.

Abstract Name: **The Persistence of Memory in Other Mediums: Creating a Digital Audio Archive of Anastasia Tsvetaeva**

In March 2022, the University of Kentucky Libraries received a donation of books, papers, artifacts and archival materials concerning the Russian writers Marina (1892-1941) and Anastasia (1894-1993). These materials were donated by Uli Zislin, the 92-year-old Jewish Russian-American curator of the Washington Museum of Russian Poetry and Music, located in Washington, DC. Among the two dozen boxes of donated materials is a set of VHS tapes of interviews and literary events that Zislin filmed in Russia in the late 1990s. In this presentation, I explore the background and content of the materials as well as offer an overview of the software and methodology I used with the audio-visual materials to catalog and annotate them as well as make them legible to researchers. In my paper, I explore the personality and style of the videographer, Uli Zislin, through the layers of memory captured within the specific video materials, consisting of event recordings and oral histories by Anastasia Tsvetaeva's contemporaries and enthusiasts, as well as through the narrative construction of the materials. Using Michael Frisch's concept of "shared authority," I analyze the performance of memory in space, oral history and video editing to demonstrate how such materials offer avenues for new insights into the practice of recovering literary memory during the early years of post-Soviet Russia.

Abstract Name: **Cumulative Health Risk Assessment of Drinking Water Contaminants in Cascade and Lewis and Clark Counties, MT**

Lifetime consumption of water with unsafe levels of certain contaminants can negatively impact one's health. The levels of these contaminants in Montana water sources are not easily accessible to the public. The goal of this research is to calculate and create awareness of the cumulative risk from consuming the groundwater and stream water in Cascade and in Lewis and Clark counties, Montana. It is hypothesized that the average cumulative risk for each of the six observed watersheds is above 1.0, and hence unsafe for lifetime consumption.The water quality data were obtained from the Montana Ground Water Information Center (GWIC) which is managed by the Montana Bureau of Mines and Geology. Data for each of the HUC-8 level watersheds in the two counties of interest were downloaded from the GWIC website then were cleaned and analyzed in Excel. R studio was used to visualize the water quality data.The cumulative risk values for wells were calculated based on the sum of the ratios of each contaminant's average in relation to the respective EPA health standards, the values exceed the 1.0 safety benchmark in all six watersheds: Smith 1.98, Upper Missouri 1.98, Sun River 6.58, Blackfoot 1.41, Belt 3.37, and Upper Missouri-Dearborn 32.68. Many contaminants were above the recommended safe level, such as arsenic, nitrate, cadmium, and strontium. Exposure to these contaminants over an extended period can result in many negative health effects including increased risks of cancer, liver damage, etc.Up to date and accessible information on the water quality is important to the health and wellbeing of a community. We are meeting with the Health Departments in Cascade and in Lewis and Clark Counties to share results and discuss how we can support increased home well testing in their communities.

Abstract Name: Conformity and Friendship Satisfaction Among University Students

The rhetoric around one's role in a friendship or relationship is largely shaping up to promote a lack of conformity. Adolescents and young adults are now regularly told to "stand out" and perhaps that fitting in isn't always the best option. This, however, prompts the question of what role conformity plays in impacting friendship satisfaction. This paper explores whether there's a correlation between an individual's level of conformity and their level of friendship satisfaction. Gender and relationship status are explored as potential mediators in this relationship. The participants' level of conformity was measured using the Elevator experiment, where participants enter an elevator and find 4 other people facing the rear end of the elevator. Participants accordingly make one of three decisions, they either turn and face the rear end (conformity), continue standing the same way (non-conformity), or hesitate (mid-level conformity). Participants then completed a questionnaire that assesses their level of platonic friendship satisfaction across three scales. This process was completed 75 times by participants, with 25 students conforming, 25 not conforming, and 25 mid. Results of the Anova show that there is no significant correlation between conformity and friendship satisfaction; however, there was a significant correlation between gender and friendship satisfaction, which indicated that girls are overall more content with their friendships. This opens lots of areas for future research, as it can be worthwhile to explore some of the other factors that result in girls being more satisfied with their friendships at this specific age.

Abstract Name: Blockbusting and Racial Transition in Washington, D.C.

Blockbusting is the intentional action of one or more real estate agents to provoke white flight and fear in a previously racially homogeneous area, in order to sell properties for high profit to racialized minority groups. There is limited research on the causation of blockbusting, its distinguishing factors, and the living conditions in these neighborhoods. Our research aims to address these through a case study of Petworth, Washington, D.C., a neighborhood which underwent significant racial transition between 1950 and 1970, showcasing examples of possible instances of blockbusting and its mechanisms and key actors. Based on previous indications of blockbusting researched in the same area, our analyses explore the mechanisms of racial transition and possible blockbusting in Washington, D.C. and its impact on neighborhood disparities. While previous literature has often reinforced a dichotomous argument of either a structural model of racial transition (for example, invasion and succession) or an agent-based narrative (focusing on the influence of both white and Black individuals involved in blockbusting), this case study explores the circumstances which directly affected the racial transition and subsequent disinvestment of Petworth while bridging previous methodologies to provide a greater understanding of blockbusting as a practice. This is accomplished through a mixed analysis of both quantitative profit and loss statistics in home sales as well as individual narratives from oral histories. Oral histories from Washington D.C. residents are analyzed to examine blockbusting on a more personal level rather than at a group level. The sources come from three different oral history archives alongside property records from the Office of Tax and Revenue's (OTR) real property tax database. Preliminary results find repeating instances of likely motives for blockbusting as well as a complex story of profit and loss by potential blockbusters.

Abstract Name: **The impact that former American Missionary children had on the 1898 annexation of Hawaii**

In the mid to late nineteenth century, Hawaii underwent a series of political events that resulted in the 1898 annexation by the United States Government which was instigated by American politicians and businessmen who had grown up in Hawaii as the children of American missionaries. Three of the most prominent actors included are Lorrin A. Thurston, Sanford Dole, and Albert F. Judd. Through analyzing a series of political and personal documents written by key figures of the annexation movement it can be seen that their intimate understanding of Hawaiian culture and the prestigious positions trusted to them because of their unique place in society allowed these individuals' leverage against the monarchy in crucial moments. These individuals are largely responsible for the annexation of Hawaii and their background as the children of American missionaries was the most significant common variable.

Abstract Name: **Home Range and Habitat Selection of Rehabilitated and Released Female Black Bears in Northern Wisconsin**

The Eastern American Black Bear (Ursus americanus americanus) is a valued species among many for its biological, intrinsic, and cultural significance. Black bears are considered habitat generalists, taking advantage of the resources available to them. In the state of Wisconsin, previous studies suggest black bears select for habitats in northern hardwood forests and near beaver flowages. Habitat selection data from rehabilitated and released bears is lacking in Wisconsin, although this is a practiced management technique. The purpose of our study is to investigate the home range and habitat selection of rehabilitated and released female black bears in northern Wisconsin. The rehabilitated yearlings are fixed with GPS radio-collars prior to release, and location data is received every four hours. Habitat data from the received GPS points are compared to habitat data from random locations within the bears' home range (third-order analysis). Habitat data such as landcover type and distance to nearest road, stream, and open water source is collected. Understanding habitat selection of rehabilitated black bears in comparison to previously known black bear selection behavior is important for determining the impacts of rehabilitation and release as a management technique.

Abstract Name: **Paleontology of Faunas from Initial Transgression to Deep Marine, Cretaceous (Albian) of Central Texas.**

The Early Cretaceous (Albian, 100-113 million years old) Walnut Formation crops out in the low valleys of the Lampasas Cut Plain in Central Texas. The Walnut records the transition from nonmarine into fully marine conditions with various lithologies of limestone, marls and shales, and is extremely fossiliferous, dominated by Bivalves, gastropods, Echinoids and Cephalopods. The succeeding stratigraphic Members of the formation contain distinct faunas: 1) the basal Bull Creek Member contains a low species richness, low evenness fauna dominated by the large gastropod, Peruviella dolium; 2) the Cedar Park Member contains an ichnofauna of arthropod burrows representing a tidal flat paleoenvironment; 3) the Keys Valley Marl Member contains both a high species richness fauna dominated by the ammonites Oxytropidoceras salasi and Engonoceras pierdenale and an oyster biostrome of Texigryphaea mucronata and 4; the Upper Marl Member is dominated by the bivalves Protocardia multistriata and Homomya bravoensis. Gastropods are abundant throughout all Members, and include several possible new species at the top of the formation. Overlying the Walnut, the wavy-bedded limestones of the Comanche Peak Formation contain a similar, open-marine fauna. Expected results will include multiple diversity indices and size-frequency histograms for dominant species at all fossiliferous horizons.

Abstract Name: **The effects of restoration projects on phosphorus concentrations throughout Manitowoc County streams and Lake Michigan**

Phosphorus poses an ongoing challenge to Lake Michigan. Excess levels cause algae blooms resulting in degraded water quality in near-shore waters. As local tributaries serve as important phosphorus sources to Lake Michigan, we analyzed phosphorus levels in two streams in Manitowoc County, WI—Centerville Creek and the Little Manitowoc River. These streams have historically exceeded Wisconsin DNR surface water phosphorus standards of 0.075 mg/l phosphorus. Each stream has undergone restoration near where they enter Lake Michigan in order to slow stream flow and reduce phosphorus loading into Lake Michigan.Each creek showed a different trend in phosphorus concentration along its length.Centerville Creek showed lower phosphorus concentrations within the restoration area compared to the upstream branches, although all significantly exceeded the WDNR threshold. North branch averaged 0.510 mg/L phosphorus, and the south branch averaged 0.430 mg/L.Sites within the restoration project averaged 0.307 mg/L. In contrast, no difference in phosphorus concentration was noted between the upstream and restoration sites in the Little Manitowoc River.This may be because this restoration was more recently completed (2020 vs 2012), or due to the surrounding land use as the Little Manitowoc River runs through the city of Manitowoc, while Centerville Creek goes through agricultural land.However, overall concentrations across the Little Manitowoc River were lower than any of the Centerville sites, with an average concentration of 0.071 mg/L, below the WDNR threshold, and rain events did not increase phosphorus as much as in Centerville Creek. Future work will focus on identifying future sources as

Abstract Name: **Physiological Changes in Dienococcus aquaticus During Long-Term Stationary Phase Under Carbon Source Availability Stress**

There is a complicated interaction between a bacterium and its environment driving adaptation. Usually, bacterial physiology is studied during the exponential phase, but investigations during the long-term stationary phase are not as well understood. Here, we followed two strains ofDeinococcus aquaticus in the long-term stationary phase in low and high-nutrient environments. The evolutionary trajectory was assessed through surveillance of cell viability, colony morphology, genomic content, and protein content over 54 days at three time points. We predicted that nutrient depletion and waste accumulation in the flask environment would result in phenotypic variation. Interestingly, there was an environmental shift toward a basic pH. Despite the shift in pH, cultures remained viable after 54 days. Differences among strains were observed in generation time, pigmentation, and colony morphology, among other phenotypic and metabolic characteristics. Divergence in extracellular protease activity was also observed throughout the study. Significant variation between samples equally subjected to the same growth conditions suggested thatD. aquaticusis capable of short-term evolution under resource-scarce conditions.Our findings suggest that further research to evaluate variation in proteins as a carbon source is warranted.

Abstract Name: **Prenylated Stilbenoid Arachidin-1 Increases Effectiveness of Paclitaxel in Triple Negative Breast Cancer**

Triple-negative breast cancer (TNBC) is one of the deadliest forms of breast cancer. Investigating alternative therapies to increase survival rates for this disease is essential. Plant natural products, such as the prenylated stilbenoid arachidin-1 (A-1) from peanut, have shown cytotoxicity to certain cancer cells. The goal of this study was to examine the apoptotic effects of A-1 in TNBC cell lines MDA-MB-231; MDA-MB-436 as well as investigating the impacts of A-1 as an adjuvant for the popular chemotherapy drug, paclitaxel (Pac). The apoptosis induction capability of A-1 and Pac treatment in TNBC cells was evaluated through measuring the activation of key apoptosis proteins via western blotting. Flow cytometry was used to detect apoptosis and cell cycle arrest in the A-1-treated cells. Additionally, TNBC cells were treated with specific concentrations of A-1and/or Pac for 24 h and apoptosis induction was observed by Annexin V-FITC/PI staining and flow cytometry. Results showed a dose-dependent increase in levels of cleaved PARP and cleaved caspase-9; additionally, the amount of survivin, an apoptosis inhibitor protein, decreased at increased A-1 concentrations. This indicates an A-1 dose-dependent intrinsic apoptosis increase in treated TNBC cells. In addition, flow cytometry assays showed cell cycle arrest in G2/M phase and induction of apoptosis in treated cells. Cells treated with the combination of A-1; Pac showed a statistically significant, dose-dependent increase of early apoptosis induction. This research accentuates the importance of further understanding the effects of stilbenoids as an adjuvant treatment for TNBC. In future research, we will apply these methods to a spheroid model to observe the effects of A-1; Pac treatment within the tumor-like microenvironment.

Abstract Name: **Determining Interactions between Neurotransmitters and DNA Sequences Associated with Neurodegenerative Diseases**

The interaction of various neurotransmitters with G-rich DNA sequences was analyzed to understand its role in the associated neurodegenerative disease. The neurotransmitter may promote or inhibit the formation of quadruplex DNA in G-rich sequences, which may affect disease pathology. Additionally, the binding of the neurotransmitter may be concentration dependent or dependent on the presence of a monovalent cation. The interaction of four DNA sequences, NOP56 5'-(GCG CTG)-3', CSTB promoter 1 5'-(CGG GGC GGG GCG)-3', PRNP 5'-(CCT CAT GGT GGT GGC TGG GGG CAG)-3' and c-myc 5'-(TGA GGG TGG GTA GGG TGG GTA)-3'were separately studied with the neurotransmitters tryptophol, melatonin, serotonin, and dopamine. Fluorescence spectroscopy, DNA melting, molecular docking and surface enhanced Raman spectroscopy (SERS) were used to study the interactions. Dopamine promoted the formation of quadruplex in CSTB and c-myc but inhibited it in NOP56. The DNA sequences NOP56 and CSTB only formed quadruplex with melatonin in the presence of potassium ions. Melatonin promoted quadruplex formation with c-myc. Serotonin promoted the formation of quadruplex DNA in NOP56, CSTB, and c-myc. Tryptophol inhibited the formation of quadruplex DNA in NOP56 and CSTB samples, but c-myc formed quadruplex with or without tryptophol and potassium ions. PRNP did not form quadruplex even after the addition of each neurotransmitter. The SERS data showed a vibrational signature, that was dependent on DNA concentration. Further analysis will be completed to determine how these disscovered interactions can affect the progression and characteristics of the respective diseases.

Abstract Name: **Teaching Sexual Education to Adolescents as a Single Father**

Single fathers face the unique challenge of having the responsibility to provide their child with a sexual education without the help of a partner. This paper examines the single-parent family dynamic and parenting roles through a family systems perspective. Risk factors for single fathers not giving their child a comprehensive sexual education include discomfort talking about sexual topics, uncertainty about adolescent developmental needs, and traditional gender role expectations. However, fathers may overcome these barriers if they feel the responsibility of talking to their child about sex, feel well-educated on the developmental stage of their child, and are able to share their experience with families in similar situations. The importance of sexual education for adolescents, and how single fathers would like to be helped throughout this journey, will also be highlighted in this paper. When educated and supported, single fathers can be equipped to give their child a sex education that can allow adolescents to make healthy and safe decisions in the future.

Abstract Name: **Flexible Finger Design for Robotic Gripper**

In industry, the safety and productivity of collaborative robots make them a vital part of many pick and place applications in production. Collaborative robots offer many advantages including their flexibility. In keeping with the advantages of collaborative robots, this flexibility should be extended to the grippers and fingers to reflect human-like dexterity. Flexible fingers have several advantages over traditional, rigid grippers. Adaptive fingers can pick and place a much broader array of oddly shaped objects than traditional grippers. Flexible fingers are also advantageous when working with fragile objects, such as produce, as the gripping force can be distributed by the flexing of the finger.The purpose of this project was to design, optimize, build and evaluate flexible fingers which can be mounted to a Schunk gripper on the end of a Fanuc collaborative robotic arm. Flexible fingers were designed in SolidWorks to integrate with the robotic gripper assembly. By testing prototypes, aspects were identified to improve the flexibility and functionality of the gripper. Using DOE (Design of Experiment) as an optimization strategy, the effects of each variable such as material, wall thickness, infill, etc. was studied. Mechanical simulators were used to isolate and test these variables to see their effects on the system with realistic situational constraints.The manufacturing of the flexible fingers consisted of using SLA and FDM printing to test, compare, and combine the more promising features into a robust finished product, capable of gripping and lifting various objects.Using technologies such as CAD, additive manufacturing, and agile engineering methodologies; it was possible to accomplish the design process and optimize the finger design in a collaborative manner.

Abstract Name: **The Effect of Ambient Noise Within A Vehicle on the Audibility of Safety Sirens**

Reaction time while driving is crucial, and even one second can be the difference between life and death. As safety vehicles use sirens to alert civilians, the ability of the public to respond appropriately to such signals will depend on the audibility of sirens. This project aims to evaluate the impacts of sound dampening from the inside of vehicles on the audibility of safety sirens (police car/ambulance/fire truck) in the presence of varying levels of auditory stimuli or in the absence of such stimuli. These questions are crucial to public safety as more than 90% of people listen to some sort of auditory stimuli, such as music, while driving. In fact, my initial findings have demonstrated that sound intensity levels were reduced by more than half in terms of relative decibel level outside the vehicle, even without any ambient noise present within the vehicle (a baseline was established by measuring the output of the siren at the safety vehicle to find what level the signal is emitted at). When drivers can't hear emergency sirens, they can't properly react to them; thus endangering both themselves and the emergency personnel. Future steps is to quantify siren intensity levels in terms of the A-weighted decibels (dBA - measure of sound intensity relevant to human hearing) and to determine how different sound frequencies (hertz) of each safety siren attenuate various distances. Results will then be compared with various sound levels inside the vehicle to determine the minimum masking value. Findings will be discussed in terms of the effectiveness of sirens in alerting drivers in the presence of ambient noise, and hope to suggest how drivers may be better alerted to the presence of sirens. This research not only aims to benefit the field of audiology, but the safety of the public as well.

Abstract Name: **U/Pb Geochronology and Zircon Trace Element Geochemistry of the Pembine-Wausau and Marshfield Terranes of the Proterozoic Penokean Orogen, Wisconsin**

This study presents new U/Pb and trace element data from zircons obtained from volcanic and intrusive rocks from the Pembine-Wausau and Marshfield terranes of the Paleoproterozoic (1.8-1.9Ga) Penokean Orogen in northern Wisconsin. This terrane is best known for hosting almost 150 Mt of volcanogenic massive sulfide (VMS) mineralization. However, challenging socio-political obstacles preventing mining and exploration activities coupled with extensive overlying Paleozoic and Quaternary deposits has limited the study of the terrane. The current need for critical minerals highlights the importance of improving our understanding of this underexplored and poorly exposed orogen. This study aims to improve regional tectonic and metallogenic models for base and precious metal exploration. Samples were collected from within the Ladysmith-Rhinelander and Eau Claire volcanic belts, and zircons from these samples were then analyzed at Laurentian University (Sudbury, Ontario, Canada) via Split-Stream Laser Ablation Inductively Coupled Plasma Mass Spectrometer (LASS-ICP-MS) to obtain radiogenic isotopic, and trace element data. Preliminary results reveal complex age relationships and basement architectures that were previously unrecognized. The samples obtained from the Eisenbrey deposit within the Ladysmith-Rhinelander belt temporally correlate with felsic rocks from the Back Forty deposit in Michigan supporting a recently recognized wide-spread younger VMS forming event. Samples from the Lynne deposit reveal the presence of a co-eval subvolcanic intrusion in the presence of Archean basement, but the distribution of this older basement is poorly constrained. Samples from the Eau Claire volcanic complex reveal ages that correlate with other VMS-forming strata across the Pembine-Wausau terrane, but do not show evidence of older basement rock despite existing models. Therefore, tectonic models for the development of the Penokean Orogen and the formation of VMS deposits need to be revisited.

Abstract Name: **Do You See Your Bias? An Accent Perception Study**

Accents are an important social stimulus that influence how we form groups and interact with others. The purpose of our study is to identify variables that influence accent perception. Meltem et al. (2019) found that demographic categories such as gender, skin color, and physical features can influence accent perception. English speakers listened to recordings from non-native English speakers presented with different images and rated their accent in a Qualtrics survey on a scale from 0-10 (following Cal State LA and the University of Wisconsin-Whitewater's IRB guidelines). They answered demographic and language background questions. A one-way repeated measures analysis of variance was conducted to identify differences between the ratings for each image. A statistical significant difference between conditions was found. The results indicate that visual stimuli have an effect on accent perception; foreign accent ratings were higher when a Latinx person was presented with the audio. These results show how physical traits influence accent perception, therefore accent should be understood as a bidirectional relationship between the speaker and listener.

Abstract Name: **Compression and Contact of The Glenohumeral joint; a Cadaveric Study Comparing Angles of Internal and External Rotation**

Previous research has indicated that immobilization in external rotation for shoulder dislocation may reduce the recurrence rates of dislocation and instability of the Glenohumeral Joint (GHJ). The purpose of this research is to calculate the extent to which the humeral head is in contact with the glenoid fossa and the amount of pressure it applies in various positions of immobilization while comparing it to geometric analysis calculations. To accomplish this, we will be performing cadaver-based research using manipulation of the joint position as the primary independent variable. The joint will be positioned between 50° and 60° of internal rotation accompanied with adduction of the arm for the internal rotation measurements. For the external rotation portion, we will be measuring in multiple angles from 0° to 45° combined with abduction. The total contact and compression of the humeral head in the glenoid fossa will be measured using a Trill capacitive touch sensor. The geometric analysis involves measuring the superoinferior (SI) diameter of the humeral head, anteroposterior diameter of the humeral head, radius of curvature of the humeral head, humeral head retroversion, humeral head thickness, inclination angle, critical shoulder angle, glenoid width, glenoid length, and radius of curvature of the glenoid. Comparing our GHJ analysis with a geometric analysis will provide insight into possible reasons for the advantages of external rotation for anterior shoulder dislocation immobilization.

Abstract Name: **Location of cartoid body oxygen sensors in the Alligator mississipiensis**

This research sought to identify the location of the carotid bodies in the Alligator missisippiensis. Biologists are interested in alligators due to their evolutionary success and distinct physiology. Their unique cardiopulmonary system has been researched, yet to date little has been published about the exact location of alligator carotid bodies. In humans, carotid bodies detect changes in blood levels of CO2, O2, and H+ and help maintain blood-gas homeostasis. Carotid body dysfunction can cause congenital central hypoventilation syndrome (or Ondine's Curse) and other forms of sleep apnea. Alligators are useful as a study model for understanding the evolution of blood-gas regulation in terrestrial vertebrates since they have changed little in the last eight million years. Further research on their vasculature and carotid bodies may help researchers understand how to treat certain human carotid body related diseases. Prior studies have determined that the carotid bodies in mammals are typically located at the bifurcation of the internal and external carotid arteries found laterally in the neck. The authors hypothesized that alligator carotid bodies would also be located at the bifurcation of the internal and external carotid arteries, although in alligators, this bifurcation is located on the posterior surface of the skull. Methods used in this study included vascular dissection of seven juvenile, female alligators, vascular casting, and Kluver-Barrera histological tissue staining for identifying myelin. The researchers' results showed that myelin was located at the bifurcations of the external and internal carotid arteries, indicating the likely presence of nerve fibers from the glossopharyngeal nerve and carotid body. Interestingly, as suggested by prior CT scans of alligator vasculature, the researchers also confirmed via direct dissection that the branching patterns of the left and the right carotid arteries were asymmetrical in the alligators studied.

Abstract Name: **"I wish you would throw that bone out of the window.": The Bone Wars and Cultural Nationalism in the late Nineteenth Century**

In the United States, an episode of unethical fossil hunting called the “Bone Wars” took place between the 1870’s and 1910, creating a paleontological collections competition in American natural history museums. The actions and field collecting of two key figures, Othniel Charles Marsh and Edward Drinker Cope drove the narrative of the Bone Wars and garnered attention from European institutions and paleontologists. Although most of the current literature on the Bone Wars follow Marsh, Cope, and their hired fossil hunters as they search the field for the next big fossil find, little has been said about the relationship between American paleontologists and institutions and their British and European counterparts, especially the role of cultural and intellectual nationalism on the field of paleontology. The large collections of fossils that were found in the West built up a sense of identity on both a regional and national scale. Even with fossils building up an identity in institutions, American paleontologists still referred to European texts and knowledge, because the competitiveness of the Bone Wars was not an isolated event. It played on the prior successes of British and European paleontologists in the early nineteenth century in Europe. Conversely, the Bone Wars’ competitive nature spurred many new discoveries that impacted both American and European paleontology and institutions alike. By acknowledging this relationship and the intellectual/cultural nationalism in which the Bone Wars are set, one can investigate other national relationships within the field, enabling an analysis of the history of paleontology in a more whole sense.

Abstract Name: **Community Gardens and the Effects on Participants**

When we think of community gardens, we think about green spaces where people can come together to grow food. This research will examine how community gardens impact the community around them and how people benefit from them. Prior research indicates that community gardens have a positive impact on the community and provide many benefits including improved food access as well as economic, health, social, and environmental benefits. For example, because people are growing and selling food in their community, they can keep money in their community. Individuals who work or are involved with the gardens also shape their identity. People can express themselves through garden-based art and in how they get to grow their plots. Gardens are also a good way to connect and build relationships with local farmers and with other members of the community. The purpose of this research is to understand the impact community gardens have on the people who participate in them. Specifically, we will examine the impacts and benefits (environmental, subsistence, social, emotional) that community gardens have for the participants in UWO’s Community Gardens program, their perspective on why they participate in this program, and what they think sustainable agriculture is. We will use surveys, interviews, and participant observation to gather this information. We hope this research will help us to understand the benefits people in our regions get from community gardens and how we could adjust community garden programs to provide more benefits and reach more people. This research can help us better define what we mean by sustainable agriculture and understand how it can be expanded.

Abstract Name: **The Effect of 3D and VR on the Perception of Robot Humanlikeness**

My project focuses on investigating the effect of a 3D/VR space on the perception of robot humanlikeness. The research question I am investigating is "How do people's perceptions of robot humanlikeness change when viewing anthropomorphic bots in VR?" Using the ABOT (Anthropomorphic roBOT) database with over 200 images of humanlike robots, I created an environment in Unity to visualize these bots in 3D. After collecting demographic information such as age, gender, and ethnicity, the participant takes a short cybersickness screening questionnaire to better understand their capacity to participate in a 10-minute long VR experiment. Icollect data by having participants view a curated 3D environment where robot models may be examined and subsequently judged as "Not humanlike at all" to "Very humanlike" on a 100-point sliding scale. The participantanswer thehumanlikeness questionfrom within an HTC Vive Pro 2headset by using the provided controls to rate robots. My project builds on current research conducted in 2D and uses the same questionnaire type assessment to rate each robot models' humanlikeness. As an attempt to fill the gap in literature as well as an extension to the ABOT databse, this study will allow robot-researchers and designers to see how their bots are perceived as humanlike in an ecologically valid environment, as well as compare 2D and 3D humanlikeness scores from pre-existing data.

Abstract Name: **Building a Research Collaboration Between a Community College and a Research University**

Bridge programs are a popular method to enhance student success and is often documented as a key factor for easing the transition of students into college or university life. After seeing and hearing results regarding bridge programs at several conferences, a question became obvious: Is there any reason a research type program could also be used in such a way? With the personal experience of doing undergraduate research at a home institution as inspiration, decisions were made to pursue a research experience where the more limited facilities at a community college could work in collaboration with a local research based university. The concept of this summer research experience would allow for students to work on innovative projects in a facility they are already familiar with. This presentation will explore how such relationships can be developed, lessons learned along the way, and plans for the future.

Abstract Name: **Creating a Pseudoscience Scale: Identifying Gaps in Critical Thinking in Acceptance of Pseudoscience Topics**

Pseudoscience pervades discourse across the world. Acceptance and consideration of pseudoscience was especially highlighted during the COVID-19 pandemic, demonstrating the threat of pseudoscientific beliefs to public health and the prevention of disease. Teovanović et al. (2020) conducted a study that revealed those who were less likely to participate in guidelines such as hand washing or physical distancing were more likely to believe in pseudoscience practices. Additionally, a study by Desta and Mulugeta (2020) revealed that the spread of pseudoscientific beliefs related to COVID-19 had a negative effect on the containment of COVID-19. Across the world, researchers recognize the importance of understanding the origins of pseudoscientific beliefs. García-Arch et al. (2022) created a validated psychometric tool to measure a range of pseudoscientific beliefs, though this scale was developed and validated in Spain. Our goal is to create a pseudoscience scale focused on specific medical beliefs within a United States sample. This is particularly important as pseudoscience beliefs can vary significantly across cultures. We aim to investigate how pseudoscientific beliefs about health and medicine in the United States correlate with intelligence and critical thinking. We created a survey which was distributed electronically to college students, with a goal of obtaining at least 100 responses across different school levels and other demographic characteristics. We began data collection in fall 2022 and plan to continue throughout winter and spring of 2023. This study will contribute to knowledge about what gaps in logic or critical thinking contribute to acceptance and belief in pseudoscience. We hypothesize that individuals with lower levels of critical thinking and intelligence will indicate higher agreement with pseudoscientific ideas. The analysis will aid us in more effectively targeting people with pseudoscientific beliefs in an effort to reduce the acceptance of pseudoscience.

Abstract Name: **Investigation of Novel Hippocampal Cell Population's Modulation over Spatial Memory**

The supramammillary area (SuM) is a ventral hypothalamic nucleus with direct connections to the hippocampus. The SuM has been shown to modulate hippocampal theta rhythm - a measure of synchrony between hippocampal regions - and other processes such as cognition, learning, and memory. We recently identified a novel population of inhibitory hippocampal-based neurons projecting to the SuM. Referred here as inhibitory hippocampal-hypothalamic (IHH) cells, IHHs are believed to be localized to the hippocampal dentate gyrus (DG). IHH fibers have been identified near SuM-DG projecting neurons, a neuronal population which signals spatial novelty. Hence, this largely uncharacterized hippocampal cell population shows promise in modulating spatial novelty signals originating from the SuM (SuM-DG cells). We specifically hypothesized that IHH activation may suppress spatial novelty signals from the SuM and thereby impair discrimination of novelty and familiarity in a hippocampal-dependent task. To further investigate such claims, in-vivo optogenetic stimulation of IHH terminals (DG-SuM) was conducted during two behavioral assays: the hippocampal-dependent Object Location Memory (OLM) and the hippocampal-independent Object Recognition Memory (ORM) assessment. Opsin-positive and negative animals were prepared with ChR2 expression or a control virus expressing EGFP, respectively, localized to the hippocampal DG. Both groups completed the respective OLM and ORM assessments with a one-week break separating each behavior assessment. MATLAB was used to demarcate the time of investigation each animal spent per object, and a discrimination index was used to identify the investigatory preference of an animal. Following completion of the behavioral assessments, animals were euthanized to investigate implant location, virus expression and location, and tissue damage. Future experiments will continue to further characterize and investigate IHH's connections and modulation over spatial-novelty signals originating from the supramammillary area.

Abstract Name: Implications of COVID-19 on College Counseling Services

Many aspects of college life were impacted by the restrictions set in place due to the Covid pandemic, especially when it came to mental health. During this time, the demand for counseling services increased and many students were reporting that the pandemic had negatively impacted their mental health (APA, 2020; Castonguay et al., 2021). Prior to Covid, studies have found that some of the most common concerns students present tocounseling with include anxiety, depression, and relationship difficulties (Cairns et al., 2010; Barr et al., 2011). It is unclear how the pandemic may have impacted the prevalence of these concerns on college campuses. One focus of our study was to uncover whether the most common presenting concerns have changed from pre-covid compared to post-covid. Another adjustment that was made due to Covid was the transition to treatment through an online setting. While these changes have been beneficial in managing depression, anxiety, stress, and other concerns, there have been mixed results when it comes to effectiveness compared to in-person treatments (Bambling et al., 2021). A second focus of our study sought to identify how satisfied patients of college counseling services were with online treatment. To complete our study, we looked at archival deidentified program evaluation data collected from a large Midwestern University System's counseling outcome evaluation tool including responses from our local campus. Our findings note that both at our campus and throughout thesystem, the most prominentpresenting concern both pre-covid (2017-2018) and post-covid (2021-2022) was anxiety, followed by stress and depression. Additionally, a majority (57%) of those who received counseling post-covid chose a telehealth appointment compared to an in-person appointment. Additional analyses examining group differences in satisfaction with counseling services are currently being completed. Implications of the results for counseling services on college campuses will be discussed.

Abstract Name: Studying the Electrochemical Activity of Methanol Dehydrogenase in Lanthanide-Modified Methylobacterium extorquens

Recent studies have demonstrated that some enzymes in bacteria isolated from lanthanide-rich areas use lanthanides as metal cofactors in place of more common metals like calcium and that these lanthanide-enzymes have enhanced catalytic properties. For example, Methylobacterium extorquens is a methylotroph that conducts redox chemistry using methanol dehydrogenase (MDH). MDH is a type of quinoprotein that contains a pyrroloquinone and either a lanthanum (La3+) or calcium (Ca2+) metal cofactor. Here, the bioelectrocatalytic activity of MDH from M. extorquens grown in La3+ rich media is compared to MDH from M. extorquens grown in typical Ca2+ rich media. Biochemical assays have shown that La3+-MDH has higher activity than Ca2+-MDH. However, the bioelectrochemical activities from these bacteria have not been compared. If La3+ grown M. extorquens has higher bioelectrochemical activity than Ca2+ grown M. extorquens, then improved biofuel cells and sensors can be created. M. extorquens is grown in two separate cultures, one with La3+-rich media and one with Ca2+-rich media. Methylene blue is polymerized onto the surface of a glassy carbon electrode, then harvested bacteria or isolated enzyme is immobilized on the electrode by casting a mixture of the bacteria and tetrabutylammonium bromide (TBAB)-modified Nafion® onto the electrode surface. The bioelectrochemical activity for oxidation of methanol to formaldehyde is measured by cyclic voltammetry and amperometric i-t curves for various concentrations of methanol in a tris-HCl buffer. In addition to comparing the bioelectrochemical activity of the La3+-MDH and Ca2+-MDH, the activity of the whole bacteria and isolated enzyme electrodes will be compared along with the electrode lifetimes.

Abstract Name: **Galaxy Morphology and it's Relation to Gas Content in Nearby, Star-Forming Galaxies**

Stars are formed in galaxies from the collapse of gas clouds composed mostly of hydrogen. It has been previously shown that the amount of gas in a galaxy depends on its shape and structure (its morphology), and that spiral galaxies tend to host more gas. Measuring gas content is somewhat difficult to do, so it would be beneficial to use easy-to-measure quantities to estimate gas content in galaxies. Our gas measurements are taken from archival data, yielding a sample of 108 galaxies with molecular hydrogen (H2) measurements and 3,338 with atomic hydrogen (HI) measurements. We examine the correlations between HI and H2 gas content and different structural parameters that measure the distribution of mass within the galaxies. We find that gas content is correlated most strongly with the density of stars in the inner regions of the galaxies, especially within the inner 3,000 light-years. Our findings offer a method for astronomers to estimate the gas content using easily obtainable morphological parameters, which is very useful in situations where it is difficult or impossible to obtain direct gas measurements.

Abstract Name: **Development of an antiplasmodial polyprotein for paratransgeneis to combat malaria**

Malaria is a deadly vector-borne disease responsible for over 600,000 deaths in 2020[1] alone, and is caused by Plasmodium parasites. These parasites are transmitted to humans through a bite of an infected female Anopheles mosquito. Current preventive measures include bednets and indoor spraying of insecticides. However, due to increasing resistance from both the parasite and the mosquito vector, these are rapidly becoming ineffective, therefore indicating new control strategies are needed. One strategy to control the spread of malaria is paratransgenesis. Paratrangenesis is a technique that manipulates the microbiota of the mosquito vector to inhibit and kill the parasite within the mosquito. Asaia bogorensis is a commonly found bacterial species in the mosquito microbiome and has previously been engineered to express single antiplasmodial effectors and reduce the oocyst burden in the mosquito. This project looks to engineer strains of A. bogorensis that secrete a “polyprotein” of known antiplasmodial molecules. Each antiplasmodial has a different mechanism of action against Plasmodium, and should behave similarly to a drug cocktail. This should reduce the likelihood of Plasmodium developing resistance against any one antiplasmodial. In this study, we developed various strains of A. bogorensis that expressed two-effector polyproteins. We analyzed these strains for their ability to secrete our antiplasmodial polyprotein, and the effects of these polyproteins on fitness of transgenic A. bogorensis.

Abstract Name: **Perception of Information and Source Reliability B**

The term misinformation is being used so frequently now that it has become an annoying word to represent almost nothing. The perception of whether information is valid seems to be very dependent on who is giving the information. There are many different factors that play a role in deciding whether a source is credible or not. In the US today we are seeing that individuals are siding with news sources that have a similar political ideology when deciding what is fact and what is misinformation. The purpose of this research is to determine what factors correlate with someone'ssuseptiblity to misleading information. The personal characteristincs being studied include racial/ethnic background of the messenger and receiver, political ideology of the messenger and receiver, news media sourcepreference, expertise level of the messenger and receiver, and percieved trustworthiness of the messenger. The study will use information about controversial topics given by various sources and determine the level of confidence the subjects have about the legitimacy of the information. Demographics regarding the subjects will be collected. A correlational analysis will be made between traits of the message sender and receiver and the rating of the source information. Data analysis will be completed in the spring semester of 2023.

Abstract Name: **Accumulated Damage and Recovery in Drought-Stressed P. tremuloides**

Past research has demonstrated that prolonged drought, or multiple consecutive droughts, can lead to accumulated hydraulic damages in plant tissues. Drought stress, coupled with secondary or predisposing factors, is thought to be contributing tolarge-scale quaking aspen die-off events observed in recent decades (Anderegg et al. 2013). This research project aims to better understand these compounded hydraulic changes resulting from repeated droughts and whether aspen are more susceptible to other stressors, particularly pathogen invasion, during or after a drought season. Over a two year-period, aspen propagules were raised in an experimental garden under four different treatment conditions: true-drought, recovering, once-treated, and control. In 2022, we measured drought stress responses throughout the growing season and took mortality surveys at the end of the season. We will now be quantifying and characterizing leaf microbiomes in each of the plants in an attempt to identify recognizable pathogens. We will then be analyzing whether water stress is potentially linked to increased pathogen vulnerability. This research will begin to answer larger questions about how plants allocate their resources under stress, and how compounded stressors can affect overall forest health year to year.Anderegg, W.R.L. et al. 2013. Drought's legacy: multiyear hydraulic deterioration underlies widespread aspen forest die-off and portends increased future risk. Global Change Bio. 19:1188-1196.

Abstract Name: **Grendel and Grief: Grendel's Sorrow as a Humanizing Agent**

From consuming entire human bodies to losing his arm in a ferocious wrestling match, the character of Grendel from the epic poem Beowulf is notorious. Opinions on him abound, but, at the core of the conversation, one hotly debated question persists: what is he? Is he a monstrous human or a deceptively human-like monster? For decades, scholarship on him has grappled with this question, with most scholars tending to focus on his body. Further, many scholars have argued that Grendel is othered or made completely monstrous in a variety of ways: through his abnormal corporeality, through his consumption of human bodies, through his alienation from human community and through his inability to use human language, to name just a few aspects. Fewer studies, however, have considered him in terms of the recent affective turn medieval studies has taken. For example, Robin Norris's 2019 book chapter "Sad Men in Beowulf," which discusses the range of grief experienced by men in the poem, does not consider how Grendel fits into this "sad man" paradigm or how his place within this framework affects our understanding of whether he is human or monster. In this paper, then, I argue that the grief Grendel experiences throughout the poem connects him to a network of other sad human men within the text, thus traversing a variety of othering boundaries that alienate him or work to render him monstrous. Consequently, Grendel's grief humanizes him.Furthermore, I argue that Grendel should be viewed on a spectrum that runs from fully monstrous to fully human and, throughout the poem, he slides more towards one categorization or the other. Thus, I suggest that the moments where he experiences and expresses grief like other sad men in the poem push him towards the human end of the spectrum.

Abstract Name: **Investigating the Diagnostic Potential of Optical Emission Lines for Finding Dwarf AGN**

Intermediate mass black holes (IMBHs), while scarce, are between 100 and 1,000,000 times the mass of the sun and give insight into how black holes and galaxies evolve. All massive galaxies contain a black hole at their center, and black holes which actively influence the observed properties of their harboring galaxy are called active galactic nuclei (AGN). Dwarf galaxies, often around 100 times smaller than the Milky Way, are the most likely sites to harbor IMBHs and resemble early universe galaxies in their composition and star formation rate. These dwarf galaxies can elucidate how IMBHs evolve into the supermassive variety found at the heart of massive galaxies. Diagnostic diagrams using emission lines can differentiate between star forming galaxies and AGN. These diagrams use the ratios of the amount of light emitted at optical wavelengths emitted from star forming galaxies or AGN. The most widely used diagram struggles to distinguish AGN in the IMBH range. New diagrams that use different emission lines are likely more resistant to the effects of a galaxy's physical environment. Simulations of AGN can help to corroborate these new diagrams by identifying the effects of a galaxy's physical parameters on the predicted emission line spectrum. Our preliminary results confirm that weaker optical emission lines (e.g., He II 4686) can differentiate between purely star forming dwarf galaxies and those harboring active IMBHs. We also show that strong emission lines commonly found in more distant galaxies (e.g., [O II] 3727, [Ne III] 3869) can effectively distinguish between the two classes when the weaker lines are undetected, a valuable tool for the newly launched James Webb Space Telescope.

Abstract Name: **Undergraduate Nursing Students' Knowledge and Attitudes Toward LGBTQ+ Patients: An Assessment Related to an LGBTQ+ Cultural Competency Module**

Background: Nursing research has demonstrated knowledge deficits specific to care of the patient who identifies as lesbian, gay, bisexual, transgender, queer, + (LGBTQ+). Lack of knowledge specific to the care of people in LGBTQ+ communities continues in spite of this populations' increased health disparities. In an effort to address this lack of knowledge, both the Institute of Medicine and the US Department of Health and Human Services have called for prioritization in addressing these disparities. In fact, in their position statement on LGBTQ+ populations, the American Nurses Association (ANA) recognizes that nurses need to deliver care that is culturally congruent for LGBTQ+ populations. The ANA has therefore put forth recommendations that nursing education help to fill the void in the existing knowledge by incorporating content specific to the issues faced by LGBTQ+ populations. Toward that goal, this study sought to include a learning module covering healthcare considerations for the patient who identifies as LGBTQ+ within a required undergraduate nursing cultural competency course.Method:Student (N=124) knowledge related to care of the patient who identifies as LGBTQ+ was assessed before and after participating in a module entitled Cultural Consideration in Clinical Care: Working with LGBTQ+ Patients. Attitudes toward sexual orientation and gender identity were assessed before and after participation using the Modern Homonegativity Scale and Transphobia Scale respectively. A Wilcoxon signed rank test was conducted to evaluate whether students showed improved knowledgeand attitudes.Findings:Student knowledge scores related to care of the LGBTQ+ patient improved significantly after participating in the module. In addition, attitudes toward sexual orientation and gender identity improved significantly.Discussion:Incorporating content specific to issues faced by LGBTQ+ populations within undergraduate nursing education has the potential to improve clinical knowledge necessary for culturally competent care of LGBTQ+ population, as well as to improve attitudes toward these populations.

Abstract Name: **International Media Framing and the North Korean Missile Crisis**

This comparative study investigates coverage of the nuclear missile crisis in the United States, China, North Korea, and surrounding countries with the aim of advancing discussions around international media framing, nuclear policy, and nation building. The main research question concerns the extent to which news coverage is interconnected with the relationship of the media system and national interests within the dominant ideology of each country. The Cold War remained hot in the Korean Peninsula. North Korea and the United States have had a rocky relationship, especially due to North Korea's missile launch, ICBM, and nuclear tests. Our study examines the media coverage through a framework of Herman and Chomsky's (1988) Propaganda Model. This meant adopting different frames depending on dominant country ideology in the news media. North Korea's nuclear politics were framed in very different ways by each agency. Differences found in the amount and nature of news coverage, specifically themes, frame nature, sources used, and news geography for readers. Such variances are likely attributed to the propaganda efforts and those implications on news efforts in each country. Therefore, questions still endure about the level of connectedness between information systems and internal country ideals. Such scholarship will help explore the interconnectedness between press and politics, along with other sources of data and news collection from various contrasting global sources. Therefore, this study combines a quantitative content analysis with a qualitative assessment of the overall framing. Data collection will include the persistence of news frames cross-nationally, and then will analyze the current issue debates within international news coverage. The Asia-Pacific region has been an area of interest for propaganda scholars. This study is noteworthy and has the potential to contribute to propaganda studies based on based on the context in which it is taking place.

Abstract Name: **Patterns of convergent somatic hypermutations in the adaptive immune response of Mus musculus**

During an adaptive immune response, it only takes 5 to 15 somatic hypermutations to turn a naïve B-cell receptor, which has moderate affinity for the cognate antigen, into a high-affinity binder with exquisite specificity for antigen. Understanding the underlying mechanisms that make this feat of adaptive evolution possible has been a longstanding goal of immunological research, since it determines antibody functionality. We propose that convergent somatic hypermutations (cSHMs), i.e. mutations at the same sequence position with the same germline and mature amino acid identity arising independently in different individuals, may contribute to antibody maturation in an antigen-independent manner by stabilizing the resulting antibody fold and rigidifying its binding site.To identify cSHMs, we analyzed all murine antibodies for which structures have been deposited in the Protein Databank, resulting in a dataset of 454 antibodies that are clonally unrelated and have gapless germline assignments and a moderate number of somatic hypermutations. Interestingly, we found that cSHMs are fairly common. For example, 329 of the 454 antibodies share at least two mutations, and 53 antibodies share at least five mutations with another antibody in the dataset. We also searched for cSHMs that are structurally in close proximity to each other. Approximately 400 clusters of cSHMs that are located within 10 Å of one another were identified.The observation of a large number of structurally related cSHMs suggests that this may be a common mechanism of antibody maturation. Structural proximity of cSHMs suggest that they act synergistically to improve function. Clusters of cSHMs may have evolved in the germline repertoire to increase the likelihood of a successful and timely adaptive immune response by providing “molecular switches” that can be easily “turned” during antibody maturation, and identification of such clusters may have implications for the development of vaccines and antibody-based therapeutics.

Abstract Name: **The Prevalence of Urinary Incontinence in Female Collegiate Athletes**

The unintentional loss of urine, or urinary incontinence (UI), can have a negative impact on quality of life, including low self-esteem, depression, and reduced participation in social activities. UI has been studied in post-partum and older women; however, there is little research on female collegiate athletes, likely due to the fact that most collegiate athletes are young, relatively healthy, and have not given birth. The purpose of this study is to identify the prevalence of UI among National Collegiate Athletic Association (NCAA) Division-III female athletes at a Midwestern university. Emails and fliers were used to recruit all 159 eligible student-athletes; potential participants were asked to complete a voluntary, anonymous, online survey regarding their experience with UI during sport. Questions included information about unintentional leakage of urine during sport participation (practice, training, competition), as well as everyday life. The response rate was 80.5%. In everyday life, 59.4% of participants experienced UI, while 43.0% experienced UI related to sport. Based on prior literature, the eleven sports were divided into three impact groups: high, moderate and low. According to a chi-square analysis, there was no statistically significant difference in prevalence of UI between impact groups. Based on the high prevalence of UI in this study population, it is recommended to screen for UI in the female athletic population, beginning in adolescence, to treat the condition in its early stages. It is important to encourage screening to allow women to continue to be physically active and improve their overall quality of life. Further research should include how education for healthcare providers, athletes, and athletic staff can impact the prevention of UI and assist in promoting early interventions to keep athletes in sport and mitigate future issues.

Abstract Name: **Evaluating corn ear attributes in a perennial cover crop system**

Corn fuels the United States and a significant portion of the world, whether through feed, human or animal, or fuel, ethanol. However, current intensive corn production strategies/practices have led to negative environmental impacts such as soil erosion, poor water quality, and an increase risk of flooding. As a potential solution to mitigate these impacts, cover crops, planted between the corn rows,have been proposed. Benefits of cover crops include reduced soil erosion, pest and disease control, increase in crop diversity, and improved soil health. Current cover crop practices utilize annual species that must be replanted every growing season. Instead of using annual species, what if perennial ones were used instead? This would eliminate the need for annual replanting.Corn is a wind pollinated plant. Each kernel of corn must be pollinated. If less than 50% of the kernels are pollinated the plant will drop the ear prematurely. Also, if less than 50% of the kernels of the bottom two rows of the ear are pollinated then the plant will also prematurely drop the ear. In both these scenarios, the ears dropped lead to a reduction in yield. Ultimately, reduced yield leads to less money in the farmers' pockets. Will cover crops reduce corn yield through reduction of pollination?To examine potential impacts of perennial cover crops on corn yields, three different perennial cover crop systems were sampled along with one conventional system. Yield data was obtained from each system and 48 ears were randomly sampledfrom each system. Each of these ears was weighed, percent pollination calculated, and number of kernels recorded. Using these three parameters, statistical analysis will be conducted to determine if there is a significant difference between yield and pollination in conventional and perennial cover crop systems.

Abstract Name: **Drug Design: Development of a Small Molecule Inhibitor for TIPE2 for the Treatment of Cancer**

Tumor necrosis factor a-induced protein 8 like 2, or TIPE2, is a protein involved in the proliferation of tumor cell growth through the facilitation of leukocyte polarization. Leukocyte polarization, the structural change to a white blood cell enabling motility, supports chronic inflammation; providing the necessary angiogenic factors for tumor cells to thrive. The aim of this project is to develop a small molecule inhibitor for TIPE2, which could act as a therapeutic agent to prevent further growth of cancerous tumors. Target selection begins the process of drug design; a biomolecule involved in the pathway of disease is identified, herein, TIPE2 is the target. Virtual screening follows with libraries of fragments, docked in the protein using AutoDock Vina. For different linking strategies the ligands were docked in a moderate grid box, spanning the cavity entrance; four small grid boxes, breaking the entrance into four quadrants; and a high grid box, occluding the entrance. The highest binding fragments were determined and linked to other high-binding fragments. This process was repeated using molecules from the various grid boxes to optimize the locations of binding within the cavity. These compounds are being modified for the desired absorption, distribution, metabolism, and excretion (ADME) properties. The observed results appear promising and suggest that developing a compound that has the desired properties is possible with more manipulation.

Abstract Name: **Continuous Compliance Monitoring of Water Quality to Determine the Effects of Urbanization on Richland Creek**

This project aims to establish a long-term water quality compliance monitoring system to determine the degree to which urbanization is impacting physical and chemical indicators crucial to the health of Richland Creek and Schenck Forest. Continuous monitoring allows us to observe the changes in these indicators as commercial, residential, and transportation development expand in the surrounding area. The area of study consisted of two sites situated along Richland Creek, located in Raleigh, North Carolina, where biweekly YSI and nutrient testing were conducted. The sites' data were compared to observe two trends: (1) the initial contrasts stemming from their different existing degrees of urbanization, and (2) the changes in these contrasts due to their differing rates of increasing urbanization. Our goal is to influence city and community programs in Schenck Forest to protect water resources for the people who consume them and the ecosystems that depend on them. We hope this research can help establish a baseline for these indicators to inform future research around water quality, aquatic life, and human health in Richland Creek and the field as a whole.

Abstract Name: **Role of Motivation on Academic Success**

The collegiate world is constantly discussing how student motivation is related to student success. How true is this correlation? Does the motivation importance change with the specific course or the format the course is taught in? Can the institution or instructor impact the student motivation level by understanding intrinsic and extrinsic factors that motivate students? The aim of this study is to determine what motivation in education is and how it impacts the academic success of college students. Factors that will be studied include intrinsic and extrinsic motivation factors, academic performance, familial college experience (1st generation students vs non 1st generation students), and the role of the institution and faculty. The study will be completed through a survey with a battery of questions adressing all the key areas mentioned above. Demographics will also be collected to compare possible inter-group differences. Correlational analysis will be completed through data collection in the spring semester of 2023.

Abstract Name: **Re-imagining Auschwitz in Graphic Narratives**

The medium of graphic novels has largely been underestimated in the landscape of art and literature. Yet, the metaphysics of graphic novels yields itself to depict atrocity in ways that traditional art cannot through the intersection of temporal linearity and spatial boundaries. Comics such as Bernie Krigstein's 1955 "Master Race" depicted the atrocities of the Holocaust while excluding the identity of its victims, but the creation of graphic novels as a genre of Holocaust representation and the specific reference to a Nazi death camp would emerge decades after "Master Race" with Art Spiegelman's Maus, the graphic novel depicting his father's memories of Auschwitz in the past while simultaneously visualizing how these traumatic memories of the Holocaust continue to linger in the present and in large part shape the future for the descendants of survivors. Maus inspired other second-generation survivors to depict their stories, through the medium of comics, of the influence of parent(s) who survived Auschwitz. These artists use differing artistic and textual styles and have varying reasoning for wanting to depict their parent's stories, yet they all evoke postmemory in showing the intergenerational memory of the Holocaust. The continuation of artists using the graphic novel medium to depict Auschwitz, a medium where time and space merge, has influenced the way we remember and understand the site where trauma and inhumanity still remain in the memory of survivors and their descendants. Our research project, bringing together the disciplines of History and English, examines the representation of Auschwitz in graphic novels in order to contribute a chapter to the Routledge Handbook of Auschwitz-Birkenau, a collection of essays designed to contribute to a shared understanding of the role of Auschwitz-Birkenau in the implementation of genocide and the continuing legacy of the Holocaust.

Abstract Name: **Three-State Biaryl Lactone Molecular Switches with Amine donors**

Our research is focused on the synthesis of four bridged biphenyl molecules with amine donors. These three-state biphenyl molecules, due to their chemical properties, will find applications as nanoscale fluorescent sensors and molecular mechanical devices. Biphenyl molecules have known dihedral angles, leading to differing optical and conducting properties when manipulated. By using a lactone-bridge we can force the molecule into and out of planarity; at low pH the molecule takes a planar conformation ("ON"), while at high pH it's non-planar ("OFF"). Research from previous groupshas shown similar two-state molecules' effectiveness at readily switching conformations when exposed to different chemical environments. We are researching the addition of diethylamine and diphenylamine donor groups. By combining cyano and nitro acceptors used previously and differing amino donors within biphenyl molecules, we can enhance optical properties and pH sensitivity. This pH sensitivity will be more precise with the addition of a third "OFF" of the molecule. At low pH, the amino group should become protonated, leading to the second "OFF" state and giving the molecule a narrow "ON" state. The "ON" state would result in visible color differences than the "OFF" state of the molecule. These characteristics would improve the usefulness of these molecules as pH sensors. We have successfully synthesized two of our target molecules, one molecule is a cyano acceptor group with diethylamine donor group and the other is a nitro acceptor group and diethylamine donor group. We will be continuing this work to synthesize the other two molecular switches.

Abstract Name: **Music Listening Activities with Adaptations for People who are Neurodiverse**

This presentation will provide a description for how people who are neurodiverse hear music differently than others and therefore respond differentially. It will include a neuroscience description of what happens in the brain to allow communication skills to develop and provide meaningful interaction with others. Perspectives from a college student with autism spectrum disorder (ASD) who became interested in this area of research while taking the college course Influence of Music on Behavior participated with students who were neurotypical and their professor to test out different styles of music and identify responses. Descriptions of the funding will be shared, including considerations of properties of music and their corresponding effects on perceptions of people who are neurodiverse. Findings were also implemented in a group home with residents with ASD who responded well to the specific properties identified. A description of eight sensory systems, sensory overload, and co-occurring health conditions will be described along with an explanation about communication development. Considerations for minimizing agitation and maximizing positive responses will be included for these eight sensory systems: proprioceptive, interoceptive, visual, tactile, auditory, vestibular, olfactory, and taste.People who are neurodiverse respond well to ascending arpeggios, louder volume, detached and staccato style, full chords, and complex and accented rhythms more than to lyrical, flowing melodies, although responses are unique for each individual. A discussion of theories related to “Overlearning Phenomenon” and Broken Mirror Hypothesis will be included related to mirror neurons and applications for teaching music. Hyperactive responses based on circuitry signaling patterns overpowering other functions will be described within the context of striatal loops. Perspectives of people who are neurodiverse on different types of intervention usually used will be included. Adaptations based on national standards for music and social justice will be provided.

Abstract Name: **Role of Fear in an Eco-epidemiological Model with Species Aggregation**

In this talk, an eco-epidemiological model with species aggregation and disease in prey subject to fear of predators will be discussed. We assume that the reproduction of the susceptible class of the prey population is affected by fear induced by the predators. We present some basic mathematical results such as positivity, boundedness, and local stability. The coexistence of the species at the endemic state is possible for our proposed model via numerical simulations. This coexistence equilibrium can be destroyed by increasing the strength of fear of predators. We will show that the strength of fear can create and destroy the coexistence equilibrium. In some cases, we will show that the strength of fear can drive a stable endemic state into extinction in finite time. We will also present some interesting and rich bifurcation behaviors revealed by our model.

Abstract Name: **Designing the Ideal Woman: From Gibson?s Girls to TikTok?s "That Girl"**

This paper discusses approximately 100 years of history in graphic design, from the era of Charles Dana Gibson as a predominant illustrator to contemporary times, specifically focusing on how men have used design practices to shape feminine ideals in popular American culture, ultimately for profit and the continued subjugation of women. Moving in to its discussion of contemporary graphic design, this paper will address newfound modes of power for women in graphic design and the different ways that these women either uphold traditional ideals of femininity or expand them. This paper highlights contemporary examples such as the highly curated content of TikTok micro-influencers and the personal brands of macro-influencers like Kim and Kourtney Kardashian, drawing conclusions about the state of feminine progress in light of these examples. In order for all women to truly achieve the social, political, and economic equality they have long fought for, they must use contemporary modes of dispersing media and graphic design to make portrayals of “the ideal woman” vastly more inclusive.

Abstract Name: **An Application of Mortality Salience on Self-Esteem and Exercise**

Terror management theory (TMT; Greenberg, Pyszczynski,; Solomon, 1986) posits that we naturally fear mortality and attempt to decrease anxiety by increasing self-esteem and adhering to cultural worldviews which provide meaning to life. Past research supports cultural worldview and self-esteem as strategies for relieving anxiety. Exercise and health are central values of many contemporary worldviews and can also be viewed as a literal means to prolong life (Andreasson et al., 2016). Additionally, exercise is linked to increased self-esteem in gym attendees because it is an important value of gym culture (Zervou et al., 2017). For instance, basketball players primed with death increased their performance in the sport when considered a valuable activity (Zestcott et al., 2016). The same was discovered for strength trainers with increases in strength occurring after mortality primes when self-esteem was derived from lifting weights (Peters et al., 2005). The current study builds on this past research to investigate whether anxiety about mortality can be reduced by increasing self-esteem through exercise. The way to test this relationship is to utilize the mortality salience (MS) hypothesis, the process of bringing death to the forefront of a person’s mind to increase need for these protective structures. The participants are randomly assigned to either think about their death (MS) or a control topic and then asked to lift 5 or 7lb weights. The dependent measure will be which weights participants choose, how many reps with the weights they complete and their ratings of self esteem on the Rosenberg self-esteem scale before and after lifting weights. Based on previous research, it is hypothesized that if self-esteem protects against mortality salience, then the need for exercise will increase. It is anticipated that fitness plays a considerable role in how we gain self-esteem and manage anxiety-inducing thoughts about health and death.

Abstract Name: **Undergraduate Nursing Students' Knowledge and Attitudes Toward LGBTQ+ Patients: An Assessment Related to an LGBTQ+ Cultural Competency Module**

Background: Nursing research has demonstrated knowledge deficits specific to care of the patient who identifies as lesbian, gay, bisexual, transgender, queer, + (LGBTQ+). Lack of knowledge specific to the care of people in LGBTQ+ communities continues in spite of this populations' increased health disparities. In an effort to address this lack of knowledge, both the Institute of Medicine and the US Department of Health and Human Services have called for prioritization in addressing these disparities. In fact, in their position statement on LGBTQ+ populations, the American Nurses Association (ANA) recognizes that nurses need to deliver care that is culturally congruent for LGBTQ+ populations. The ANA has therefore put forth recommendations that nursing education help to fill the void in the existing knowledge by incorporating content specific to the issues faced by LGBTQ+ populations. Toward that goal, this study sought to include a learning module covering healthcare considerations for the patient who identifies as LGBTQ+ within a required undergraduate nursing cultural competency course.Method:Student (N=124) knowledge related to care of the patient who identifies as LGBTQ+ was assessed before and after participating in a module entitled Cultural Consideration in Clinical Care: Working with LGBTQ+ Patients. Attitudes toward sexual orientation and gender identity were assessed before and after participation using the Modern Homonegativity Scale and Transphobia Scale respectively. A Wilcoxon signed rank test was conducted to evaluate whether students showed improved knowledgeand attitudes.Findings:Student knowledge scores related to care of the LGBTQ+ patient improved significantly after participating in the module. In addition, attitudes toward sexual orientation and gender identity improved significantly.Discussion:Incorporating content specific to issues faced by LGBTQ+ populations within undergraduate nursing education has the potential to improve clinical knowledge necessary for culturally competent care of LGBTQ+ population, as well as to improve attitudes toward these populations.

Abstract Name: **Salvation, Sallman, and the Simulacra: Applying Jean Baudrillard's "Phases of the Image" to a History of Christian Art**

This paper explores the history of "Christian" art through the lens of sociologist Jean Baudrillard's "successive phases of the image" in an effort to understand why Jesus has become an icon of the Republican party. In his book Simulacra and Simulation, Baudrillard asserts that all representation is a simulation of itself, not a representation of the truth. Different representations interact with each other and build off one another, until an image is so departed from depicting the truth that it represents something else entirely. The four successive phases of the image are as follows: 1. a reflection of basic reality, 2. the masking of reality, 3. the masking of the absence of reality, and 4. bearing no relation to reality whatsoever. Primarily, I will be focusing on two artists: Warner Sallman and Jon McNaughton. By analyzing the art of Warner Sallman, the history of an Americanized Jesus can be outlined and understood, as well as the history of the fundamentalist movement, which will eventually become evangelicalism. McNaughton's work capitalizes on the groundwork of nostalgia laid by Sallman but uses the image of Jesus to make much stronger, right-leaning political statements which are a complete departure from any semblance of Christian truth. For those that believe, the image of Jesus has become a replacement for the idea of divine truth, which the Republican party has made use of by associating Jesus with nationalist concepts.

Abstract Name: Geology of the Proposed Dreamer Segment of the Ice Age National Scenic Trail, Rusk County, Wisconsin

The Ice Age National Scenic Trail (IAT) showcases Pleistocene glacial features in the State of Wisconsin. The Ice Age Trail Alliance has proposed a new Dreamer Segment trail to focus on landforms in the Blue Hills region of western Wisconsin. The Alliance commissioned a study the geomorphology of the proposed trail segment to create publication-quality materials (both text and figures) for a future interpretive guide.GIS analyses and field work have been used to study the proposed Dreamer Segment and the surrounding region. Published papers about the glacial geomorphology of the area were read. LiDAR-based shaded DEMs were used to evaluate glacial landforms in the region and determine potential interpretive stops. This was followed by five days of field work to determine the best locations for potential interpretive sites.Multiple geomorphic features are proposed as interpretive stops along the Dreamer Segment. Glacial landforms of the Chippewa Moraine are well represented, including kettles, hummocks, and ice-walled-lake plains. Precambrian Barron Quartzite is exposed in Gundy's Canyon. The most unique feature is the Blue Hills Felsenmeer State Natural Area. During the late Chippewa Phase of the late Wisconsin Glaciation, meltwater from the ice margin eroded a westward-dipping, subaerial "box canyon". Frost shattering and rock falls produced the angular "sea of rocks" of the Blue Hills Felsenmeer. The final product of this research will be interpretive text, publication-quality figures, and a research poster to be donated to the Alliance and the National Park Service.

Abstract Name: Queer Monstrosity

In Fall 2022, 18 students enrolled in an honor's course A Queer Lens, Representation Art, Photography and Film. Like the idea of queer theory itself, students were given the opportunity to dismantle the traditional assumptions about gender, sex, sexuality, heteronormativity, and more through a creative project. With the given prompt,create your own queer monster, each student could sculpt, draw or paint their concept. Students then applied their queer optic (Gopinath) of monster theory, queer artistic practices, and queer theory to realize their own aestheticThe creative process started with a rough sketch, pitched concepts to the class, and then consultationswith a monster making expert. If creating a sculpture then an armature was crafted for paper mâché clay application. Students will then take another week to finalize a queer monster by painting, dressing, adorning with different materials and textures. Within monster theory, beasts, demons, freaks, and fiends are symbolic expressions of cultural unease that pervade a society and shape its collective behavior. This aligns with queer theory because of the monsterization of queer characters in film and the queer coded monsters and ideasthatare usually prevalent in horror films. Taking the idea of monstrosity and refiguring it into a work of art, depictingand evokingsome sort of feeling (horror, longing, confusion, desire, etc.) was a goal for each student. In gathering all 18 works together we see the different interpretations of monstrosity. With this proposed exhibition, we envisioned monstrosity as a whole other level of what it means to be queer. Thus, each student will include a statement about their piece that explains their understanding of queer monstrosity. Final critique is taking place Decemeber 22nd, 2022. Images will be posted to Ellen Mahaffy's website shortly afterwords. (www.redcatphoto.com)

Abstract Name: Engineering a Biological Habitat for real-time monitoring of plastic consumption in a Microgravity Environment Onboard the International Space Station

Low-density polyethylene (LDPE) is a widely used thermoplastic polymer, with applications ranging from packaging to radiation shielding. LDPE is substantially less recyclable than other common plastics, such as polyethylene terephthalate (PET), high-density polyethylene (HDPE), and polypropylene (PP), with a 5% EPA-reported recycle rate. Therefore, LDPE disposal is an imminent and growing environmental challenge on Earth, and similarly affects future needs for waste disposal during long-term space travel. Recently, Galleria mellonella, commonly known as the waxworm, was shown to degrade LDPE into ethylene glycol in offering a sustainable approach for plastic use and disposal. In July 2022, Arkansas State University sent an experiment to the International Space Station (ISS) to test if waxworms can degrade LDPE in a microgravity environment as a part of the NASA Student Payload Opportunity with Citizen Science (SPOCS) program. The engineering challenge required designing an instrumented waxworm habitat, that met NASA's operational constraints for ISS experiments, capable of maintaining waxworms during a ~30 day flight while monitoring their mortality, overall health, and LDPE consumption. Constraints included a standardized form factor, maximum power at 900mA/5V, and full environmental containment. The final module (10x10x15 cm) was instrumented with cameras for observing waxworm behavior during flight, as well as temperature sensors and humidity sensors, all controlled by a Raspberry Pi Zero microcontroller. A rapid design and testing approach was used during the design phase, utilizing 3D printing to quickly test and validate designs. This approach resulted in the build of an autonomously operated module to capture images and log temperature and humidity data. Real-time imaging capabilities confirmed the hypothesis that waxworms can survive microgravity stress and validated food and plastic consumption patterns and behaviors similar to earth controls. These results may enable new strategies in the future for improving sustainability and waste efficiency during long-term space travel.

Abstract Name: The Role of the OsaA Gene in Aspergillus fumigatus Development

The filamentous fungus Aspergillus fumigatusis an important saprophytic, airborne, and opportunistic human pathogen. It causes respiratory aspergillosis, which is one of the leading causes of deaths among individuals affected by fungal infections worldwide, particularly in immunocompromised population groups. The pathogenicity of the fungus is attributed to its virulence factors such as thermotolerance and effective germination rate at 37°C (human body temperature). The small size of A. fumigatus spores (2-3 µm) allows them to easily enter the human respiratory tract. Once inside the host, the spores germinate to form mycelial mass. Several virulence factors such as cell wall adhesins and hydrolytic enzymes degrade the protective membrane of immune host cells. Additionally, A. fumigatus produces secondary metabolites which are proven to be highly cytotoxic to human system. Nowadays, the number of immunocompromised individuals affected by aspergillosis is on the rise. At the same time, resistance to current antifungal treatments is occurring, therefore, it is paramount to find new treatments. Our study investigates possible new genetic targets against A. fumigatus infections. In the phylogenetically close model organism, Aspergillus nidulans, the osaA gene was identified to orchestrate both asexual and sexual development, suppressing the formation of fruiting bodies and promoting conidiation. Our research focuses on investigating the role of osaA in development, toxin production, and virulence of A. fumigatus. Our results revealed that osaA has an important role in fungal growth and conidiation in this fungus. Deletion or overexpression of the osaA gene showed significant phenotypic changes in its colony morphology and reduced conidial production, generating abnormal conidiophores in the absence of osaA.

Abstract Name: Parental Involvement in Education B

How relative is parental involvement in a child's education to the overall success of the child? Can parents be too involved in their child's education? In society today we are seeing an increased debate over the different types of parents and how good or bad they are to the overall growth and development of their children. Are helicopter parents harming their children's future? Are free range parents raising children with no rules or boundaries providing a need for society to deal with the evenual negative outcomes? The goal of this research is to study the different parental involvement levels in the education of their children and determine what positive and negative outcomes are present under each type of parental behavior. Some criteria that will be important in this study are the level of parental invovlement, to what age of the child does the involvement continue, academic performance and self-efficacy of the children. Other areas of interest in this study include whether gender and race/ethnicity are impacted differently under differing parenting styles. Correlational analysis will be completed through data collection in the spring semester of 2023.

Abstract Name: Investigating the anti-inflammatory effects of Pomegranate Gold Nanoparticles on LPS stimulated THP-1 macrophages

While inflammation is a crucial response to illness or injury, chronic inflammation has been shown to be a contributing factor to autoimmune diseases like multiple sclerosis, systemic lupus, and rheumatoid arthritis. The therapies currently used to treat these diseases focus on immunosuppression which can put someone at high risk for infection and many other opportunistic illnesses. Emerging therapies are targeting inflammatory cytokines by using plant-based derivatives. Several of these plant-derived molecules like curcumin, colchicine, capsaicin, and quercetin have demonstrated anti-inflammatory properties. The anti-inflammatory properties of pomegranates are correlated to a unique ellagitannin known as punicalagin. It has been hypothesized that Punicalagin is key in preventing the release of IL-6, IL-1b and TNF-a cytokines by inhibiting the NF-kB pathway. The objective of this work is to investigate the anti-inflammatory ability of pomegranate gold nanoparticles (Pom AuNPs) to reduce cytokine production from differentiated THP-1 cells. The use of pomegranate juice to mediate the synthesis with the gold chloride allows for the improvement of pharmacological activity and overall stability of the AuNPs. An XTT cell viability assay indicated that the Pom AuNPs have minimal cytotoxic effects at concentrations up to 100 mg/ml. Differentiated THP-1 cells were pre-treated with increasing concentrations of Pom AuNPs for 1 hour prior to lipopolysaccharide (LPS) exposure. LPS is a component of gram-negative bacteria that induces the secretion of pro-inflammatory cytokines by triggering the activation of the NF-kB signaling pathways. Preliminary results suggests that treatment of cells with Pom AuNPs resulted in a decrease in IL-6 production when compared to LPS only treatment but had no effect on the production of TNF-a.

Abstract Name: **Watermelon Malate Dehydrogenase and Two Mutants**

Malate Dehydrogenase is an enzyme found in the glyoxysomes and mitochondria of plant cells. In glyoxysomes, Malate Dehydrogenase is part of the glyoxylate cycle which converts fatty acids to sugars. In the mitochondria, Malate Dehydrogenase is the last enzyme of the citric acid cycle. The citric acid cycle produces NADH and FADH2, two essential reactants in the electron transport chain for generating cellular energy. Malate Dehydrogenase catalyzes the reversible oxidation-reduction reaction of malate and NAD+ to oxaloacetate and NADH. Malate Dehydrogenase or MDH is an enzyme that converts fatty acids to sugars in glyoxysomes and catalyzes the reversible oxidation-reduction reaction of malate and NAD+ to oxaloacetate and NADH in the mitochondria. This study aims to investigate the effect of two mutations, D132A and R124K, on the activity of glyoxysomal watermelon MDH and determine the role of these two amino acids in the structure of the enzyme. We hypothesize that R124K will decrease activity due to broken intermolecular forces between the enzyme and substrate/ cofactor for R124K. D132A will also decrease in activity because of a disruption of a hydrogen bond in the loop region, which may affect the ability of the loop to close effectively. PYMOL was used to generate the mutated protein structures of 1SMK, and the lowest energy conformations were identified using SPRUCE and SZYBKI. The effects of the mutations were analyzed using computer modeling by superimposing the mutated versions on the crystal structure of the human mitochondrial MDH (4WLU). The activity of the mutants was compared to the wild-type using kinetic assays.In conclusion, the initial rates, specific activity, and turnover numbers calculated for the two mutants were significantly lower than the wild-type confirming that both mutations hindered the wild-type's activity efficiency.

Abstract Name: **The Influence of Restricted Abortion on Women's Mate Choices**

Reproductive rights have been fiercely contested over the past several decades. With the recent overturning of Roe v. Wade, women's liberty and bodily autonomy is once more at stake. The US Supreme Court's decision to overturn Roe v. Wade has taken away the constitutional right to seek abortion: a decision that has harmful and inequitable repercussions on the reproductive health of many Americans. Given the anxiety and confusion surrounding the removal of Roe v. Wade, it is even more precedent to examine how women's behaviors across of spectrum of disciplines change with the now limited rights. We investigated through an experimental study whether a reminder of the recent Supreme Court decision influences women's mating strategies in the online environment. From past research, we were able to conclude that women who were looking at pictures of men, for mating purposes, preferred faces that were more masculine in appearance.Thus, leading us to hypothesize that women remined of abortion restrictions would be more selective of men, and would exhibit greater interest in masculine-appearing men. Participants were randomly assigned to read an article reviewing the overturning of Roe v. Wade, or an article reviewing a recent Supreme Court decision on open-carry gun laws, or to read no article. They then examined several fictitious Tinder profiles, varying in facial masculinity, and rated their interest in the men.Data will be analyzed through an ANOVA test in SPSS to determine whether the priming of an abortion article has an effect on female college students mate selection. Considering the recency of the overturning of Roe v. Wade, this study is among the first to document how women's behavior might change in the post-Roe v. Wade landscape.

Abstract Name: **Obtaining a complete set of reference DNA sequences for North American bladderworts (Utricularia)**

Carnivorous aquatic plants in the genus Utricularia, known as bladderworts, are fascinating for having complex snap-traps, for lacking roots, and for having branched shoots that function like underwater leaves. There are 19 bladderwort species in North America, including nine that are native to Wisconsin. Bladderwort diversity has been studied in a phylogenetic context before, but curiously the existing data are incomplete for North American species. Specifically, there are gene regions for which not every species has been sequenced, and the missing data make it impossible to identify any one plant using DNA sequence comparisons, or truly to construct an effective phylogeny for the genus.We plan on using the findings of this study to enable new methods for identifying unknown species. Further studies can be conducted once a full catalog of DNA sequences for nuclear and chloroplast DNA is acquired because currently there are species that are missing DNA sequence data for one or more of the gene regions that are commonly used for Utricularia. There are several species in this genus that have not been sequenced for one or more gene regions, and this makes it impossible to identify the plants confidently using DNA sequence data.We used genes from the nucleus (internal transcribed spacer, or ITS) and the chloroplast (rps16 gene, matK gene, rpl20-rps12 intergenic spacer, trnL-F intergenic spacer) to fill in missing data and construct updated phylogenetic trees for Utricularia. These regions were chosen because they have already been sequenced for a large number of Utricularia species, as part of a phylogenetic study of the genus. For the first time ever, we confirmed close relationships between species pairs (e.g., U. inflata and U. radiata) that could not be compared effectively before.

Abstract Name: **Signal Recovery from Sampling Erasures**

The Shannon-Whittaker Sampling Theorem guarantees that any band-limited signal with frequency band [−B, B] can be reconstructed using only its sampled values at times from an evenly spaced lattice. That is, the signal f is completely determined by its sampled values on the lattice, giving us a discrete (digital) representation of an analog signal. Human hearing is limited to frequencies within B = 20,000 Hz; therefore, band-limited signals are ubiquitous in signal processing. Sampling erasures occur when some of the sampled values are omitted or erased in the transmission of the signal. A new algorithm was recently developed that utilizes finite matrix computations to reconstruct a signal from sampling erasures. In this poster, we will discuss this reconstruction and demonstrate several numerical applications. Moreover, we will present updated bounds to prove that the reconstruction procedure is stable under fairly mild assumptions.

Abstract Name: **Chimeric PD1 Expressing T cells as a Therapy for Pediatric Osteosarcoma and Rhabdomyosarcoma**

Currently, the 5-year survival rate for pediatric osteosarcoma and rhabdomyosarcoma is 68% and 70-90% respectively. Unfortunately, the available treatments for these pediatric cancers have many harmful side effects including nausea, vomiting, fever, pain, infections, and exhaustion. Therefore, a new treatment to increase survival and reduce side effects is desperately needed for children with these cancer types. Using immune cells to treat cancer is quickly becoming a new option. One type of immunotherapy uses chimeric antigen receptor expressing T cells (CAR T cells). CARs are modified receptors that use genetic engineering to create a novel receptor that targets tumor-associated antigens and enhances T cell responses. We developed a CAR, chimeric-PD1(chPD1),with the Programmed Death 1 (PD-1) receptor as the tumor-targeting domain attached to CD3 zeta activation and Dap10 costimulatory domains. Since the ligands for the chPD1 receptor are expressed on most tumor types and not on healthy cells, they are ideal for CAR T cell therapies.Previously, chPD1 T cells were shown to effectively treat murine models of pancreatic, kidney, colon, prostate, and other cancers. The purpose of this study was to testthe anti-tumor efficacy of chPD1 T cells against murine pediatric osteosarcoma and rhabdomyosarcoma. Flow cytometry and RT-PCR were used to determine thatpediatric osteosarcoma and rhabdomyosarcomacell lines expressed PD-1 ligands. Therefore, these tumor cells were potential targets for our chPD1 T cells. Using LDH cytotoxicity assays, we demonstrated that chPD1 T cells increased lysis of tumor cells compared to control T cells. ELISAs and LEGENDplex assays were used to assess cytokine secretion by chPD1 T cells. For all tumor types tested, chPD1 T cells secreted pro-inflammatory cytokines, including IFN-γ, TNF-α, and GM-CSF, but did not secrete the anti-inflammatory cytokine IL-10. Therefore, chPD1 T cells could be a novel treatment forpediatric osteosarcoma and rhabdomyosarcoma

Abstract Name: **How can ponderosa pine seedlings be propagated to improve drought resistance in the field?**

Ponderosa pine, a widespread species in the western US, is a valuable species economically and environmentally. The preservation of this species is important for the ecological health of many forests due to increased temperatures, drought, and frequency of forest fires. Reforestation efforts following fire and timber removal often fail because seedlings propagated in greenhouses are not resilient to stressful field conditions. To increase seedling field survivorship, drought resistance, and to decrease mortality rates, we implemented a number of treatments in the greenhouse during the initial propagation. The treatments were a manipulation of water supply and different types of fertilizer, tested with seeds collected from varied elevations. After threemonths of growth in the greenhouse under these treatments, we measured height and both shoot and root biomass of the seedlings. We also measured days to mortality on a subset of the seedlings. Seedlings subjected to drought treatment and amino fertilizer grew shorter but survived longer. These seedlings allocated more biomass below ground, which likely contributed to their longer survivorship in the days to mortality test. However, despite the potential benefits these treatments conferred to seedlings in the greenhouse, all seedlings experienced nearly 99% mortality after they were outplanted to a nearby field site. We suspect that most of this mortality was due to frost-heaving, a process whereby seedlings can be pushed out of the ground during frost-thaw cycles that occur in soils in the winter, and is exacerbated by the creation of bare patches of soil around the seedling during planting.

Abstract Name: **Topology Optimization of Ceramic-Metal Composites for Implant Design**

A growing aging population is increasing the demand for total joint replacement for the hip and knee. In modern hip and knee metal implants, ceramics play an important role in implant fixation through bone ingrowth and wear resistance. Unfortunately, the brittle nature of ceramics significantly limits its use. This undergraduate research project is focused on finding an innovative approach to enhance the properties of ceramics used in total joint replacements. Ceramics and bio-glass have been shown to have excellent biocompatibility but poor physical properties, often failing by fracture under tensile and compressive loads. In contrast, metals are known for their impressive physical properties but lack the osteoinductive properties or wear resistance of ceramics. A composite of these materials maximizes the benefits to the patient while simultaneously reducing the risk of long-term medical complications.The study aims to apply multi-material topology optimization to create a simple part made of a ceramic-metal composite that maximizes its load-bearing capabilities. Topology optimization will be used to determine the distribution of the ceramic within a metal matrix to limit the tensile stresses in the ceramic phase.The study is focused on two specific combinations: bioglass with titanium to enhance osteoinductivity and zirconia with cobalt-chrome to enhance the wear resistance of joint surfaces. The multi-material topology optimization will be performed using Finite Element Analysis (FEA) in ANSYS, a Computer Aided Engineering software package. A BeAM Modulo 250 directed energy deposition printer will be used to produce the prototyped parts. This study is relevant to applications such as ingrowth stimulation for spinal fusion cages and knee and hip replacements.

Abstract Name: **Furry Spotting in the World of Graphic Design**

Anthropomorphic animals or “furries” have been seen throughout graphic design history. Anthropomorphic references humanistic qualities, which characterizes furries as animals that have human characteristics, such as the abilty to walk, talk, and think as a human does. While the term "furry" has been only recently coined as a term, the ideals behind these characters have been around since time began. In ancient Egypt, there were many gods to rule over the land -many of which inhibited traits that would classify as an anthropomorphic animals (as many of them only had the head of an animal, while few others inhabited more features of the animal and only the mind of a diety.) More places these anthropomorphic animals have been seen is in native american lore. Stories passed down from one generation to the next of animals that have inherantly humanistic qualites have been used to teach lessons for many years. The animals in this lore exhibit human traits much as the furries seen in ancient Egyptian times. Along the Native American lines, many see animals as guides, with wisdom unfathomable to help teach those around them, giving them humanistic thinking capabilites. While furries have been seen pushing Graphic Design forward, they are far from separated from the trade. Many furries study graphic design and seek careers in it as they go hand in hand. Mordern examples of furries in graphic design can be seen in many people's favorite mouse -Mickey Mouse- an iconic symbol that has driven graphic design forward in and of itself.

Abstract Name: Measurements of Body Composition in Division III Men's Cross Country Runners During a Competitive Season

INTRODUCTION: Body composition is an important measurement for athletes such as cross-country (XC) runners who expel a significant amount of energy during training and competition. Maintaining a healthy body composition could be the difference between getting injured or competing at the highest level. Therefore, the purpose of this study was to examine the body composition of Division III men's XC runners during a competitive fall season. METHODS: Twenty-three male collegiate XC runners (age- 19.3 ± 1.4 years, height- 179.7 ± 10.0 cm, body mass- 68.3 ± 6.9 kg) completed dual-energy x-ray absorptiometry exams on three occasions during the fall season, pre-season (T1), mid-season (T2), and post-season (T3). Body mass, fat mass, lean mass, percent body fat, bone area, bone mineral content, and bone mineral density were analyzed. Data were analyzed using a repeated measures analysis of variance. RESULTS: Body mass significantly increased from T1 to T2 and T3 (0.05), with no differences between T2 and T3. Lean body mass significantly changed across the season (p = 0.003) with T2 being significantly greater than T1 and T3 (0.05). Fat mass, bone area, bone mineral content, and bone mineral density did not change across the season (0.05). CONCLUSION: The results from the current study suggest Division III men's XC runners can maintain a favorable body composition across a competitive season. Increasing lean tissue, while maintaining fat mass, and bone health are important for a runner to be successful. Often athletes at the Division III level lack education and nutrition to support positive performance. However, the sample of subjects we tested suggests athletes at this level can be successful and maintain a healthy body composition with limited resources.

Abstract Name: Using Mathematical Modeling to Increase Crop per Drop

Chippewa Valley Bean (CVB), located in Menomonie, Wisconsin is the world's largest producer of dark red kidney beans. There is limited research available on dark red kidney beans as they account for less than 1 % of the nation's agricultural land use. CVB agronomists asked, "How much water is required to grow one hundred pounds of dark red kidney beans?" There are many factors that impact the answer to this question. This project focuses on soil characteristics while holding temperature and nutrients fixed. Plant disease and weather-related damage is also neglected.A mathematical model consisting of a system of three coupled differential equations was developed to simulate water use through the soil, plant canopy, and reproductive biomass. The model predicts a kidney bean plant's reproductive biomass at the end of the growing season. Numerical experiments show how much water is needed via daily irrigation to achieve maximum yield for given soil characteristics. The intended use of this model is to help agronomists advise growers on the efficient use of water resources to obtain maximum kidney bean yields.

Abstract Name: **Music Listening Activities with Adaptations for People who are Neurodiverse**

This presentation will provide a description for how people who are neurodiverse hear music differently than others and therefore respond differentially. It will include a neuroscience description of what happens in the brain to allow communication skills to develop and provide meaningful interaction with others. Perspectives from a college student with autism spectrum disorder (ASD) who became interested in this area of research while taking the college course Influence of Music on Behavior participated with students who were neurotypical and their professor to test out different styles of music and identify responses. Descriptions of the funding will be shared, including considerations of properties of music and their corresponding effects on perceptions of people who are neurodiverse. Findings were also implemented in a group home with residents with ASD who responded well to the specific properties identified. A description of eight sensory systems, sensory overload, and co-occurring health conditions will be described along with an explanation about communication development. Considerations for minimizing agitation and maximizing positive responses will be included for these eight sensory systems: proprioceptive, interoceptive, visual, tactile, auditory, vestibular, olfactory, and taste.People who are neurodiverse respond well to ascending arpeggios, louder volume, detached and staccato style, full chords, and complex and accented rhythms more than to lyrical, flowing melodies, although responses are unique for each individual. A discussion of theories related to “Overlearning Phenomenon” and Broken Mirror Hypothesis will be included related to mirror neurons and applications for teaching music. Hyperactive responses based on circuitry signaling patterns overpowering other functions will be described within the context of striatal loops. Perspectives of people who are neurodiverse on different types of intervention usually used will be included. Adaptations based on national standards for music and social justice will be provided.

Abstract Name: **Effects of Microplastics Exposure in the Sea Anemone, Exaiptasia pallida**

Microplastics are one of the most common forms of pollution found in marine environments, and their small size (5mm) allows them to be easily ingested by marine biota. Exaiptasia pallida is a solitary anemone native to the western Atlantic that harbors symbiotic dinoflagellates like those of reef building corals, and passively feed on prey such as brine shrimp. To assess the influence of microplastics on E. pallida, a series 48-hour laboratory experiments were conducted in which symbiotic and aposymbiotic anemones were exposed to 100 µm polystyrene microplastic beads in the presence and absence of brine shrimp. Ingestion and egestion of microplastics, and photosynthetic parameters were measured at 3, 24, and 48 hours following initial exposure. At 48 h, anemone tentacles were harvested and analyzed for algal symbiont density. Physiological stress in the anemones was investigated via assessment of antioxidant enzymes, superoxide dismutase, catalase, and glutathione peroxidase. E. pallida consumed polystyrene beads in every microplastic treatment, and both presence of brine shrimp and symbiotic state significantly increased microplastic ingestion. Aposymbiotic anemones ingested more microplastics than symbiotic anemones, suggesting that bleached anemone communities may be more susceptible to microplastic pollution.

Abstract Name: **EFFECTS OF ATYPICAL ANTIPSYCHOTICS IN RATS TRAINED TO DISCRIMINATE BETWEEN 22 AND 2 HOURS FOOD DEPRIVATION**

In humans, weight gain is a side effect of atypical antipsychotics. In rats, clozapine increases eating, but reduces food-related, operant behaviors. Ziprasidone has smaller or no effects on eating in rats. Given the short half-life of clozapine in rats, we tested the effects of acutely administered clozapine and ziprasidone on the discriminative stimulus effects of food deprivation. Male, Sprague-Dawley rats were trained to discriminate between 22 and 2 hrs(hours) of food deprivation in a two-lever operant task. Under 22 hrs deprivation, left lever presses were reinforced by a 45 mg food pellet. Right lever presses were punished with 8 seconds of darkness. Under 2 hrs deprivation conditions, the contingencies were reversed. Training sessions lasted until 10 reinforcers were earned or 15 minutes elapsed. Training continued until rats emitted 80% or greater condition appropriate responding before the first reinforcer was earned for 8 out of 10 sessions. After acquiring the discrimination (M = 71, SEM = 6 sessions), subjects were food deprived for 2 or 22 hrs and injected subcutaneously with either clozapine (1.0-5.6 mg/kg), ziprasidone (0.32-1.0 mg/kg) or vehicle (1.0 ml/kg). For the 5 minute or 5 reinforcer test sessions, responses toward either lever were reinforced under the FR 15. Test trials were conducted every 15 min for 2 hrs. After test session, food intake was recorded for 1 hour. Clozapine and ziprasidone did not induce hunger-like responses under 2 hrs deprivation. After 22 hrs food deprivation, clozapine (1.0-5.6 mg/kg) significantly reduced hunger-like stimuli induced by 22 hr deprivation, whereas ziprasidone had no effect. Under both deprivation conditions, clozapine decreased food intake, but ziprasidone did not. These data indicate clozapine decreases feeding-related behaviors in rats. Atypical antipsychotic medications have different effects on food-related behaviors in rats and humans

Abstract Name: **Power Within a Broken System: An Intersectional Examination of the Central Oklahoma Special Education System**

In the United States, Oklahoma's subpar public education system is ranked #45. Thus, it is critical to examine the public education systems' structure and programs. My research hones in on the special education system of publicly funded K-12 schools in Central Oklahoma. Through an intersectional approach, I will identify and examine these four structures of power (i.e. interpersonal, disciplinary, cultural, and structural) in K-12 classrooms. With this approach, I aim to answer key questions regarding which identity markers are most likely to receive a diagnosis/referral to special education.By gathering oral histories from parents and special-education educators, I am able to explore intersectional identities and unique situations. Particularly, the personal experiences of parents navigating Oklahoma's complex special-education system. My research will combine existing literature and new findings to examine the relationship between Oklahoma's special education framework and educational outcomes. These trends will assist in identifying marginalized student identities and the origin(s) of Oklahoma's stark education disparities.My research provides crucial insight on the interconnectedness of power, intersecting identities, and educational outcomes. My research can assist legislators and administrators create effective education policies, reporting systems, and plans to better support students. Furthermore, this research has the potential to help alleviate segregation in classrooms based on intellectual capability or trauma-informed behaviors. I hope to continue this research by examining educational legislation pertaining to special education systems in Oklahoma.

Abstract Name: **Elucidating the function of Cellular PCNA in HSV-1 Infection**

Proliferating cell nuclear antigen (PCNA) is a cellular protein that adds processivity to cellular DNA polymerases during DNA replication and tethers DNA repair proteins to replicating cellular DNA. Previous research has found that PCNA associates with herpes simplex virus type 1 (HSV-1) replication forks during viral DNA replication. However, the function PCNA plays during HSV-1 infection is unknown. We hypothesized that PCNA helps HSV-1 DNA replication and viral DNA repair. Two inhibitors were used to inhibit PCNA to determine its role during viral infection. Two inhibitors of interest, PCNA-I1 and T2AA, block PCNA DNA binding and protein-protein interactions, respectively. Inhibitors were incorporated into cells before viral infection to inhibit PCNA functions followed by plaque assays to quantify viral yield. We found that PCNA-I1 had a greater effect in decreasing viral yield than T2AA. We further tested the effect that both inhibitors have on different cells or virus strains. We found that regardless of the viral strain or cell type used, PCNA-I1 reduced viral yield more than T2AA. We therefore conclude that PCNA is important for viral infection and that inhibition of PCNA binding is more detrimental to infection than blocking specific protein-protein interactions. Next, to determine whether the time the inhibitors are added affect the infection cycle, we performed a time of addition experiment and measured viral genomes per cell produced. We found that PCNA-I1 inhibits replication when added before the onset of viral DNA replication. PCNA-I1 could also block ongoing viral DNA replication when added later in the viral life cycle. Our long term goal is to pinpoint the specific role of PCNA in HSV-1 infection.

Abstract Name: **Use Your Words: Impact of a Driver's Linguistic Framing on the Outcome of a Traffic Stop**

While a traffic stop is supposed to be completely objective, there is potential for biases to skew the outcome. Many authors have studied factors ranging from race, to age, to gender in order to see if a correlation exists between these variables and the result of a traffic stop (Schafer et al., 2004; Smith; Petrocelli, 2001; Gaines, 2006; Dixon et al., 2008). It has been found that these variables, as well as many others, have some sort of effect on the outcome. One variable that has not been studied much in the context of a traffic stop is language– more specifically, what the officer or driver chooses to say. The way that language is framed can have an effect on people's behavior (Banks et al., 1995, Landau et al., 2009). Previous research on this topic has found that an officer's language changes depending on who they have pulled over (Voigt et al., 2017). This study focused on what the driver says, and how it could potentially affect their traffic stop result (e.g. getting a warning instead of a ticket). Specifically, the driver's language was manipulated. The independent variables were: level of respect (respectful or disrespectful), level of agreement (agree or disagree), and goal framing (gain a positive result, avoid a negative result, or neutral). The language used in the experiment was first assessed through a manipulation check with a convenience sample crowdsourced via social media. The participants for the experiment were 500 mTurk workers from the United States. Data collection was recently completed and analysis is underway. We expect to find that respectful, agreeing language, and positive goal frames lead to more favorable (i.e., less severe) traffic stop outcomes.

Abstract Name: Novel Inhibitors of HIV Viral Infectivity Factor Using Computational Design and Analysis

Human Immunodeficiency Virus (HIV) affects 38 million individuals worldwide. Acute infection appears flu-like, consisting of fever, chills, muscle aches, sore throat, swollen lymph nodes, rash, and night sweats, although infection can be latent. Viral Infectivity Factor (VIF), an HIV protein, complexes with Cullin-5 and Elongin C; B to signal for the degradation of APOBEC3G, a cytidine deaminase that defends host cells against retroviral infections. Exploration of small molecule inhibitors in silico provides a “square one” for potential drug design. Commonly, molecular databases such as ZINC are utilized to find druggable molecules with favorable docking scores. The use of DOCK6 de novo design allows molecules to be generated from scratch using the target protein’s binding pocket. The best of the resulting molecules are simulated using AMBER16 Molecular Dynamics and analyzed using MMPBSA. Visualization of the interactions between the potential drugs and the VIF binding site allows favorable interactions to be noted, edited, and improved upon. More potent ligands from the DOCK6 de novo subset remained in the binding pocket for the entire 100 nanosecond simulation, while the less successful inhibitors displayed unfavorable interactions and dissociated from the binding pocket. Structural analysis and energy calculations were performed to rank the drug molecules based on their potential to inhibit Vif. Using one of the more successful ligands, detailed analysis of favorable intermolecular forces could be utilized to create a drug scaffold. Using the standard fragment library of DOCK6, improvements can be made to an existing druggable molecule. Recovering the immune defense against HIV and other retroviruses is a step closer to eradicating the disease.

Abstract Name: The Assessment of Aging Self-Efficacy: A Comparison of Persons in Rural and Urban Environments

Extant research shows that age-related physical and mental health outcomes often differ between persons based on the degree of urbanization of their living environment. These health outcomes differ in relation to factors such as socioeconomic status, health care access, nutritional intake, socialization opportunities, etc. However, the potential role of aging self-efficacy has not been explored. Self-efficacy itself has been studied in various adult populations, but only in the sense of their current life situations. A sample question related to memory performance might be “How able are you to remember life events from the past week?” The current study, however, will investigate prospective aging self-efficacy, which is a person’s sense of how able they will be to age healthily. A sample question (directed at a younger adult) might be “How able will you be to remember life events from the past week when you are 80 years of age?” Additionally, this mixed-methods study will investigate the reasons adults hold the beliefs they do.For example, a person answering the previous question might say that they believe they will not be able to remember the events of the past week when they are 80 years of age because their older relatives were unable to do so; or they may hold generally negative stereotypes about aging (e.g., all older adults have a bad memory).We hypothesize that aging self-efficacy will differ between undergraduate participants based on the degree of urbanization of their childhood hometowns such that those from more rural environments will feel less able to age healthily compared to those from more urban environments.Additionally, we expect that those who expect more negative aging outcomes will report feeling less in control of their aging process and hold more negative stereotypes about aging than those who expect more positive aging outcomes.

Abstract Name: **ATT&CK Technique and Tactics Detection from Noisy Cybersecurity Sensors**

Enterprises relying on large-scale networks of digital infrastructure must protect their assets from cyber attackers. Cybersecurity sensors provide one solution: detecting and monitoring adversary activity, collecting network information, and determining the presence and classification of an attack. Unfortunately, real-world sensors occasionally produce undesirable results, namely falsely activating when no attack is present or not activating when an attack is present. These misdetections can be catastrophic, and solutions to circumvent this "noise" are essential. In our research, we propose a method for using noisy cybersecurity sensors to deconstruct an adversary's profile of the techniques and tactics they used in a cyber attack. We use the Common Attack Pattern Enumeration and Classification (CAPEC) database with the ATT&CK\ ontology to create relationships between attack techniques. Since many techniques require a prerequisite attack technique, also known as a dependency, we use probabilistic modeling to simulate random walks to create adversary profiles. Using the noisy sensors as an input to a graph convolutional network (GCN) algorithm, we emulate the noisy sequence of attacks an enemy agent uses. Using products from this research, enterprises can ascertain the likely paths of attackers and build up defenses to better keep their valuable assets safe.

Abstract Name: **Rapid Foodborne Pathogen Detection via Tangential Flow Nano/Microfilter Bioseperation System**

Early detection and of pathogens is essential for preventing and mitigating the occurrence of foodborne illness and food poisoning outbreaks. Many harmful pathogens that contaminate popular food arrise from previously contaminated samples found in soil and irrigation water. The most rapid USDA/FDA/ISO approved detection protocols for the detection ofSalmonella, Escherichia coli, andListeria spp.require 1-3 days to complete. Most of the time is devoted to a lengthy 96 hour enrichment process which is vital for rapid detection to locate these harmful pathogens. Therefore a new method to detection of pathogens must be devised that preferbly decreases the already substantial time required to enrich organic samples. Microfiltration of organic material is a proposed solution that will decrease volume of sample sizes and concentrate the microbial material in the sample. The goal of this research is to develop a novel,hydrophilic nano/micro membrane-based microbial bioseparation protocol that shortens the detection time of target microorganisms and increases the sensitivity of the test to levels currently only possible via PCR and immunosensing detection methods. Through this process concentration of enviormental samples using a nano/micro membrane-based machine will reduce the substantial time required for the lengthy enrichment process. The procedure is targeted to detect food-borne pathogens in less than 10 hours and to a 1 CFU/g sensitivity of target bacteria. Therefore reducing labor intensive testing and detection time signifcantly while lowering sensitivity rate to these levels has the potential to significantly reduce food poisoning outbreaks, help improve consumer health, and improve the trust consumers put into food manufacters.

Abstract Name: **Computational Modeling of Endocytic Vesicle Formation imaged by Simultaneous Two-Wavelength Acial Ratiometry**

Clathrin-mediated endocytosis (CME) facilitates the internalization of extracellular cargoes. However, how clathrin-coated vesicles (CCVs) form remains unclear due to the limited resolution of live-cell fluorescence microscopy and the need for sample fixation in electron microscopy. To bridge this gap, our lab developed Simultaneous Two-wavelength Axial Ratiometry (STAR) microscopy that leverages the wavelength-dependent properties of Total Internal Reflection Fluorescence (TIRF) microscopy. Dual-tagging a protein of interest with two spectrally separated fluorophores allows STAR to measure the intensity ratio and retrieve the z-position of the protein. Although the exponential decay of the evanescent wave is critical for STAR, it results in an uneven excitation of fluorescently tagged proteins. This will bias STAR measurements when dual-tagged proteins are distributed on a 3D object such as CCVs. To understand the accuracy of STAR for studying vesicle formation, we used mathematical modeling. We represented the CCV as a monodisperse sphere and used the STAR equations to calculate vesicle height (Δz) and compared it to the “ground truth” center of mass (CM). We investigated the influence of vesicle formation, radius, the number and distribution of proteins, the distance of the vesicle from the plasma membrane, and Poisson noise on STAR. This mathematical model of STAR microscopy assesses how the Δz measured by STAR compares to the ground truth. The theoretical findings will be used to relate experimental Δz results to vesicle morphology and eventually to develop a 3D dynamic model of CCV formation from our experimental data.

Abstract Name: **Religion and Science: Growth vs. Security**

There is a commonly held belief that religious people are not inclined to see high compatibility between religion and science, but this may not be the case. In addition, the psychological functioning of religious beliefs may impact this compatibility or conflict. A security-focused (SF) religious orientation prioritizes certainty and security, while a growth-focused religious orientation prioritizes questioning and doubt. This study aims to look at the correlations between religion and science compatibility and the implications they have on growth and security within individuals. In light of that, the following hypotheses were proposed: 1) the Defensive Theology Scale (DTS) will be negatively correlated with Quest Scale (QS), 2) Security-focused (SF) religious orientation will be positively correlated with religious identity, human-world interactions (conflict compatibility subscale scale), and negatively correlated with explanations (conflict compatibility subscale scale), 3) Growth-focused (GF) religious orientation will be positively correlated with explanations (conflict compatibility subscale scale), scientific identity, and with human-world interactions (conflict compatibility subscale scale), 4) Explanation's subscale will be predicted by negative DTS scores and positive QS scores, 5) Human-world interactions subscale will be predicted by positive DTS scores and QS scores. The results of this study will be discussed in light of the existential tradeoffs involved with the different religious orientations.

Abstract Name: **What?s all that noise about?: Alarm-calling in California ground squirrels**

Many socially-living diurnal animals have evolved vocalizations known as alarm calls as a mechanism for reducing predation. California ground squirrels are a major prey species for coyotes, rattlesnakes, and birds of prey, but must also cope with human foot traffic and anthropogenic noise. This project characterizes the acoustic structure, duration, ecological context, and timing of these calls produced by ground squirrels. Combining naturalistic and automated acoustic monitoring, we describe the extent to which humans and dogs versus natural predators trigger naturally-occuring alarm calls in California ground squirrels across the 24-hour cycle. First, from naturalistic observations as part of my Long-term Behavioral Ecology Project on California ground squirrels at Briones Regional Park, we document that calls are associated with natural predators but not humans visitors. We also describe the contexts in which squirrels produce either a short, non-repetitive vocalization or a longer repetitive bout of alarm calls. Second, we present data from acoustic monitoring devices and camera traps that confirm ground squirrels mainly call during daylight hours, a time of day before coyotes emerge at the site. Our data confirm the alarm-calling “schedule” for these animals and offer new insights into not only what triggers them to call but also the temporal patterning of fear responses over time.

Abstract Name: **A Balancing Act: Reconciling the Relationship Between Tourism and Sustainable Water Management Strategies in Caribbean Island Countries**

The regional growth of the tourism industry has allowed many Caribbean island economies to compete on the global economic stage, yet mass tourism has also exacerbated existing resource scarcity challenges, particularly on islands with limited freshwater. This research project will explain how water-scarce Caribbean island countries have balanced sustainable water use and management practices with the economic potential of their tourism sectors. Through a case study-based framework analysis, I will examine the United Nation’s Integrated Water Resources Management (IWRM) approach on the water-scarce island country of Antigua and Barbuda. I will evaluate the ways the Antigua and Barbudan government has considered the tourism sector in its existing IWRM strategy, with a special focus on the thematic areas of social equity, economic efficiency, ecological sustainability, and participatory planning. I will assess official proposals and reports produced by Antigua and Barbuda’s government outlining their IWRM design and conduct semi-structured interviews with key government officials to analyze the country’s progress toward its implementation, especially within the tourism sector. I aim to identify the country’s successes and failures in integrating tourism into its IWRM approach and build recommendations for adapting this framework to encourage more sustainable interactions between water and tourism in the Caribbean. These findings are relevant as climate change-based impacts are expected to place additional stress on the Caribbean’s existing freshwater resources, warranting new context-specific perspectives on sustainable development strategies forisland countries.

Abstract Name: **Improving Sustainability Awareness with K-12 Citizen Scientists Using Authentic, Interdisciplinary Project-Based Learning to Support an International Space Station Experiment**

Plastic waste disposal is a serious environmental challenge that is important to incorporate into K-12 curriculum. While the 3R's (Reduce, Reuse, Recycle) are commonly taught at this level, empowering K-12 students to contribute meaningful and authentic sustainability research data in efforts to increase awareness is needed. A potential plastic waste solution is Galleria mellonella (waxworm), a common beehive pest that can be easily incorporated into curriculum for K-12 classrooms. Waxworm larvae are capable of biodegrading low-density polyethylene (LDPE) films (e.g sandwich bags) into a reusable product, ethylene glycol. The A-State SPOCS (Student Payload Opportunity with Citizen Science) team was awarded a NASA grant to assess the plastic biodegradative properties of waxworm larvae in a microgravity environment on the International Space Station. A major component of this grant was partnering with Citizen scientists (CS) from two Arkansas K-12 intermediate schools who actively conducted preliminary experiments. Their classroom efforts optimized conditions for waxworm larvae plastic consumption, calculated mortality rates, and established the ability of waxworms to survive on minimal food stocks (beeswax only). CS contributed important data in establishing waxworm larvae' preference for the plastic type, Ziploc. This data was key to the final design of the ISS experiment and will be presented in various outlets. In addition, CS participated in engineering activities utilizing NASA constraints and independently manufactured the 3D-printed waxworm larvae habitats for the project. In July 2022, our team completed a successful launch of the experiment aboard the NASA resupply mission CRS-25. This project highlights efforts in finding innovative and sustainable waste management solutions for long-term space travel as well as bringing authentic, project-based learning opportunities in K-12 to increase awareness of this pervasive environmental problem.

Abstract Name: **Diclofenac Cytotoxicity in Two- and Three- Dimensional Rat Hepatocytes**

The Food and Drug Administration (FDA) heavily regulates pharmaceuticals in preclinical and clinical trials. A current challenge is accurately depicting the occurrence of hepatotoxicity of drugs. Due to related idiosyncratic reactions when the liver metabolizes pharmaceuticals. To determine potential hepatotoxicity, animal testing and two-dimensional (2-D) mammalian cell cultures are utilized. Both are viable options for testing, but animal testing has proven to be expensive, while 2-D monolayer cell cultures do not accurately depict toxicity and efficacy of drugs in vivo. To establish an accurate model of liver damage, three-dimensional (3-D) cell cultures are an alternative option allowing for a more realistic representation of organs in vitro. Diclofenac, used as a model drug, was tested on H4 Rat Hepatoma cells in 2- and 3-D cell cultures. The comparison of 2- and 3-D cell cultures led to a better understanding of how sensitive the liver is to diclofenac. Hepatocytes were treated with varying concentrations of Diclofenac for a period of 24, 48, and 72 hours and analyzed for cytotoxicity. Cell functionality was determined from the quantification of Albumin released using enzyme-linked immunosorbent assay (ELISA) in comparison to total number of cells for 2-D and 3-D cultures exposed to diclofenac. Cytotoxicity assay showed that at a 24-hour period, cells were not exposed to diclofenac for a long enough period to obtain conclusive results. However, at 48 and 72 hours, cell death for 3-D cell cultures ranged from 95% to 105% and 80% to 100%, respectively. 2-D cell cultures demonstrated a cell death at 80% to 90% and 60% to 80% for a 48- and 72-hour period, respectively. Results based on the cytotoxicity allowed for further cell functionality assays. Albumin specific ELISA was performed at 48 hours of drug treatment where the 3-D cell cultures displayed a significantly lower albumin secretion.

Abstract Name: **Comparison of Untreated Urban Runoff in the San Antonio River versus UTSA?s Bioretention Basins**

The city of San Antonio has experienced a continuous phase of rapid urban growth and development over the last century. One consequence of urbanization is the production of polluted runoff, especially during rain events. To assess the impact of urban water pollution, we tested for salinity, temperature, pH, total suspended solids, overall nutrient composition, and the presence of Escherichia coli and other bacterial coliforms at three different sites along the San Antonio River. Data for the San Antonio River's water quality was also collected from the Texas Commission on Environmental Quality's website and compared to the water quality sampled. Sites differed in terms of surrounding urban populations and land uses. The quality of the water samples from the San Antonio River were compared to water quality retrieved from the inflow and outflow of UTSA's bioretention basin. A detailed analysis is ongoing, but according to the past ten years of water sample data, acquired from the Texas Commission on Environmental Quality's (TCEQ) website, the San Antonio River had a significant amount of nutrients, and bacterial coliforms. In comparison, the inflow samples of UTSA's bioretention basin also had significant amounts of nutrients, and bacterial coliforms, yet the outflow water samples indicated a drastic decrease in these amounts. This study emphasizes the need for the San Antonio River Authority to implement a filtration system to mitigate the high concentrations of urban runoff and to protect the San Antonio River's natural ecosystem.

Abstract Name: **"Great Women of Art and Their Inspiration in My Protest Series: ?The Right to Reproductive Rights- Dear Governor Abbott, I am writing to inform you..."**

On May 21, 2021, we gathered a group of like-minded individuals felt the need to exercise our First Amendment rights and speak out against Texas Governor Greg Abbott's SB 8 bill, otherwise known as the Heartbeat Bill, enacted on May 19, 2021. It was a warm early summer Texas night when we gathered on the square in downtown Waxahachie, Texas. There, I stood with my friends, family members, and people from the community. A small but mighty gathering of voices that wished to be heard. With brightly colored poster boards adorning phrases like "I am a woman, not a womb," seen repeated in 'The Words We Need to Hear' (Figure 1), we circumambulated the courthouse calling out chants crying for an end to this "new normal" we were supposed to accept. The following evening at a show, a friend gave me his insight and experiences on the topic of abortion concerning the Heartbeat Bill, his words touched me so deeply that they motivated me to apply for the IDEAS fellowship. As an IDEAS fellow, I have rendered a series of eight compositions titled 'The Right to Reproductive Rights- Dear Governor Abbott, I am writing to inform you...' in acrylic paint on 16x20 stretched canvases from December 2021 to March 2022. Seven of these paintings are based on the experience and the photographs taken during the protest. The final artwork is based on the friend, his experience, and why accessibility is vital for the young women of Texas. In this paper, I introduce for the reader the topic that drove my inspiration for 'The Right to Reproductive Rights- Dear Governor Abbott, I am writing to inform you...', the individuals involved with its execution, and three great women of art that have influenced different aspects of this series.

Abstract Name: **Studying the effect of aryl hydrocarbon receptor activation on affinity maturation**

Oral immunization with protein antigens, such as cholera toxin, will result in production of antibodies by intestinal B cells. These antibodies can neutralize the toxin's ability to cause harm. Repeated immunization will increase the average affinity of toxin-specific antibodies over time, a process called affinity maturation. The aryl hydrocarbon receptor (AhR) acts as a sensor of friendly gut microbes and, in so doing, plays a role in moderating gut inflammation. Strong activation of the AhR by drugs and other chemicals can suppress B cell function and antibody responses, but those responses recover over time with repeated immunization. It is currently unknown if affinity maturation also recovers over time after strong AhR activation. To fill this gap in knowledge, we hypothesized that average antibody affinity would decrease over time with repeated immunization, in parallel with antibody levels, after strong AhR activation in mice. Because the AhR is a target for drug therapy to treat autoimmune disease, this work is important for understanding the potential implications of drug therapy.Based on the results of preliminary experiments, we were able to determine that antibody concentration increases as number of inoculations increase, providing a baseline knowledge necessary for future AhR activation experiments.

Abstract Name: **Performance on Executive Functioning and Attention Measures in Children with Neurofibromatosis Type 1 Compared to Unaffected Controls**

Neurofibromatosis type 1 (NF1) is a neurogenetic condition caused by a pathogenic variant of the NF1 gene. Cognitive problems in executive functioning and attention are prevalent in children with NF1. Executive function is an umbrella term for the cognitive processes that drive goal-directed and self-regulatory behavior. Executive function deficits in NF1 have been identified in the domains of inhibition, working memory, planning, and organization. Attention is the ability to focus one's cognitive resources on a relevant stimulus while ignoring irrelevant stimuli. In NF1, attentional difficulties have been identified in the areas of sustained, selective, divided, and switching attention. This project will examine measures of attention and executive function in children ages 7-11 years with NF1 compared to an age-matched unaffected group. Attention and executive functioning will be assessed using behavioral measures and caregiver rating scales. The Conners Continuous Performance Test-Third Edition (CPT-3) is a computer software-based neuropsychological assessment that yields information about four dimensions of attention: inattentiveness, impulsivity, sustained attention, and vigilance. Dependent measures include: omission errors (missed responses), commission errors (incorrect responses), and variability (speed consistency). The NEPSY-2 Auditory Attention and Response Set subtest (AARS) is an instrument used to assess auditory attention and impulsivity. Dependent measures include: omission errors, commission errors, and inhibitory errors (responses which indicate impulsivity or deficits in shifting). The Behavior Rating Inventory of Executive Function-Second Edition (BRIEF-2), a caregiver rating scale, assesses executive function and self-regulatory behavior. Dependent measures include ratings on scales assessing: behavior regulation, emotion regulation, and cognitive regulation indexes. We will characterize the performance of the NF1 group using descriptive statistics and compare the performances of children with NF1 and unaffected children using independent samples t-tests. We expect the NF1 group will show difficulty in comparison to normative data and to the unaffected group across all dependent measures.

Abstract Name: **Protect Your GPA From COVID-19: The Power of Grit and Resilience**

Academic performance concerns were prompted by COVID-19 and the transition to class policies like online learning or wearing masks. Previous research identified resilience and grit as protective factors for academic outcomes. Resilience refers to an individual's ability to bounce back following an aversive event. Grit refers to the ability to persist toward the completion of long-term goals. Limited research has assessed whether these factors can predict academic performance during COVID-19 or whether they can mitigate student concerns about COVID-19. The current study seeks to fill this gap in the literature by examining the correlation between resilience and grit in relation to perceived academic performance, actual academic performance, and COVID-19-related concerns. The current study hypothesized that grit and resilience would positively predict students' GPA and perceived academic performance and negatively predict students' academic and job-related concerns about COVID-19. College students (n = 48; 64.6% women; 89.6% White) completed a survey assessing their perception of their academic performance, perception of the impact of COVID-19 on their academics and future job prospects, GPA, grit (with subscales of consistency of interest and perseverance), resilience, and demographic information. We found through a series of Pearson's r correlations that the persistence subscale of grit was positively associated with perceived academic performance (r = .33) and GPA (r = .29). The consistency of interest subscale of grit was positively correlated with GPA (r = .33) and negatively correlated with concern for future job prospects (r = -.36). Resilience was only found to be positively correlated with perceived academic performance (r = .61). The current results are consistent with past research on grit and resilience and suggest the need for additional research on the impact of grit-promoting training and developing resilience skills for improving academic performance under sustained adversity.

Abstract Name: **Mathematical Modeling of Immune Response to SARS-CoV-2**

In response to the profound impact the COVID-19 pandemic has had on society, the mathematics and broader scientific community has focused considerable research efforts to understand the spread of the virus. Despite a tremendous volume of research in this area, how the human immune system responds to SARS-CoV-2 has not been yet fully understood due to limited analysis of the experimental or clinical information to date. Mathematical models that account for the interaction between SARS-CoV-2 and the human immune system will improve the scientific community's ability to analyze the vast amount of data available. The model we developed helps in understanding the role of various molecular pathways in successful viral clearance and the key mechanisms responsible for disease severity exhibited by some patients. Specifically, our in-host model explicitly represents the virus, innate immune cells, selected cytokines, and their interactions. These interactions are formulated in a system of coupled ordinary and delay differential equations. We conduct parameter estimation based on experimental data and literature review and investigate qualitative and quantitative behaviors of the model via numerical simulations. Using this model, we then determine the implications of variation of parameters by sensitivity analysis. Our model demonstrates key aspects of immune response to SARS-CoV-2, specifically its sensitive pathways, which might be responsible for differences in disease severity exhibited by COVID-19 patients. Our preliminary results of the mechanisms involved in COVID-19 pathology could identify several therapeutic targets that would provide hypotheses to be tested clinically, thus, serving as a foundation for the development of evidence-based therapeutic strategies.

Abstract Name: **Investigation of Ventilation and Air Quality in Classrooms**

The transmission of the coronavirus can be greatly impacted by indoor ventilation and air purifiers according to the U.S. Environmental Protection Agency and other public and private institutions and researchers. The concentration of aerosols in the air that contain the virus can be reduced by proper ventilation systems, which circulate and filter the air for increased quality. Aerosols with a diameter of2.5µm or lessare a possible carrier of SARS-CoV-2. PM 2.5 pollution may also increase the cellular expression of ACE2, associated with greater viral susceptibility. Ventilation to reduce PM 2.5 levels addresses both risks. Tests using incense as an indicator before, during, and after burning were used to see how quickly the ventilation in the rooms was able to remove excess PM 2.5. A calibrated DustTrak II monitor was used to record particulate matter, then Honeywell HEPA air purifiers were emplaced to see if further purification would aid in ventilation compared to only an HVAC system. Room air exchange rates (ACH, hr-1) were calculated using a spreadsheet by Jimenez at UC-Boulder. ACH rates in a small (15 person) meeting room were 5.88 hr-1 with HVAC alone and 16 hr-1 with two added air purifiers. Corresponding rates in an average (35 person) classroom were 9.62 hr-1 and 12.0 hr-1 with a single purifier. In this case, HVAC and air purifier coverage was 1.25–2.72 times as efficient as just HVAC coverage. Results for local weightlifting rooms are currently being investigated and will be included. A limitation of this research was the occasional pooling of incense smoke near the opening of the air monitor leading to a temporary spike in PM 2.5 levels. Use offans can address this issue. HEPA air purifiers reduce PM 2.5 levels and in turn may help lessen transmission risk of SARS-CoV-2 aerosols and airborne viruses

Abstract Name: **Undergraduate Student Identified Solutions to Advance Sexual Health**

Cultivation and adoption of knowledge, attitudes and behaviors that promote sexual health across the lifespan is a normative task of emerging adulthood. Policies of educational institutions can support, or impede, sexual health of students. Universities have a responsibility to provide education and programming to promote sexual health for their students (Carrasco, 2021). The goal of this community-based assessment was to identify prioritized, actionable ideas to improve sexual health among undergraduate students at Marquette University (MU).Group concept mapping provided a structured process to generate and implement ideas to solve a community problem. To begin the process, an online survey was distributed with three questions for idea generation: “In order to prevent sexual assault and other unwanted sexual contact on MU’s campus, we need _____”. “In order for undergraduate students at MU to have healthier relationships with intimate partners, we need _____”, and “In order to help undergraduate students at MU to be sexually healthier, we need _____”. The survey yielded about 40 unique ideas for each question. These ideas were rated in terms of importance, then sorted into domains by undergraduate students.Approximately 275 undergraduates participated. Mean age was 19.7 years, 83% were female, 15% male, and 2% non-binary. 74% identified as straight and 16% as LGBTQ. 34% had direct experience of sexual assault. Data analysis is underway using software to generate concept maps that depict ideas prioritized and sorted into domains. Examples of preliminary results include free STD testing at the student med clinic ranked as very important to promote sexual health, more campus spaces for open conversation about sex as very important for healthy relationships, and consent education as very important to prevent sexual violence. In spring 2023, final results will be presented to relevant audiences, and work groups formed to put the ideas into action

Abstract Name: Developing Internally Structured Microfibers

A new method was developed for creating internally structured and surface structured microfibers, using non-equilibrated aqueous poly-phase systems. To generate structured fluid jets aqueous two-phase and aqueous three-phase systems were used. The two-phase system involves flowing a jet of an aqueous poly(ethylene glycol) diacrylate (PEGDa)-rich phase containing a miscible amount of glycerol surrounded by a concentrated aqueous glycerol solution. For the three-phase system, the jet is PEGDa-rich, with a miscible amount of dipotassium phosphate salt, surrounded by a glycerol solution. For both systems, the concentrations of the species in the jet and the outer stream are chosen such that upon contact, water diffuses from the inner stream towards the outer stream, allowing for nucleation of salt/glycerol droplets within the PEGDa jet. A unique approach to pulling glass capillary tubes in-house, instead of utilizing a conventional micropipette puller, was used to create a coaxial glass capillary flow device to generate fluid jets. Microscopy is used to observe the nucleated droplets growing downstream and coalescing, creating various morphologies along the length of the device. The initial concentration of the species and flow rates were varied (due to different inner capillary diameters) to identify regimes where structured jets are formed before pinching off to form droplets. The PEGDa-rich jet with the addition of photoinitiator was UV-polymerized to create structured microfibers. This system has important implications for the generation of fiber-based hydrogels that could be used for drug delivery and tissue engineering applications due to their biocompatibility.

Abstract Name: The Gilgo Beach Investigation: How Prejudice Delays Justice

In December 2010, investigators for missing person Shannan Gilbert searched the marshes of Gilgo Beach, only to find a body, but the body wasn't Shannan. This discovery led to the recovery of body parts from 10-16 women found to be escorts on Craigslist. Consequently, a new investigation was opened known as the Gilgo Beach murders, in a search to find the serial killer who killed these women. Recognizing the prejudice that the prostitutes in the Gilgo Beach investigation suffered in several aspects of the investigation is important. By referring to the Gilgo Beach killings, the following argument builds and expands on the previous literature that establishes the problem of prostitutes being more likely to be victims of serial murders, while the primary sources of news articles are utilized to examinethe investigation itself. With several points to establish, this paper argues clear facts supported by reputable primary sources to state that the police were biased in their actions on the case. These indicators can range from the publication dates of newspapers and police comments to the search of a police officer as a probable suspect. The paper includes literature from researchers and previous experiences describing prostitutes as serial murderer victimsas well as details from primary sources about the Gilgo Beach investigation. The paper concludes that there is enough evidence to debate the question of why the Gilgo Beach investigation hasn't been solved in over two decades.

Abstract Name: **A Culturally Informed Approach to Improving Forest Diversity in Bad River Tribal Lands**

Forest diversification is essential to creating and maintaining healthy, resilient forest ecosystems. Forest diversification buffers the effects of climate change, creates new habitats for plants and animals, and improves biodiversity increasing the speed of succession. Without forest diversification, plant and animal life are at higher risk of localized extinction. More species and populations of plants and animals thrive in an ecosystem that facilitates their habitat needs. In this project we worked with the Mashkiiziibii (Bad River) Natural Resources Department to diversify their forested lands. We acknowledge that the Mashkiiziibii tribal lands are of cultural significance and their cultural values play an important role within their community. For this project, we used LiDAR images and superimposed soil maps to locate sand lenses that have the potential to house new tree species and improve biodiversity. By collecting and analyzing samples from the study areas in the field, we were able to verify our observations from remotely sensed data.

Abstract Name: **Analysis of Volatile Chemicals in Dog Urine using SPME?**

Urinary markings by domestic dogs have been seen to act as social indicators for other dogs. Although dogs urinating to mark territory is not a novel idea, the compounds responsible for this communication need to be studied. This project is a first step in analysis of the volatile organic compounds (VOC's) present in samples of dog urine to find chemicals important in communications by scent. Solid phase microextraction (SPME) with a polymer fiber is a growing method to detect VOC's. Extraction is done by heating and stirring the samples with the polymer fiber inserted into the headspace of the sample vial, and allowing the VOC's to adsorb on the fiber, which then is analyzed by gas chromatography. We use GC both with flame ionization detection (GC-FID) and mass spectrometer(GC-MS) for analysis. This project focuses on the effect of pH on extraction using buffer solutions. By altering the pH of our samples with a variety of buffer solutions (2, 7, 12 pH), the charge on acidic and basic compounds is changed, which significantly affects volatility

Abstract Name: **A Comparison of Alluvial Fills in Former Glacial Meltwater Stream Valleys in West-Central Wisconsin**

The Lower Chippewa River (LCR), a tributary to the Upper Mississippi River (UMR) in west-central Wisconsin, drained meltwater from the Chippewa Lobe of the Laurentide Ice Sheet and filled its valley with glacial outwash ca. 30 to 15,000 years ago. Then, as the region deglaciated, the UMR incised abruptly, initiating a wave of incision that progressed up the LCR in a prolonged and episodic manner (Faulkner et al. 2016). For this study, we examined the LCR's two largest tributaries, the Eau Claire River (ECR) and the Red Cedar River (RCR), as part of an ongoing project to determine how incision propagated through the entire LCR fluvial system and to identify what controlled the incision process. The specific objective of our research was to ascertain the sedimentological characteristics of the alluvial fills in each river valley in order to determine if the fills are similar (as expected, given that both were meltwater streams that drained the Chippewa Lobe) or different. We accomplished this objective by kayaking each river, mapping the location of terrace cutbanks, and describing the alluvium exposed in them. Contrary to what we expected, we found the fills in the two valleys to be clearly different. While both are characterized by tabular cross beds of medium-to-coarse sand with rare gravel, along with planar interbeds of gravelly sand, gravelly sand interbeds are generally more common—and gravel-size clasts typically larger—in the RCR valley. We are uncertain why the RCR fills are coarser. One hypothesis is that the RCR was the larger meltwater river and able to transport coarser material away from the ice margin. Whatever the explanation, the differences in valley-fill sedimentology may have influenced the process of incision as it propagated up each valley. Future research should take these differences into consideration.

Abstract Name: **Bumblebee Distribution on UW-Parkside's Campus**

Purpose Bumblebees are known pollinators and contributors to healthy ecosystems. In Wisconsin, UW-Parkside is a known location for the federally endangered Rusty-patched-bumblebee (Bombus affinis) and other bumblebee species. The objective of this project was to locate and identify various members of Bombus in four distinct campus phases (phase 1 and 2: completed restoration, phase 3: current restoration, phase 4: pre-restoration). Artificial nests were deployed into phases to encourage nesting and assess feasibility of monitoring resident bumblebee populations.Methods and Materials Weekly, one-hour, surveys were conducted under appropriate conditions from 11 May to 5 October, 2022. Sites of ~15m radius within each phase were surveyed for Bombus activity. Information regarding location, weather, and topography were recorded. During surveys, specimens were tallied and photographed for later identification. In each phase, six randomly placed artificial nests were either wood-covered or unsheltered to resemble natural nesting conditions. Early in the season nests were regularly inspected for activity. Results During 50 surveys, 199 bumblebees were recorded on the UW-Parkside campus; no Rusty patched bumblebees were observed during the first year of this project. Bumblebees appeared to prefer phases based on habitat composition rather than levels of restoration. In spring, it appeared queens frequented wooded areas, presumably for nesting purposes. Artificial nests were unoccupied this season perhaps due to delayed placement and challenges from vegetation encroachment. This pilot project provides guidelines for future artificial nesting placement and construction. Overall, our first season of survey data provides needed information on the current state of bumblebee activity on campus which serves as a guide for further restoration.

Abstract Name: **End Correction in Cylindrical Pipes**

The goal of this project was to determine the end correction for circular tubes of varying lengths and diameters. Unlike a vibrating string, which has a node at each fixed end, a tube with open ends has a pressure node that extends beyond the physical end of the tube. This extra distance, which depends on the diameter, is the end correction. To determine this end correction, measurements of the tube's harmonics, length, diameter, and speed of sound were made. This presentation will display the frequencies (of the fundamental and first harmonic) and corresponding end corrections for tubes with varying lengths and diameters. Our results were compared to a well-known theoretical model. We found that the model underestimated the size of the end correction for low harmonics.

Abstract Name: **Locating Jewish Holocaust Sites Near Alytus, Lithuania, Using Noninvasive Ground Penetrating Radar**

The Holocaust was the systematic killing of over six million European Jews andothers deemed undesirable by the Naziregime and their collaborators leading up to, and during World War II. Many of these killing sites remain hidden. Between 1941–1944, 60,000-70,000 Jewish people were killed and buried in mass graves in the Vidzgiris Forest near Alytus, Lithuania. The exact location of these mass graves is disputed amongst existing archival evidence and eyewitness testimonies. Ground penetrating radar (GPR) offers a means of detecting, and therefore locating, these burials. GPR is a non-invasive method that utilizes electromagnetic pulses to create subsurface profiles, allowing the user to image objects or sediment horizons underground. GPR was applied to a large trench-like physical feature, which measured 5m wide and exceeded 100m in length. The trench feature representsa potential burial site based on thephysical landscapeas well asdirect mentions of a trench in the literature, however, this feature currently contains no memorial.In an investigative effort, 48 parallel GPR lines were collected 0.25m apart perpendicular tothe trench using the Sensors and Software pulse EKKO Pro500 MHz antennae. A 0.02m step size was triggered by an odometer wheel to create a 12x12m grid of data. Local elevation data was recorded using the Topcon RL-H4C self-leveling laser and receiver every 1x1m. Parabolic subsurface features indicative to that of other burials wereidentified while using the EKKO_Project 5 GPR processing program. The feature represented by these parabolas extends the entire width of the grid, at 1.7m below the surface. Further investigations–such as electrical resistivity tomography (ERT) profiling and aerial photography–are suggested to determine the full scale of thesubsurface feature identified. Future study methods should remain noninvasive in nature, as it is considered disrespectful to excavate, exhume,or disturb the remains of Holocaust victims.

Abstract Name: **The Sex Talk: Conversations Between Fathers and Sons About Familial Upbringing and Impacts on Perceptions of Contraceptive Responsibility**

Sexual socialization is the process in which children and adolescents develop a knowledge and understanding of sexuality, sex, and safe sex practices. Parents play a crucial role in sex education and have been known to have conversations with their children about safe sex practices, consent, and sexuality. Family discussions, especially discussions between fathers and sons, allow adolescents to learn about the complexities of sex in a safe and honest environment. The significant gendered gap in sex education often encourages women to be responsible for learning about sex and using contraception, leaving men out of the discussion. Fathers today are in a unique position to start new conversations with their children; breaking the cycle of toxic masculinity and gendered divisions of labor in the home. Through surveys and interviews of college-aged sons and their fathers, this research aims to gain insight into the under-researched conversations between fathers and sons. In figuring out what young men and their fathers know and understand about sex, contraception, and gendered division of labor, we can determine how to better our sex education programs and pinpoint opportunities to support and educate men. This research asks three important questions: 1) How do perceived gendered divisions of labor impact feelings of responsibility for contraception among men? 2) When and how do conversations about sex and contraception happen between fathers and sons? 3) In what ways do these conversations impact masculinity, fatherhood, and men's influence on contraceptive management?

Abstract Name: **Factors that Influence College Students' Mathematical Identity and Perceived Proficiency**

The nature of mathematical knowledge is loosely defined by Kean (2017) as an individual's belief of how mathematical knowledge is organized and the source, justification, and content of this knowledge. Students' beliefs about the nature of mathematics can impact many aspects of their academic and overall life pursuits, and can be influenced by a myriad of experiences. In this study, we specifically examine the beliefs and experiences of college students enrolled in College Algebra courses, as we know the course is a gatekeeper that often predicts students' graduation (Bailey, et al., 2010). We use the figured worlds conceptual framework in the learning of mathematical experiences, to understand the multi-layered components of identity in varying contexts (Holland, et al., 1998). To examine undergraduate college students' past mathematics education experiences, beliefs about the nature of mathematics, and experiences in a College Algebra course, pre- and post-surveys were administered in spring 2022. We had 50 participants complete both the pre- and post-surveys. The Likert-items ranging from strongly agree to strongly disagree include scales intended to measure perceptions of mathematics proficiency and sense of belonging in mathematics. The open-ended questions aimed to understand participants' past mathematics experiences, experiences in College Algebra, and beliefs about the nature of mathematics. Preliminary results of open-ended responses indicated themes such as affective factors (e.g., stress, confusion), achievement (e.g., success or failure), acknowledgement (e.g., feeling seen, participation) and application (e.g., careers, daily life) of mathematics. Pre- to post-survey comparisons demonstrate gender differences with female participants showing a positive increase in their self-perceived proficiency in mathematics with pre-data starting lower than male participants and post-data higher than males. This change suggests that perceived gains in proficiency are related to female students experiencing a more positive mathematics college environment, which could influence their mathematics identity.

Abstract Name: **Identifying Mental Health Issues from Social Media using Machine Learning**

The way we think and feel psychologically, emotionally, and socially contributes to our overall mental health. We cannot help but let our thoughts, emotions, and behaviors be influenced by mental health. How we respond to pressure, interact with others, and make decisions are all influenced by it. Because of the changes in lifestyle brought about by technology, mental health issues are now more common than ever. The way someone interacts on social media platforms can reveal the presence of certain mental health issues. Detecting these issues early would allow us to aid the affected individual. It is challenging to pinpoint the reason behind all these issues because of the massive amounts of data available on social media and the inherent biases of humans. Deep neural networks excel at processing highly complex data and interpreting intricate aspects. In this project, we utilize the potential of deep learning to develop a Long short-term memory (LSTM) model, a special kind of recurrent neural network (RNN) model that helps us correctly identify the reason behind mental health issues from social media data. LSTM performs very well in Natural Language Processing (NLP) classification problems because it is more adept at interpreting temporal and sequential data than other types of neural networks. In this project, we are using publicly available social media datasets. We anticipate that by using our model, we would be able to correctly find the causes, allowing us to help and alleviate mental health-related sufferings more effectively.

Abstract Name: **ESK981 Increases The Effectiveness Of MEK Inhibitors For Therapeutic Treatment Of PDAC**

Pancreatic Ductal Adenocarcinoma (PDAC) is a highly deadly cancer, with a 5-year survival rate of only 11%. Nearly all cases of PDAC involve a mutation in KRAS, which leads to overactivation of the KRAS-RAF-MEK-ERK pathway, an important process in maintaining PDAC metabolic homeostasis. MEK inhibitors such as Trametinib target this KRAS pathway, but PDAC has recently been shown to protect itself from MEK inhibitors with autophagy–the recycling of cellular materials using the lysosome. Independently, PDAC has already been shown to be dependent upon autophagy for survival in its harsh microenvironments. Unfortunately, current autophagy inhibitors, like chloroquine, have been ineffective in clinical trials. In 2021, our lab reported ESK981, a phase I-cleared drug, as an autophagy inhibitor in prostate cancer models. This project aims to evaluate ESK981's ability to prevent PDAC cells from utilizing protective autophagy in response to MEK inhibitors. In our study, we performed western blot analyses, which showed an increase in both LC3 A/B and p62 for PDAC cells treated with ESK981, suggesting autophagy inhibition. To confirm this, we used the GFP-LC3-RFP-LC3ΔG system in Mia-paca2 cells and saw that the GFP/RFP ratio was maintained at 1:1. In contrast, Trametinib increased the levels of LC3 A/B but not p62, suggesting an increase in autophagy as expected. Furthermore, the GFP/RFP ratio in the GFP-LC3-RFP-LC3ΔG system decreased upon Trametinib treatment, confirming this. However, this decrease was reduced when cells were pretreated with ESK981 prior to Trametinib. This suggests that ESK981 was able to block autophagy driven by Trametinib. Finally, Cell-Titer Glo assays confirmed that Trametinib and ESK981 have synergistic effects (BLISS score >10) in suppressing the growth of PDAC cells. When taken together, our studies indicate that ESK981 can increase the effectiveness of Trametinib and suggest potential use of ESK981 as a therapeutic in PDAC treatment.

Abstract Name: Structural Insights into Molecular Recognition by Human Chemokine CCL19

The human chemokines CCL19 and CCL21 bind to the G protein-coupled receptor (GPCR) CCR7 and play an important role in the trafficking of immune cells as well as cancer metastasis. Conserved binding sites for sulfotyrosine residues on the receptor contribute significantly to the chemokine/GPCR interaction and have been shown to provide promising targets for new drug-discovery efforts to disrupt the chemokine/GPCR interaction and, consequently, tumor metastasis. Here, we report the first X-ray crystal structure of a truncated CCL19 (residues 7–70) at 2.50 Å resolution, revealing molecular details crucial for protein–protein interactions. Although the overall structure is similar to the previously determined NMR model, there are important variations, particularly near the N terminus and the so-called 30's and 40's loops. Computational analysis using the FTMap server indicates the potential importance of these areas in ligand binding and the differences in binding hotspots compared to CCL21. NMR titration experiments using a CCR7-derived peptide (residues 5–11, TDDYIGD) further demonstrate potential receptor recognition sites, such as those near the C terminus and 40's loop, which consist of both positively charged and hydrophobic residues that may be important for receptor binding. Taken together, the X-ray, NMR, and computational analysis herein provide insights into the overall structure and molecular features of CCL19 and enables investigation into this chemokine's function and inhibitor development.

Abstract Name: Race Predicts Reactions to Controversial Information About Racism in Policing

Humans are not impartial receivers of information. Several cognitive biases are known to influence individuals' evaluations of new information. For example, individuals' assessments may be influenced by the identity or lived experience of the person presenting such information (i.e., a messenger), as well as the individual's own identity or lived experience. We investigated the degree to which people's reactions to scientific information about a controversial issue, racism in policing, are influenced by three factors: 1) participants' own racial identity (black or white), 2) the messenger's racial identity (black or white), and 3) the news platform on which the messenger presents their information (MSNBC or Fox News). In this study, participants were asked to read a handout containing a set of bulleted statistics that run counter to prominent narratives about the ubiquity of racist policing. For example, the handout included a breakdown of the number of unarmed white (26) and unarmed black (12) people that were shot and killed by the police in 2019, and it described data showing that many people drastically overestimate the number of unarmed black people that are shot and killed by police. Participants were led to believe through random assignment that the information came from either a black or white police chief who appeared on either Fox News or MSNBC, for a total of four experimental conditions. We hypothesized that participant racial identity, messenger racial identity, and news platform would independently predict participants' reactions to the information and also interact to affect participants' receptivity to the information. Contrary to expectation, the manipulations (messenger race and news platform) did not influence participants' reactions to the handout; however, one robust pattern in the data was that white participants viewed the message more favorably and were less inclined to censor it than were black participants.

Abstract Name: The effects of Time Poverty on Stress and Life Satisfaction in university students and workforce participants

In an increasingly connected world, where work and school are just a click away, work-life has integrated more and more into personal-life taking more of one's personal time. Advancements in telecommunication, telecommuting to work, has contributed to an 'always on' culture that values productivity and always being available. In light of this, there is limited research on perceived time poverty. This study examines perceived time poverty in conjunction with environmental demands and their effects on stress and life satisfaction in the context of university students and workforce participants. A survey using scales on time poverty, irritation, and environmental demands were used in a quantitative analysis to measure their effects on stress and life satisfaction.

Abstract Name: Effect of Central Ghrelin Receptor Signaling on Avoidance Behavior in Wistar-Kyoto and Sprague-Dawley Rats

Behavioral inhibition (BI) is believed to be a genetically determined trait which causes individuals to respond to stressful situations differently than their non-behaviorally inhibited (NBI) counterparts. This research has been extended to the rodent population wherein the Wistar-Kyoto (WKY) rat models BI anxiety-like behavior, and the Sprague-Dawley (SD) strain serves as a control. We have previously demonstrated that a single overnight fast can enhance avoidance responses in SD rats to the level of avoidance exhibited by WKY rats. Overnight fasting elicits a variety of physiological changes that might directly or indirectly contribute to avoidance and anxiety-like behaviors, including reduced levels of gastric distention, reduced circulating levels of glucose and leptin, and increased circulating levels of ghrelin and corticosterone. Here we sought to investigate potential mechanisms that contribute to the fasting-induced increase in avoidance behavior we observed in SD rats. Since fasting increases circulating levels of the hunger hormone ghrelin, we hypothesized that central ghrelin signaling may contribute to the observed behavioral effect of fasting. We tested this by examining the effect of central ghrelin receptor activation on our signaled lever press avoidance task in female WKY (n = 8) and SD (n = 8) rats. All rats were implanted with cannulas targeting the lateral ventricle (LV) and receivedintra-LV injections of ghrelin or saline 45 minutes prior to the signaled lever press avoidance session. Ghrelin did not affect avoidance in SD rats. Surprisingly, intra-LV ghrelin significantly reduced avoidance performance in WKY rats, which resulted in a significant increase in the number of shocks that WKY rats received following intra-LV ghrelin relative to saline treatment. These findings suggest that central ghrelin may have an anxiolytic-like effect in WKY rats. Additional studies are necessary to further elucidate mechanisms by which central ghrelin signaling affects mood-related behavior in both NBI and BI models.

Abstract Name: **The Evolution of Prominent Female Figures in Fashion of the 1900s**

Fashion is evolving and ever-changing. While fashion includes everyone, it is a practice that predominantly highlights and affects women. Despite this, there is a gap in literature on the representation of women who have influenced fashion. Our research aims to trace the development of styles, forms of dress, and appearance in relation to changing social, cultural, economic, technological, environmental, and political factors in the Western world while highlighting prominent female figures who helped make these changes in the 20th century.To explore this topic further, we first conducted a content analysis using scholarly publications and books to identify prominent female figures of the 20th century. We researched the historical climate of each of these decades, then selected female figures who represented these decades and their respectful fashions. After analyzing each decade, we focused on four decades, the 1920s, 1940s, 1960s, and the 1980s. The women identified include Greta Garbo, Marlene Dietrich, Jacqueline Kennedy, Twiggy, and Madonna. Greta Garbo and Marlene Dietrich were actresses of the 1920s and 1940s who influenced women to move away from cultural norms of dress; Twiggy and Jacqueline Kennedy. were prominent figures of the 1960s who showcased the polarized climate of the time, and Madonna was a singer who was known for her rebellious image in the 1980's. We then conducted an artifact analysis of styles and silhouettes of clothing from the 20th century using the historic dress collection at St. Catherine University in St. Paul, Minnesota. This collection contains over 2,000 garments and accessories dating back to the 1850, which provides evidence of silhouettes of the past. The findings of this research fill a gap in the literature and highlight women's accomplishments and fashion influence throughout the decades. These Findings will be presented in a visual window exhibition at Saint Catherine University.

Abstract Name: **Body Positivity as Promotional Strategy**

The third wave of the body-positive movement began about a decade ago. Its primary purpose: confront the unrealistic expectations toward and unrepresentative bodies of women in popular media and advertising. This has led to the rebranding of many notable multinational companies, including expanding their size offerings. In the United States, consumer preference trends have led to an uptick in purchasing athleisure and sportswear apparel, and many companies in these industries have been forced to reevaluate their own product strategies in order to avoid being perceived as a non-inclusive brand. The purpose of this research, generally, is to investigate the potential effect of the body-positive movement on a particular part of the integrated marketing communications strategies of a sample of brands in the United States. We created a framework that delineates brands in our sample as being or not being proactively body-positive, and using this framework, we conducted case-based analyses to explore any potential correlations between being body-positive and gaining earned publicity.

Abstract Name: **Ontogeny of the t?ngara frog eardrum tuning**

The túngara frogs of Central America and parts of South America rely on their auditory capabilities to engage in reproductive processes. The female tungara frog evaluates many calls produced by multiple males and selects to mate with the male that produces the most attractive calls. Frogs in general show a match between the tuning of the ears and that of the calls promoting effective communication. While most of the energy in the call of the tungara frog is found at 700-1000 Hz, researchers in our lab have found that the frog's eardrums are tuned around 2-3 kHz. This range of auditory tuning was not only unexpected but the results also showed peculiar variability. We replicated the sensitivity measurements of the eardrums in a new set of frogs, exploring age as a potential source of variation. Each individual was anesthetized and presented with a series of pure tones ranging from 0.2 to 18 kHz while the vibrational responses of the eardrum were characterized using Doppler laser vibrometry. This study allowed us to verify the validity of our existing measurements and test the age of the frog as a variable for the cause of the mismatch between the tuning of the ears and the calls of this species.

Abstract Name: **Following Female Adolescent Activities Participation to Career Success**

Models of human capital development generally designate childhood and adolescence as periods of investment through decisions related to education and other forms of training. Returns on these investments are realized in the form of higher incomes in adulthood. Expanding on this understanding, economists consider how participation in extracurricular activities contributes to future earnings and labor market outcomes. Prior research analyzes the relationship between various activities and transition into young adulthood, showing the relationship to be more substantial among males than females and not utilizing the most recent data on relevant variables. The National Longitudinal Study of Adolescent and Adult Health (Add Health) first collected data from a nationally representative sample of 7th-12th grade students throughout the United States in 1994-1995, and followed up with the participants in four additional surveys, the most recent collection in 2016-2019. This project utilizes Add Health data to examine patterns in the adult labor market outcomes of individuals who participated or did not participate in extracurricular activities as teens. We hypothesize that those who participated in extracurriculars during adolescence tend to have greater economic outcomes as adults. When we examine the differences between participants and nonparticipants within separate childhood socioeconomic status (SES) groups, we see more statistically significant gains in mean income for participants than non-participants among females more than males. For women ages 36 through 39 who reported growing up in a household with lower SES than their peers, the difference in mean income between activity participants and non-participants was very large, with participants reporting incomes almost double those of non-participants. While this research is still in its preliminary phases, this sizable difference inspires further investigation.

Abstract Name: How are women presented as classical deities throughout art history?

This essay focuses on three main examples to explore the art historical use of classical deities to represent real women. The three examples are: the funeral stele of Aelea Procula, an ancient roman funeary altar depicting a young girl with features resembling the goddess Diana; Dante Gabriel Rossetti's Mnemosene,which shows his mistress Jane Burden depicted as the goddess of memory - as well as an accompanying poem; and Maud Sulter's self portrait Calliope, a photograph in which she uses the visual imagery of a promenent Greek Muse and a similar personal aesthetic to Jeanne Duval, another woman who acted as a muse and mistress to Charles Baudelaire. The object of the essay is to approach each art piece from a feminist and social art historical methodology in order to discover the implications of depicting women as deities. The essay includes exploration of visual references, cultural implications and as much of the personal lives of the women depicted as is available. The examples represent a wide variety of time periods and cultures, so the reasoning behind the depiction of women as deities varied between each one. Aelia Procula was depicted as Diana as a tribute to her youth when she passed, and was a common practice in Ancient Rome. Dante Gabriel Rossetti was working at a time when the resurgence of Helenistic art and architecture, thus his work with Jane Burden reflects this themewhile including subtle references to his personal relationship with his model. Maud Sulter's is the only piece both created by a woman, and as a self portrait. In this way, her piece stands out among the others, offering a unique point of view from both a feminist and social perspective.

Abstract Name: Smartphone Use on Well Being

How has Smartphone use impacted the general well-being of people today? The Smartphone usage has certainly increased over the past generation. The use is so prevalent that nearly everyone from 9-99 has one. Questions regarding how this intense Smartphone use is impacting the overall health and well-being of society has been discussed across many different aspects of research. This research intends to study how Smartphone use impacts the physical, psychological, cognitive, and social well-being of individuals across the generations. Previous research tendedto focus on one aspect or another of well-being, for example sleep or academic performance (cognitive functioning) or anxiety (psychological functioning). The research is lacking when looking at the global health of an individual and its association with Smartphone use. Thisstudy will also examine the specific ways individuals are using the Smartphones as well as how much of their daily life is consumed by the use. A correlational analysis will be completed in the spring semester of 2023 to determine what factors are impacted by Smartphone use.

Abstract Name: Modeling and Simulation of Compliant Mechanisms in MATLAB Simscape

Compliant mechanisms are the mechanisms that transfer the input force, displacement, or torque from one point to another through the deformation of its compliant members and flexible body rather than the joints such as ball bearings. They have superiorities over the traditionally designed mechanisms such that since they can be designed and manufactured as a single piece using injection molding or additive manufacturing, they are light weighted, and no need for assembly and have no friction loss. Thus, the compliant mechanisms have better performance and accuracy and find application areas in the design of locomotive robots, grippers, medical robots, and microelectromechanical (MEMs) devices. Despite all the advantages, deriving the mathematical model of compliant mechanisms is much more challenging compared to traditional rigid body mechanisms as the complexity of the design increases. Although there are several methods available to find the load-deflection curves of flexible members such as pseudo rigid body modeling (PRBM) and the first and second of the Elliptica theory, they are limited to the simple geometries including fixed-free, fixed-guided, and fixed-fixed buckling beams. In this study, we present the design, modeling, and simulation of several compliant mechanisms in MATLAB Simscape. We adopted two approaches: the model can be created using the Simulink library blocks or by importing the cad model and then introducing the flexibility using discrete beam elements. We created the models of a fully compliant five-bar mechanism including 4 rigid bars connected by large deflecting flexure hinges, a compliant dwell mechanism incorporating buckling beams, a slider, and a rail, and a compliant bistable mechanism consisting of 6 rigid bars, a slider, and fixed-free flexible beams. The Simscape models not only provide kinematic insight but also visualizes the displacement and motion of each mechanism in the mechanics explorer.

Abstract Name: Detecting Onion Pathogenic Gut Bacteria in Utah Thrips

The number of onions consumed per person has risen drastically over the last twenty years, from 12 pounds to 20 pounds. This 70% increase places onions as the fourth most consumed vegetable in the United States. As such, increased pressure is put on farmers and growers to meet this growing demand, and their ability to identify and manage bacterial diseases which cause onion bulb rots is vital. However each year, the onion industry loses over $60 million dollars as a result of damage and rot. Thrips are insects that damage economical crops, but are particularly harmful to onions and other vegetables. Thrips thrive in the warm and dry environment of Utah and can cause significant damage to entire fields. Thrips puncture plant tissue during feeding creating wounds. They also defecate on leaves and bacteria from their feces can enter these wounds. Gut bacteria from thrips have been shown to cause bacterial bulb rots in onions in some states. The objectives of this project are to identify gut bacteria from thrips collected in Utah onion fields and determine pathogenicity of bacterial isolates. Thrips were collected from five Utah onion fields during the onion growing season (June-September). Individual thrips were crushed in sterile water and the water was plated on nutrient agar. Resulting bacterial colonies were cultured and identified using PCR and 16S region primers. Bacterial genera identified from thrips to date have been found in rotten bulbs, indicating that Utah thrips could contribute to storage rot of onions.

Abstract Name: **Microplastics in Soil: Identifying Their Prevalence in Northwest Florida and Their Effects on the Growth of Kale**

Current estimates suggest that land used for agriculture and horticulture has up to 13,000 microplastics per kilogram of soil, which is almost double the amount of microplastics found per kilogram of ocean water. Given that microplastics in soil can have a negative effect on the growth of some crops, the purpose of this research was to test for effects that different levels of microplastics in soil might have on kale, and to analyze agricultural sites in Northwest Florida region and test them for microplastics. Kale was planted from seed at a greenhouse in four groups of five replicates with different low-density polyethylene (LDPE) microplastic amounts, including 0g, 0.045g, 7.5g, and 15g. After cultivation, average stem diameter, number of leaves, root biomass, shoot biomass, and chlorophyll content of the kale were measured. Soil samples were collected from a farm in Walnut Hill, a community gardenin Pensacola, and the University of West Florida Community Garden. Microplastics were extracted from these soils using density separation with NaI, organic matter was removed with 30% H_2O_2, and the microplastics were classified by shape and color, and quantified by their abundance. The results showed that there was little significant effect of LDPEmicroplasticson kale growth except for root and shoot biomass which decreased with higher amounts of LDPE and root length which increased with higher amounts of LDPE. All of the soils collected from Northwest Florida had microplastics in them, though less than the global average. This study reveals microplastic trends in Northwest Florida and adds to the small collective of knowledge on how microplastics affect plant growth.

Abstract Name: **The Stability of Planets in an S-Type Binary Star System**

Observations of extrasolar planets suggest that not only are planetary systems common, but they can also be found in binary star systems. The dynamics of planetary systems in which there are two stars are inherently more complicated than single star systems. In this study, we are interested in the stability of S-type planetary systems when orbital parameters are differed. If a planet can be determined to be in a stable orbit, then other questions such as whether the planet can support life can be addressed. An S-Type binary star system is defined by a planetary body orbiting a star, with a secondary external star orbiting outside of the initial star-planet system. We used REBOUND, an open-source N-body code, to investigate the marginal stability boundaries of S-Type systems. The marginal boundary is the distance in astronomical units (AU) between the central star and the secondary star -- with an initial condition of the planet orbiting at a semimajor axis of 1 AU around the initial star – such that a distance of 0.1 AU or less of the value would be considered unstable. Orbital parameters were varied, including the secondary star's orbital inclination, semimajor axis of the secondary star, and the eccentricity of the secondary star.

Abstract Name: **Gait Variability is Altered After Revascularization in Patients with Peripheral Artery Disease**

Revascularization surgical procedures to restore blood flow to the legs are common treatment options for patients with peripheral artery disease (PAD) if conservative approaches are not effective. Biomechanical analysis has demonstrated altered gait variability in patients with PAD. Gait variability is an indicator of the fluctuations in motor performance that occur across multiple repetitions of a specific task. The objective of this study was to determine whether linear and nonlinear measures of gait variability improve following revascularization treatment. Patients underwent revascularization surgery and participated in experimental testing before and six months after treatment. The position of reflective markers placed on specific anatomical locations of lower limbs was recorded while patients walked on a treadmill at a self-selected speed for three minutes or until the onset of pain. Linear analysis included the calculation of standard deviation (magnitude of variability). Nonlinear analysis measures the structure of variability (i.e., the largest Lyapunov exponent and the sample entropy) which was calculated from the time series of the sagittal lower limb joint angles. We calculated all outcome variables using custom codes in MATLAB for baseline and post-surgery conditions. Sample entropy values decreased after revascularization surgery indicating joint angles become more regular following treatment. The largest Lyapunov exponent values for the ankle joint showed greater changes pre- to post-surgery compared to the hip or knee joint and the Lyapunov exponent increased after surgery. There was a significant increase from pre- to post-surgery in the range of motion mean for the knee joint. Linear and nonlinear outcomes from patients after surgery indicate a benefit from surgery as these values move closer to the values seen in healthy controls. This knowledge will be useful for clinicians in interpreting the clinical significance of functional improvements following revascularization surgery.

Abstract Name: **NLRX1 Modulation of Sars-CoV-2 Immune Response**

Since the beginning of the Covid-19 pandemic, there have been 6.6 million deaths attributed to the disease. Severe progression of Covid-19 is attributed to the cytokine storm initiated by the immune response to the virus. NLRX1 is a NOD-like pattern recognition receptor, active in innate immune pathways. NLRX1 is part of the NF-B pathway, which regulates cytokines such as IL-6 and TNF-. We hypothesize that when NLRX1 is present, it will help moderate the immune response to Covid-19 and decrease damage done to the body. When NLRX1 is knocked out, we believe we will see a more extensive immune response and therefore more damage. Post challenge with Sars-CoV-2 virus (MOI of 1), in primary mouse bone marrow derived macrophages, have shown that lack of NLRX1 significantly increases IL-6 levels. IL-6 is a pro-inflammatory cytokine. Macrophages challenged internally with nucleocapsid proteins of Sars-CoV-2 had an increase of IL-6 in Nlrx1-/- macrophages. However when challenged with nucleocapsid proteins externally, wildtype macrophages had significant levels of IL-6. Previous studies have found that increased IL-6 levels are present in patients experiencing severe Covid. Histology slides have shown a significant difference in inflammation of the lungs when infected, with Nlrx1-/- mice experiencing more inflammation. Immunohistochemistry shows a larger amount of viral cells in knockout mice compared to wildtype mice. There are very limited therapeutic options for Covid-19. The suggestive data on NLRX1 warrants further research into the potential therapeutic drug target.

Abstract Name: **SNARE Vesicles in Membrane Repair in hiPSC Cardiomyocytes**

Duchenne muscular dystrophy is a genetic neuromuscular disorder resulting from mutations in the DMD gene which codes for dystrophin, a vital protein in the dystrophin-glycoprotein complex functioning as a membrane stabilizer during muscle contractions. Dysfunctional dystrophin in the sarcolemma results in loss of membrane integrity, rendering the plasma membrane prone to contraction-induced injuries which occur at a rate beyond that of membrane repair. The ability to facilitate membrane repair is necessary for cells to survive membrane disruptions, and better understanding of membrane repair mechanisms could provide future treatment for DMD patients. Once an injury has occurred, Ca2+triggered exocytosis is mediated by intracellular vesicles translocating to the plasma membrane injury site to facilitate membrane repair. However, the exact mechanism in which membrane repair occurs once these intracellular vesicles have translocated to the plasma membrane is not known. Previous research has suggested SNAREs function as possible mediators of membrane repair. In this study, we aimed to validate and establish expression of eGFP-labeled SNARE components in cardiomyocytes to study their compartment localization and role in membrane repair using immunofluorescence in paraformaldehyde-fixed cells. Human-induced pluripotent stem cells-derived cardiomyocytes (hiPS-CMs) were purified, lipo-transfected with eGFP-VAMP2, and mechanically stretched with the presence of propidium iodide to identify injury. Immunofluorescence revealed eGFP-VAMP2 appeared to be more evenly distributed throughout hiPS-CMs compared to non-CMs. Immunofluorescence also revealed that eGFP-VAMP2 in hiPS-CMs did not colocalize with LAMP1, but partially colocalized with GM130, suggesting VAMP2 resides in the Golgi but not lysosomes. After mechanical stretch-induced injury, immunofluorescence determined greater colocalization of eGFP-VAMP2 and Syntaxin 4 (Syn4), suggesting more SNARE colocalization after injury. Our results suggest eGFP-VAMP2 may form a SNARE complex with Syn4 to mediate membrane repair in injured hiPS-CMs. Further work will investigate the incorporation of eGFP-VAMP2 vesicles in the sarcolemma following laser-induced injury.

Abstract Name: **Analysis of 2 variants of CERKL, a gene associated with ocular disease**

Genetic testing, including whole genome and exome sequencing, is quickly becoming a standard healthcare practice, especially for patients with rare diseases. While some changes to DNA sequences can be benign, there are several variants that have not been characterized. One large group of these variants are classified as variants of uncertain significance (VUS), as the effects have not been directly studied yet. However, effectively interpreting the relationship between identified variants and disease remains challenging. VUS can include variants that are predicted in silico analyses to affect splicing of the pre-mRNA into mature mRNA. Disruption of splicing can result in loss of a functional gene product due to exon skipping, changes in the reading frame, or introduction of a premature stop codon. In collaboration with PreventionGenetics, our lab analyzes VUS predicted to affect splicing of genes using a minigene system. Briefly, the minigene system involves cloning a single gene segment into a plasmid vector which is transfected into eukaryotic cells. Processed mRNA transcripts are then sequenced to determine the effects of the variant on splicing. We will present our analysis of 2 variants in the CERKL gene and their potential clinical relevance.

Abstract Name: **Maternal Stress Associated With Infant Gut Microbiota and Infant Health in Cebu, Philippines**

Infant early-life health outcomes are impacted by maternal health in the pre- and postnatal periods. Stress related to socioeconomic factors can contribute to variable maternal health. Both maternal and infant health are tied to the composition of the gut microbiota, a collection of microorganisms in the human gastrointestinal tract that has been shown to modulate stress through functioning of the hypothalamus-pituitary adrenal axis. Previous research has linked maternal stress to the infant gut microbiota and infant cognitive developmental issues, which often coexist with physical health problems, but associations between maternal stress, the infant microbiota, and infant physical health have not been explored directly. Using data from the Cebu Longitudinal Health and Nutrition Survey (CLHNS), we investigated connections between levels of maternal stress, composition of the infant gut microbiota, and infant health outcomes. Maternal stress was measured in 42 mothers using a validated stress survey composed of 16 variables, and infant gut microbiota composition was determined at 2 weeks and 6 months of age using 16s rRNA gene sequencing. Preliminary PERMANOVA results showed that differing infant microbial compositions were associated with quantified levels of stress, including variables of feeling irritated (p=0.04) and feeling upset (p=0.04). We predict that these differing infant microbial compositions will also be related to early-life infant health outcomes as measured in the CLHNS and will be supported by associations with maternal C-reactive protein (CRP) levels. These results demonstrate that varying maternal stress levels can impact infant early-life health outcomes and provide a potential mechanism for intergenerational transmission of stress.

Abstract Name: **Effects of Social Media**

Social media has become one of the biggest aspects of our everyday lives. They allow us to share our lives with loved ones, research our interests, and expose ourselves to all kinds of new things. Due to how ubiquitous the sites are, they inevitably will have a profound effect on mental health. Existing literature shows that there are many ways that social media can affect people's lives. It shows that social media can affect people's health choices and personal lifestyle decisions. Research also shows that people tend to compare themselves to others more when using social media often, which can lead to a multitude of mental health and self-perception issues. This research focuses on mental health and social media use. Using a survey implemented to a diverse sample of individuals through various social media outlets, a wide variety of different trends emerged. The main focus of the research was to determine whether social media was linked to self-esteem. The research shows a wide variety of ways social media is affecting people's mental health and their assessments of their own physical and intellectual attributes.

Abstract Name: Role of Motivation on Academic Success B

The collegiate world is constantly discussing how student motivation is related to student success. How true is this correlation? Does the motivation importance change with the specific course or the format the course is taught in? Can the institution or instructor impact the student motivation level by understanding intrinsic and extrinsic factors that motivate students? The aim of this study is to determine what motivation is and how it impacts the academic success of college students. Factors that will be studied are intrinsic and extrinsic motivation factors, academic performance, familial college experience (1st generation studens vs non 1st generation students), and the role of the institution and faculty. The study will be completed through a survey with a battery of questions addressing all the key areas mentioned above. Demographics will also be collected to compare possible inter-group differences. Correlational analysis will be completed through data collection in the spring semester of 2023.

Abstract Name: Covalent Organic Framework Membrane for the Removal of Per- and Polyfluoroalkyl Substances

Per- and polyfluoroalkyl substances (PFAS), as a group of emerging contaminants, have been ubiquitously detected in surface water, groundwater, and wastewater. Membrane-based filtration is considered an economic and effective approach to remove PFAS from contaminated water. Covalent organic framework (COF) membranes are a promising water treatment technology due to their inherent porosity and outstanding chemical stability, but remain unexplored yet for PFAS removal. In this work, a series of β-ketoenamine-linked COF membranes were prepared by interfacial polymerization method, and membrane structures were characterized by a variety of material characterization techniques. PFAS rejection rates, as well as water permeance of the synthesized COF membranes, were evaluated in a crossflow permeation system. Findings from this research will provide insight into the correlations between COF membrane structure and PFAS rejection property that will guide better design of membrane materials for the removal of emerging contaminants.

Abstract Name: Association of SNPS of the COMT Gene and Pain Experienced by Women Following Surgery for Breast Cancer

Introduction: The COMT gene is responsible for producing an enzyme called catechol-O-Methytransferace. This enzyme metabolizes various catecholamines, such as dopamine and epinephrine. This study aimed to explore the association of common single nucleotide polymorphisms (SNPs) found in the COMT gene with pain experienced by women 48 hours following surgery for breast cancer. Methods: We employed a secondary data analysis of symptom data collected as a part of a larger, longitudinal study focused on the genetic underpinnings of symptoms experienced by women treated for breast cancer. IRB approval and informed consent were obtained prior to data collection. For this project, a cross-sectional design was used to explore the association of pain assessed 48 hours postoperatively with genotypes of the identified SNPs. Pain was assessed using an 11-point verbal pain score. Genotype data were collected from DNA extracted from saliva samples obtained from all study participants.Results:The sample consisted of 296 women (85% White), aged 28-88 years (mean 60.88 years), who were scheduled for surgery for breast cancer. We investigate 5 SNPs (rs 4646312, rs165656, rs6269, rs4648, rs165599) along the COMT gene, which have known associations with the modulation of pain sensitivity and perioperative opioid use. Minor allele frequencywas at least 14% for all SNPs except for rs165599. Thus the heterozygous and homozygous variant genotypes were combined for analysis. When the AA genotype of rs 165599 was compared to the combined AG/GG group, there was a clinically significant trend for the AA group to have increased sensitivity (0.07). In addition, the AA genotype of the Val158/Met (rs 4680) was significant for higher levels of pain (0.06) compared to the AG and GG groups.Conclusion:This study demonstrates the increased potential of using genetic markers to predict patients at increased risk for experiencing pain following surgery for breast cancer.

Abstract Name: Viscosity and Viscoelastic Behavior of Stimuli-responsive Copolymers for Use as Dispersants in Architectural Coatings

Viscosity and viscoelastic properties are important for the application of stimuli-responsive polymers as dispersants in architectural coatings such as paints. Viscosity is a fluid's resistance to flow under stress, while viscoelastic materials exhibit solid-like elastic or liquid-like viscous behavior depending on experimental conditions. New stimuli-responsive polymers, which change their properties in response to changes in temperature, pH, and mechanical environments, could affect the dispersion of opacifying particles such as titanium dioxide in the coating. By adding stimuli-responsive polymers, the properties of architectural coatings can be controlled to produce a more opaque coating with controlled viscosity. This decreases costs and reduces environmental impact. A rheometer is used to test a polymer's viscoelastic properties under different pH, temperature, shear rate, and frequency conditions. Understanding how viscoelastic properties change in response to external conditions is necessary for matching these polymer properties to properties needed for architectural coatings. Viscosity testing is used to determine how well the polymer will mix with titanium dioxide particles. Ideally the coating will have the lowest polymer concentration and lowest viscosity possible to meet performance needs. Viscosity tests help determine where this minimum occurs for different copolymers. This can help determine which polymer is most suitable for dispersing titanium dioxide particles. Viscosity and viscoelastic testing can allow for determination of how changes in polymer structure result in changes in stimuli-responsive properties. The copolymer structures can be tuned, and the properties can be predicted in order to optimize properties for architectural coatings. This results in new materials to meet performance requirements to compete with traditional, commercially available dispersants.

Abstract Name: **Generating reliable amorphous structures: a comparative study**

Many technologically important materials have an amorphous structure where the arrangement of atoms or molecules is disordered. A fundamental understanding of the structures of amorphous materials is critical, and computer simulations have played an important role in revealing the structural characteristics of amorphous materials. Traditional, the simulated melt-quench method has been used to generate the amorphous structure, where the system is melted at high temperatures and then quickly quenched down. While this approach has been widely adopted, a major disadvantage is that the simulated melt-quench is computationally costly, especially if ab initio molecular dynamics (AIMD) simulations are used for the melt-quench process. Alternatively, one can use a Monte Carlo (MC) approach to generate typical amorphous configurations, although the accuracy of the structure thus generated cannot always be guaranteed. In this project, the two different approaches will be used to generate structures of amorphous silicon oxides (SiOx, x≤2) with varying oxygen concentrations. The resulting structures will be compared with available experimental data to identify the strength and weaknesses of each approach. The optimal computational protocol that produces reliable amorphous structures while maintaining computational efficiency will be proposed.

Abstract Name: **Analysis of Filament Homogeneity in composite Bi-2212 wires**

Superconductors are materials that can carry electricity without resistance at cryogenic temperatures,large magnet applications such as particle accelerators. Bi2Sr2CaCu2O8-x(Bi-2212) is a superconductor capable of producing very large magnetic fields over 20 Tesla, but processing the Bi-2212 into a usable, filamentary round wire form is challenging. In particular, fluctuations in the size and shape of Bi-2212 filaments in a composite wire can affect processing capability and wire performance. For this project, a set of twelve densified composite Bi-2212/Ag wires comprised from five different filament configurations, four final diameters, and utilizing three different powder sources were sectioned and imaged at 1 mm depth intervals to assess the longitudinal homogeneity of the filaments, to better understand the maturity of the production process for Bi-2212. Image analysis using ImageJ was then used to assess the evolution of the geometric characteristics of each filament in the cross-section, and to quantify those changes. For transverse analysis, we figured out that most wires exhibit some filament elongation at thecorners of each bundleand the distributions of filament areas and circularities for the trapezoidal filaments are clearly shifted relative to the other bundle shapes. For longitudinal analysis, for both area and circularity, larger and more circular filaments are more uniform along the length and the coefficients of variation for those parameters are relatively insensitive to the radial position of the filament in the wire. Filament size is the most important variable for longitudinal uniformity, and is considerably moreimportant than filament spacing, powder source, or overall wire architecture. This set of Bi-2212 wires represents a mature production with overall stable longitudinal filament uniformity, and this analysis will be helpful to Bi-2212 wire manufacturers as they seek to optimize wire layout and powder characteristics for fabricability and performance uniformity.

Abstract Name: **Physiological linkages in eating disorders via variance in preproglucagon**

The brain plays a crucial role in feeding behaviors through the activation and inhibition of various neural circuits. Properly understanding these mechanisms allows us the ability to create therapies and treatments for diseases relating to feeding and motivation, including obesity related illnesses and various eating disorders. One particular hormone that regulates the mechanisms of feeding is Glucagon-like peptide 1 (GLP-1), a peptide hormone produced by the intestinal cells through the processing of proglucagon. It is known that GLP-1 acts by activating GLP-1 receptors on the pancreas and brain which increases the release of insulin while simultaneously decreasing the release of glucagon, causing a decrease in appetite. Despite its well known function in the pancreas, this phenomenon is still being explored in the brain and is the focus of our study. We performed an anatomical characterization of GCG cells (GLP-1 producing cells) in the nucleus of the solitary tract (NTS) looking at two different cohorts of mice. For one cohort, we used non-transgenic mice and performed fluorescence in situ hybridization for that cohort, and for the other, we crossbred GCGicre mice with L10EGFP mice. We imaged horizontally sliced sections as well as coronal sections of the NTS and then analyzed those cell counts using software that aids in interpreting cell images. Potential sex differences in the distribution of the GCG cells was unknown, therefore this led us to the analysis of the density distribution separated by sex. In our study, we observed no sex differences in the density distribution of GcgNTS cells; however, future studies using this data will be important in understanding the impact GcgNTS cells have on feeding and motivation and what roles they play in advancing current therapies of obesity related illness.

Abstract Name: **Understanding Lung Cancer Screening Resources and Needs in Appalachian Kentucky**

Appalachian Kentucky (KY), a largely rural and under-resourced region, has the highest rates of lung cancer incidence and mortality in the US. In recent years, lung cancer screening has become increasingly available; however, in Appalachian KY, only 14% of those meeting guideline requirements are being screened. The specific aims of this study are to identify lung cancer screening health education material needs in the Appalachian KY community and to uncover the social determinants of health affecting lung cancer screening for those in the region. We are recruiting 10 Appalachian KY residents who are eligible for lung cancer screening and not currently in a healthcare-based profession to participate in 60-minute qualitative interviews. In these interviews, we share three lung cancer screening materials that are currently available online and ask the participants for their opinions. We then ask participants about specific social determinants of health in their community and how we can help members to access screening. The interviews were transcribed, and two independent coders analyzed the data to determine relevant themes. The diverse insights provided in this study can help us create better suited and culturally current infographics for the target population. There are multiple social determinants at play for rural Appalachian KY residents, which we have uncovered during our research from how participants haven't heard of being eligible for lung cancer screening from their primary care physicians to difficulty getting transportation to the fear of knowing that they have lung cancer. Future research can be conducted to determine how to improve access and understand some of the identified lung cancer screening barriers. Overall, this study can help improve the disparate lung cancer incidence and mortality among individuals in this region through generating new, accessible health education materials on lung cancer screening.

Abstract Name: **The change of the stock market in the COVID-19 and examination of the most suitable portfolio**

Purpose. The basic idea is that when holding stock stocks or financial assets, one acquires financial assets that are likely to be profitable. However, at that time, there is a limit to one's budget and one cannot buy everything. The problem of selecting the optimal financial assets under various limitations such as budget is called the portfolio optimization problem. The influence on markets is immeasurable by the infection spread of COVID-19. Therefore we made two kinds of portfolios of stocks in 3 years (2018, 2020, 2022) and checked the effects of COVID-19.Method. We have compared the two kinds of portfolios. The first one is called "the mean variance model without short sale limitations (we call this model (1))" and the second one is called "the mean variance model with short sale limitations (we call this model (2))". We analyzed the changes in 3 years (2018, 2020, 2022). I have expressed risk and the condition of assets via a mathematical formula and generated a portfolio using the programming. We used data of the listed companies in Japan from "Astra Manager".Results. In the case (1), the loss risk is unaltered in 3 years, but the expected rate of return was found to rise year by year from 2018. On the other hand, in the case (2), the loss risk at 2020 is the biggest and the risk at 2022 is the smallest in 3 years. In addition, in the case (2), the expected rates of return at 2018, 2020 and 2022 were 0.8%, 0.5% and 1.0% respectively. From these results, we see that the market was under recovery compared to the situation during COVID-19 outbreak in 2020.

Abstract Name: **Circle Packings from Tilings of the Plane**

Any circle configuration has a tangency graph, with a vertex for each circle and an edge for each tangency between circles. The well-known Apollonian circle packing can be constructed from a set of four base circles and a set of four dual circles, each of which has tetrahedral tangency graphs. The orbit of the base circles under the group generated by reflections through the dual circles is the packing, an infinite fractal set of circles.In general, one can start with a finite set of base circles whose tangency graph is the graph of any polyhedron and a finite set of dual circles whose tangency graph is the graph of the dual polyhedron. The orbit of the base circles under the group generated by the dual circles is known as a polyhedral packing, defined by Kontorovich and Nakamura. We study packings which originate from infinite configurations of base and dual circles, a further generalization. We introduce a new class of fractal circle packings in the plane and discuss its relation to crystallographic and Klenian circle packings. The existence and uniqueness of these packings are guaranteed by infinite versions of the Koebe-Andreev-Thurston theorem. The three main circle packings we study are the triangular, square, and hexagonal packings. We focus on their arithmetic properties--integrality, super-integrality, and quadratic and linear forms. We also give a broader class of examples (trapezohedron, cupola, and anticupola circle packings), with a focus on symmetries. We prove structure theorems which give a complete description of the symmetry groups for these packings and show that all 17 wallpaper groups appear in the symmetry groups of our packings. The infinite circle packings we study may reveal number theory and group theory properties of great interest, which remain to be further explored.

Abstract Name: Water Treatment by Cold Atmosphere Plasma

The purpose of this project was to quantify and investigate the mechanisms used to degrade perfluorooctanoic acid (PFOA), an emerging contaminant, through exposure to an electrically charged tungsten electrode to water discharge cold-atmospheric pressure (CAP) plasma jet. PFOA was commonly used in man-made products for commercial, industrial, and firefighting purposes, which had led to widespread contamination of groundwater and drinking water. CAP is an emerging technology undergoing intense research to understand what reactive species are produced during experimentation and how it can be used as an effective system for water treatment. A 20 micromolar solution of PFOA was exposed to plasma ignited in both air and argon gasses at a wattage of 10 ± 1 W. Under these conditions,a substantial amount of PFOA degradation occurred with argon and air plasma treatments in positive polarity. PFOA was seen to degrade an average of 54.6% when using an argon gas feed, and 50.0% when using an air gas feed after 40 minutes of treatment. These results indicate that argon plasma is a better conductor for the removal of PFOA from contaminated water. Additionally, CAP does not require expensive or wasteful resources, and does not generate harmful by-products. This project demonstrates that CAP is a promising green alternative to current water treatment processes in use.

Abstract Name: Hmong in France: History and Identity in an Age of Globalization

This study examines the experiences of Hmong refugees resettled to France after the end of the Vietnam War in 1975. The data in this study is drawn from twenty-six in-depth interviews conducted with Hmong in France in cities such as Paris, Lyon, Nimes, and Toulouse. Hmong refugees continue to experience various challenges nearly fifty years after their migration to France. This study undertakes a sustained examination of various themes, including the transformations of Hmong identity and religion, experiences of racism, their community building efforts, their histories of labor, and their hopes and dreams, all within the French national context. Since the French Republican model formally erases racial, ethnic, religious, and cultural differences among its citizens, Hmong in France have had to devise creative strategies to maintain a distinct sense of self apart from dominant French nationalism. Yet, the French Republican ideology of official colorblindness continues to inhibit the development of a strong Hmong identity and their community building efforts. Furthermore, actual racism and discrimination on the ground have profoundly shaped Hmong's exclusion from education, housing, and employment. This study attempts to provide a humane and ethical portrait of Hmong French experiences in the age of globalization, when ethnic and cultural identities, religious practices, and minoritized experiences of living are all constantly being transformed. Together, the study shows that while Hmong continue to face extreme challenges to community building in ways that demand their assimilation into a colorblind French society, they have nonetheless successfully maintained a unique sense of self in a French society by dreaming and hoping for alternative futures.

Abstract Name: **Cinematizing Immunity: The Rhetorical Effects of Science Fiction in the Public Communication of Science**

Rapid developments in computer-generated imaging (CGI) technology have enabled increasingly realistic visuals of both “science” and “fiction.” Drawing inspiration from and emulating the science fiction genre, producers of science documentaries can now harness the power of CGI and bring to the screen what was previously unseeable, communicating scientific facts more engagingly. While superficially an appealing trend, these increasingly science-fictionalized documentaries can be ethically problematic for public audiences, who are outsiders to actual scientific research. While not focused exclusively on the use of CGI, scholars such as Kirby (2008), Buehl (2016) and Lee (2022) have investigated the role of science fiction in public communication of science. Scholarship about using these documentaries for education, however, is inconclusive, as much remains unknown on the rhetorical effects of such documentaries on visual science communication, especially during public health crises. My research furthers discussion in this area by rhetorically analyzing the BBC’s 2012 CGI documentary, Our Secret Universe: Hidden Life of the Cell, which draws extensive references from famous science fiction films through cinematic techniques and which uses CGI to stage an epic war between human cells and viruses. My findings show that Secret Universe, although persuasive and visually appealing, leaves much of its awe-inspiring and overly militaristic narrative open to interpretation. Furthermore, its epic warfare narrative may promote ethically noxious messages on the nature of viruses, vaccines, and the meaning of immunological fitness. By communicating immunology through science fiction, Secret Universe illustrates that such an approach, although appealing, may also harbor undesirable outcomes and promote harmful ideals, especially when viewed in the context of global pandemics such as SARS, H1N1 and Covid-19.

Abstract Name: "Just Teasing" or "UnJust" Insulting?

The purpose of my research is to examine if outsider views on bantering scenarios are influenced by multiple factors such as demographics, recognized nonverbal cues, and personal experiences. Limited work has been conducted on the communicative act of teasing. Starting with how teasing is defined, various definitions for teasing exist, making such incidents open to interpretation. More current definitions of teasing define the act as a comment made with hidden meaning because the teaser's motives often are left unarticulated. Because of this, a tease is generally left open to interpretation, especially by the receiver. The research I am conducting attempts to extend upon this prior research by identifying how our perceptions of teasing relate to common definitions. A knowledge gap occurs in understanding if people relate more to a tease initiator or person teased and how that influences their viewpoint. A knowledge gap also occurs in understanding if an outsider can pick up nonverbal interpersonal cues when viewing a bantering situation. To fill both knowledge gaps, I will conduct two trials. In both trials, participants will anonymously complete an online survey through Qualtrics, where they will be randomly assigned a 20-30 second video of a bantering scenario. Participants will then evaluate the quality of the interaction observed and answer personal questions about their own experiences with teasing or bullying. Data collected will be analyzed to determine what variables are most influential to a participant's viewpoint. Based on preliminary data, I predict results will show nonverbal presentation has a significant impact on an observers' perception of the teasing scenarios, with factors such as gender and personal experience holding the most influence over interpretations given. My research will help determine if teasing trauma carries over and either clouds or clears judgment so we can truly understand the weight of our words.

Abstract Name: The Future of Plastic Waste: A Multi-Disciplinary Approach

Approximately 300 million tons of plastic waste is produced every year worldwide; only ~7-9% is recycled.The result is harmful plastic waste accumulation that negatively impacts ecosystems and communities around the world. Polyethylene terephthalate(PET) is one of the most abundant plastics due to its transparency and chemical strength. While naturally occurring PET-degrading bacterial enzymes have been identified (i.e., PETase and MHETase), their physiological requirements make them ill-suited for industrial use. We attempted to address this problem by bioengineering a chimeric PETase::MHETase protein for enhanced PET degradation. Review of recent literature revealed a collection of PETase and MHETase-optimizing mutations shown to enhance temperature and pH tolerance. Building from this work, our approach was to combine these nucleic acid changes into a single modified open reading frame (ORF) to support even greater PET degradation capabilities. The synthetic plasmid DNA construct was transformed intoE. coliand expressed to produce a novel chimeric protein. The biomanufactured product was purified by nickel column chromatography and quality-tested using standard assays. Finally, functional assays allowed us to measure PET plastic degradation. Recognizing that typical practices in life science laboratories are part of the plastic waste problem, our team explored and implemented ways to make our laboratory—and others like it—more sustainable. Additional methodologies from the field of STS (Science, Technology and Society) were used to consider, imagine, and develop greater understanding of the implications of plastic waste and how a bioremediation-based solution might be implemented in the future.

Abstract Name: Effect of Postural Variations on On-Task Behavior in a College Classroom Setting

Background/Study Purpose: Strategies to increase cognitive performance should be explored to increase increased attention during class in higher education. The purpose of this study was to examine the impact of sitting in a chair (traditional sitting), sitting on a physio-ball (physio-ball sitting), and standing in the classroom on on-task behavior (OTB) in undergraduate seniors. Methods: Sixteen college students, ages 20-21 years, rotated through three postures (two classes per posture) that were randomly assigned. The classes were observed for a 40-minute period, and OTB rating of 0 = "not on task" vs. 1 = "on task" was recorded 10 times (every four minutes) per class. Results: Average two-rater interrater reliability scores were 95.6% across the six data collection days. Each participant's OTB scores were averaged between the two classes per posture. Percentages of perfect scores (scores of 10 out of 10) were calculated, and all postures had an "on-task" rate of greater than 90%. Physio-ball sitting had the lowest percentage of perfect scores. One-way repeated measures analysis of variance indicated a significant different in OTB across the three postures (.05). Post-hoc multiple comparisons using paired samples t-tests with an adjusted alpha of .0167 revealed significant difference in OTB between traditional sitting and physio-ball sitting (p = .005). There were no significant differences in OTB for traditional sitting vs. standing (p = .110) and for standing vs. physio-ball sitting (p = .351). Conclusions: Findings of the study suggest that physio-ball sitting may decrease OTB during class; however, the current sample demonstrated high overall OTB, possibly for being seniors enrolled in a course required by the major. It would be of interest to examine the impact of postural variations on OTB for a larger class size with a more diverse group of undergraduate students.

Abstract Name: Using High-Throughput Assays and Computational Tools to Identify Novel Genetic Regulators of Cadmium Susceptibility

Cadmium is a non-essential trace metal that causes extreme toxicity in organisms when exposed at high concentrations. To counteract cadmium exposure, the body activates intracellular defense and repair mechanisms driven by expression of cadmium-induced stress-responsive genes. These genes vary across natural populations where exposure to cadmium can differ across landscapes. We can use the roundworm nematode Caenorhabditis elegans and leverage quantitative genetics to understand how these genes can influence one's susceptibility to cadmium. Quantitative genetic approaches were used to locate and associate molecular markers across chromosomes with phenotypic variation. In a genome-wide association study (GWAS) of 195 C. elegans strains, we conducted an established high-throughput phenotyping platform and genome-wide association mapping. The mapping revealed two different genomic intervals on the X chromosome associated with cadmium sensitivity. We also discovered that the JU3132 strain was resistant to the toxic effects of cadmium, while the NIC255 strain was sensitive. We aim to validate the two identified quantitative trait loci (QTL) that cause variation in cadmium susceptibility by generating chromosome substitution strains (CSSs) and near-isogenic lines (NILs). The same high-throughput phenotyping platform will be used on the CSSs and NILs to validate the effects of the discovered QTL on cadmium susceptibility. We can further narrow the identified genes by leveraging CRISPR-Cas9 gene editing to cut or insert the candidate genes.

Abstract Name: **Does Correcting Errors Improve Graduate Students' Ability to Write Accurate Stuttering Treatment Plans?**

For the past few decades, speech-language pathologists and graduate students have continued to report feeling under-prepared and having low self-efficacy in regard to working with adolescents who stutter. In an effort to increase self-efficacy and preparedness, two groups of graduate students participated in a class activity where they worked in teams to identify, explain, and correct unambiguous errors in case studies involving adolescents who stutter. The errors could be goals and activities that do not align with client values or goals that do not align with treatment protocol (e.g., stuttering modification, fluency shaping or a combination approach). To measure progress, students completed a knowledge and self-efficacy self-assessment and designed a treatment plan for an adolescent who stutters at two different times. Once before the error-correcting activity and again after the activity. Self-assessments were designed to measure the students' self-perceived knowledge and self-efficacy of their ability to provide treatment to people who stutter. Treatment plans were completed so that the researchers could assess the students' understanding of treating stuttering. Treatment plans were scored by a rubric that examined internal consistency, appreciation of client values and rationale. The research team reached consensus during scoring. Differences in survey ratings and treatment plan scores pre-activity and post-activity were analyzed after the course was completed, to maintain anonymity.Data analysis is ongoing. Our preliminary research findings show that there are 10 domains where the students' knowledge increased from pre-assessment to post-assessment. These domains include: reducing frequency, reducing severity, reducing tension, identifying disfluencies, speech goals, thought goals, emotion goals, bullying assertiveness, and social goals. Students also reported to have better self-efficacy in regard to working with children who stutter after the error-correcting activity. We are presently in the midst of analyzing the treatment plans. Data analysis will be complete by the end of the semester.

Abstract Name: **Blood Pressure Trajectories and Genetic Risk of Hypertension**

Introduction: Hypertension affects one in two US adults. Due to the strong heritability of hypertension, genetic variations may explain a large portion of the variation in blood pressure (BP). This study assessed the trajectory of BP traits based on the genetic risk of hypertension. Methods: Polygenic risk score (PRS) combines the risk contributed by common genetic variants into a single indicator. For this study, the PRS was generated using the continuous shrinkage method from the systolic BP genome-wide association study summary statistics derived from 417,001 individuals in the UK Biobank and applied to individuals genotyped under the TransOmics for Precision Medicine Program. Using the PRS, individuals were classified into low (<20th percentile), intermediate (20th-80th percentile), and high (>80th percentile) PRS groups. Blood pressure values were corrected for antihypertensive use (systolic:+15mmHg, diastolic:+10mmHg). The Kruskal-Wallis test was used to compare BP traits across PRS categories stratified by age. Restricted cubic splines were used to depict the non-linear relationship of BP traits with age stratified by PRS categories. Results: Among 25,251 participants (median age: 53.4 years; 55.9% women; 38.5% non-white population), the median systolic (131 vs.116 mmHg) and diastolic BP (78 vs. 71 mmHg) were higher in the high PRS group compared with the low PRS group (p:<0.001). On stratifying by age, higher systolic and diastolic BP values in the high PRS compared with the low PRS group across the age range were noted (Table). The systolic BP was consistently and incrementally higher with higher genetic risk for hypertension across the age range (likelihood ratio test $\chi 2$: 108 for systolic BP; $\chi 2$: 61 for diastolic BP; p:<0.001) (Figure). Conclusions: The trajectory of BP traits varied with the genetic risk of hypertension. Clinical implementation of PRS may allow identification and promote primordial prevention strategies in individuals at a higher risk of developing hypertension.

Abstract Name: **Development of An Unknown Barbier Organozinc Lab for Organic Chemistry?**

Barbier-type organozinc reactions have been used as Green Chemistry substitution (or additions) for Grignard reactions. The organozinc reactions use less organic solvent, as the main nucleophilic addition occurs under aqueous conditions. This can be preferable to the sensitivity to moisture that occurs with Grignard reactions, while also using Green Chemistry principles. The original organozinc lab uses 3-pentanone as the substrate and is run for 60 minutes. However, our idea is to extend to other ketone substrates and potentially longer run times, then have students try to determine their starting material based on acquired IR and NMR spectra. Multiple substrates were tested using original reaction conditions and analyzed by IR, NMR, and gas chromatography (for purity).Analysis of the results shows that the Barbier organozinc reaction is successful on a variety of ketones. Some of the products are pure enough to allow students to determine the original ketone. Spectra of various products along with standard conditions will be discussed on the poster.

Abstract Name: **Use of Iowa Eggshell Waste as Bio Cement Materials in Pavement and Gravel Road Geo-Material Stabilization**

Egg production in Iowa is important to the state economy and the national market. The Iowa egg industry's production strategy is to provide approximately 70 percent of its eggs in liquid or dry form to reduce its freight costs and increase competitiveness, so the large volumes of discarded eggshells generated by the Iowa egg industry during production have broad prospects for recycling as value-added products. Eggshells mainly composed of calcium carbonate (CaCO3) (i.e., up to 94%) were identified as the main element of calcium-based stabilizer material (CSM). Through further treatments, such as milling and grinding, oven-dry, calcination, and bleach, eggshell powder (ESP) could contain up to 98% calcium oxide (CaO) formed from CaCO3. The literature summary indicates ESP possesses the ability to bind soil and aggregates through multiple reactions, such as hydration, cation exchange, flocculation, and pozzolanic reactions. Therefore, eggshells can be used as bio-based cementitious materials for stabilizing subgrade and base course in road structures. As part of the Iowa Highway Research Board-sponsored research project, this study explored the feasibility of using eggshell waste as a CSM to improve the engineering properties of Iowa pavement foundations or gravel road systems. The experimental plan will examine the performance of ESP stabilization on Iowa subgrade and base materials through a series of laboratory testing, including Atterberg limits, compaction characteristics, unconfined compressive strength (UCS), California bearing ratio (CBR), and free-thaw durability. The various ESP treatment methods and types of Iowa subgrade/base aggregate will be assessed as well. This innovative and sustainable approach could lead to stronger, more durable pavement foundations and gravel road systems in Iowa.

Abstract Name: Cinematic Myth Today and Myth?s Deconstruction in "The Phantom of Liberty"

In this paper I look at how Barthes' concept of the myth applies to visual media and cinema, how audiovisual images function to instill a falsely natural correlation between a signifier and its signified. Drawing from the characteristics of myth noted by Claude Levi-Strauss, Barthes defines myth as a semiological system with "the task of giving an historical intention a natural justification, and making contingency appear eternal". He goes further than Levi-Strauss by emphasizing not only the content of myths but their reception, noting that the function of a myth is to make a myth-reader believe that it "naturally conjured up the concept, as if the signifier gave a foundation to the signified". I link his ideas to the apparatus theory of Jean-Louis Baudry who argues that the synthesis of the mechanisms of film making and exhibition forges "an 'organic' unity" wherein disparate images are presented as if naturally correlated. I also look at how the cinematic apparatus has changed in the digital age; how audiovisual myth finds new avenues to present itself to myth-consumers when people's everyday experience is constantly mediated. Ultimately, using Luis Buñuel's film The Phantom of Liberty as an example, I examine the ways in which films can work to deconstruct myth. They can do so by documenting their own construction, as noted by Baudry, or in Barthes' terms they can increase "the abstractness of the concept and the arbitrariness of the sign" to capture "the meaning of things themselves," both of which The Phantom of Liberty accomplishes.

Abstract Name: Identifying breast cancer education message preferences among Black college students using conjoint analysis.

Black women have excessively high breast cancer mortality rates. This disparity is due in part to the higher incidence of aggressive breast cancer among Black women under the age of 40. Early-detection and early treatment lead to significantly lower mortality rates. However, sociocultural barriers, such as lack of perceived risk for breast cancer, impede adherence to breast cancer screening guidelines for young many Black women. Cancer education interventions that are focused on increasing knowledge about breast cancer, breast cancer risk, and breast cancer screening methods have been shown to be effective at increasing breast cancer screening rates. The purpose of study is to determine the most effective way to deliver culturally-relevant breast cancer education messages to young Black women via social media. Culturally-relevant breast cancer education messages in the form of social media posts were developed using the Intervention Mapping Framework. The messages are based on the constructs of the Health Belief Model, and previous qualitative research with the target population. Conjoint analysis will be conducted with a sample of Black college-aged women. We will assess the participants preference for message frame (gain frame vs. loss frame), message format (illustration vs. photo), and message source (Black female peer vs. Black female healthcare provider vs. healthcare provider of another race and gender). Regression Analysis will be performed to determine the most desirable elements of the messages. The results of this study will be used to finalize the cancer education messages. The messages will be disseminated via social media sights.

Abstract Name: **Characterization of GLP-1 Receptor Expression in Flox & Knockout Mice**

Type 2 Diabetes mellitus (T2DM) is one of the most prevalent and costly diseases concerning modern society, characterized by impaired insulin action, inducing chronic hyperglycemia. Glucagon-like peptide-1 (GLP-1) receptor agonists (RAs) are an emerging class of drugs proven extremely effective in treating T2DM and obesity. GLP-1 is a peptide secreted by enteroendocrine L cells along the digestive tract. Secreted GLP-1 acts on the pancreas to stimulate insulin, inhibit glucagon secretion, and suppress appetite. Challenges in GLP-1R research are antibody specificity and inconsistent effects of knocking out GLP-1R globally. This study aims to examine the efficacy of tamoxifen-induced knockout of GLP1-R on protein, mRNA, and DNA levels.Breeding of Glp-1r loxP-flanked (flox) mice with tamoxifen-inducible ubiquitous Cre (UBC-Cre-ERT2) mice on a C57Bl/6 genetic background results in Cre-mediated deletion of Glp-1r in widespread tissues. The flox Glp-1r sequence is greater than 6000 bp, but after cleavage is 387 bp. The 30 second annealing step in the PCR protocol allows only for amplification of sequences less than 500 bp. Results reflected successful cleavage of Glp-1r. Western blotting identified that, among the three GLP-1R antibodies tested, the ProteinTech antibody most efficaciously detects GLP-1R, showing significant difference between GLP-1R flox and KO mice in duodenum (0.05) and a trend toward significance (p=0.08) in hypothalamus. A highly significant difference in GLP-1R mRNA expression was observed in flox and KO mice via qRT-PCR of duodenum (0.0001) and hypothalamus (0.01). Neither western blotting nor qRT-PCR identified a significant difference in liver tissue.Results support effectiveness of tamoxifen-induced GLP-1R knockout in duodenum and hypothalamus. GLP-1R KO in the liver demonstrates low success, potentially attributable to uneven Cre expression. In the future, we hope this novel mouse model may be used for GLP-1R experiments examining its relationship to comorbidities of T2D.

Abstract Name: **In Darwin's Footsteps: A Shared Genetic Control for Beak and Toe Size in Domestic Pigeons (Columba livia)**

Domestic rock pigeons (Columba livia) display an incredible amount of variation among different breeds. Even though they can look and act differently, these breeds all belong to the same species. We are therefore able to breed individuals with very different traits and perform genetic mapping. For example, variation at a locus on Chromosome Z, ROR2, is linked to beak size. In The Variation of Plants and Animals Under Domestication, Darwin observed that the data he collected “indicate pretty plainly some kind of correlation between the length of the beak and the size of the feet”. The goal of my research is to determine whether there is a shared genetic control of foot size and beak size in domestic rock pigeons. First, I collected limb length measurements from the F2 generation of a cross between a Homer (medium beaked) and an Old German Owl (small beaked) pigeon. This cross segregates different beak lengths so it presents an ideal opportunity to test for associations between beak and toe lengths. My data confirmed that foot and beak size are indeed associated. Next, I used quantitative trait locus (QTL) mapping and found that toe size is controlled by at least two genetic loci, one of which maps to the same genomic region that controls beak length. Therefore, it is likely that toe size and beak length have a shared genetic control or are controlled by closely linked genes. Thus, variation in one genomic region – and possibly one gene – can potentially lead to coordinated changes in seemingly unrelated anatomical structures.

Abstract Name: Campuswide Sustainability: Designing an Early Intervention Training Module to Cultivate a Sustainably Minded Culture

Implementation of sustainable practices are being pursued at universities across the globe. However, getting student buy-in to adopt sustainable habits can be challenging. Over a seven-year period, the University of Wisconsin-Eau Claire has collected data on student behavior as they discard lunchtime waste and conducted audits on the waste found in the compost, recycle, and landfill bins. That data has been used in multiple intervention attempts to educate students on proper waste-sorting when having access to those bins. These interventions have had limited success in generating a statistically significant shift in student behaviors. During the 2022-2023 academic year, we are pursuing a new effort with the goal of preemptively educating students on multiple aspects of sustainability before they arrive on campus. Our university currently requires incoming students to participate in online training modules on topics such as sexual assault awareness (Title IX), equity diversity and inclusion, and information security. We have received approval to add a sustainability-focused online training module for incoming students. We are designing a module that will focus on four sustainability topics: campus-wide sustainability goals, public transportation routes, using the campus's reusable food container program, and proper waste-sorting habits. Each topic will contain microlessons consisting of readings and videos. Each microlesson has questions that must be answered before the student can progress. Our goals are to educate students on effective sustainability practices, encourage them to adopt those practices as incoming students, and for them to see our campus as a place that values sustainability. We will assess the effectiveness of this intervention through future waste audits, observational studies of student behavior and survey responses. Our training module is intended to be used by all incoming students and we expect that our audits and survey results will reflect wider adoption as more and more students complete the training.

Abstract Name: Music Brings a Smile to My Face: Assessing the Effects of Familiar Music on Happiness in Older Adults Living in Long Term Care

The positive effect of music on overall health and psychological well-being has been well documented. In older adults, listening to music has been correlated to positive emotions, happiness, increased mental awareness, and decreased stress levels. Further, implementing music therapy/programs in long-term care facilities has resulted in improved depression symptoms, improved well-being, and decreased use of mood stabilizing medications. For purposes of this project, only happiness was measured, but aspredicted there wasan improvement in several other aspects of the participants' health and well-being. It is anticipated that this program will be continued beyond the designated four week mark because of interest in the service aspect of the project from current students.This programallowed students from complementary disciplines to participate in a research project that assessedthe effects of familiar music on happiness in older adults living in long term care. Two nursing students and a recent psychology graduate, who were all well versed in Cajun and Zydeco music performed a one-hour music set once a week for four weeks for residents of a local assisted living facility. Permission was granted by the the facility and all COVID protocols were followed. Approval was also obtained from the university's IRB department prior to implementation of the program. Prior to the first music program, residents were asked to complete a reliable and validated, Subjective Happiness Scale, consisting of 4 questions with Likert scale responses via pen and paper. Students, with the assistance of their faculty advisors, enteredthis data into the Intellectus software program. At the end of the fourth/final music set, residents wereonce againasked to complete the Subjective Happiness Scale. Students are inputting post project scale data into the Intellectus software program. Data will beanalyzed using a paired t-test to evaluate effectiveness of this intervention.

Abstract Name: **Exposure to Counterstereotypical Scientific Role Models Impact how Students Identify with and Perceive Scientists**

To test the hypothesis that diversifying and humanizing scientists impact student perceptions, we measured (1) the extent to which students related to a counterstereotypical scientist and (2) how students viewed the types of people who do science. Students worked on a biology activity that highlighted counterstereotypical contemporary scientists but that varied in the depth to which students learned about the scientists: in treatment one, the biology activity was not accompanied by a picture of the scientist or humanizing information; in treatment two, the activity included a picture but no humanizing information; in treatment three, the activity included a picture and an extended 'About Me' section that included humanizing information. We recruited 34 biology instructors across the United States, and they randomly implemented one of the three treatments (N > 1700 students). We collected survey data across the semester from three surveys administered at the end of each biology activity. We analyzed open-ended responses to the prompts: (1) "Describe how you related to the featured scientist" and (2) "What did you learn about the types of people who do science?". Two researchers used qualitative coding in order to obtain the student logic behind their reasoning. We found that for the first prompt (1) students who engaged in treatment three, an activity that also included a picture and an extended 'About Me' section highlighting the scientist, were more likely to relate to diversifying elements of the scientist than students who received no information about the scientist or just a picture. For the second prompt (2), we found that students exposed to treatment three were most likely to report that scientists have diverse identities. Our results underscore the importance of highlighting counterstereotypical scientists during biology activities.

Abstract Name: **Tipping Culture in America**

In America, there is a striking escalation of tipping in coffee shops, restaurants, salons, and more. According to articles in Forbes and New York Times, there are many passionate users debating about tipping and other writers revealing their own beliefs on tipping. This common etiquette has strong controversy regarding its necessity and effect. The purpose of this study is to analyze people's views on tipping. I believed that there would be more agreeance about tipping among the older generations. To test this hypothesis, I wrote a survey of 15 questions using Survey Monkey and collected the data through Amazon MTurk with the sample for the analysis consisting of 196 participants over 18 years of age residing in the United States. The results indicated a statistically significant difference in responses among the participants' gender and age and how these demographics affected their idea of the amount and necessity of tipping. This survey can help to understand consumers and the reasoning for the amount of gratuity they leave behind.

Abstract Name: **Enhancement of Two-Phase Immersion Cooling Using Submerged Synthetic Jet Impingement on Simulated High-Power Electronic Components**

Electronics used in data centers include high-performance servers which contain CPUs, GPUs, and power distribution elements. As the processing units get faster, their power dissipation increases in direct proportion. Liquid cooling has emerged in two primary methods as the next step in the evolution of cooling technologies. (1.) Indirect cooling involves placing a cold plate on top of the hot component and circulating liquid through it. (2.) Direct cooling involves immersion cooling in which the server is immersed in dielectric fluid. This project investigates the improvements to two-phase immersion cooling in which 3M Novec 7100 Engineered fluid boils on the component surface, causing vapor bubbles to form. The bubbles leave the surface by their own buoyancy, and fresh liquid flows in to replace the departing vapor. This research examines the enhanced performance of two-phase immersion cooling by forcing a liquid jet to impinge on a boiling vertical heated surface using a synthetic jet approach. The figure of merit is the heat transfer coefficient on the boiling surface, h= q''/(Tsurface-Tsat).A synthetic jet is a jet formed by providing a time-dependent flow into and out of a nozzle submerged in the fluid. The nozzle expels a jet flow in the forward stroke half cycle and ingests inflow during the backstroke half cycle. This periodic flow has no net mass flux but a positive momentum flux. The hypothesis is that the impinging jet will force the bubbles off the surface at a faster rate, thus accelerating the bubble formation cycle which controls pool boiling. The objective is to evaluate the efficacy of jet impingement on increasing heat transfer by documenting the increases in the heat transfer coefficient as a function of heat flux, synthetic jet frequency and amplitude, and distance from jet to target.

Abstract Name: **Classification of Seaweeds and Tannin Characterization Using Differential Sensing and Untargeted Mass Spectrometry-based Metabolomics**

Ruminating animals account for nearly half of global methane emissions. Recently, several types of brown seaweed have been identified to reduce enteric methane emissions when supplemented in ruminant animal diets, as methane production is highly linked to the composition of the feedstock. Tannins are a class of polyphenolic molecules that are abundant in brown seaweeds with protein binding properties that play a role in methane reduction. Therefore, it is of importance to study seaweed tannin composition to understand the impacts when presented in livestock feed.Herein, we investigated both the phenolic and metabolic profile of four species of brown seaweeds - Ascophyllum nodosum, Fucus serratus, Fucus vesiculosus, and Fucus spiralis - obtained by Professor Pamela Walsh at Queen's University Belfast. The first aim was to classify each seaweed based on its tannin fingerprint through differential sensing. The second aim was to characterize metabolites in each sample by applying untargeted mass spectrometry-based metabolomics.A fraction of the seaweed extracts was utilized for differential sensing analysis to detect existing tannins. In adding the seaweed extracts to the peptidic array, the tannins displaced the indicators from peptidic ensembles via Indicator Displacement Assays (IDAs), giving measurable absorbance changes. Principal Component Analysis (PCA) and Linear Discriminant Analysis (LDA) were utilized to analyze the polydimensional data and the seaweed species were correctly differentiated with 100% accuracy according to their tannin composition. Furthermore, the seaweeds were classified according to their genus where the Fucus samples were found clustered together while distinctly separated from the Ascophyllum genus.Finally, another fraction of seaweed extracts was analyzed with a high-resolution mass spectrometer to characterize their metabolomic profile. The standard untargeted metabolomic workflow includes 1) experimental analysis using HR-MS 2) data preprocessing and validation, and 3) data analysis to identify putative biomarkers. Currently, we are working with stages 2 and 3.

Abstract Name: Exploring Hyperspectral Image Classification using Deep Learning

Classification of hyperspectral images is an important step of image interpretation from high spatial resolution imagery. Different studies demonstrate that spatial features can provide complementary information for increasing the accuracy of hyperspectral image classification. In this study, we propose a method of spectral-spatial classification of hyperspectral images that is based on a hybrid feature selection approach with stacked autoencoders. The resulting high-dimensional vectors of spectral features are classified by several supervised classification algorithms such as support vector machine (SVM), maximum likelihood (ML) and random forest (RF). The experiments are performed on several widely known test hyperspectral images. Preliminary results have demonstrated that the proposed method provides a higher accuracy matrix than existing traditional models.

Abstract Name: Strategy Evaluation and Automated Strategy Acquisition for Game 2048

The goal of this work is to acquire effective, computerized strategies to play the popular puzzle game "2048". The game has a 4x4 tiled board with numbers of 2 or 4 randomly added to blank tiles over time between the player's moves. The player can choose to slide numbers up, down, left, or right into blank tiles, and any two adjacent tiles with the same number will collide and collapse into one tile having the sum. The game terminates either when the largest number reaches 2048 or when the board is full with no possible movements. Although the game is straightforward for a human player, it is not trivial but rather challenging to play in a computerized fashion. Indeed, enthusiasts have designed various computerized strategies for 2048. For instance, one strategy is minimax, which chooses the move that produces the best outcome at the worst-case scenario. Another strategy, expectimax, evaluates moves based on their outcomes at the average-case scenario rather than the worst-case scenario.We have built a Java program that supports both manual and computerized plays and allows easy implementation and execution of computerized strategies. We have started to implement existing strategies in the literature and compare their performances against those of our own. Our ultimate goal is to design a parameterized framework that covers a broad range of strategies and use the genetic algorithm - an optimization method in AI that mimics the evolutionary process in the biological world - to automatically acquire effective strategies for 2048.As far as we are aware, our work is one of the first in automated acquisition of such strategies for 2048. We believe our work would shed light on the process of tackling similar games and provide insights into the effectiveness of relevant AI methods and techniques.

Abstract Name: **How Social Media Has Impacted the Perception of Investing**

There has been a surge of interest in finance-related topics and investing after the COVID-19 pandemic, which is attributed to the rise of easy-to-access trading platforms such as Robinhood. Social media platforms have significantly increased public interest in investing. For example, the internationally reported event of the GameStop short squeeze brought over 5 million new members to reddit group WallStreetBets. This event was organized on Reddit, which propelled other social media platforms like Instagram and TikTok into the investing sphere. The purpose of this study is to analyze the impacts of social media on investing trends and investor sentiment. Furthermore, this study examines if there is a shift from mainstream media to social media as a source of investment advice. To do this, I conducted a 16-question survey through Amazon Mechanical Turk and collected 189 responses. Then, I ran statistical analysis and crosstabulation in order to identify if there was any statistically significant difference with gender and age in relation to how often one views investing related news or posts on social media, and how that impacts how individuals themselves view investing as a whole. I found that while younger individuals have a positive view on how social media impacts their financial literacy, the percentage that maintain this positive view decreases as age increases. I also see a statistically significant difference in the responses of males and females, with more males investing because of social media than females.

Abstract Name: **Effects of Non-Native Watersipora on the Abundance and Percent Cover of Native Olympia Oysters, Ostrea lurida**

Non-native fouling organisms settling onto natural hard substrata in estuaries can harm native species via mechanisms like space competition and predation. Understanding how non-native foulers influence native species recruitment is critical for management of native species. The effects of the non-native bryozoan, Watersipora subtorquata, and other native and non-native foulers onOstrea lurida recruitment were studied to determine whether their percent cover affects native oyster abundance and cover. Terracotta tiles were deployed in Newport Bay, California at tidal elevations between -0.5 and -1.0 feet MLLW during the oyster's spawning and recruitment season. Four treatment groups (n=10 per treatment) were established to examine the effects of foulers on O. luridarecruitment: unmanipulated controls, W. subtorquata removal, other fouler removal, and all fouler removal. Treatments were maintained by monthly removal of W. subtorquata and other foulers as appropriate per treatment from March-September 2022. Oysters recruiting to the tiles were measured for length and width, identified, and quantified. Point contact technique was used to record cover of species recruiting to tiles. We hypothesized that presence of W. subtorquata and other foulers would lead to low abundance and cover of O. lurida recruits. Surprisingly, W. subtorquata and other foulers had no significant effect on abundance or cover of O. lurida. Fouling species, including ubiquitous non-natives like W. subtorquata, may not be as harmful to native species in local estuarine habitats as predicted. However, our 6-mo study may have been too short-term to detect space competition since open space was still available across all treatments.

Abstract Name: **Cytocompatibility of Electrospun Chitosan Membranes Treated with Decanoic Anhydride and loaded with Biofilm Inhibitors and Bupivacaine**

Cellular responses to loaded electrospun membranes have previously been shown to promote healing in wound applications such as burns by reducing pain, preventing infection, and modifying inflammatory responses through the release of local anesthetics. In this study, we use RAW264.7 mouse cells, a transformed macrophage-like cell line, to observe expression of inflammatory and anti-inflammatory cytokines and cell response to decanoic anhydride(DA) treated chitosan membranes loaded with therapeutics, both with and without stimulation with Lipopolysaccharide(LPS). RAW cells are generally loosely adherent and simple to detach from a plate, detaching after scraping the remaining adherent cells gently with a cell scraper. LPS is a bacterial polysaccharide that activates this macrophage cell type and drives them into inflammatory phenotypes present in wounded tissue. Macrophages are extremely sensitive to LPS endotoxin from Gram-negative bacteria. Electrospun chitosan membranes treated with fatty acid decanoic anhydride were placed in a 24 well plate and loaded with either 0.15mg of anti-biofilm cis-2-decenoic aid(C2DA), 0.5mg of local anesthetic Bupivacaine, or a combination of the two in ethanol(combo). Each membrane was loaded with a total of 30µL of solution, except for the unloaded membranes, which served as the control. The effect of membranes exposed to RAW cells, both in the presence of LPS and not, were observed to simulate acute response and inflammatory phases of wound healing. We hypothesized that RAW cells will express inflammatory or anti-inflammatory proteins in the presence of different concentrations of therapeutics. Results suggest that BUP and 2CP groups without LPS are cytocompatible, as they were not significantly different than the control. Comparatively, 2CP and combo groups are cytocompatible for activated macrophages. Statistically significant differences, tested using ANOVA followed by Tukey's multiple comparisons test, also demonstrateda minimal effect of DA treated membranes on the cellular inflammatory response of RAW cells in the presence of LPS.

Abstract Name: **Synthesis of flexible tridentate pincer ligands featuring a rigid backbone and pendant carbene**

Catalysts are involved in the production of fuels and feedstock chemicals and are even found in living organisms as enzymes. An important classification of catalysts are organometallic complexes whose identity and reactivity are correlated to the coordination sphere defined by its ligand(s). Tridentate pincer ligands, which coordinate to a metal center via three different atoms within a plane, have been of interest for redox active and polymerization catalysis among other catalyzed reactions. Our interest is to explore the incorporation of flexibility to an asymmetric pincer ligand to identify which geometric or electronic properties influence catalytic behavior. Variation in ligand flexibility may afford unique properties that tune the action of the metal center. We are developing a ligand to feature two unique imine-N and pendant N-heterocyclic carbene-C to complex with a metal. The ligand is labeled as an NNC-type ligand by the three elements that coordinate to the metal; nitrogen, nitrogen, and carbon. Our NNC ligand features a bisimine rigid backbone and a pendant N-heterocyclic carbene which can flex to accommodate a range of coordination motifs of pentacoordinate complexes. Presented is the multi-step synthesis using air-sensitive techniques and the precursor structures that have been identified. Molecules obtained throughout the process are analyzed using 1H-NMR, FT-IR, single crystal XRD and computational analysis for prediction of optimal geometry of the target organometallic complexes. Future work will detail the properties of precursors and the synthetic approaches to metallate the NNC tridentate pincer ligand with first-row transition metals.

Abstract Name: **Electrochemical Characterization of Recast Nafion? Film Modified Electrodes in Nonaqueous Systems**

The behavior of recast Nafion® films on platinum working electrodes in nonaqueous solutions is characterized by cyclic voltammetry and rotating disk voltammetry. The behavior of recast Nafion® films in nonaqueous solutions has been observed to be different from the well-studied behavior in aqueous solutions. This work seeks to extensively study that behavior. The reversible redox couple tris(2,2′-bipyridine)ruthenium(II) hexafluorophosphate is studied in nonaqueous solvent acetonitrile with different electrolytes (tetrabutylammonium tetrafluoroborate, tetrabutylammonium trifluoromethanesulfonate, tetrabutylammonium hexafluorophosphate, and ammonium trifluoromethanesulfonate). The effects of the electrolytes will be compared against each other and controls (an unmodified platinum electrode and a recast Nafion® platinum electrode equilibrated in aqueous solutions of the redox couples). Electrolytes have been chosen for a variety of ion charges and ion sizes; in aqueous solutions, Nafion® is a cation exchange polymer and will exclude neutral and anionic redox molecules, however this does not necessarily occur in nonaqueous solutions. Additionally, there is some preliminary evidence that trifluoromethanesulfonate electrolyte may interact with the Nafion® sulfonate groups, so this will also be explored. Studies of each electrolyte variation will involve both transient cyclic voltammetry and rotating disk voltammetry; the relationship between scan rate and peak current will be explored for transient cyclic voltammograms and the relationship between rotation rate and limiting current will be explored for rotating disk voltammetry. The data from both techniques will be combined to identify the thickness of the in situ film and the diffusion coefficient for each variation.

Abstract Name: **Independent Component Analysis of Resting State Brain Connectivity in Autism**

Autism Spectrum Disorder (ASD) is a neurodevelopmental condition that is characterized by deficits in social communication as well as restrictive and repetitive patterns of behaviors and interests. Differences in brain functional connectivity (the synchronization of brain activity across spatially distant regions) between autistic and non-autistic individuals, especially in resting-networks such as the default mode network (DMN), have been reported. Neuroimaging, especially through advances in modern Functional Magnetic Resonance Imaging (fMRI) and task-free resting-state techniques have provided significant insights into brain functioning and connectivity in typical and atypical populations without the need for active cognitive tasks. Applying data-driven techniques like the Independent Component Analysis (ICA) to resting state fMRI data can provide valuable insights into the brain functioning in autistic individuals. ICA extracts and separates data from the entirety of the fMRI brain scans, and then groups them together based on similarity. The current study examines the functional differences in resting brain connectivity between autistic and non-autistic children with special emphasis on key brain networks like the DMN. Eyes-open resting fMRI data were collected from 33 autistic and non-autistic children (ages 7-13 years) on a Siemens Prisma 3T MRI scanner. After sorting the components based on their correlation values (from higher to lower), the ICA revealed several large-scale networks that were particularly active across both autistic and non-autistic children: the DMN, the visual network (VN), the dorsal attention network (DAN), the language network (LN), the sensorimotor network (SMN), the cerebellar network (CN), and the frontal-parietal network (FPN). The autistic children showed significantly weaker DMN connectivity, and stronger DAN and FPN connectivity compared to non-autistic children. These findings align with the disrupted connectivity hypothesis (hyper and hypo connectivity) in autistic individuals. Examining these patterns and their impact on the neurocognitive profiles of autism can provide valuable insights into autism symptomology.

Abstract Name: **Transitioning Towards Transgender Inclusive Language Within Primary Medical Education: A Content Analysis on Language Change Throughout Textbooks**

Inclusivity expectations within medical settings have changed over the past three decades based on shifting social norms. New additions to the practice of medicine, through the training of physicians, have been influenced by movements happening in the greater social sphere. The discussion of intersectional identities such as racial diversity, gender, and LGBTQIA+ individuals is a possible adaptation to medical educational materials. I hypothesized that occurrences of transgender language would increase over time within primary care textbooks. The inclusion of cultural competency and diversity-related topics within past editions of primary care textbooks makes it more likely for current editions of the same text to include transgender-related language. This hypothesis was tested through the utilization of content analysis on 913 chapters from five titles and 21 individual textbooks. A coding scheme was used to collect data based on five separate variables specifically looking at the number of mentions and connotations associated with the identified code words. STATA was used to analyze the data collected. It was found that between 2003-2022 there was an increase in language referring to diversity, LGBTQIA+, and transgender patients within the selected primary care textbooks. There are no substantial correlations between diversity mentions and LGBTQIA+ or transgender-focused mentions. Within the chapters selected, less than 1% included mentions of transgender-focused language. My findings indicate an avenue for growth within the field of primary care textbook writing and publishing.

Abstract Name: **Investigation of Ventilation and Air Quality in Classrooms**

The transmission of the coronavirus can be greatly impacted by indoor ventilation and air purifiers according to the U.S. Environmental Protection Agency and other public and private institutions and researchers. The concentration of aerosols in the air that contain the virus can be reduced by proper ventilation systems, which circulate and filter the air for increased quality. Aerosols with a diameter of2.5µm or lessare a possible carrier of SARS-CoV-2. PM 2.5 pollution may also increase the cellular expression of ACE2, associated with greater viral susceptibility. Ventilation to reduce PM 2.5 levels addresses both risks. Tests using incense as an indicator before, during, and after burning were used to see how quickly the ventilation in the rooms was able to remove excess PM 2.5. A calibrated DustTrak II monitor was used to record particulate matter, then Honeywell HEPA air purifiers were emplaced to see if further purification would aid in ventilation compared to only an HVAC system. Room air exchange rates (ACH, hr-1) were calculated using a spreadsheet by Jimenez at UC-Boulder. ACH rates in a small (15 person) meeting room were 5.88 hr-1 with HVAC alone and 16 hr-1 with two added air purifiers. Corresponding rates in an average (35 person) classroom were 9.62 hr-1 and 12.0 hr-1 with a single purifier. In this case, HVAC and air purifier coverage was 1.25–2.72 times as efficient as just HVAC coverage. Results for local weightlifting rooms are currently being investigated and will be included. A limitation of this research was the occasional pooling of incense smoke near the opening of the air monitor leading to a temporary spike in PM 2.5 levels. Use offans can address this issue. HEPA air purifiers reduce PM 2.5 levels and in turn may help lessen transmission risk of SARS-CoV-2 aerosols and airborne viruses

Abstract Name: Screening for Novel Antibiotic Producers

The continual emergence of antibiotic resistant microbes is of great concern in the medical community. Many pathogenic bacteria previously susceptible to common antibiotic treatments have evolved resistance, resulting in serious medical and public health concerns. Infections caused by these resistant bacteria are not only costly, but difficult to treat. In response to this growing crisis, we aim to identify novel antibiotic producing microbes that we have isolated from soil samples. These samples have been collected from a variety of locations and underwent testing to determine the presence of produced substances that inhibit or kill one or more of several tester strains (Escherichia coli, Enterococcus faecalis, Staphylococcus aureus, Salmonella enteritidis, or Sityphimurium). Several organisms from soil samples that produce these antimicrobial substances have been isolated and underwent physiological characterization and rRNA gene sequencing to reveal possible identities.

Abstract Name: Examining Low-Income Household Shopping with Supplemental Nutrition Assistance Program Benefits at the Eau Claire Downtown Farmers? Market Using the Market Match Incentive Program From 2018-2022

Food insecurity is a significant issue facing many American households. The Supplemental Nutrition Assistance Program (SNAP) provides increased access to food for families in need. Additionally, fruit and vegetable (FV) consumption has been shown to improve health and reduce the risk of a variety of chronic diseases. However, poor nutrition among children and adults, including low FV intake have contributed to rising rates of obesity among US children which have been shown to persist into adulthood. It is particularly challenging for low-income households to purchase/eat the recommended amount of FV. Farmers' markets offer a wide variety of fresh, local and healthy foods, especially FV, but data show that low-income households are much less likely to shop at farmers' markets. The Eau Claire Downtown Farmers' Market (ECDFM) sponsors a Market Match Program (MMP) incentivizing SNAP households to shop at the market. In 2020, COVID-19 increased the number of families facing food insecurity while the ECFM also faced challenges regarding how to operate safely. This poster uses administrative data to analyze shopping by SNAP households at the ECDFM using the MMP between 2018-2022. The number of SNAP households shopping at the ECDFM increased in 2020 and 2021 while the associated spending also increased in both years as the SNAP caseload was rising due to the pandemic. As the SNAP caseload declined to about the same level as in 2020, the number of SNAP households shopping at the ECDFM using the MMP and the corresponding spending declined in 2022. The remainder of this study provides more detailed results regarding the patterns in SNAP household shopping at the ECDFM using the MMP over this period. This poster is connected to a another submitted poster analyzing a variety of data from surveys of SNAP households shopping at the ECDFM using the MMP during these years.

Abstract Name: **Modeling a Bifacial Solar Panel for Characterization and Performance Evaluation**

Bifacial solar panels are gaining attention due to their superior performance that comes from their ability to generate additional output power (5-10%) by absorbing the solar irradiance from the back surface. Bifacial PV modules still need to be characterized for their overall performance. To evaluate the performance of the bifacial PV modules, attempts are underway at San Jose State University to develop a solar model along with a thermal analysis model that will be then validated by our experimental data. In the current presentation, a thermal analysis model developed for a bifacial PV model is included. For this purpose, a JJN Solar Panel 200 W bifacial PV panel was selected. Basic measurements include the short circuit current and open circuit voltages at various operating conditions. The thermal analysis model includes the basic structure of the panel by considering various layers of the PV module e.g., front surface with antireflection (AR) coating, followed by an emitter layer (P+ Si) and N type wafer that is followed by aluminum back surface layer with AR coating. Thermal conductivities and respective thicknesses of all layers were used to complete the thermal resistance model that was then used to find panel's surface temperatures by keeping a constant flux condition on both the front and back surfaces. Depending on the incident flux, surface temperatures were found varying from 50 to 60 C at the front side as compared to 35 – 30 degrees on the back side of the PV model. For he electrical modeling, five parameters equivalent circuit model proposed by MA et. al. [2019] was employed. Skockley diode equation was modified for the PV panel and IV characteristics were plotted by obtaining the data from the experiment. Final poster will include the details on our experiments and the associated results.

Abstract Name: **The Impact of Monoculture Turfgrasses on Soil Nutrient Content in Southeast Houston Topsoil**

It has been shown in multiple studies that turfgrass lawns make up nearly 70% of green places in the urban world. Besides its aesthetic look, turfgrass does not provide any other benefit. In fact, it has been shown to have many adverse consequences. To even manage a turfgrass lawn to the degree that most Americans require, they would need an excess amount of water usage, an extraordinary number of fertilizers, and lastly, time. This knowledge has been known for decades, but the public has yet to understand the consequences. Even though much knowledge of turfgrass is known, one area that is not currently well researched is the impact of soil nutrient content from monoculture turfgrass lawns. It is well known that the use of monoculture methods in agriculture will have adverse effects on soil nutrition, but whether this can be correlated in gardening circumstances is yet to be seen. This situation opens a gap in the knowledge of turfgrass that could incentivize the United States government further to encourage the favoring of native biodiversity over monoculture turfgrasses. This gap in the research will be the focus of this study due to the fact it can help lead to the reduction of monoculture turfgrass lawns. Lowing the use of turfgrass can prevent water consumption, lessen fertilizer usage, and provide habitats for wildlife. The content of this research focuses on collecting and preparing samples from different area around Houston, testing for the pH values, nitrogen, phosphorous, and potassium content from each sample using testing vessels. The research also includes the x-ray analysis of samples of different monoculture turfgrasses to determine the percentage of nitrogen, potassium, and phosphorus, the essential nutrients of the soil.

Abstract Name: The Accuracy of Gluten-free Labeling in European and Middle Eastern Food Products Compared to Samples from the United States

Gluten is a protein complex found in wheat, barley, and rye, and even in foods that do not normally contain these grains. Previous work in this lab has shown that 29.8% of labeled “gluten free” products made in the United States (n = 248) have significant amounts of gluten in them (20 ppm). The current study was designed to investigate the reliability of “gluten-free” food labels in the international consumer marketplace. This research helps to inform and potentially caution those with gluten intolerance, especially with Celiac disease, to avoid gluten cross contamination and be skeptical of the gluten levels in food products advertised as “gluten-free”. A total of 49 samples labeled “gluten-free” were obtained from grocery stores in Europe and the Middle East; samples were manufactured in 18 countries there. A Nima Gluten Sensor (antibody based colorimetric assay) was used to determine if gluten content was 20ppm, the maximum allowed by the European Commission and local Middle Eastern countries, for a product labeled “gluten free”. Of the 49 samples tested, 41 of them were confirmed to be “gluten free” (20ppm), with only 8 (16.3%) having significant levels of gluten. When European and Middle Eastern samples are compared to those from the US, it appears that the food from these countries are more accurately labeled than in the United States; the percent of samples with measurable gluten is approximately half of that for products produced in the US. While gluten-free labeling can be trusted in most cases, the risk of cross contamination with gluten is still possible and continues to pose some risks to those who are gluten intolerant.

Abstract Name: Addressing the Longevity of Positive Health Status in Immigrant, Hispanic/Latin Communities Using the PROMIS Scale- Global Health Instrument

Migrants may be disproportionately at risk for poor mental or physical health due to migration status, limiting access to health care or poor mental health because of traumatic or stressful experiences. Additionally, social determinants of health, literacy, and low cultural competency result in poor healthcare education. A gap in the literature surrounding the perception of physical and mental wellbeing in Hispanic/Latin adults exists. Our objective is to understand the perceptions of health dimensions using the PROMIS Scale and individual interviews for an immigrant, Hispanic/Latin community. A 21-question survey was administered to 46 patients (36 women, 10 men) at St. Mary’s Health Clinic in St. Paul, MN. The participants are immigrants, self identify as Hispanic or Latin, have low income, and are uninsured. The survey utilized the Phenx demographic toolkit, the PROMIS Scale V 1.2– Global Health instrument, and the USDA 6-question food security screening tool to collect demographic information, perceptions of health, and food security status. The average age of participants in the sample of 46 patients was 42.8 years. All of the participants reported average or above average for general health. None of the participants reported poor health. For physical and mental health, 89.8% of participants reported good or excellent health. Social activities and roles were rated above good or fair for 100% of participants. 54.3% of participants are able to completely carry out everyday physical activities and only 2.2% reported inability. Qualitative data was obtained from 6 in-person interviews in which participants answered questions regarding perceptions in the dimensions of health. A variety of health perceptions emerged after the qualitative interviews. Overall, the importance of balancing the dimensions of wellness was communicated.

Abstract Name: **Acute Salivary Hormonal Responses to Resistance Training Exercises with and Without Blood Flow Restriction**

PURPOSE: The purpose of this study was to examine the effects of different resistance exercise protocols on salivary cortisol (C), growth hormone (GH), and testosterone (T) concentrations, heart rate (HR), and rate of perceived exertion (RPE). METHODS: Eight males and eight females (age = 21.8 ± 2.6) performed three randomly assigned exercise protocols on separate occasions: low-intensity resistance training (RT) exercises with blood flow restriction (BFR) at 20% of one repetition maximum (1-RM) (BFR20), moderate-intensity RT exercises with BFR at 40% of 1-RM (BFR40), and traditional high-intensity RT exercises at 80% of 1-RM (HI80). Participants completed 2-3 circuits of four sets in the leg press and leg extension machines. Saliva samples were collected before and immediately after each exercise session and stored at -80 ℃ for later analysis with ELISA. RESULTS: No significant differences in any of the three hormone concentrations were noted between conditions, but significant increases in C (0.039), GH (0.01), and T (0.015) concentrations were seen from pre- to post-exercise. The BFR40 condition resulted in significantly lower HR values in the leg press when compared to BFR20 (0.037), and HI80 (0.01). HI80 resulted in higher RPE values in the leg press when compared to BFR40 (0.01) and BFR20 (0.012). The HI80 condition resulted in significantly higher HR values in the leg extension when compared to BFR40 (0.01). Lastly, BFR20 (0.033) and HI80 (0.01) resulted in significantly higher RPE values in leg extension compared to BFR40. CONCLUSION: Both BFR and HI exercise protocols resulted in similar level of glucocorticoid and anabolic hormone responses, but there are differences in objective (i.e., HR) and subjective level of exertion (i.e., RPE). Even though acute responses of the BFR20 session with lowest training volume and intensity was the most similar to HI80, training-related chronic adaptations may be different.

Abstract Name: **Health metric scoring for specific-pathogen-free sheep infected with Mycoplasma ovipneumoniae shows greater severity of infection in the lower respiratory tract**

Mycoplasma ovipneumoniae (M. ovi) is a facultative pathogen that colonizes the respiratory tract in ruminants. The focus of this study was to determine whether the route of M. ovi administration would impact clinical disease in specific-pathogen-free (SPF) sheep - upper versus lower respiratory tract (URT and LRT). We hypothesize that pathogen administration directly into the LRT would lead to more severe disease. Four to five 2 - 3 month old domestic SPF lambs per group were experimentally infected via treated nasal wash from infected sheep intratracheally (LRT), nasally (URT), or remained uninfected. The sheep were monitored daily after PCR confirmed infection, and scored based on their health following pathogen administration. We used a 0-5 point system for the following criteria: general behavior, appetite, body temperature, clinical signs, and medications/treatment. A low score indicated the absence of symptoms while a high score indicated the presence of symptoms.We compared the total scores between the control sheep and infected sheep for the LRT/URT infections. There was a significant increase in the average total score from 0.387 for the control to 1.660 for the LRT infection (Student's t-test, 0.0001), and from 0.303 for the control to 1.075 for the URT infection (Student's t-test, 0.0001). In addition, the LRT total score mean of 1.660 showed a significant increase from the URT score mean of 1.075 (Student's t-test, 0.0001), supporting our hypothesis that LRT infection increases severity when compared to the URT infection. These results show that the establishment of infection resulted in significant clinical signs and that the LRT infection resulted in increased severity of infection as compared to the URT.

Abstract Name: Mix Down Altitude Based Wind Gust Prediction During Various Weather Types

A wind gust is fast moving air high up in the atmosphere that is mixed down to the surface, with stronger winds typically being found higher up in the atmosphere. Wind gusts are important factors of a weather forecast because they cause damages to structures and in turn can affect the economy negatively. Forecasting these wind gusts is a challenging task for operational weather forecasters and evaluating the accuracy of gust forecasts is an issue because wind gusts are only reported during the last 10 minutes of the hour, rather than the entire hour. This causes a large portion of wind gust reports during each hour to go unreported. Recently, work in the Meteorologically Stratified Gust Factor Model at the University of Wisconsin-Milwaukee derived a database that recorded the true surface wind gust across all minutes of the hour between 2010-2017 at many stations across the country. With this database, the ratio of peak wind gust speed to mean wind speed at the surface was developed to accurately forecast a speed and direction-specific gust. In this project, we are using the same database that was derived in the Meteorologically Stratified Gust Factor Model to create a new wind gust forecasting model. We analyze various weather types across several stations across the country and determine a relationship between the mix down altitude of wind gusts. Preliminary results show that there is a noticeable pattern with mix down altitudes for wind gusts at each station. By utilizing this information, one can better forecast an accurate wind gust at the surface, which in turn will work as a tool that can not only be used by forecasters to improve accuracy, but also to make cost effective decisions.

Abstract Name: Car Dependency and Transportation System in Houston

For many decades, Houston has been a very car-dependent city. In certain parts of the city's interior, it is possible to get around by bus, light rail, bicycle or even walking, however for most people who live in the surrounding suburbs, use of public transportation is not very feasible. Because housing tends to be more expensive in densely populated areas in which public transportation is more readily available, people of low socioeconomic status are often pushed to the suburbs. This has a negative impact on them because they many times cannot afford cars and struggle to find the transportation necessary to secure basic needs. These suburbs are characterized by wide highways and long distances, making transportation even more difficult. For most of Houston's residents living in the suburbs, getting to the places that they need to go to in their daily lives such as school, work, or grocery stores is nearly impossible, and the efforts made by the government to improve transit have not been very effective in this city exclusively designed for cars. While 50% of Houstonians report desiring to have a more walkable lifestyle, the government has failed to adequately meet that desire. This presentation will explore the various factors that might explain that disconnect between the desire and policy. Part of that explanation will look at low ridership, stigma of public transportation as a welfare project, and the vicious cycle that comes from public stigma and lack of funding. While this presentation will use Houston as a case study, the hope is that it can offer a generalized appeal for future urban planners to take into account nationwide, as this car dependency case is present in many other cities around the United States.

Abstract Name: **Development of Photocrosslinking Click Chemistry Probes to Investigate the Function of Falcilysin, an Essential Malarial Metalloprotease**

Human malaria is a parasitic disease caused by 6 different Plasmodium species, leading to approximately 600,000 annual deaths. All clinical symptoms of the disease result from the intraerythrocytic development of the parasite. During this part of the life cycle, the parasite expresses an array of proteases to carry out many essential processes, such as host cell protein degradation, host cell invasion, and parasite protein export. Falcilysin (FLN) is an essential metalloprotease expressed by the parasite during intraerythrocytic infection, and it is known to function in host hemoglobin degradation and in processing of apicoplast-targeted parasite proteins. Recent studies have identified FLN as a target of the clinical antimalarial drug chloroquine, and it appears likely that the protease carries out additional roles in the cell.We are developing chemical tools to enable further investigation of FLN biology and its potential as a chemotherapeutic target. Here we report our work to synthesize and evaluate a series of piperazine-based hydroxamic acids as inhibitors of FLN. As well as incorporating photocrosslinking and click chemistry moieties into the scaffold. These studies will provide the rationale for the development of increasingly potent FLN inhibitors while identifying possible off-targets in the cell.This work builds upon our previous research by further optimizing the N1 position on the piperazine core. We synthesized and tested a series of 10+ compounds with diverse substituents which were installed using a range of synthetic methodologies. In a subset of compounds we incorporated diazirine and alkyne moieties to enable identification of cellular targets using a combination of photocrosslinking and click chemistry. All compounds were tested against cultured parasites and purified FLN, and we identified additional structural requirements for potent inhibition of FLN. Multiple inhibitors were discovered with similar or improved potency relative to our previous lead compounds.

Abstract Name: **What is Happening in Myanmar: Post-Colonial Violence, Decolonial Revolution**

Violence is endemic in Burma. For over 70 years, the country has been home to the longest running civil war in the world. However, on the 1st of February 2021, Burma's short 'democracy' ended abruptly through a coup conducted by the Burmese military, the Tatmattaw and since, the country has seen the severity and extent of violence worsen. This latest iteration of Burma's endemic violence nevertheless provides an opportunity to look at the unique characteristics and motivations of this violence that emerged in post-coup Burma. Through Franz Fanon's critical framework in The Wretched Of the Earth, this paper analyzes the colonial roots of Burma's military oppression and the people's resistance against it, and finds that Fanon's descriptions of the colonial experience illustrate a distinction between the post-colonial and the decolonial. On Violence reveals the violence inherent in the colonial arrangement and how the violence of the oppressed is eventually always directed towards decolonization. However, failed or insufficient decolonial movements leads to 'independent' post-colonial states left with colonial laws, institutions, and ideas, which remain destructive long after the colonial armies leave. Parallels between Burma's colonial and post-colonial experiences indicates that Burma's endemic violence have its roots in colonial institutions, and thus, a post-colonial phenomenon i.e., Burma is not decolonized. This project uses historical text and contemporary sources to show the colonial legacy of modern-day Burma. This includes historical texts in both English and Burmese, social media sites, and even firsthand observations of the violence while in the country from February to December 2021. Burma, unfortunately, remains one of the prime examples of post-colonial intra-state violence and conflict and this paper offers a nuanced Fanon-informed analysisto provide a broader understanding of the current situation in Burma.

Abstract Name: **Biomarker analysis of the Eastern Himalaya Foreland Basin (EHFB) as a proxy for paleogeographic identification**

The deposits of the Eastern Himalayan Foreland Basin (EHFB) have recently spurred debate between a terrestrial fluvial and marginal marine setting. Previous studies have identified these deposits as fluvial sediments. Some recent studies of the Eastern Siwalik deposits from the Tista Valley, Bhutan, and Arunachal Pradesh have shown the presence of wave-generated sedimentary structures and marine trace fossils, indicating a marine deltaic depositional setting. Organic biomarkers are another helpful resource in determining and understanding the depositional environment. These geochemical analyses can differentiate between primarily aquatic or terrestrial plant assemblage. We analyzed n-alkane distribution, organic δ13C, and C/N ratio from 33 mudstone samples from the Neogene Siwalik deposits of Arunachal Pradesh, India. The samples were collected along the Siji River section in the eastern end of the foreland basin and spans across the Lower Siwalik Dafla (8 samples), Middle Siwalik Subansiri (4 samples), Upper Siwalik Siji (12 samples), and the Kimin (9 samples). Recent facies analysis identified Dafla as tidal, Subansiri as braided fluvial. Siji as shoal water fan delta and Kimin as alluvial fan or braided stream deposits. Seven Dafla and four Siji samples, show bimodal peaks centered on C19 and C31, indicating a mixture of marine and terrestrial matters. Ourdata set shows a strong correlation with the recently proposed facies distribution and supports a possible marine incursion in the Eastern Siwaliks.

Abstract Name: **How to build a successful First-Year Mentor Program?**

The First-Year Honors Mentor program (FHMP) at Iowa State University is a successful high-impact practice that started in 1987. FHMP offers about 400 honors first-year honors students from all majors the opportunity to get research experience with faculty mentors. The main objectives of the FHMP are to develop students' interests in research involvement, to enhance their knowledge and understanding of the academic field, and to help them identify a research area for an honors capstone project. FHMP participants conduct research during the spring semester of their first year with an opportunity to continue during the following summer and fall semesters. At this presentation, you will learn about FHMP modules and schedules, including student recruitment, principals of matching mentors and mentees, the outline of the mentor training workshop, a list of students' requirements to complete the program, and variables to measure students' successes. To track and assess program outcomes, all student FHMP participants were asked to complete an entry and exit survey. The purpose of this assessment project is to assess how the FHMP impacts honor students' interests in continuing research throughout their academic careers. During the session, we will share these program outcomes:1) changes in the number of FHMP participants over the last twelve years and how it was affected by the COVID pandemic; 2) the demographic data and college distribution of the FHMP participants; 3) the number of FHMP participants who decided to continue research involvement in a following year 4) the number of FHMP participants who completed an honor capstone project and graduated with honors.

Abstract Name: **Does Microcredit Improve Well-Being in Developing Countries?: Evidence from Ethiopia**

Credit helps people to finance investments, and therefore holds promise for the reduction of poverty in developing countries. However, access to credit is limited for low-income households in developing countries, particularly in rural areas. This is because it is difficult for commercial banks to determine debtors' trustworthiness in order to avoid intentional defaults, and because low-income households often have little transferable property to offer as collateral. One frequently proposed solution is microcredit, the provision of loans by microfinance institutions, such as the Nobel Peace Prize-winning Grameen Bank in Bangladesh. These loans are small in size and are offered without collateral to groups to make them obtainable for those with low incomes. For several decades, much literature has been dedicated to estimating the effectiveness of microcredit at improving the well-being of households in various countries and regions. However, no clear consensus has emerged on the international level. Since microfinance is more prevalent in Asia than in Africa, there is a relative shortage of research on African microcredit, including in Ethiopia. I am contributing to this literature by studying the impact of microfinance in Ethiopia using a nationally representative panel dataset of more than 4,000 rural households from three different periods. In order to estimate the impact of microcredit on poverty and housing improvements, I will use a two-way fixed effects model, which will control for time-invariant unobservable traits of borrowers that may be correlated both with the decision to borrow money and with these outcomes. Based on the most recent and relevant research in Ethiopia, I expect to find a positive relationship between the usage of microcredit and these outcomes.

Abstract Name: **Structural Dynamics of a Hemolytic Protein**

A common technique utilized by pathogenic bacteria to infect hosts is the secretion of cytotoxic proteins, which break open host cells, exposing the bacteria to all the nutrients stored within. Proteus mirabilis, a gram-negative bacteria commonly associated with urinary tract infections, uses this very technique, secreting hemolysin A (HpmA) to infect hosts. Secretion of HpmA requires a second component, HpmB, located on the outer membrane of the cell. In this two-partner secretion pathway, HpmB couples the folding and transport of HpmA, allowing HpmA to achieve its folded and active form upon secretion. The proposed mechanism for this involves a Brownian Ratchet model, in which all energy for transport is derived from random motion of the protein within its environment. It is hypothesized that the β-helical HpmA is sequentially folded as it passes through HpmB, and that the folded segments serve as a mechanical stop, thus, ratcheting the protein down, preventing movement back into the cell. The β-helical structure of HpmA is characterized by circuits consisting of approximately 21 amino acids. To test if full circuits represent the mechanical stops, we have created a series of truncations variants that differ in length by a few amino acids. Using CD monitored denaturation experiments and functional experiments, we show that there are potential pause points of increased stability. To obtain a better understanding of the structural dynamics and stability of HpmA as they relate to the protein's mechanism of secretion, we are implementing NMR spectroscopy. The results of these various experiments will be discussed in the context of the Brownian Ratchet secretion model.

Abstract Name: **The Effect of Oxidoreductases on Proinsulin Secretion**

Proinsulin is a precursor protein for the production of the hormone, insulin. Proinsulin is folded and oxidized in the endoplasmic reticulum (ER) of the pancreatic beta cell. The formation of native disulfide-bonds is essential for the ER quality control of proinsulin. Only the properly folded protein can leave the ER and enter the Golgi and post-Golgi compartments, where mature insulin is synthesized and stored. Oxidoreductases are enzymes that transfer electrons between two molecules. Specifically, the oxidoreductin ERO1a has been shown to increase proinsulin secretion. We are interested in examining the effects of oxidoreductases PDI, Erp72, P5, and Erp57 on proinsulin secretion. Bacteria will be transformed and plasmid DNA will be isolated. 293T cells will be transfected using Lipofectamine 2000 and after 24 hours, media will be collected and cells lysed. The samples will be resolved by SDS-PAGE page and transferred to nitrocellulose for western blotting, the membranes will be incubated with primary and secondary antibodies, and immunoblots will be developed using enhanced chemiluminescence. We expect these data to help determine the effect of individual oxidoreductases on the secretion of proinsulin. We will compare the results of our experiments to our positive control, ERO1a, and to the vector (negative) control. The results of this study should help us answer questions about which oxidoreductases are important players in proinsulin oxidation and secretion.

Abstract Name: **Evaluation of esters of hydroxycinnamic acids as UVB-UVA filters in emulsion: A naturally sourced alternative to synthetic UV filters in commercial sunscreens**

Synthetic UV filters approved for use in US sunscreen formulations have come under increasing scrutiny in recent years due to the suspicion of undesirable effects on human health and the environment. A growing body of research points to their potential for endocrine disruption, and recent state legislation in both Florida and Hawaii banned two of the most common of such filters — octinoxate and oxybenzone — upon evidence of coral bleaching and toxicity to marine life. Plant-based hydroxycinnamic acids (HCAs) and their corresponding esters have been shown to absorb in the UVB-UVA (290–400nm) region of solar radiation. This study sought to evaluate the UV-filtration potential of these compounds in emulsion, against existing commercial sunscreen filters.In the first phase of the project, three HCA derivatives (ferulic acid, sinapic acid, and 3,4-Dimethoxycinnamic acid) were each converted into their respective ethyl esters by Fischer esterification under microwave irradiation. The same process was used to synthesize isopropyl esters of the three HCA derivatives. Following isolation and purification by column chromatography, each ester product was incorporated by weight in combination with up to 3% avobenzone into a separate sunscreen emulsion and subsequently applied to a polymethylmethacrylate plate for UV-Vis spectrophotometric transmittance testing.Nearly all HCA-based sunscreens performed on par with or more effectively in blocking UVB-UVA radiation than a commercial sunscreen formulation containing a combination of synthetic UV filters (specifically homosalate, octisalate, octocrylene, and 3% avobenzone) at a much higher concentration. Ethyl ferulate- and ethyl sinapate-based sunscreens offered the best coverage across the UVB and UVA range, minimizing the need for avobenzone.The in vitro data generated from this study suggest that each of the naturally sourced HCA-derivatives has the potential to offer an exciting alternative to the cocktail of synthetic UV filters in sunscreens currently available in the US.

Abstract Name: **Relative Clause in Tibetan**

The aim of this study is to analyze the formation of Relative Clauses (hereafter RC) in Central Tibetan (Phjuik). Previous studies have suggested that the Tibetan relativization is a type of nominalization with multiple variations (pa, sa, mkhan, yag; DeLancey 1999). We elicited 328 words and sentences from two Central Tibetan speakers. Their ages range from late 20 to early 30, both from India, currently living in the United States. The current study confirms and extends previous findings in two ways: (1) Out of 4, three variants were confirmed, and (2) an additional vowel /i/ was found to follow the three variants, resulting in pronunciation change. As DeLancey (1999)'s data is from a female speaker in her 60's, the variant lost and a vowel addition could be due to a generation difference. An alternative explanation, especially on the /i/ vowel addition was explored in detail. /i/ vowel also appears in other noun phrases (hereafter NP), such as possessive NPs and genitive NPs. As RC is a type of NP in Tibetan, we propose that RC should be analyzed as a type of case, similar to possessive case and genitive case. The advantage of this proposal will be further discussed in terms of grammatical paradigm uniformity.

Abstract Name: **U.S. Monetary Shocks and International Downside Risks Spillover**

Using quantile regression and orthogonalized high-frequency surprises, I estimate effects of US monetary shocks on international downside growth risks, in a panel of 20 AEs and EMEs from 1988-2016. It is shown that contractionary US monetary shocks lead to decreases in low quantiles of international projected growth, thereby amplifying downside risks up to 9 quarters after the shock. Heterogeneity exists in the magnitude of spillover at the country level, related to features including financial openness and market development, preceding financial conditions, and debt buildup. Furthermore, effects of shocks are largely insignificant for median and upside growth projections. The results suggest that US monetary surprises primarily impact the lower segment of conditional growth distributions of international economies, which might be hard to rationalize in a conventional setup via induced interest rate and risk premia changes. In view of the empirical estimates, I propose a financial constraint view of tail risks spillover, where US contractionary shocks tighten financial and credit constraints in foreign economies, contributing to amplification effects under downside growth realizations.

Abstract Name: **Rehabilitation Improves Functional Recovery and Induces IL-4 Signaling in Rats after Stroke**

Plasticity associated with the reorganization of cortical motor representations plays a critical role for enabling functional recovery following central nervous system (CNS) injuries, including stroke and traumatic brain injury. Such cortical plasticity was identified by the expansion of the rostral forelimb area (RFA) following lesions in the adjacent caudal forelimb area (CFA), which was significantly larger in cortex-lesioned animals that underwent rehabilitative training compared to animals without rehabilitation. Our preliminary study shows improved functional recovery in animals that underwent rehabilitative training. Further studies in our group have demonstrated that rehabilitation focused on skilled forelimb motor tasks robustly drives structural compensation, seen in enhancement of axon sprouting and dendritic architecture on neurons surrounding the perilesional cortex, in turn driving functional recovery. Additionally, RNA sequencing of RFA neurons identified Interleukin 4 (IL-4) signaling as one of the top canonical pathways associated with rehabilitation training after stroke. IL-4 has been shown to be secreted by glial cells or ischemic neurons as an endogenous mechanism of neuroprotection, playing a vital role in stroke repair. For this study we hypothesized that rehabilitation after cortical lesion increases the IL-4 secretion at the adjacent lesion area, thereby playing a vital role in the regulation of brain plasticity. Thus, this study aims to quantify rehabilitation-induced IL-4 regulation after stroke lesion in the RFA using q-PCR, as well as whether rehabilitation induces plasticity in the CFA at the contralateral side of the lesion area. To date, the molecular mechanisms of rehabilitation have not been identified. Using modern tools of neuroscience, we aim to parcel out the effects of rehabilitation on motor systems and to further utilize these findings towards improved therapies for ischemic spinal strokes.

Abstract Name: **Management of 3D Printer G-code for Simulation of Malicious Attacks**

Increased digitization of manufacturing systems, referred to as “Industry 4.0”, includes machine-to-machine communications on the internet of things. In addition to the efficiencies realized, there are also additional opportunities for malicious attacks on the data that is being passed around. We focused on two types of manipulations involving thermal and cavity attacks associated with fused filament fabrication (a 3D printing process). The thermal and cavity attacks were generated through different methods at separate points of the manufacturing process. The cavity attacks were generated during the slicing process where software transforms the selected 3D model into a machine language known as G-code. A cavity is generated in the selected 3D model without disrupting the surface appearance. The said cavity takes the shape of a rectangle and can be adjusted to any size and/or location within the 3-dimensional space provided by the selected 3D model. This entire process happens before the G-code is generated, which differs from the methods of thermal attacks. The process of implementing thermal attacks happens after the 3D model’s transformation into G-code. A specific line of command that controls the nozzle temperature within the machine code is targeted and maliciously replaced with the new attack temperature. The new temperature can take the form of minor changes affecting part performance or major changes resulting in catastrophic failure. Material testing on both types of attacked parts was performed and compared back to non-attacked control specimens. The results further demonstrated the effects of malicious manipulations involving cavity and thermal attacks, all specimen data presented different degrees of structural integrity damage proportional to the severity of attacks performed.

Abstract Name: **Integrating the Effects of Male Mating Calls and Food Availability on Flight and Reproduction**

In nature, organisms face environmental challenges in their pursuit to reproduce and pass on their genes. However, the allocation of resources towards reproduction can directly conflict with survival, which leads to a tradeoff between survival and reproduction. To navigate this tradeoff, animals can use information about the quality of their environment to make adaptive decisions. For example, a high-quality environment may favor reproductive investment while a low-quality environment favors survival. Yet, resource (e.g., food) availability may alter allocation or investment decisions. For example, resource limitation may favor survival regardless of cues related to environmental quality. Therefore, we used the variable field cricket (Gryllus lineaticeps) to study the roles of male song and resource availability in females' investment into survival (dispersal or flight capacity) and reproduction (ovary mass). Throughout early adulthood, each female was exposed to one of two acoustic environments (60-70 decibels)—either white noise (signaling a low quality, mate-free environment) or male cricket mating calls (signaling a high-quality environment with abundant mating opportunities). Females were supplied with unlimited or limited food. Flight capacity (investment into flight muscle) and reproductive investment (dry ovary mass) were measured in females to determine whether male song promoted reproduction at the expense of flight capacity, and food consumption was determined to assess whether the tradeoff between flight and reproduction is mediated by resource acquisition or availability. Our preliminary results with food-unlimited females indicate that male mating calls increase reproductive investment and reduce investment into flight/dispersal capacity. Song-induced differential investment was due to increased food take rather than an increased efficiency by which ingested food was converted into ovary mass. In sum, our work will inform the determinants of plasticity in two critical, but often competing, traits—reproduction and survival.

Abstract Name: **The Hobbesian Assumptions behind Mearsheimer's Offensive Realism and Notion of Hegemony**

Contemporary political thought is more heavily shaped by its predecessors than is usually recognized. This research investigates how Thomas Hobbes, a 17th-century political theorist, continues to influence our contemporary "realist" interpretations of global dynamics. The project explores how Hobbes' work has shaped that of John Mearsheimer, a prominent neoliberal International Relations scholar known for his theory of "offensive realism." The research asks: How does a Hobbesian understanding of the state of nature inform contemporary theories of political realism within international relations? More specifically, what Hobbesian assumptions shape John Mearsheimer's understanding of hegemony, and how does this purport to predict "great power politics" within international relations? This researchwill also address Mearsheimer's account of China's rise to power to illustrate the implications of a Hobbesian framework in the present.

Abstract Name: **The Role of Guanxi on Knowledge Sharing Online: A Systematic Review**

In China, guanxi is the foundation of all social relationships and it is characterized by multiple elements which facilitate interpersonal relationships, such as face (mianzi), reciprocity (huibao), and trust (xinren). Research established that guanxi can enable greater knowledge sharing in typical face-to-face interactions. However, our understanding of the role of guanxi and its elements on knowledge sharing online is limited. Considering the increasing uses of digital technologies for communication and knowledge sharing (KS) and the growing importance of Chinese enterprises, a better understanding of the role of guanxi and its elements on online knowledge sharing is of critical importance. Thus, this paper reviews relevant studies published between 2010-2022 to synthesize the extant research on knowledge sharing online under guanxi systems. Our findings suggest that although recent studies have begun to conceptualize online KS frameworks while considering the effects of guanxi, the majority of studies use existing Western theories such as the social capital theory and the social cognitive theory to interpret what variables induce KS in Chinese populations. Furthermore, while guanxi dimensions like reciprocity and trust have been frequently the subject of study in existing literature, the manner in which it impacts KS outcomes and attitudes largely depends on the type of online platform being used and the role of the user. Currently, literature on the role of mianzi and ganqing on KS online is scarce, with conflicting findings regarding the effects of these dimensions on knowledge sharing behaviour (KSB). In this paper, we also identify research gaps and propose directions for future research.

Abstract Name: **Phylogenetic Diversification of Monkeypox and Related Poxviridae**

Monkeypox (hereinafter MPXV) is a zoonotic virus that is localized in Western and Central Africa but has recently spread to 82 non-endemic countries with roughly 66,000 cases worldwide, as of September, 2022 (CDC.org). MPXV can enter the body via the oral or skin routes. MPXV mainly targets the airway epithelium leading to infection of nearby immune cells. For the skin route, the virus first infects keratinocytes and fibroblasts. Similarly, to the oral route, MPXV thereafter infects nearby immune cells, such as dendritic cells, and macrophages. In both cases, the infected immune cells allow MPXV to gain access to a draining lymph node. It is hypothesized that an infected draining lymph node subsequently becomes a site of MPXV virion dissemination. The WHO declared MPXV an international health emergency in July of this year (aha.org) and advised caution regarding travel to countries with rising caseloads. As a virus of the Orthopoxvirus genus, which contains the Vaccinia virus that causes smallpox disease, MPXV has a similar double-stranded DNA genome, life cycle, and mode of transmission. Double-stranded DNA (ds DNA) genomes are generally associated with lower mutation rates. In contrast, the current outbreak exhibits an unexpectedly high level of mutations,roughly 6 times the typical rate for ds viral DNA. To pinpoint the evolutionary origins of this elevated mutation rate, we will: (1) reconstruct phylogenetic relationships among MPXV and its relatives in the Poxviridae, using MrBayes; (2) calibrate a penalized-likelihood molecular clock, using BEAST, to estimate divergence times within the clade; (3) compare rates of molecular evolution for selected proteins among Poxviridae sub-lineages, using Mesquite; and (4) model patterns of structural evolution in viral proteins using PyMol. These results have the potential to shed light on the underlying causes of shifts inprotein evolution rates and the shifting dynamics interactions with host immune systems.

Abstract Name: GLOBAL CITIZENSHIP DEVELOPMENT IN SECONDARY SCHOOLS: A CASE STUDY OF THE UNITED STATES

Global Competence, a key concept raised by United Nations in Global Citizenship Education (GCE), emphasizes the development of critically knowledgeable and skillful individuals who can understand and appreciate different cultures. The present research investigated American secondary schools' performance in implementing the GCE theory. Specifically, I looked into how high schools help students develop a global perspective through social studies classes, world language classes, and extracurricular programs. Using interview protocols based on a synthesis of the Global Competence theoretical frameworks raised by the Asia Society, UNESCO, and OECD, I interviewed 14 current Colgate students and alums: 7 Caucasian American students, 5 international students, 1 Mexican American student, and 1 African American student.The research yields mainly three types of students' attitudes toward their high schools' performance in Global Competent development: (1) schools took students' global development seriously and were effective in developing them into global citizens, (2) schools did not take students' global development seriously and should be improved, and (3) while schools did not prioritize global development a priority they should not be blamed. The research also revealed 3 pragmatic tensions exist in American high schools hindering GCE's effective implementation: (1) conservative religious/political environments hinder critical thinking development, (2) low diversity hinders effective intercultural communication, and (3) priority in academic performance hinders in-class global/multicultural education.To alleviate the tensions mentioned above, schools can encourage teachers (especially world language teachers) to bring critical global ideas into classes. Teachers can intentionally create open classroom spaces to allow students who might be more globally knowledgeable than teachers to initiate meaningful discussions. Finally, schools can try to mix day (mostly local students) and boarding students (mostly international students) to promote intercultural communication.

Abstract Name: Understanding an Engineer's Brain: Developing Problem Solving and Intuition

Ever wonder how intuition affects individual problem-solving skills? Does getting an A in a class correlate to an increase in intuition in that subject? As technology-aided problem-solvingincreases, it is critical for engineering students to develop the necessary skills to predict and analyze solution outcomes, which we call engineering intuition. Intuition has been previously studied in nursing, business management, and law, and is a key component in the development of expertise. To increase how intuition is taught in classrooms, we need to first understand how intuition is used in problem-solving and then develop a method to measure it.With the goal of measuring intuition, we analyzed results from a survey with two statics inventory concept questions based on the Concept Assessment Tool for Statics (CATS) (Steif; Dantzler, 2005). The first question focused on assessing a problem outcome as a sensibility check and the second question focused on predicting the outcome. In addition to solving the concept questions, participants were asked questions based on their confidence in the answer, how they answered the question, the likelihood of taking additional steps to justify their answer, and the likelihood of going to a manager with just the answer. We analyzed open-ended responses from 271 participants and identified emergent themes across the responses. We used these themes to create a codebook that was applied to all open-ended responses. The resultant coding showed the correlation between the open-ended questions and qualitative analysis of the multiple-choice questions, confirming that the questions were answered in similar ways. Efforts are ongoing to determine how well the survey measured intuition, but we believe this survey is the first step to encourage intuition use in the classroom.

Abstract Name: **Using Survey Data to Report on Low-Income Household Experiences Shopping at the Eau Claire Downtown Farmers? Market**

Food insecurity is a significant issue facing many American households. The Supplemental Nutrition Assistance Program (SNAP) provides increased access to food for families in need. Additionally, fruit and vegetable (FV) consumption has been shown to improve health and reduce the risk of a variety of chronic diseases. However, poor nutrition among children and adults, including low FV intake have contributed to rising rates of obesity among US children which have been shown to persist into adulthood. It is particularly challenging for low-income households to purchase/eat the recommended amount of FV. Farmers' markets offer a wide variety of fresh, local and healthy foods, especially FV, but data show that low-income households are much less likely to shop at farmers' markets. The Eau Claire Downtown Farmers' Market (ECDFM) sponsors a Market Match Program (MMP) incentivizing SNAP households to shop at the market. Administrative data on program utilization suggests that most SNAP households shop at the ECDFM using the MMP relatively infrequently. This poster presents data from surveys of SNAP shoppers at the ECDFM in 2022 (N=349) to learn more about their experiences using the program including what limits their shopping at the market and what might increase their ability to shop at the market. Our results indicate that the most significant limitations to shopping at the ECDFM were the market location/hours, SNAP benefits running out and just not remembering. Correspondingly, the most mentioned things that would encourage more frequent shopping at the ECDFM were expanded market locations/hours, a larger match amount and also being reminded. Among our other key findings are that the ECDFM MMP provides many benefits including reducing food insecurity among EC SNAP households. This poster is connected to another submitted poster analyzing a variety of administrative data from recorded transactions of SNAP shoppers using the ECDFM MMP.

Abstract Name: **How Horror Movies Reflect Political and Cultural Anxieties**

In the late 20th century, Japan, China and the United States all produced many horror films that reflected the cultural and political anxieties of their time, such as the fear of invasion by outsiders, concerns about government mismanagement and technological advances, and the fear of unknown creatures. These universal world anxieties stem from the trauma of World War II, the economic crisis and rapid developments in technology. At the same time, horror films from different countries also show some unique anxieties that arise from different social contexts. For China, the revolt against the ideology of feudalism's residuals was a major theme of late twentieth century movies. Feudalism has a history of over 2,000 years in China, so it has left an indelible, damaging impact on the country. During this period, ghosts often played the role of kindness and bravery in Chinese films because they are not required to follow the rules of feudalism. Directors use ghosts instead of humans to break the shackles of society. In Japan, the fear of nuclear weapons and nuclear war gave birth to the classic monster movie. The Japanese used the image of giant monsters to represent nuclear weapons with their terrible power and nuclear radiation, and used these monsters destroying cities as a metaphor for the devastation of nuclear power in Japan. In the United States, the number of serial killers began to grow in the 1960s and peaked in the 1980s. A fear of serial killers implies a concern for individual safety felt at a societal level, which is reflected in the large number of slasher movies in the 1980s. According to this project, the inside values of horror films can be explored. These values demonstrate that horror films are not just for entertainment, but that they present serious social issues.

Abstract Name: **Mapping institutional cultures in global high-tech R&D institutions**

This study analyzes organizational cultures across global elite R&D institutions (n = 455). We identity and examine inter-institutional differences across mission, vision, and values (MVV) to predict effects on institutional performance and caliber. Meta-data is also aggregated via such rankings, institutions' research productivity, results, and effective integration of information and communication technologies (ICTs). By understanding strategic differences as expressed in MVVs, this project determines ways in which strategic planning collateral may affect aggregate organizational performance. Furthermore, the study evaluates institutions' research methodology and efforts on a global scale, looking at how different organizations organize data, present findings, and take action based on their results.It is anticipated that institutions with a focus on data diversity, meaning a broad range of ongoing projects, will also have diversity-based MVVs. Notably, we test the hypothesis that institutions which value diversity and inclusion–whether cultural, intellectual, etc–may produce the top-most quality of research execution and analysis. This, as a result, classifies some research institutions as more productive than others and are often seen as leaders in particular fields and have large growth potential. This is commonly demonstrated in their university rankings, thus affecting how many students apply for the college, what these students study once enrolled, and the research these students produce. As a result of these institutions' successes, they are likely to receive higher amounts of funding and therefore yield more research in the future. MVVs are critical in determining what values universities follow and, in many cases, depict why certain projects are undertaken and how they will be executed.

Abstract Name: **Validating a Method for Rapid Handling and Measuring of Museum Specimens**

Large functional trait datasets provide the basis for many studies of avian morphology. However, collecting these data by hand is extremely time consuming. One approach to generating the large scale datasets necessary to scale up the spatial and temporal scales of avian research is to generate methods for quickly and easily accessing data from thousands of museum specimens. To do this, machine learning methods are being developed, however their accuracy remains poorly quantified. We address this problem by testing the accuracy of 'Skelevision', a method developed for rapidly handling, photographing, and measuring museum specimens using computer vision. Skelevision generated accurate functional trait estimates for the entirety of the University of Michigan Museum of Zoology's collection of passerine specimens. Here we assess the accuracy of Skelevision when used to measure specimens in a new Museum setting (the Field Museum of Natural History) by comparing Skelevision-generated and hand-made measurements. This method allows us to test whether Skelevision estimates are accurate regardless of the environment in which images were captured. Using machine learning to generate functional traits in ecology and evolution holds great promise, but also has unique challenges. Our work tests whether this class of approaches can be applied outside of the systems in which they are developed, a key feature to their broad utility in ecology and evolution.

Abstract Name: **Investigating Fluoride Tolerance and Gene Expression of crcB in Pseudomonas putida F1**

Fluorinated compounds are increasingly being utilized for pharmaceutical, commercial and industrial products, leading to an increasing presence in the environment. Carbon-fluorine bonds are anthropogenic and rarely found in nature, as a result there are no known natural pathways that have evolved to easily degrade these compounds. Fluoride anions are toxic to living organisms, impairing necessary cellular activity such as metabolism, ATP synthesis, and important enzyme functions. Previous studies showed that Pseudomonas putida F1 can degrade fluorinated compounds. The purpose of this study was to investigate the fluoride tolerance of this organism and its relationship to the expression of crcB gene, which encodes a fluoride exporter protein. Tolerance experiments were carried out by measuring microbial growth at various concentrations ofNaF after 20 hours of incubation. Total RNA was extracted from each culture, converted to cDNA, amplified, and quantified using qRT-PCR. Results from the tolerance experiment show Pseudomonas putida F1 had tolerance to NaF up to a concentration of 125mM and 200mM in rich and minimal medium respectively. Growth experiments showed that P. putida F1 had similar generation times at lower concentrations and longer generation times at higher concentrations. Overnight incubation with 20mM NaF decreased the generation times of the cells grown with 50-125 mM NaF. The reduction in generation time is probably due to induction of the crcB gene through a fluoride response riboswitch, which upon recognition activates fluoride exporter genes, such as crcB. We expected the bacterial cultures subjected to high concentrations of fluoride to express the gene crcB at higher levels than lower concentrations. The qRT-PCR analyses did not show a trend of crcB expression in response to different concentrations of fluoride. The substantial level of variability between the experimental and control groups indicate that the crcB qRT-PCR assay needs to be optimized and repeated.

Abstract Name: **Smartphone Use on Well Being**

How has Smartphone use impacted the general well-being of people today? The Smartphone usage has certainly increased over the past generation. The use is so prevalent that nearly everyone from 9-99 has one. Questions regarding how this intense Smartphone use is impacting the overall health and well-being of society has been discussed across many different aspects of research. This research intends to study how Smartphone use impacts the physical, psychological, cognitive, and social well-being of individuals across the generations. Previous research tendedto focus on one aspect or another of well-being, for example sleep or academic performance (cognitive functioning) or anxiety (psychological functioning). The research is lacking when looking at the global health of an individual and its association with Smartphone use. Thisstudy will also examine the specific ways individuals are using the Smartphones as well as how much of their daily life is consumed by the use. A correlational analysis will be completed in the spring semester of 2023 to determine what factors are impacted by Smartphone use.

Abstract Name: **Development of Electromagnetic Coils for UCN Polarization in nEDM Experiments**

Discovering the neutron electric dipole moment (nEDM) poses a significant goal in nuclear and particle astrophysics. An observed nonzero nEDM would provide evidence for both parity (P) violation and time reversal invariance (T) violation. This breaking of symmetry is required to explain the prevalence of matter over antimatter, and would be evidence for new laws beyond the Standard Model of particle physics. Variations in the precession frequency of the neutron spin, caused by reaction with ultracold polarized atoms in the uniform field of electromagnetic coils, will be used to measure the nEDM. However, measuring the nEDM proves difficult due to the hypersensitivity of neutrons to magnetic fields. Any changes in the uniformity of the generated field could mimic the signal for an nEDM. Therefore, designing electromagnetic coils with extremely uniform magnetic fields is essential for this experiment. The coils I would help to design would increase the sensitivity of the experiment to an unprecedented sensitivity of 10-28 e cm. I will be solving for boundary conditions for the magnetic scalar potential on a coil to be used at an experiment conducted at the Paul Scherrer Institut (PSI). By solving for the boundary conditions, equipotential contours can be constructed, which give the location of wire windings for the coil. The placement of the wire windings based on the geometry of the coil and the material used for it creates the uniform magnetic fields within the coil. This project will consist of development of the PSI coil by solving partial differential equations, printing test coils, mapping the fields, and editing the design.

Abstract Name: **Not just a pretty picture: evaluating the efficacy of new visual aids in undergraduate science education**

Scientific visual communication is a unique interdisciplinary field that integrates the visual arts–from traditional and digital illustration to 3D modeling and animation, and more–to communicate and teach topics in health and sciences. With the increasing availability of new media technologies such as 3D printing and VR/AR in the classroom, new forms of visual aids will supplement the standard learning materials and will play an important role in the classroom experience and learning outcomes for undergraduate science students. Students training in the field of scientific visualization are engaged in the creative design process to develop new visual aids,but often stop short of evaluating their utility and measured impact on learning outcomes. Research on newly developed scientific visual media has historically been limited or lacking; this is true at the undergraduate level as well as in graduate-level training in science visual communication and in industry. There is therefore a need within this field to encourage early engagement in research, ideally starting at the undergraduate level, to promote academic scholarship and investigation into evidence-based best practices for designing new scientific visual media to improve undergraduate science education. Following themes 3 and 4 for this year's FAN conference, this session will present on efforts in the Biological/Pre-Medical Illustration Major at Iowa State University to engage undergraduate students in research that evaluates the utility and efficacy of new visual learning aids on learning outcomes for science students. Whether by implementing design thinking methods into course projects or developing research studies for creative capstone projects, students go beyond thinking of the visual media developed in their coursework as mere end products to seeing them as a means to study how people learn and to understand how visual information can be best presented to improve learning.

Abstract Name: **"I get physically ill when I think about us?: Making sense of memorable breakup messages**

All relationships have a beginning; some have an end. The experiences we have as we disengage from relationships influence our understanding of those relationships. To better understand the memorable messages that individuals received during romantic relationship breakups, we sought to answer the following questions: What is the significance of memorable breakups? Which words or phrases are consistently remembered during a breakup? Do memorable messages usually come from the person breaking up or the person being broken up with? To answer these questions, the research team conducted 16 semi-structured interviews; participants were recruited via convenience sampling. Thematic analysis techniques (Nowell, Norris, White; Moules, 2017) were used to identify the following themes: Many of the reasons for a breakup appealed to an individual's desire for independence as they looked toward the future. Many memorable breakups also had connections with an individual's family or friends' disapproval of the relationship. In general, negative or harmful relationships yielded negative breakup memories while healthy relationships usually yielded more positive or mutual disengagement conversations. As participants reflected on a memorable breakup and pondered future breakup communication they would execute, every individual mentioned something they learned from in their memorable breakup.

Abstract Name: **Transparency in the Apparel Global Supply Chain**

Practicing sustainable manufacturing principles is essential in the global supply chain, as it ensures workers' safety and well-being and limits pollution. Currently, a lack of transparency creates a disconnect between apparel brands and the manufacturers. Without a clear responsible party, pollution and carbon emissions are not accounted for, and factory workers receive unfair and dangerous treatment.
Transparency is necessary for a sustainable supply chain to ensure that all production follows the legal requirements regarding pollution and workers' rights. There is no legal obligation for manufacturers to have transparency resulting in the destruction of ecosystems and catastrophes such as the 2013 Rana Plaza collapse, resulting in the death of 1,134 workers. The current research aims to bridge the gaps in transparency within the apparel supply chain, identifying the weakest areas that need to be addressed to ensure sustainability in the future of global sourcing.
Through a review of the literature, we identified a connection between expansion and trade and the development of low-cost production, frequently through subcontracting to factories unknown by the vendors. However, the cost benefits of offshore production comes with the added challenge of ensuring environmental and social compliance from manufacturers.
To further explore this research question more, a content analysis was conducted using academic literature, government websites, and industry trade publications and websites. Common themes found in the literature were a disconnect between brand and subcontractor, competition between low-cost factories, noncompliance with legal regulations, and factory pollution destroying waterways and ecosystems. Through further research, these areas will be explored further to understand where gaps in the supply chain exist and what needs to be changed to establish a transparent and sustainable supply chain.

Abstract Name: **A limit to the prosocial spending effect: Parents are not happier spending money on their children than themselves.**

The finding that spending money on others (vs. the self)—particularly close others—promotes happiness has been well established. However, no research has investigated whether this prosocial spending effect emerges for parents when spending on their children. Testing this question is important for both the prosocial spending and parental well-being literatures. In a separate study, we found preliminary support for the hypothesis that parents are happier after spending on a child than themselves, but the study was only correlational and had some sampling issues. Therefore, in the current research we conducted an online experiment in which parents (N= 228) were randomly assigned to recall and describe a memory in which they spent $20 onthemselves (personal spending), another person (prosocial spending), or on their child (child spending). After the manipulation they reported their positive emotions. Controlling for baseline positive emotions, parents were happier after reliving a time they spent money on someone else than themselves—the well-established prosocial spending effect. In contrast to our prediction, parents reported being similarly happy after reliving a time they spent money on themselves as in their children. As a stronger test of this hypothesis, future research should replicate this study with three improvements: 1) modify the writing prompt to focus on discretionary spending, 2) increase sample size, and 3) include a measure of inclusion of other in the self. Although prosocial spending is a strategy people can use to increase their well-being, it may not apply to parents spending on their children.

Abstract Name: **Prescribed Burn Effects on Animal Species in the St. John's Abbey Arboretum**

We investigated the impacts of prairie prescribed burns on small mammal diversity in the Saint John's Abbey Arboretum, Collegeville Minnesota. We hypothesized that there would be a correlation between burn age and degree of diversity. Based on this hypothesis, we predicted that older burns would have greater diversity. During June and July of 2022, we placed 18 traps on each of three different burn age plots (four, two and one years). Traps were placed 15 meters apart and were opened in the evening and checked early morning on the next day (H.B. Sherman live traps, model 3310A). Traps were baited with peanuts, oats, and raisins. Data collected for each trapped animal was plot name, trap ID, species, weight, gender, reproductive status, total body length and left hind leg length. Captured animals were released at their trapping site. A Chi-square goodness of fit was used to analyze data. Our mammal diversity among plots was not as expected – we trapped only house mice (Mus musculus). There was a difference in number of animals trapped on the three plots ($\chi 2$= 22.65, df = 2, p = 0.0001). More animals were trapped on the plot with a one-year burn. One factor that might contribute to trapping only one species is an extremely wet spring and summer. The ground was frequently saturated, and the vegetation density was hard for even us to walk through. We plan on continuing this study in 2023. We think that this research is important because today less than 1% of prairies remain in North America and are fragmented and scattered around.

Zolenski, Luke

Abstract Name: **Creating... Creating...**

What does it mean to create something? Depending on who you ask, you will be met with very different answers. In Jean-Michelle Basquiat's case, it meant making a painting, in Roger Waters', writing songs, Marco Pierre White's, pushing culinary barriers. Nonetheless a pattern emerges when one analyzes the creative habits of the most famous artists throughout history: they all made something original. A trait that is becoming harder to come by as the modern age takes form, and creation gives way to bureaucracy. But what does the artist do? The artist creates,and new avenues for originality present themselves as they become more experienced. The artist - like the entrepreneur they are - recognizes a need in the market. And it is through constant immersion into their craft that these incredible powers of observation mature. The artist then looks to address this need; here is where their creative abilities serve them the most. Over the last few years, the current entertainment and creative mediums afforded to us have worn their welcome. As a result, the need for a new artistic medium has presented itself. The need for the next paradigm shift. As such, I have attempted to address this need by combining pre-existing realms of artistic expression, to produce an entirely new one. Further, this process is a direct result of computational and mathematical analysis, thus further integrating other disciplines. A new medium altogether; one that encapsulates mathematics and art – and within art, those realms of musical and dynamic expression. A bridge between those forms that are intangible with those that are defined. Total oneness as is attained mentally now exists literally and physically. Originality in it's truest sense, creating creating...

Zoll, Jacob

Abstract Name: **Accessing Nanosecond Chemistry in a Undergraduate Research Lab**

Most chemical reactions occur on a timescale ranging from seconds to hours, the chemistry that occurs in the excited state occurs much faster, and some progress over the course of an attosecond. The past few decades have seensuch advances in femtosecond spectroscopy, allowing researchers to interrogate these ultrafast processes experimentally. However due to the price tag, at most liberal arts institutions, students are not able to observe reactions happening at such fast time scales. Transient Absorption or pump-probe spectroscopy is one of the straighter forward techniques in time-resolved spectroscopy and can interrogate time scales from milliseconds-femtoseconds.Using a sub-nanosecond pulsed laser, we build on the work of Farr et al to develop a home-built nanosecond pump-probe spectrometer that is easily accessible to undergraduate students to be used across all sub-disciplines of chemistry and related fields. To reduce costs, a passive Q-switched pulsed laser is used as the pump source, and a photodiode connected to a bench-top oscilloscope comprised the detector. We plan on first programming a user-friendly interface in LabVIEW that will allow for easy changing of parameters for multiple different possible reactions. We have also developed a plan on how to set up our optics for a user-friendly experience that does not have to be changed.

Abstract Name: Percussion Activities with Adaptations for DEI and Integration of National Music Standards

This presentation will showcase graphic adaptations created for the secure setting of a juvenile detention center housed inside a jail. Social-emotional learning applications and social justice standards were connected with national music standards for lesson plans integrating the adaptations. Due to interest of the students involved inside the detention center, Latin rhythms were chosen as a major focus area. Rhythmic patterns for claves and basic Latin idioms were chosen and paired with specific Latin songs. Because different students needed different types of adaptations, a composite template was developed to include cues of words, images, music notation on a staff, and adaptive notation with counting boxes integrated to depict the organizational structure of the rhythm. How to show special effects such as accents, tremolos, and brushing technique to add sound on the tabletop and on clothing will be demonstrated. Students in the juvenile detention center assisted in creating each layer of adaptations, performing them, and conducting them. Input provided from juveniles for how to best facilitate their successful responses will be shared. Latin styles reflected by properties of music included switching between major and minor chords frequently, triplet patterns in both accompaniment and melody lines, and offbeat accents were represented across different cultures. Examples will be performed while graphics are shown with audience invited to join in and participate. Rhythms included three-two Son, three-two Rhumba, Samba, Bossa Clave, Samba Clave, swing patterns, Tumba, and Merengue, with each of these rhythms being paired with one or more songs for the music lessons. Considerations for meeting the needs of everyone in the group when those needs are not the same will be explored. Hasty considerations based on jail precautions and the pandemic will be described. Charts to show connections for social justice, social-emotional learning, and national music standards will be presented.
